**Plan** The boiling point depends in part on the attractive forces in each substance. We need to order these substances according to the relative strengths of the different kinds of intermolecular attractions.

**Solve** The attractive forces are stronger for ionic substances than for molecular ones, so  $\text{BaCl}_2$  should have the highest boiling point. The intermolecular forces of the remaining substances depend on molecular weight, polarity, and hydrogen bonding. The molecular weights are  $\text{H}_2$ , 2 amu;  $\text{CO}$ , 28 amu;  $\text{HF}$ , 20 amu; and  $\text{Ne}$ , 20 amu. The boiling point of  $\text{H}_2$  should be the lowest because it is nonpolar and has the lowest molecular weight. The molecular weights of  $\text{CO}$ ,  $\text{HF}$ , and  $\text{Ne}$  are similar. Because  $\text{HF}$  can hydrogen-bond, it should have the highest boiling point of the three. Next is  $\text{CO}$ , which is slightly polar and has the highest molecular weight. Finally,  $\text{Ne}$ , which is nonpolar, should have the lowest boiling point of these three. The predicted order of boiling points is, therefore,

**Check** The boiling points reported in the literature are  $\text{H}_2$ , 20 K;  $\text{Ne}$ , 27 K;  $\text{CO}$ , 83 K;  $\text{HF}$ , 293 K; and  $\text{BaCl}_2$ , 1813 K—in agreement with our predictions.

## Practice Exercise 1

List the substances  $\text{Ar}$ ,  $\text{Cl}_2$ ,  $\text{CH}_4$ , and  $\text{CH}_3\text{COOH}$  in order of increasing strength of intermolecular attractions.

- (a)  $\text{CH}_4 < \text{Ar} < \text{CH}_3\text{COOH} < \text{Cl}_2$
- (b)  $\text{Cl}_2 < \text{CH}_3\text{COOH} < \text{Ar} < \text{CH}_4$
- (c)  $\text{CH}_4 < \text{Ar} < \text{Cl}_2 < \text{CH}_3\text{COOH}$
- (d)  $\text{CH}_3\text{COOH} < \text{Cl}_2 < \text{Ar} < \text{CH}_4$
- (e)  $\text{Ar} < \text{Cl}_2 < \text{CH}_4 < \text{CH}_3\text{COOH}$

## Practice Exercise 2

(a) Identify the intermolecular attractions present in the following substances and (b) select the substance with the highest boiling point:  $\text{CH}_3\text{CH}_3$ ,  $\text{CH}_3\text{OH}$ , and  $\text{CH}_3\text{CH}_2\text{OH}$ .

SAE 40  
higher number  
higher viscosity  
slower pouring

SAE 10

faster pouring

▲ **Figure 11.16** Comparing viscosities. The Society of Automotive Engineers (SAE) has established a numeric scale to indicate motor-oil viscosity.

## Viscosity

Some liquids, such as molasses and motor oil, flow very slowly; others, such as water and gasoline, flow easily. The resistance of a liquid to flow is called **viscosity**. The greater a liquid's viscosity, the more slowly it flows. Viscosity can be measured by timing how long it takes a certain amount of the liquid to flow through a thin vertical tube (Figure 11.16). Viscosity can also be determined by measuring the rate at which steel balls fall through the liquid. The balls fall more slowly as the viscosity increases. The SI unit for viscosity is  $\text{kg/m}\cdot\text{s}$ .

The viscosity of a liquid is related to how easily its molecules flow past one another. It depends on the attractive forces between molecules and on whether the shapes and flexibility of the molecules are such that they tend to become entangled (for example, long molecules can become tangled like spaghetti). For a series of related compounds, viscosity increases with molecular weight, as illustrated in Table 11.3.

**TABLE 11.3** Viscosities of a Series of Hydrocarbons at 20 °C

| Substance | Formula  | Viscosity ( $\text{kg/m}\cdot\text{s}$ ) |
|-----------|--|--|
| Hexane    | $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$   | $3.26 \times 10^{-4}$                    |
| Heptane   | $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$                                  | $4.09 \times 10^{-4}$                    |
| Octane    | $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$                       | $5.42 \times 10^{-4}$                    |
| Nonane    | $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$            | $7.11 \times 10^{-4}$                    |
| Decane    | $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ | $1.42 \times 10^{-3}$                    |

## CHEMISTRY PUT TO WORK Ionic Liquids

The strong electrostatic attractions between cations and anions explain why most ionic compounds are solids at room temperature, with high melting and boiling points. However, the melting point of an ionic compound can be low if the ionic charges are not too high and the cation–anion distance is sufficiently large. For example, the melting point of  $\text{NH}_4\text{NO}_3$ , where both cation and anion are larger polyatomic ions, is  $170^\circ\text{C}$ . If the ammonium cation is replaced by the even larger ethylammonium cation,  $\text{CH}_3\text{CH}_2\text{NH}_3^+$ , the melting point drops to  $12^\circ\text{C}$ , making ethylammonium nitrate a liquid at room temperature. Ethylammonium nitrate is an example of an *ionic liquid*: a salt that is a liquid at room temperature.

Not only is  $\text{CH}_3\text{CH}_2\text{NH}_3^+$  larger than  $\text{NH}_4^+$  but also it is less symmetric. In general, the larger and more irregularly shaped the ions in an ionic substance, the better the chances of forming an ionic liquid. Among the cations that form ionic liquids, one of the most widely used is the 1-butyl-3-methylimidazolium cation (abbreviated  $\text{bmim}^+$ , Figure 11.17 and Table 11.4), which has two arms of different lengths coming off a five-atom central ring. This feature gives  $\text{bmim}^+$  an irregular shape, which makes it difficult for the molecules to pack together in a solid.

▲ Figure 11.17 Representative ions found in ionic liquids.

TABLE 11.4 Melting Point and Decomposition Temperature of Four 1-Butyl-3-Methylimidazolium ( $\text{bmim}^+$ ) Salts

| Cation          | Anion           | Melting Point ( $^\circ\text{C}$ ) | Decomposition Temperature ( $^\circ\text{C}$ ) |
|-----------------|-----------------|------------------------------------|--|
| $\text{bmim}^+$ | $\text{Cl}^-$   | 41                                 | 254  |
| $\text{bmim}^+$ | $\text{I}^-$    | $-72$                              | 265  |
| $\text{bmim}^+$ | $\text{PF}_6^-$ | 10                                 | 349  |
| $\text{bmim}^+$ | $\text{BF}_4^-$ | $-81$                              | 403  |

Common anions found in ionic liquids include the  $\text{PF}_6^-$ ,  $\text{BF}_4^-$ , and halide ions.

Ionic liquids have many useful properties. Unlike most molecular liquids, they are nonvolatile (that is, they don't evaporate readily) and nonflammable. They tend to remain in the liquid state at temperatures up to about  $400^\circ\text{C}$ . Most molecular substances are liquids only at much lower temperatures,  $100^\circ\text{C}$  or less in most cases. Because ionic liquids are good solvents for a wide range of substances, ionic liquids can be used for a variety of reactions and separations. These properties make them attractive replacements for volatile organic solvents in many industrial processes. Relative to traditional organic solvents, ionic liquids offer the promise of reduced volumes, safer handling, and easier reuse, thereby reducing the environmental impact of industrial chemical processes.

**Related Exercises:** 11.31, 11.32, 11.82

The viscosity of a substance decreases with increasing temperature. This can be seen in the viscosity of octane:

$$7.06 \times 10^{-4} \text{ kg/m}\cdot\text{s at } 0^\circ\text{C}$$

$$4.33 \times 10^{-4} \text{ kg/m}\cdot\text{s at } 40^\circ\text{C}$$

At higher temperatures, the greater average kinetic energy of the molecules overcomes the attractive forces between molecules.

## Surface Tension

The surface of water behaves almost as if it had an elastic skin, as evidenced by the ability of certain insects to “walk” on water. This behavior is due to an imbalance of intermolecular forces at the surface of the liquid. As shown in Figure 11.18, molecules in the interior are attracted equally in all directions, but those at the surface experience a net inward force. This net force tends to pull surface molecules toward the interior, thereby reducing the surface area and making the molecules at the surface pack closely together.

Because spheres have the smallest surface area for their volume, water droplets assume an almost spherical shape. This explains the tendency of water to “bead up” when it contacts a surface made of nonpolar molecules, like a lotus leaf or a newly waxed car.

A measure of the net inward force that must be overcome to expand the surface area of a liquid is given by its surface tension. **Surface tension** is the energy required to increase the surface area of a liquid by a unit amount. For example, the surface tension of water at  $20^\circ\text{C}$  is  $7.29 \times 10^{-2} \text{ J/m}^2$ , which means that an energy of  $7.29 \times 10^{-2} \text{ J}$

▲ **Figure 11.18** Molecular-level view of surface tension. The high surface tension of water keeps the water strider from sinking.

must be supplied to increase the surface area of a given amount of water by  $1 \text{ m}^2$ . Water has a high surface tension because of its strong hydrogen bonds. The surface tension of mercury is even higher ( $4.6 \times 10^{-1} \text{ J/m}^2$ ) because of even stronger metallic bonds between the atoms of mercury.

### Give It Some Thought

As the temperature increases, do you expect the surface tension of a liquid to increase, decrease, or stay the same?

## Capillary Action

Intermolecular forces that bind similar molecules to one another, such as the hydrogen bonding in water, are called *cohesive forces*. Intermolecular forces that bind a substance to a surface are called *adhesive forces*. Water placed in a glass tube adheres to the glass because the adhesive forces between the water and the glass are greater than the cohesive forces between water molecules; glass is principally  $\text{SiO}_2$ , which has a very polar surface. The curved surface, or *meniscus*, of the water is therefore U-shaped (**Figure 11.19**). For mercury, however, the situation is different. Mercury atoms can form bonds with one another but not with the glass. As a result, the cohesive forces are much greater than the adhesive forces and the meniscus is shaped like an inverted U.

### Go Figure

If the inside surface of each tube were coated with wax, would the general shape of the water meniscus change? Would the general shape of the mercury meniscus change?

▲ **Figure 11.19** Meniscus shapes for water and mercury in glass tubes.

When a small-diameter glass tube, or capillary, is placed in water, water rises in the tube. The rise of liquids up very narrow tubes is called **capillary action**. The adhesive forces between the liquid and the walls of the tube tend to increase the surface area of the liquid. The surface tension of the liquid tends to reduce the area, thereby pulling the liquid up the tube. The liquid climbs until the force of gravity on the liquid balances the adhesive and cohesive forces.

Capillary action is widespread. For example, towels absorb liquid, and “stay-dry” synthetic fabrics move sweat away from the skin by capillary action. Capillary action also plays a role in moving water and dissolved nutrients upward through plants.

## 11.4 | Phase Changes

Liquid water left uncovered in a glass eventually evaporates. An ice cube left in a warm room quickly melts. Solid  $\text{CO}_2$  (sold as a product called dry ice) *sublimes* at room temperature; that is, it changes directly from solid to gas. In general, each state of matter—solid, liquid, gas—can transform into either of the other two states. **Figure 11.20** shows the names associated with these transformations, which are called either **phase changes** or *changes of state*.

### Energy Changes Accompany Phase Changes

Every phase change is accompanied by a change in the energy of the system. In a solid, for example, the particles (molecules, ions, or atoms) are in more or less fixed positions with respect to one another and closely arranged to minimize the energy of the system. As the temperature of the solid increases, the particles vibrate about their equilibrium positions with increasing energetic motion. When the solid melts, the particles begin moving freely relative to one another, which means their average kinetic energy increases.

Melting is called (somewhat confusingly) *fusion*. The increased freedom of motion of the particles requires energy, measured by the **heat of fusion** or *enthalpy of fusion*,  $\Delta H_{\text{fus}}$ . The heat of fusion of ice, for example, is 6.01 kJ/mol:

As the temperature of the liquid increases, the particles move about more vigorously. The increased motion allows some particles to escape into the gas phase. As a result, the concentration of gas-phase particles above the liquid surface increases with temperature. These gas-phase particles exert a pressure called *vapor pressure*. We explore vapor pressure in Section 11.5. For now we just need to understand that vapor pressure increases with increasing temperature until it equals the external pressure above the liquid, typically atmospheric pressure. At this point the liquid boils—bubbles of the vapor form within the liquid. The energy required to cause the transition of a given quantity of the liquid to the vapor is called either the **heat of vaporization** or the *enthalpy of vaporization*,  $\Delta H_{\text{vap}}$ . For water, the heat of vaporization is 40.7 kJ/mol.

**Figure 11.21** shows  $\Delta H_{\text{fus}}$  and  $\Delta H_{\text{vap}}$  values for four substances. The values of  $\Delta H_{\text{vap}}$  tend to be larger than the values of  $\Delta H_{\text{fus}}$  because in the transition from liquid to gas, particles must essentially sever all their interparticle attractions, whereas in the transition from solid to liquid, many of these attractive interactions remain operative.

## Go Figure

Why does water have a higher heat of vaporization than diethyl ether?

▲ Figure 11.21 Heats of fusion, vaporization, and sublimation.

The particles of a solid can move directly into the gaseous state. The enthalpy change required for this transition is called the **heat of sublimation**, denoted  $\Delta H_{\text{sub}}$ . As illustrated in Figure 11.20,  $\Delta H_{\text{sub}}$  is the sum of  $\Delta H_{\text{fus}}$  and  $\Delta H_{\text{vap}}$ . Thus,  $\Delta H_{\text{sub}}$  for water is approximately 47 kJ/mol.

Phase changes show up in important ways in our everyday experiences. When we use ice cubes to cool a drink, for instance, the heat of fusion of the ice cools the liquid. We feel cool when we step out of a swimming pool or a warm shower because the liquid water's heat of vaporization is drawn from our bodies as the water evaporates from our skin. Our bodies use this mechanism to regulate body temperature, especially when we exercise vigorously in warm weather. ∞ (Section 5.5) A refrigerator also relies on the cooling effects of vaporization. Its mechanism contains an enclosed gas that can be liquefied under pressure. The liquid absorbs heat as it subsequently evaporates, thereby cooling the interior of the refrigerator.

What happens to the heat absorbed when the liquid refrigerant vaporizes? According to the first law of thermodynamics ∞ (Section 5.2), this absorbed heat must be released when the gas condenses to liquid. As this phase change occurs, the heat released is dissipated through cooling coils in the back of the refrigerator. Just as for a given substance the heat of condensation is equal in magnitude to the heat of vaporization and has the opposite sign, so too the *heat of deposition* for a given substance is exothermic to the same degree that the heat of sublimation is endothermic; the *heat of freezing* is exothermic to the same degree that the heat of fusion is endothermic (see Figure 11.20).

## Give It Some Thought

What is the name of the phase change that occurs when ice left at room temperature changes to liquid water? Is this change exothermic or endothermic?

## Heating Curves

When we heat an ice cube initially at  $-25^{\circ}\text{C}$  and 1 atm pressure, the temperature of the ice increases. As long as the temperature is below  $0^{\circ}\text{C}$ , the ice cube remains in the solid state. When the temperature reaches  $0^{\circ}\text{C}$ , the ice begins to melt. Because melting is an endothermic process, the heat we add at  $0^{\circ}\text{C}$  is used to convert ice to liquid water, and *the temperature remains constant until all the ice has melted*. Once all the ice has melted, adding more heat causes the temperature of the liquid water to increase.

A graph of temperature versus amount of heat added is called a *heating curve*. **Figure 11.22** shows the heating curve for transforming ice,  $\text{H}_2\text{O}(s)$ , initially at  $-25^\circ\text{C}$  to steam,  $\text{H}_2\text{O}(g)$ , at  $125^\circ\text{C}$ . As heat is added at a constant rate, the heating curve forms distinct regions:

- Line AB: Heating increases the temperature of  $\text{H}_2\text{O}(s)$  from  $-25$  to  $0^\circ\text{C}$ .
- Line BC: Heating converts  $\text{H}_2\text{O}(s)$  to  $\text{H}_2\text{O}(l)$  as the ice melts at a constant temperature of  $0^\circ\text{C}$ .
- Line CD: Heating increases the temperature of the  $\text{H}_2\text{O}(l)$  from  $0^\circ\text{C}$  to  $100^\circ\text{C}$ .
- Line DE: Heating converts  $\text{H}_2\text{O}(l)$  to  $\text{H}_2\text{O}(g)$  as the water boils at a constant temperature of  $100^\circ\text{C}$ .
- Line EF: Heating increases the temperature of the  $\text{H}_2\text{O}(g)$  to  $125^\circ\text{C}$ .

We can calculate the enthalpy change of the system for each region of the heating curve. Lines AB, CD, and EF show the heating of a single phase from one temperature to another. As we saw in Section 5.5, the amount of heat needed to raise the temperature of a substance is given by the product of the specific heat, mass, and temperature change (Equation 5.21). The greater the specific heat of a substance, the more heat we must add to accomplish a certain temperature increase. Because the specific heat of water is greater than that of ice, the slope of line CD is less than that of line AB. This lesser slope means the amount of heat we must add to a given mass of liquid water to achieve a  $1^\circ\text{C}$  temperature change is greater than the amount we must add to achieve a  $1^\circ\text{C}$  temperature change in the same mass of ice.

Lines BC and DE show the conversion of one phase to another at a constant temperature. The temperature remains constant during these phase changes because the added energy is used to overcome the attractive forces between molecules rather than to increase their average kinetic energy. For line BC, the enthalpy change can be calculated by using  $\Delta H_{\text{fus}}$ , and for line DE we can use  $\Delta H_{\text{vap}}$ .

If we start with 1 mol of steam at  $125^\circ\text{C}$  and cool it, we move right to left across Figure 11.22. We first lower the temperature of the  $\text{H}_2\text{O}(g)$  ( $F \rightarrow E$ ), then condense it ( $E \rightarrow D$ ) to  $\text{H}_2\text{O}(l)$ , and so forth.

Sometimes as we remove heat from a liquid, we can temporarily cool it below its freezing point without forming a solid. This phenomenon, called *supercooling*, occurs when the heat is removed so rapidly that the molecules have no time to assume the ordered structure of a solid. A supercooled liquid is unstable; particles of dust entering the solution or gentle stirring is often sufficient to cause the substance to solidify quickly.

## Critical Temperature and Pressure

A gas normally liquefies at some point when pressure is applied. Suppose we have a cylinder fitted with a piston and the cylinder contains water vapor at  $100^\circ\text{C}$ . If we increase the pressure on the water vapor, liquid water will form when the pressure is 760 torr. However, if the temperature is  $110^\circ\text{C}$ , the liquid phase does not form until the pressure is 1075 torr. At  $374^\circ\text{C}$  the liquid phase forms only at  $1.655 \times 10^5$  torr (217.7 atm). Above this temperature, no amount of pressure causes a distinct liquid phase to form. Instead, as pressure increases, the gas becomes steadily more compressed. The highest temperature at which a distinct liquid phase can form is called the **critical temperature**. The **critical pressure** is the pressure required to bring about liquefaction at this critical temperature.

The critical temperature is the highest temperature at which a liquid can exist. Above the critical temperature, the kinetic energies of the molecules are greater than

### Sample Exercise 11.3

#### Calculating $\Delta H$ for Temperature and Phase Changes

Calculate the enthalpy change upon converting 1.00 mol of ice at  $-25^\circ\text{C}$  to steam at  $125^\circ\text{C}$  under a constant pressure of 1 atm. The specific heats of ice, liquid water, and steam are 2.03, 4.18, and  $1.84\text{ J/g}\cdot\text{K}$ , respectively. For  $\text{H}_2\text{O}$ ,  $\Delta H_{\text{fus}} = 6.01\text{ kJ/mol}$  and  $\Delta H_{\text{vap}} = 40.67\text{ kJ/mol}$ .

#### SOLUTION

**Analyze** Our goal is to calculate the total heat required to convert 1 mol of ice at  $-25^\circ\text{C}$  to steam at  $125^\circ\text{C}$ .

**Plan** We can calculate the enthalpy change for each segment and then sum them to get the total enthalpy change (Hess's law, Section 5.6).

#### Solve

For line *AB* in Figure 11.22, we are adding enough heat to ice to increase its temperature by  $25^\circ\text{C}$ . A temperature change of  $25^\circ\text{C}$  is the same as a temperature change of 25 K, so we can use the specific heat of ice to calculate the enthalpy change during this process:

$$\begin{aligned} AB: \Delta H &= (1.00\text{ mol})(18.0\text{ g/mol})(2.03\text{ J/g}\cdot\text{K})(25\text{ K}) \\ &= 914\text{ J} = 0.91\text{ kJ} \end{aligned}$$

For line *BC* in Figure 11.22, in which we convert ice to water at  $0^\circ\text{C}$ , we can use the molar enthalpy of fusion directly:

$$BC: \Delta H = (1.00\text{ mol})(6.01\text{ kJ/mol}) = 6.01\text{ kJ}$$

The enthalpy changes for lines *CD*, *DE*, and *EF* can be calculated in similar fashion:

$$\begin{aligned} CD: \Delta H &= (1.00\text{ mol})(18.0\text{ g/mol})(4.18\text{ J/g}\cdot\text{K})(100\text{ K}) \\ &= 7520\text{ J} = 7.52\text{ kJ} \end{aligned}$$

$$DE: \Delta H = (1.00\text{ mol})(40.67\text{ kJ/mol}) = 40.7\text{ kJ}$$

$$\begin{aligned} EF: \Delta H &= (1.00\text{ mol})(18.0\text{ g/mol})(1.84\text{ J/g}\cdot\text{K})(25\text{ K}) \\ &= 830\text{ J} = 0.83\text{ kJ} \end{aligned}$$

The total enthalpy change is the sum of the changes of the individual steps:

$$\Delta H = 0.91\text{ kJ} + 6.01\text{ kJ} + 7.52\text{ kJ} + 40.7\text{ kJ} + 0.83\text{ kJ} = 56.0\text{ kJ}$$

**Check** The components of the total enthalpy change are reasonable relative to the horizontal lengths (heat added) of the lines in Figure 11.22. Notice that the largest component is the heat of vaporization.

#### Practice Exercise 1

What information about water is needed to calculate the enthalpy change for converting 1 mol  $\text{H}_2\text{O}(g)$  at  $100^\circ\text{C}$  to  $\text{H}_2\text{O}(l)$  at  $80^\circ\text{C}$ ?

(a) heat of fusion (b) heat of vaporization (c) heat of vaporization and specific heat of  $\text{H}_2\text{O}(g)$  (d) heat of vaporization and specific heat of  $\text{H}_2\text{O}(l)$  (e) heat of fusion and specific heat of  $\text{H}_2\text{O}(l)$

#### Practice Exercise 2

What is the enthalpy change during the process in which 100.0 g of water at  $50.0^\circ\text{C}$  is cooled to ice at  $-30.0^\circ\text{C}$ ? (Use the specific heats and enthalpies for phase changes given in Sample Exercise 11.3.)

the attractive forces that lead to the liquid state regardless of how much the substance is compressed to bring the molecules closer together. *The greater the intermolecular forces, the higher the critical temperature of a substance.*

Several experimentally determined critical temperatures and pressures are listed in **Table 11.5**. Notice that nonpolar, low-molecular-weight substances, which have weak intermolecular attractions, have lower critical temperatures and pressures than substances that are polar or of higher molecular weight. Notice also that water and ammonia have exceptionally high critical temperatures and pressures as a consequence of strong intermolecular hydrogen-bonding forces.

#### Give It Some Thought

Why are the critical temperature and pressure for  $\text{H}_2\text{O}$  so much higher than those for  $\text{H}_2\text{S}$ , a related substance (Table 11.5)?

Because they provide information about the conditions under which gases liquefy, critical temperatures and pressures are often of considerable importance to engineers

**TABLE 11.5 Critical Temperatures and Pressures of Selected Substances**

| Substance  | Critical Temperature (K) | Critical Pressure (atm) |
|--|--------------------------|-------------------------|
| Nitrogen, N <sub>2</sub>                                 | 126.1                    | 33.5                    |
| Argon, Ar  | 150.9                    | 48.0                    |
| Oxygen, O <sub>2</sub>                                   | 154.4                    | 49.7                    |

| Propane, CH <sub>3</sub> CH <sub>2</sub> CH <sub>3</sub> | 370.0                    | 42.0                    |
| Hydrogen sulfide, H <sub>2</sub> S                       | 373.5                    | 88.9                    |
| Ammonia, NH <sub>3</sub>                                 | 405.6                    | 111.5                   |
| Water, H <sub>2</sub> O                                  | 647.6                    | 217.7                   |

and other people working with gases. Sometimes we want to liquefy a gas; other times we want to avoid liquefying it. It is useless to try to liquefy a gas by applying pressure if the gas is above its critical temperature. For example, O<sub>2</sub> has a critical temperature of 154.4 K. It must be cooled below this temperature before it can be liquefied by pressure. In contrast, ammonia has a critical temperature of 405.6 K. Thus, it can be liquefied at room temperature (approximately 295 K) by applying sufficient pressure.

When the temperature exceeds the critical temperature and the pressure exceeds the critical pressure, the liquid and gas phases are indistinguishable from each other, and the substance is in a state called a **supercritical fluid**. A supercritical fluid expands to fill its container (like a gas), but the molecules are still quite closely spaced (like a liquid).

Like liquids, supercritical fluids can behave as solvents dissolving a wide range of substances. Using *supercritical fluid extraction*, the components of mixtures can be separated from one another. Supercritical fluid extraction has been successfully used to separate complex mixtures in the chemical, food, pharmaceutical, and energy industries. Supercritical CO<sub>2</sub> is a popular choice because it is relatively inexpensive and, if used in closed-loop systems, may be a way to reduce CO<sub>2</sub> emissions into the atmosphere.

## 11.5 | Vapor Pressure

Molecules can escape from the surface of a liquid into the gas phase by evaporation. Suppose we place a quantity of ethanol (CH<sub>3</sub>CH<sub>2</sub>OH) in an evacuated, closed container, as in **Figure 11.23**. The ethanol quickly begins to evaporate. As a result, the pressure exerted

◀ **Figure 11.23** Vapor pressure over a liquid.

### Go Figure

As the temperature increases, does the rate of molecules escaping into the gas phase increase or decrease?

▲ **Figure 11.24** The effect of temperature on the distribution of kinetic energies in a liquid.

by the vapor in the space above the liquid increases. After a short time, the pressure of the vapor attains a constant value, which we call the **vapor pressure**.

At any instant, some of the ethanol molecules at the liquid surface possess sufficient kinetic energy to overcome the attractive forces of their neighbors and, therefore, escape into the gas phase. As the number of gas-phase molecules increases, however, the probability increases that a molecule in the gas phase will strike the liquid surface and be recaptured by the liquid, as shown in the flask on the right in Figure 11.23. Eventually, the rate at which molecules return to the liquid equals the rate at which they escape. The number of molecules in the gas phase then reaches a steady value, and the pressure exerted by the vapor becomes constant.

The condition in which two opposing processes occur simultaneously at equal rates is called **dynamic equilibrium** (or simply *equilibrium*). Chemical equilibrium, which we encountered in Section 4.1, is a kind of dynamic equilibrium in which the opposing processes are chemical reactions.

A liquid and its vapor are in dynamic equilibrium when evaporation and condensation occur at equal rates. It may appear that nothing is occurring at equilibrium because there is no net change in the system. In fact, though, a great deal is happening as molecules continuously pass from liquid state to gas state and from gas state to liquid state. *The vapor pressure of a liquid is the pressure exerted by its vapor when the liquid and vapor are in dynamic equilibrium.*

### Go Figure

What is the vapor pressure of ethylene glycol at its normal boiling point?

▲ **Figure 11.25** Vapor pressure for four liquids as a function of temperature.

## Volatility, Vapor Pressure, and Temperature

When vaporization occurs in an open container, as when water evaporates from a bowl, the vapor moves away from the liquid. Little, if any, is recaptured at the surface of the liquid. Equilibrium never occurs, and the vapor continues to form until the liquid evaporates to dryness. Substances with high vapor pressure (such as gasoline) evaporate more quickly than substances with low vapor pressure (such as motor oil). Liquids that evaporate readily are said to be **volatile**.

Hot water evaporates more quickly than cold water because vapor pressure increases with increasing temperature. To see why this statement is true, we begin with the fact that the molecules of a liquid move at various speeds. Figure 11.24 shows the distribution of kinetic energies of the molecules at the surface of a liquid at two temperatures. (The curves are like those shown for gases in Section 10.7.) As the temperature is increased, the molecules move more energetically and more of them can break free from their neighbors and enter the gas phase, increasing the vapor pressure.

Figure 11.25 depicts the variation in vapor pressure with temperature for four common substances that differ greatly in volatility. Note that the vapor pressure in all cases increases nonlinearly with increasing temperature. The weaker the intermolecular forces in the liquid, the more easily molecules can escape and, therefore, the higher the vapor pressure at a given temperature.

### Give It Some Thought

Which compound do you think is more volatile at 25 °C:  $\text{CCl}_4$  or  $\text{CBr}_4$ ?

## Vapor Pressure and Boiling Point

The **boiling point** of a liquid is the temperature at which its vapor pressure equals the external pressure, acting on the liquid surface. At this temperature, the thermal energy of the molecules is great enough for the molecules in the interior of the liquid to break free from their neighbors and enter the gas phase. As a result, bubbles of vapor form within the liquid. The boiling point increases as the external pressure increases. The boiling point of a liquid at 1 atm (760 torr) pressure is called its **normal boiling point**. From Figure 11.25 we see that the normal boiling point of water is 100 °C.

The time required to cook food in boiling water depends on the water temperature. In an open container, that temperature is 100 °C, but it is possible to boil at higher temperatures. Pressure cookers work by allowing steam to escape only when it exceeds a predetermined pressure; the pressure above the water can therefore increase above atmospheric pressure. The higher pressure causes the water to boil at a higher temperature, thereby allowing the food to get hotter and to cook more rapidly.

The effect of pressure on boiling point also explains why it takes longer to cook food at high elevations than it does at sea level. The atmospheric pressure is lower at higher altitudes, so water boils at a temperature lower than 100 °C, and foods generally take longer to cook.

### A CLOSER LOOK The Clausius–Clapeyron Equation

Notice that the plots in Figure 11.25 have a distinct shape: For each substance, the vapor-pressure curves sharply upward with increasing temperature. The relationship between vapor pressure and temperature is given by the *Clausius–Clapeyron equation*:

$$\ln P = \frac{-\Delta H_{\text{vap}}}{RT} + C \quad [11.1]$$

where  $P$  is the vapor pressure,  $T$  is the absolute temperature,  $R$  is the gas constant (8.314 J/mol·K),  $\Delta H_{\text{vap}}$  is the molar enthalpy of vaporization, and  $C$  is a constant. This equation predicts that a graph of  $\ln P$  versus  $1/T$  should give a straight line with a slope equal to  $\Delta H_{\text{vap}}/R$ . Using this plot, we can determine the enthalpy of vaporization of a substance:

$$\Delta H_{\text{vap}} = -\text{slope} \times R$$

As an example of how we use the Clausius–Clapeyron equation, the vapor-pressure data for ethanol shown in Figure 11.25 are graphed as  $\ln P$  versus  $1/T$  in Figure 11.26. The data lie on a straight line with a negative slope. We can use the slope to determine  $\Delta H_{\text{vap}}$  for ethanol, 38.56 kJ/mol. We can also extrapolate the line to obtain the vapor pressure of ethanol at temperatures above and below the temperature range for which we have data.

### Sample Exercise 11.4

#### Relating Boiling Point to Vapor Pressure

Use Figure 11.25 to estimate the boiling point of diethyl ether under an external pressure of 0.80 atm.

#### SOLUTION

**Analyze** We are asked to read a graph of vapor pressure versus temperature to determine the boiling point of a substance at a particular pressure. The boiling point is the temperature at which the vapor pressure is equal to the external pressure.

**Plan** We need to convert 0.80 atm to torr because that is the pressure scale on the graph. We estimate the location of that pressure on the graph, move horizontally to the vapor-pressure curve, and then drop vertically from the curve to estimate the temperature.

*Continued*

**Solve** The pressure equals  $(0.80 \text{ atm})(760 \text{ torr/atm}) = 610 \text{ torr}$ . From Figure 11.25 we see that the boiling point at this pressure is about  $27^\circ\text{C}$ , which is close to room temperature.

**Comment** We can make a flask of diethyl ether boil at room temperature by using a vacuum pump to lower the pressure above the liquid to about 0.8 atm.

### Practice Exercise 1

In the mountains, water in an open container will boil when

- (a) its critical temperature exceeds room temperature.
- (b) its vapor pressure equals atmospheric pressure.
- (c) its temperature is  $100^\circ\text{C}$ .
- (d) enough energy is supplied to break covalent bonds.
- (e) none of these is correct.

### Practice Exercise 2

Use Figure 11.25 to determine the external pressure if ethanol boils at  $60^\circ\text{C}$ .

## 11.6 | Phase Diagrams

The equilibrium between a liquid and its vapor is not the only dynamic equilibrium that can exist between states of matter. Under appropriate conditions, a solid can be in equilibrium with its liquid or even with its vapor. The temperature at which solid and liquid phases coexist at equilibrium is the *melting point* of the solid or the *freezing point* of the liquid. Solids can also undergo evaporation and therefore possess a vapor pressure.

A **phase diagram** is a graphic way to summarize the conditions under which equilibria exist between the different states of matter. Such a diagram also allows us to predict which phase of a substance is present at any given temperature and pressure.

The phase diagram for any substance that can exist in all three phases of matter is shown in Figure 11.27. The diagram contains three important curves, each of which represents the temperature and pressure at which the various phases can coexist at equilibrium. The only substance present in the system is the one whose phase diagram is under consideration. The pressure shown in the diagram is either the pressure applied

### Go Figure

Imagine that the pressure on the solid phase in the figure is decreased at constant temperature. If the solid eventually sublimates, what must be true about the temperature?

▲ **Figure 11.27** Generic phase diagram for a pure substance. The green line is the sublimation curve, the blue line is the melting curve, and the red line is the vapor-pressure curve.

to the system or the pressure generated by the substance. The curves may be described as follows:

1. The red curve is the *vapor-pressure curve* of the liquid, representing equilibrium between the liquid and gas phases. The point on this curve where the vapor pressure is 1 atm is the normal boiling point of the substance. The vapor-pressure curve ends at the **critical point** (C), which corresponds to the critical temperature and critical pressure of the substance. At temperatures and pressures beyond the critical point, the liquid and gas phases are indistinguishable from each other, and the substance is a *supercritical fluid*.
2. The green curve, the *sublimation curve*, separates the solid phase from the gas phase and represents the change in the vapor pressure of the solid as it sublimates at different temperatures. Each point on this curve represents a condition of equilibrium between the solid and the gas.
3. The blue curve, the *melting curve*, separates the solid phase from the liquid phase and represents the change in melting point of the solid with increasing pressure. Each point on this curve represents an equilibrium between the solid and the liquid. This curve usually slopes slightly to the right as pressure increases for most substances because the solid form is denser than the liquid form. An increase in pressure usually favors the more compact solid phase; thus, higher temperatures are required to melt the solid at higher pressures. The melting point at 1 atm is the **normal melting point**.

Point  $T$ , where the three curves intersect, is the **triple point**, and here all three phases are in equilibrium. Any other point on any of the three curves represents equilibrium between two phases. Any point on the diagram that does not fall on one of the curves corresponds to conditions under which only one phase is present. The gas phase, for example, is stable at low pressures and high temperatures, whereas the solid phase is stable at low temperatures and high pressures. Liquids are stable in the region between the other two.

## The Phase Diagrams of $\text{H}_2\text{O}$ and $\text{CO}_2$

Figure 11.28 shows the phase diagram of  $\text{H}_2\text{O}$ . Because of the large range of pressures covered in the diagram, a logarithmic scale is used to represent pressure. The melting curve (blue line) of  $\text{H}_2\text{O}$  is atypical, slanting slightly to the left with increasing pressure, indicating that for water the melting point *decreases* with increasing pressure. This unusual behavior occurs because water is among the very few substances whose liquid form is more compact than its solid form, as we learned in Section 11.2.

◀ **Figure 11.28** Phase diagram of  $\text{H}_2\text{O}$ .

Note that a linear scale is used to represent temperature and a logarithmic scale to represent pressure.

► **Figure 11.29** Phase diagram of  $\text{CO}_2$ .

Note that a linear scale is used to represent temperature and a logarithmic scale to represent pressure.

If the pressure is held constant at 1 atm, it is possible to move from the solid to liquid to gaseous regions of the phase diagram by changing the temperature, as we expect from our everyday encounters with water. The triple point of  $\text{H}_2\text{O}$  falls at a relatively low pressure, 0.00603 atm. Below this pressure, liquid water is not stable and ice sublimates to water vapor on heating. This property of water is used to “freeze-dry” foods and beverages. The food or beverage is frozen to a temperature below  $0^\circ\text{C}$ . Next it is placed in a low-pressure chamber (below 0.00603 atm) and then warmed so that the water sublimates, leaving behind dehydrated food or beverage.

The phase diagram for  $\text{CO}_2$  is shown in **Figure 11.29**. The melting curve (blue line) behaves typically, slanting to the right with increasing pressure, telling us that the melting point of  $\text{CO}_2$  increases with increasing pressure. Because the pressure at the

### Sample Exercise 11.5

#### Interpreting a Phase Diagram

Use the phase diagram for methane,  $\text{CH}_4$ , shown in **Figure 11.30** to answer the following questions. (a) What are the approximate temperature and pressure of the critical point? (b) What are the approximate temperature and pressure of the triple point? (c) Is methane a solid, liquid, or gas at 1 atm and  $0^\circ\text{C}$ ? (d) If solid methane at 1 atm is heated while the pressure is held constant, will it melt or sublime? (e) If methane at 1 atm and  $0^\circ\text{C}$  is compressed until a phase change occurs, in which state is the methane when the compression is complete?

#### SOLUTION

**Analyze** We are asked to identify key features of the phase diagram and to use it to deduce what phase changes occur when specific pressure and temperature changes take place.

**Plan** We must identify the triple and critical points on the diagram and also identify which phase exists at specific temperatures and pressures.

▲ **Figure 11.30** Phase diagram of  $\text{CH}_4$ . Note that a linear scale is used to represent temperature and a logarithmic scale to represent pressure.

**Solve**

- (a) The critical point is the point where the liquid, gaseous, and supercritical fluid phases coexist. It is marked point 3 in the phase diagram and located at approximately  $-80^{\circ}\text{C}$  and 50 atm.
- (b) The triple point is the point where the solid, liquid, and gaseous phases coexist. It is marked point 1 in the phase diagram and located at approximately  $-180^{\circ}\text{C}$  and 0.1 atm.
- (c) The intersection of  $0^{\circ}\text{C}$  and 1 atm is marked point 2 in the phase diagram. It is well within the gaseous region of the phase diagram.
- (d) If we start in the solid region at  $P = 1$  atm and move horizontally (this means we hold the pressure constant), we cross first into the liquid region, at  $T \approx -180^{\circ}\text{C}$ , and then into the gaseous region, at  $T \approx -160^{\circ}\text{C}$ . Therefore, solid methane melts when the pressure is 1 atm. (For methane to sublime, the pressure must be below the triple point pressure.)
- (e) Moving vertically up from point 2, which is 1 atm and  $0^{\circ}\text{C}$ , the first phase change we come to is from gas to supercritical fluid. This phase change happens when we exceed the critical pressure ( $\sim 50$  atm).

**Check** The pressure and temperature at the critical point are higher than those at the triple point, which is expected. Methane is the principal component of natural gas. So it seems reasonable that it exists as a gas at 1 atm and  $0^{\circ}\text{C}$ .

**Practice Exercise 1**

Based on the phase diagram for methane (Figure 11.30), what happens to methane as it is heated from  $-250$  to  $0^{\circ}\text{C}$  at a pressure of  $10^{-2}$  atm?

- (a) It sublimates at about  $-200^{\circ}\text{C}$ . (b) It melts at about  $-200^{\circ}\text{C}$ .
- (c) It boils at about  $-200^{\circ}\text{C}$ . (d) It condenses at about  $-200^{\circ}\text{C}$ .
- (e) It reaches the triple point at about  $-200^{\circ}\text{C}$ .

**Practice Exercise 2**

Use the phase diagram of methane to answer the following questions. (a) What is the normal boiling point of methane? (b) Over what pressure range does solid methane sublime? (c) Above what temperature does liquid methane not exist?

triple point is relatively high, 5.11 atm,  $\text{CO}_2$  does not exist as a liquid at 1 atm, which means that solid  $\text{CO}_2$  does not melt when heated, but instead sublimates. Thus,  $\text{CO}_2$  does not have a normal melting point; instead, it has a normal sublimation point,  $-78.5^{\circ}\text{C}$ . Because  $\text{CO}_2$  sublimates rather than melts as it absorbs energy at ordinary pressures, solid  $\text{CO}_2$  (dry ice) is a convenient coolant.

## 11.7 | Liquid Crystals

In 1888 Friedrich Reinitzer, an Austrian botanist, discovered that the organic compound cholesteryl benzoate has an interesting and unusual property, shown in Figure 11.31. Solid cholesteryl benzoate melts at  $145^{\circ}\text{C}$ , forming a viscous milky liquid; then at  $179^{\circ}\text{C}$  the milky liquid becomes clear and remains that way at temperatures above  $179^{\circ}\text{C}$ . When cooled, the clear liquid turns viscous and milky at  $179^{\circ}\text{C}$ , and the milky liquid solidifies at  $145^{\circ}\text{C}$ .

Reinitzer's work represents the first systematic report of what we call a **liquid crystal**, the term we use today for the viscous, milky state that some substances exhibit between the liquid and solid states.

This intermediate phase has some of the structure of solids and some of the freedom of motion of liquids. Because of the partial ordering, liquid crystals may be viscous and possess properties intermediate between those of solids and those of liquids. The region in which they exhibit these properties is marked by sharp transition temperatures, as in Reinitzer's sample. Just like solid, liquid, and gas phases, the liquid crystalline phase is represented by a distinct region on a phase diagram.

Today liquid crystals are used as pressure and temperature sensors and as liquid crystals displays (LCDs) in such devices as digital watches, televisions, and computers. They can be used for these applications because the weak intermolecular forces that hold the molecules together in the liquid crystalline phase are easily affected by changes in temperature, pressure, and electric fields.

### Types of Liquid Crystals

Substances that form liquid crystals are often composed of rod-shaped molecules that are somewhat rigid. In the liquid phase, these molecules are oriented randomly. In the liquid crystalline phase, by contrast, the molecules are arranged in specific patterns as

$145^{\circ}\text{C} < T < 179^{\circ}\text{C}$   
Liquid crystalline phase

$T > 179^{\circ}\text{C}$   
Liquid phase

**▲ Figure 11.31** Cholesteryl benzoate in its liquid and liquid crystalline states.

▲ **Figure 11.32** Molecular order in nematic, smectic, and cholesteric liquid crystals. In the liquid phase of any substance, the molecules are arranged randomly, whereas in the liquid crystalline phases the molecules are arranged in a partially ordered way.

illustrated in **Figure 11.32**. Depending on the nature of the ordering, liquid crystals are classified as nematic, smectic A, smectic C, or cholesteric.

In a **nematic liquid crystal**, the molecules are aligned so that their long axes tend to point in the same direction but the ends are not aligned with one another. In **smectic A** and **smectic C liquid crystals**, the molecules maintain the long-axis alignment seen in nematic crystals, but in addition they pack into layers.

Two molecules that exhibit liquid crystalline phases are shown in **Figure 11.33**. The lengths of these molecules are much greater than their widths. The double bonds, including those in the benzene rings, add rigidity to the molecules, and the rings, because they are flat, help the molecules stack with one another. The polar  $\text{—OCH}_3$  and  $\text{—COOH}$  groups give rise to dipole-dipole interactions and promote alignment of the molecules. Thus, the molecules order themselves quite naturally along their long axes. They can, however, rotate around their axes and slide

▲ **Figure 11.33** Molecular structure and liquid crystal temperature range for two typical liquid crystalline materials.

parallel to one another. In smectic liquid crystals, the intermolecular forces (dispersion forces, dipole-dipole attractions, and hydrogen bonding) limit the ability of the molecules to slide past one another.

In a **cholesteric liquid crystal**, the molecules are arranged in layers, with their long axes parallel to the other molecules within the same layer.\* Upon moving from one layer to the next, the orientation of the molecules rotates by a fixed angle, resulting in a spiral pattern. These liquid crystals are so named because many derivatives of cholesterol adopt this structure.

The molecular arrangement in cholesteric liquid crystals produces unusual coloring patterns with visible light. Changes in temperature and pressure change the order and, hence, the color. Cholesteric liquid crystals are used to monitor temperature changes in situations where conventional methods are not feasible. For example, they can detect hot spots in microelectronic circuits, which may signal the presence of flaws. They can also be fashioned into thermometers for measuring the skin temperature of infants. Because cholesteric liquid crystal displays can be built that draw very little power, they are also being investigated for use in electronic paper (Figure 11.34). Such applications are possible because an applied electrical field changes the orientation of liquid crystal molecules and thus affects the optical properties of the device.

▲ **Figure 11.34** Electronic paper (e-paper) based on cholesteric liquid crystal technology. Electronic paper mimics the appearance of ordinary ink on paper (like a page of a book or magazine). It has numerous potential uses including thin displays on walls, electronic labels, and electronic book readers.

### Sample Exercise 11.6

#### Properties of Liquid Crystals

Which of these substances is most likely to exhibit liquid crystalline behavior?

#### SOLUTION

**Analyze** We have three molecules with different structures, and we are asked to determine which one is most likely to be a liquid crystalline substance.

**Plan** We need to identify all structural features that might induce liquid crystalline behavior.

**Solve** Molecule (i) is not likely to be liquid crystalline because the absence of double and/or triple bonds makes this molecule flexible rather than rigid. Molecule (iii) is ionic, and the generally high melting points of ionic materials make it unlikely that this substance is liquid crystalline. Molecule (ii) possesses the characteristic long axis and the kinds of structural features often seen in liquid crystals: The molecule has a rod-like shape, the double bonds and benzene rings provide rigidity, and the polar  $\text{COOCH}_3$  group creates a dipole moment.

#### Practice Exercise 1

Liquid crystalline phases are produced by which of the following?

- (a) short, flexible molecules
- (b) complete lack of order among molecules
- (c) three-dimensional order among molecules
- (d) highly branched molecules
- (e) rod-shaped molecules

#### Practice Exercise 2

Suggest a reason why decane ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ ) does not exhibit liquid crystalline behavior.

### Sample Integrative Exercise

#### Putting Concepts Together

The substance  $\text{CS}_2$  has a melting point of  $-110.8^\circ\text{C}$  and a boiling point of  $46.3^\circ\text{C}$ . Its density at  $20^\circ\text{C}$  is  $1.26\text{ g/cm}^3$ . It is highly flammable. (a) What is the name of this compound? (b) List the intermolecular forces that  $\text{CS}_2$  molecules exert on one another. (c) Write a balanced equation for the combustion of this compound in air. (You will have to decide on the most likely

*Continued*

\*Cholesteric liquid crystals are sometimes called chiral nematic phases because the molecules within each plane adopt an arrangement similar to a nematic liquid crystal.

oxidation products.) (d) The critical temperature and pressure for CS<sub>2</sub> are 552 K and 78 atm, respectively. Compare these values with those for CO<sub>2</sub> in Table 11.5 and discuss the possible origins of the differences.

### SOLUTION

- (a) The compound is named carbon disulfide, in analogy with the naming of other binary molecular compounds such as carbon dioxide. (Section 2.8)
- (b) Because there is no H atom, there can be no hydrogen bonding. If we draw the Lewis structure, we see that carbon forms double bonds with each sulfur:

Using the VSEPR model (Section 9.2), we conclude that the molecule is linear and therefore has no dipole moment. (Section 9.3) Thus, there are no dipole–dipole forces. Only dispersion forces operate between the CS<sub>2</sub> molecules.

- (c) The most likely products of the combustion will be CO<sub>2</sub> and SO<sub>2</sub>. (Section 3.2) Under some conditions, SO<sub>3</sub> might be formed, but this would be the less likely outcome. Thus, we have the following equation for combustion:

- (d) The critical temperature and pressure of CS<sub>2</sub> (552 K and 78 atm, respectively) are both higher than those given for CO<sub>2</sub> in Table 11.5 (304 K and 73 atm, respectively). The difference in critical temperatures is especially notable. The higher values for CS<sub>2</sub> arise from the greater dispersion attractions between the CS<sub>2</sub> molecules compared with CO<sub>2</sub>. These greater attractions are due to the larger size of the sulfur compared to oxygen and, therefore, its greater polarizability.

## Chapter Summary and Key Terms

### A MOLECULAR COMPARISON OF GASES, LIQUIDS, AND SOLIDS (INTRODUCTION AND SECTION 11.1)

Substances that are gases or liquids at room temperature are usually composed of molecules. In gases, the intermolecular attractive forces are negligible compared to the kinetic energies of the molecules; thus, the molecules are widely separated and undergo constant, chaotic motion. In liquids, the **intermolecular forces** are strong enough to keep the molecules in close proximity; nevertheless, the molecules are free to move with respect to one another. In solids, the intermolecular attractive forces are strong enough to restrain molecular motion and to force the particles to occupy specific locations in a three-dimensional arrangement.

**INTERMOLECULAR FORCES (SECTION 11.2)** Three types of intermolecular forces exist between neutral molecules: **dispersion forces**, **dipole–dipole interactions**, and **hydrogen bonding**. Dispersion forces operate between all molecules (and atoms, for atomic substances such as He, Ne, Ar, and so forth). As molecular weight increases, the **polarizability** of a molecule increases, which results in stronger dispersion forces. Molecular shape is also an important factor. Dipole–dipole forces increase in strength as the polarity of the molecule increases. Hydrogen bonding occurs in compounds containing O—H, N—H, and F—H bonds. Hydrogen bonds are generally stronger than dipole–dipole or dispersion forces. **Ion–dipole forces** are important in solutions in which ionic compounds are dissolved in polar solvents.

**SELECT PROPERTIES OF LIQUIDS (SECTION 11.3)** The stronger the intermolecular forces, the greater is the **viscosity**, or resistance to flow, of a liquid. **Surface tension** is a measure of the tendency of a liquid to maintain a minimum surface area. The surface tension of a liquid also increases as intermolecular forces increase in strength. The adhesion of a liquid to the walls of a narrow tube and the cohesion of the liquid account for **capillary action**.

**PHASE CHANGES (SECTION 11.4)** A substance may exist in more than one state of matter, or phase. **Phase changes** are transformations from one phase to another. Changes of a solid to liquid (melting), solid to gas (sublimation), and liquid to gas (vaporization) are all endothermic processes. Thus, the **heat of fusion** (melting), the **heat of sublimation**, and the **heat of vaporization** are all positive quantities. The reverse processes (freezing, deposition, and condensation) are exothermic.

A gas cannot be liquefied by application of pressure if the temperature is above its **critical temperature**. The pressure required to

liquefy a gas at its critical temperature is called the **critical pressure**. When the temperature exceeds the critical temperature and the pressure exceeds the critical pressure, the liquid and gas phases coalesce to form a **supercritical fluid**.

**VAPOR PRESSURE (SECTION 11.5)** The **vapor pressure** of a liquid is the partial pressure of the vapor when it is in **dynamic equilibrium** with the liquid. At equilibrium the rate of transfer of molecules from the liquid to the vapor equals the rate of transfer from the vapor to the liquid. The higher the vapor pressure of a liquid, the more readily it evaporates and the more **volatile** it is. Vapor pressure increases with temperature. Boiling occurs when the vapor pressure equals the external pressure. Thus, the **boiling point** of a liquid depends on pressure. The **normal boiling point** is the temperature at which the vapor pressure equals 1 atm.

**PHASE DIAGRAMS (SECTION 11.6)** The equilibria between the solid, liquid, and gas phases of a substance as a function of temperature and pressure are displayed on a **phase diagram**. A line indicates equilibria between any two phases. The line through the melting point usually slopes slightly to the right as pressure increases, because the solid is usually more dense than the liquid. The melting point at 1 atm is the **normal melting point**. The point on the diagram at which all three phases coexist in equilibrium is called the **triple point**. The **critical point** corresponds to the critical temperature and critical pressure. Beyond the critical point, the substance is a supercritical fluid.

**LIQUID CRYSTALS (SECTION 11.7)** A **liquid crystal** is a substance that exhibits one or more ordered phases at a temperature above the melting point of the solid. In a **nematic liquid crystal** the molecules are aligned along a common direction, but the ends of the molecules are not lined up. In a **smectic liquid crystal** the ends of the molecules are lined up so that the molecules form layers. In **smectic A liquid crystals** the long axes of the molecules line up perpendicular to the layers. In **smectic C liquid crystals** the long axes of molecules are inclined with respect to the layers. A **cholesteric liquid crystal** is composed of molecules that align parallel to each other within a layer, as they do in nematic liquid crystalline phases, but the direction along which the long axes of the molecules align rotates from one layer to the next to form a helical structure. Substances that form liquid crystals are generally composed of molecules with fairly rigid, elongated shapes, as well as polar groups to help align molecules through dipole–dipole interactions.

## Learning Outcomes After studying this chapter, you should be able to:

- Identify the intermolecular attractive interactions (dispersion, dipole-dipole, hydrogen bonding, ion-dipole) that exist between molecules or ions based on their composition and molecular structure and compare the relative strengths of these intermolecular forces. (Section 11.2) *Related Exercises: 11.17, 11.18, 11.25, 11.26*
- Explain the concept of polarizability and how it relates to dispersion forces. (Section 11.2) *Related Exercises: 11.19–11.22*
- Explain the concepts of viscosity, surface tension, and capillary action. (Section 11.3) *Related Exercises: 11.35, 11.36*
- List the names of the various changes of state for a pure substance and indicate which are endothermic and which are exothermic. (Section 11.4) *Related Exercises: 11.39, 11.40*
- Interpret heating curves and calculate the enthalpy changes related to temperature changes and phase changes. (Section 11.4) *Related Exercises: 11.45, 11.46*
- Define critical pressure, critical temperature, vapor pressure, normal boiling point, normal melting point, critical point, and triple point. (Sections 11.4, 11.5, and 11.6) *Related Exercises: 11.47, 11.48, 11.51, 11.52*
- Interpret and sketch phase diagrams. Explain how water's phase diagram differs from most other substances and why. (Section 11.6) *Related Exercises: 11.57–11.60*
- Describe how the molecular arrangements characteristic of nematic, smectic, and cholesteric liquid crystals differ from ordinary liquids and from each other. Recognize the features of molecules that favor formation of liquid crystalline phases. (Section 11.7) *Related Exercises: 11.65, 11.69, 11.71*

## Exercises

### Visualizing Concepts

- 11.1** (a) Does the diagram best describe a crystalline solid, a liquid, or a gas? (b) Explain. [Section 11.1]

- 11.2** (a) Which kind of intermolecular attractive force is shown in each case here?

- (b) Predict which of the four interactions is the weakest. [Section 11.2]

- 11.3** (a) Do you expect the viscosity of glycerol,  $\text{C}_3\text{H}_5(\text{OH})_3$ , to be larger or smaller than that of 1-propanol,  $\text{C}_3\text{H}_7\text{OH}$ ? (b) Explain. [Section 11.3]

Glycerol

1-Propanol

- 11.4** If 42.0 kJ of heat is added to a 32.0-g sample of liquid methane under 1 atm of pressure at a temperature of  $-170^\circ\text{C}$ , what are the final state and temperature of the methane once the system equilibrates? Assume no heat is lost to the surroundings. The normal boiling point of methane is  $-161.5^\circ\text{C}$ . The specific heats of liquid and gaseous methane are 3.48 and 2.22 J/g·K, respectively. [Section 11.4]

- 11.5** Using this graph of  $\text{CS}_2$  data,

determine (a) the approximate vapor pressure of  $\text{CS}_2$  at  $30^\circ\text{C}$ , (b) the temperature at which the vapor pressure equals 300 torr, (c) the normal boiling point of  $\text{CS}_2$ . [Section 11.5]

### 11.6 The molecules

Propanol

Ethyl methyl ether

have the same molecular formula ( $\text{C}_3\text{H}_8\text{O}$ ) but different chemical structures. (a) Which molecule(s), if any, can engage in hydrogen bonding? (b) Which molecule do you expect to have a larger dipole moment? (c) One of these molecules has a normal boiling point of  $97.2^\circ\text{C}$ , while the other one has a normal boiling point of  $10.8^\circ\text{C}$ . Assign each molecule to its normal boiling point. [Sections 11.2 and 11.5]

### 11.7 The phase diagram of a hypothetical substance is

(a) Estimate the normal boiling point and freezing point of the substance. (b) What is the physical state of the substance under the following conditions: (i)  $T = 150\text{ K}$ ,  $P = 0.2\text{ atm}$ ; (ii)  $T = 100\text{ K}$ ,  $P = 0.8\text{ atm}$ ; (iii)  $T = 300\text{ K}$ ,  $P = 1.0\text{ atm}$ . (c) What is the triple point of the substance? [Section 11.6]

### 11.8 At three different temperatures, $T_1$ , $T_2$ , and $T_3$ , the molecules in a liquid crystal align in these ways:

(a) At which temperature or temperatures is the substance in a liquid crystalline state? At those temperatures, which type of liquid crystalline phase is depicted? (b) Which is the highest of these three temperatures? [Section 11.7]

## Molecular Comparisons of Gases, Liquids, and Solids (Section 11.1)

**11.9** List the three states of matter in order of (a) increasing molecular disorder and (b) increasing intermolecular attraction. (c) Which state of matter is most easily compressed?

**11.10** (a) How does the average kinetic energy of molecules compare with the average energy of attraction between molecules in solids, liquids, and gases? (b) Why does increasing the temperature cause a solid substance to change in succession from a solid to a liquid to a gas? (c) What happens to a gas if you put it under extremely high pressure?

**11.11** As a metal such as lead melts, what happens to (a) the average kinetic energy of the atoms and (b) the average distance between the atoms?

**11.12** At room temperature, Si is a solid,  $\text{CCl}_4$  is a liquid, and Ar is a gas. List these substances in order of (a) increasing intermolecular energy of attraction and (b) increasing boiling point.

**11.13** At standard temperature and pressure, the molar volumes of  $\text{Cl}_2$  and  $\text{NH}_3$  gases are 22.06 and 22.40 L, respectively. (a) Given the different molecular weights, dipole moments, and molecular shapes, why are their molar volumes nearly the same? (b) On cooling to 160 K, both substances form crystalline solids. Do you expect the molar volumes to decrease or increase on cooling the gases to 160 K? (c) The densities of crystalline  $\text{Cl}_2$  and  $\text{NH}_3$  at 160 K are 2.02 and  $0.84\text{ g/cm}^3$ , respectively. Calculate their molar volumes. (d) Are the molar volumes in the solid state as similar as they are in the gaseous state? Explain. (e) Would you expect the molar volumes in the liquid state to be closer to those in the solid or gaseous state?

**11.14** Benzoic acid,  $\text{C}_6\text{H}_5\text{COOH}$ , melts at  $122^\circ\text{C}$ . The density in the liquid state at  $130^\circ\text{C}$  is  $1.08\text{ g/cm}^3$ . The density of solid benzoic acid at  $15^\circ\text{C}$  is  $1.266\text{ g/cm}^3$ . (a) In which of these two states is the average distance between molecules greater? (b) If you converted a cubic centimeter of liquid benzoic acid into a solid, would the solid take up more, or less, volume than the original cubic centimeter of liquid?

## Intermolecular Forces (Section 11.2)

**11.15** (a) Which type of intermolecular attractive force operates between all molecules? (b) Which type of intermolecular attractive force operates only between polar molecules? (c) Which type of intermolecular attractive force operates only between the hydrogen atom of a polar bond and a nearby small electronegative atom?

**11.16** (a) Which is generally stronger, intermolecular interactions or intramolecular interactions? (b) Which of these kinds of interactions are broken when a liquid is converted to a gas?

**11.17** Describe the intermolecular forces that must be overcome to convert these substances from a liquid to a gas: (a)  $\text{SO}_2$ , (b)  $\text{CH}_3\text{COOH}$ , (c)  $\text{H}_2\text{S}$ .

**11.18** Which type of intermolecular force accounts for each of these differences? (a)  $\text{CH}_3\text{OH}$  boils at  $65^\circ\text{C}$ ;  $\text{CH}_3\text{SH}$  boils at  $6^\circ\text{C}$ . (b) Xe is a liquid at atmospheric pressure and 120 K, whereas Ar is a gas under the same conditions. (c) Kr, atomic weight 84 amu, boils at 120.9 K, whereas  $\text{Cl}_2$ , molecular weight about 71 amu, boils at 238 K. (d) Acetone boils at  $56^\circ\text{C}$ , whereas 2-methylpropane boils at  $-12^\circ\text{C}$ .

- 11.19** (a) List the following molecules in order of increasing polarizability:  $\text{GeCl}_4$ ,  $\text{CH}_4$ ,  $\text{SiCl}_4$ ,  $\text{SiH}_4$ , and  $\text{GeBr}_4$ . (b) Predict the order of boiling points of the substances in part (a).
- 11.20** True or false: (a) For molecules with similar molecular weights, the dispersion forces become stronger as the molecules become more polarizable. (b) For the noble gases the dispersion forces decrease while the boiling points increase as you go down the column in the periodic table. (c) In terms of the total attractive forces for a given substance, dipole-dipole interactions, when present, are always greater than dispersion forces. (d) All other factors being the same, dispersion forces between linear molecules are greater than those between molecules whose shapes are nearly spherical. (e) The larger the atom, the more polarizable it is.
- 11.21** Which member in each pair has the greater dispersion forces? (a)  $\text{H}_2\text{O}$  or  $\text{H}_2\text{S}$ , (b)  $\text{CO}_2$  or  $\text{CO}$ , (c)  $\text{SiH}_4$  or  $\text{GeH}_4$ .
- 11.22** Which member in each pair has the stronger intermolecular dispersion forces? (a)  $\text{Br}_2$  or  $\text{O}_2$ , (b)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{SH}$  or  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{SH}$ , (c)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{Cl}$  or  $(\text{CH}_3)_2\text{CHCl}$ .
- 11.23** Butane and 2-methylpropane, whose space-filling models are shown here, are both nonpolar and have the same molecular formula,  $\text{C}_4\text{H}_{10}$ , yet butane has the higher boiling point ( $-0.5^\circ\text{C}$  compared to  $-11.7^\circ\text{C}$ ). Explain.

- 11.24** Propyl alcohol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ) and isopropyl alcohol [ $(\text{CH}_3)_2\text{CHOH}$ ], whose space-filling models are shown, have boiling points of  $97.2$  and  $82.5^\circ\text{C}$ , respectively. Explain why the boiling point of propyl alcohol is higher, even though both have the molecular formula,  $\text{C}_3\text{H}_8\text{O}$ .

- 11.25** (a) What atoms must a molecule contain to participate in hydrogen bonding with other molecules of the same kind? (b) Which of the following molecules can form hydrogen bonds with other molecules of the same kind:  $\text{CH}_3\text{F}$ ,  $\text{CH}_3\text{NH}_2$ ,  $\text{CH}_3\text{OH}$ ,  $\text{CH}_3\text{Br}$ ?
- 11.26** Rationalize the difference in boiling points in each pair: (a)  $\text{HF}$  ( $20^\circ\text{C}$ ) and  $\text{HCl}$  ( $-85^\circ\text{C}$ ), (b)  $\text{CHCl}_3$  ( $61^\circ\text{C}$ ) and  $\text{CHBr}_3$  ( $150^\circ\text{C}$ ), (c)  $\text{Br}_2$  ( $59^\circ\text{C}$ ) and  $\text{ICl}$  ( $97^\circ\text{C}$ ).
- 11.27** Ethylene glycol ( $\text{HOCH}_2\text{CH}_2\text{OH}$ ), the major substance in antifreeze, has a normal boiling point of  $198^\circ\text{C}$ . By comparison, ethyl alcohol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) boils at  $78^\circ\text{C}$  at atmospheric pressure. Ethylene glycol dimethyl ether ( $\text{CH}_3\text{OCH}_2\text{CH}_2\text{OCH}_3$ ) has a normal boiling point of  $83^\circ\text{C}$ ,

and ethyl methyl ether ( $\text{CH}_3\text{CH}_2\text{OCH}_3$ ) has a normal boiling point of  $11^\circ\text{C}$ . (a) Explain why replacement of a hydrogen on the oxygen by a  $\text{CH}_3$  group generally results in a lower boiling point. (b) What are the major factors responsible for the difference in boiling points of the two ethers?

- 11.28** Based on the type or types of intermolecular forces, predict the substance in each pair that has the higher boiling point: (a) propane ( $\text{C}_3\text{H}_8$ ) or *n*-butane ( $\text{C}_4\text{H}_{10}$ ), (b) diethyl ether ( $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$ ) or 1-butanol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$ ), (c) sulfur dioxide ( $\text{SO}_2$ ) or sulfur trioxide ( $\text{SO}_3$ ), (d) phosgene ( $\text{Cl}_2\text{CO}$ ) or formaldehyde ( $\text{H}_2\text{CO}$ ).
- 11.29** Look up and compare the normal boiling points and normal melting points of  $\text{H}_2\text{O}$  and  $\text{H}_2\text{S}$ . Based on these physical properties, which substance has stronger intermolecular forces? What kinds of intermolecular forces exist for each molecule?
- 11.30** Carbon tetrachloride,  $\text{CCl}_4$ , and chloroform,  $\text{CHCl}_3$ , are common organic liquids. Carbon tetrachloride's normal boiling point is  $77^\circ\text{C}$ ; chloroform's normal boiling point is  $61^\circ\text{C}$ . Which statement is the best explanation of these data? (a) Chloroform can hydrogen-bond, but carbon tetrachloride cannot. (b) Carbon tetrachloride has a larger dipole moment than chloroform. (c) Carbon tetrachloride is more polarizable than chloroform.
- 11.31** A number of salts containing the tetrahedral polyatomic anion,  $\text{BF}_4^-$ , are ionic liquids, whereas salts containing the somewhat larger tetrahedral ion  $\text{SO}_4^{2-}$  do not form ionic liquids. Explain this observation.
- 11.32** The generic structural formula for a 1-alkyl-3-methylimidazolium cation is

where R is a  $-\text{CH}_2(\text{CH}_2)_n\text{CH}_3$  alkyl group. The melting points of the salts that form between the 1-alkyl-3-methylimidazolium cation and the  $\text{PF}_6^-$  anion are as follows: R =  $\text{CH}_2\text{CH}_3$  (m.p. =  $60^\circ\text{C}$ ), R =  $\text{CH}_2\text{CH}_2\text{CH}_3$  (m.p. =  $40^\circ\text{C}$ ), R =  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$  (m.p. =  $10^\circ\text{C}$ ), and R =  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$  (m.p. =  $-61^\circ\text{C}$ ). Why does the melting point decrease as the length of alkyl group increases?

### Select Properties of Liquids (Section 11.3)

- 11.33** (a) What is the relationship between surface tension and temperature? (b) What is the relationship between viscosity and temperature? (c) Why do substances with high surface tension also tend to have high viscosities?
- 11.34** Based on their composition and structure, list  $\text{CH}_2\text{Cl}_2$ ,  $\text{CH}_3\text{CH}_2\text{CH}_3$ , and  $\text{CH}_3\text{CH}_2\text{OH}$  in order of (a) increasing intermolecular forces, (b) increasing viscosity, (c) increasing surface tension.
- 11.35** Liquids can interact with flat surfaces just as they can with capillary tubes; the cohesive forces within the liquid can be stronger or weaker than the adhesive forces between liquid and surface:

(a) In which of these diagrams, i or ii, do the adhesive forces between surface and liquid exceed the cohesive forces within the liquid? (b) Which of these diagrams, i or ii, represents what happens when water is on a nonpolar surface? (c) Which of these diagrams, i or ii, represents what happens when water is on a polar surface?

- 11.36** Hydrazine ( $\text{H}_2\text{NNH}_2$ ), hydrogen peroxide ( $\text{HOOH}$ ), and water ( $\text{H}_2\text{O}$ ) all have exceptionally high surface tensions compared with other substances of comparable molecular weights. (a) Draw the Lewis structures for these three compounds. (b) What structural property do these substances have in common, and how might that account for the high surface tensions?

- 11.37** The boiling points, surface tensions, and viscosities of water and several alcohols are as shown below:

|  | Boiling Point<br>(°C) | Surface Tension<br>( $\text{J/m}^2$ ) | Viscosity<br>( $\text{kg/m}\cdot\text{s}$ ) |
|--|-----------------------|---------------------------------------|---|
| Water, $\text{H}_2\text{O}$  | 100                   | $7.3 \times 10^{-2}$                  | $0.9 \times 10^{-3}$                        |
| Ethanol, $\text{CH}_3\text{CH}_2\text{OH}$                                 | 78                    | $2.3 \times 10^{-2}$                  | $1.1 \times 10^{-3}$                        |
| Propanol, $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$                     | 97                    | $2.4 \times 10^{-2}$                  | $2.2 \times 10^{-3}$                        |
| <i>n</i> -Butanol, $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{OH}$ | 117                   | $2.6 \times 10^{-2}$                  | $2.6 \times 10^{-3}$                        |
| Ethylene glycol, $\text{HOCH}_2\text{CH}_2\text{OH}$                       | 197                   | $4.8 \times 10^{-2}$                  | $26 \times 10^{-3}$                         |

(a) From ethanol to propanol to *n*-butanol the boiling points, surface tensions, and viscosities all increase. What is the reason for this increase? (b) How do you explain the fact that propanol and ethylene glycol have similar molecular weights (60 versus 62 amu), yet the viscosity of ethylene glycol is more than 10 times larger than propanol? (c) How do you explain the fact that water has the highest surface tension but the lowest viscosity?

- 11.38** (a) Would you expect the viscosity of *n*-pentane,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ , to be larger or smaller than the viscosity of *n*-hexane,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ ? (b) Would you expect the viscosity of neopentane,  $(\text{CH}_3)_4\text{C}$ , to be smaller or larger than the viscosity of *n*-pentane? (See Figure 11.6 to see the shapes of these molecules.)

## Phase Changes (Section 11.4)

- 11.39** Name the phase transition in each of the following situations and indicate whether it is exothermic or endothermic: (a) When ice is heated, it turns to water. (b) Wet clothes dry on a warm summer day. (c) Frost appears on a window on a cold winter day. (d) Droplets of water appear on a cold glass of lemonade.

- 11.40** Name the phase transition in each of the following situations and indicate whether it is exothermic or endothermic: (a) Bromine vapor turns to bromine liquid as it is cooled. (b) Crystals of iodine disappear from an evaporating dish as they stand in a fume hood. (c) Rubbing alcohol in an open container slowly disappears. (d) Molten lava from a volcano turns into solid rock.

- 11.41** (a) What phase change is represented by the “heat of fusion” of a substance? (b) Is the heat of fusion endothermic or exothermic? (c) If you compare a substance’s heat of fusion to its heat of vaporization, which one is generally larger?

- 11.42** Ethyl chloride ( $\text{C}_2\text{H}_5\text{Cl}$ ) boils at  $12^\circ\text{C}$ . When liquid  $\text{C}_2\text{H}_5\text{Cl}$  under pressure is sprayed on a room-temperature ( $25^\circ\text{C}$ ) surface in air, the surface is cooled considerably. (a) What does this observation tell us about the specific heat of  $\text{C}_2\text{H}_5\text{Cl}(\text{g})$  as compared with that of  $\text{C}_2\text{H}_5\text{Cl}(\text{l})$ ? (b) Assume that the heat lost by the surface is gained by ethyl chloride. What enthalpies must you consider if you were to calculate the final temperature of the surface?

- 11.43** For many years drinking water has been cooled in hot climates by evaporating it from the surfaces of canvas bags or porous clay pots. How many grams of water can be cooled from  $35$  to  $20^\circ\text{C}$  by the evaporation of  $60$  g of water? (The heat of vaporization of water in this temperature range is  $2.4$  kJ/g. The specific heat of water is  $4.18$  J/g·K.)

- 11.44** Compounds like  $\text{CCl}_2\text{F}_2$  are known as chlorofluorocarbons, or CFCs. These compounds were once widely used as refrigerants but are now being replaced by compounds that are believed to be less harmful to the environment. The heat of vaporization of  $\text{CCl}_2\text{F}_2$  is  $289$  J/g. What mass of this substance must evaporate to freeze  $200$  g of water initially at  $15^\circ\text{C}$ ? (The heat of fusion of water is  $334$  J/g; the specific heat of water is  $4.18$  J/g·K.)

- 11.45** Ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) melts at  $-114^\circ\text{C}$  and boils at  $78^\circ\text{C}$ . The enthalpy of fusion of ethanol is  $5.02$  kJ/mol, and its enthalpy of vaporization is  $38.56$  kJ/mol. The specific heats of solid and liquid ethanol are  $0.97$  and  $2.3$  J/g·K, respectively. (a) How much heat is required to convert  $42.0$  g of ethanol at  $35^\circ\text{C}$  to the vapor phase at  $78^\circ\text{C}$ ? (b) How much heat is required to convert the same amount of ethanol at  $-155^\circ\text{C}$  to the vapor phase at  $78^\circ\text{C}$ ?

- 11.46** The fluorocarbon compound  $\text{C}_2\text{Cl}_3\text{F}_3$  has a normal boiling point of  $47.6^\circ\text{C}$ . The specific heats of  $\text{C}_2\text{Cl}_3\text{F}_3(\text{l})$  and  $\text{C}_2\text{Cl}_3\text{F}_3(\text{g})$  are  $0.91$  and  $0.67$  J/g·K, respectively. The heat of vaporization for the compound is  $27.49$  kJ/mol. Calculate the heat required to convert  $35.0$  g of  $\text{C}_2\text{Cl}_3\text{F}_3$  from a liquid at  $10.00^\circ\text{C}$  to a gas at  $105.00^\circ\text{C}$ .

- 11.47** Indicate whether each statement is true or false: (a) The critical pressure of a substance is the pressure at which it turns into a solid at room temperature. (b) The critical temperature of a substance is the highest temperature at which the liquid phase can form. (c) Generally speaking, the higher the critical temperature of a substance, the lower its critical pressure. (d) In general, the more intermolecular forces there are in a substance, the higher its critical temperature and pressure.

- 11.48** The critical temperatures and pressures of a series of halogenated methanes are as follows:

| Compound                 | $\text{CCl}_3\text{F}$ | $\text{CCl}_2\text{F}_2$ | $\text{CClF}_3$ | $\text{CF}_4$ |
|--------------------------|------------------------|--------------------------|-----------------|---------------|
| Critical temperature (K) | 471                    | 385                      | 302             | 227           |
| Critical pressure (atm)  | 43.5                   | 40.6                     | 38.2            | 37.0          |

(a) List the intermolecular forces that occur for each compound. (b) Predict the order of increasing intermolecular attraction, from least to most, for this series of compounds. (c) Predict the critical temperature and pressure for  $\text{CCl}_4$  based on the trends in this table. Look up the experimentally determined critical temperatures and pressures for  $\text{CCl}_4$ , using a source such as the *CRC Handbook of Chemistry and Physics*, and suggest a reason for any discrepancies.

### Vapor Pressure (Section 11.5)

- 11.49** Which of the following affects the vapor pressure of a liquid? (a) Volume of the liquid, (b) surface area, (c) intermolecular attractive forces, (d) temperature, (e) density of the liquid.
- 11.50** Acetone ( $\text{H}_3\text{CCOCH}_3$ ) has a boiling point of  $56^\circ\text{C}$ . Based on the data given in Figure 11.25, would you expect acetone to have a higher or lower vapor pressure than ethanol at  $25^\circ\text{C}$ ?
- 11.51** (a) Place the following substances in order of increasing volatility:  $\text{CH}_4$ ,  $\text{CBr}_4$ ,  $\text{CH}_2\text{Cl}_2$ ,  $\text{CH}_3\text{Cl}$ ,  $\text{CHBr}_3$ , and  $\text{CH}_2\text{Br}_2$ . (b) How do the boiling points vary through this series? (c) Explain your answer to part (b) in terms of intermolecular forces.
- 11.52** True or false: (a)  $\text{CBr}_4$  is more volatile than  $\text{CCl}_4$ . (b)  $\text{CBr}_4$  has a higher boiling point than  $\text{CCl}_4$ . (c)  $\text{CBr}_4$  has weaker intermolecular forces than  $\text{CCl}_4$ . (d)  $\text{CBr}_4$  has a higher vapor pressure at the same temperature than  $\text{CCl}_4$ .
- 11.53** (a) Two pans of water are on different burners of a stove. One pan of water is boiling vigorously, while the other is boiling gently. What can be said about the temperature of the water in the two pans? (b) A large container of water and a small one are at the same temperature. What can be said about the relative vapor pressures of the water in the two containers?
- 11.54** You are high up in the mountains and boil water to make some tea. However, when you drink your tea, it is not as hot as it should be. You try again and again, but the water is just not hot enough to make a hot cup of tea. Which is the best explanation for this result? (a) High in the mountains, it is probably very dry, and so the water is rapidly evaporating from your cup and cooling it. (b) High in the mountains, it is probably very windy, and so the water is rapidly evaporating from your cup and cooling it. (c) High in the mountains, the air pressure is significantly less than 1 atm, so the boiling point of water is much lower than at sea level. (d) High in the mountains, the air pressure is significantly less than 1 atm, so the boiling point of water is much higher than at sea level.
- 11.55** Using the vapor-pressure curves in Figure 11.25, (a) estimate the boiling point of ethanol at an external pressure of 200 torr, (b) estimate the external pressure at which ethanol will boil at  $60^\circ\text{C}$ , (c) estimate the boiling point of diethyl ether at 400 torr, (d) estimate the external pressure at which diethyl ether will boil at  $40^\circ\text{C}$ .
- 11.56** Appendix B lists the vapor pressure of water at various external pressures. (a) Plot the data in Appendix B, vapor

pressure (torr) versus temperature ( $^\circ\text{C}$ ). From your plot, estimate the vapor pressure of water at body temperature,  $37^\circ\text{C}$ . (b) Explain the significance of the data point at 760.0 torr,  $100^\circ\text{C}$ . (c) A city at an altitude of 5000 ft above sea level has a barometric pressure of 633 torr. To what temperature would you have to heat water to boil it in this city? (d) A city at an altitude of 500 ft below sea level would have a barometric pressure of 774 torr. To what temperature would you have to heat water to boil it in this city?

### Phase Diagrams (Section 11.6)

- 11.57** (a) What is the significance of the critical point in a phase diagram? (b) Why does the line that separates the gas and liquid phases end at the critical point?
- 11.58** (a) What is the significance of the triple point in a phase diagram? (b) Could you measure the triple point of water by measuring the temperature in a vessel in which water vapor, liquid water, and ice are in equilibrium under 1 atm of air? Explain.
- 11.59** Referring to Figure 11.28, describe all the phase changes that would occur in each of the following cases: (a) Water vapor originally at 0.005 atm and  $-0.5^\circ\text{C}$  is slowly compressed at constant temperature until the final pressure is 20 atm. (b) Water originally at  $100.0^\circ\text{C}$  and 0.50 atm is cooled at constant pressure until the temperature is  $-10^\circ\text{C}$ .
- 11.60** Referring to Figure 11.29, describe the phase changes (and the temperatures at which they occur) when  $\text{CO}_2$  is heated from  $-80$  to  $-20^\circ\text{C}$  at (a) a constant pressure of 3 atm, (b) a constant pressure of 6 atm.
- 11.61** The phase diagram for neon is

Use the phase diagram to answer the following questions. (a) What is the approximate value of the normal melting point? (b) Over what pressure range will solid neon sublime? (c) At room temperature ( $T = 25^\circ\text{C}$ ) can neon be liquefied by compressing it?

- 11.62** Use the phase diagram of neon to answer the following questions. (a) What is the approximate value of the normal boiling point? (b) What can you say about the strength of the intermolecular forces in neon and argon based on the critical points of Ne and Ar (see Table 11.5.)?
- 11.63** The fact that water on Earth can readily be found in all three states (solid, liquid, and gas) is in part a consequence

of the fact that the triple point of water ( $T = 0.01^\circ\text{C}$ ,  $P = 0.006\text{ atm}$ ) falls within a range of temperatures and pressures found on Earth. Saturn's largest moon Titan has a considerable amount of methane in its atmosphere. The conditions on the surface of Titan are estimated to be  $P = 1.6\text{ atm}$  and  $T = -178^\circ\text{C}$ . As seen from the phase diagram of methane (Figure 11.30), these conditions are not far from the triple point of methane, raising the tantalizing possibility that solid, liquid, and gaseous methane can be found on Titan. **(a)** In what state would you expect to find methane on the surface of Titan? **(b)** On moving upward through the atmosphere, the pressure will decrease. If we assume that the temperature does not change, what phase change would you expect to see as we move away from the surface?

- 11.64** At  $25^\circ\text{C}$  gallium is a solid with a density of  $5.91\text{ g/cm}^3$ . Its melting point,  $29.8^\circ\text{C}$ , is low enough that you can melt it by holding it in your hand. The density of liquid gallium just above the melting point is  $6.1\text{ g/cm}^3$ . Based on this information, what unusual feature would you expect to find in the phase diagram of gallium?

Heat added  
A

Heat added  
B

## Liquid Crystals (Section 11.7)

- 11.65** In terms of the arrangement and freedom of motion of the molecules, how are the nematic liquid crystalline phase and an ordinary liquid phase similar? How are they different?
- 11.66** What observations made by Reinitzer on cholesteryl benzoate suggested that this substance possesses a liquid crystalline phase?
- 11.67** Indicate whether each statement is true or false: **(a)** The liquid crystal state is another phase of matter, just like solid, liquid, and gas. **(b)** Liquid crystalline molecules are generally spherical in shape. **(c)** Molecules that exhibit a liquid crystalline phase do so at well-defined temperatures and pressures. **(d)** Molecules that exhibit a liquid crystalline phase show weaker-than-expected intermolecular forces. **(e)** Molecules containing only carbon and hydrogen are likely to form liquid crystalline phases. **(f)** Molecules can exhibit more than one liquid crystalline phase.
- 11.68** Two heating curves, A and B, are shown. In both cases, point 1 corresponds to the crystalline solid phase.

**(a)** One of these graphs shows data for a liquid crystalline material. Which one? **(b)** In graph A, what process does the 2–3 line segment correspond to? **(c)** In graph B, what process does the 2–3 line segment correspond to? **(d)** In graph A, what process does the 3–4 line segment correspond to? **(e)** In graph B, what process does the 3–4 line segment correspond to?

- 11.69** For a given substance, the liquid crystalline phase tends to be more viscous than the liquid phase. Why?
- 11.70** Describe how a cholesteric liquid crystal phase differs from a nematic phase.
- 11.71** It often happens that a substance possessing a smectic liquid crystalline phase just above the melting point passes into a nematic liquid crystalline phase at a higher temperature. Account for this type of behavior.
- 11.72** The smectic liquid crystalline phase can be said to be more highly ordered than the nematic phase. In what sense is this true?

## Additional Exercises

- 11.73** As the intermolecular attractive forces between molecules increase in magnitude, do you expect each of the following to increase or decrease in magnitude? **(a)** Vapor pressure,

**(b)** heat of vaporization, **(c)** boiling point, **(d)** freezing point, **(e)** viscosity, **(f)** surface tension, **(g)** critical temperature.

- 11.74** The table below lists the density of  $O_2$  at various temperatures and at 1 atm. The normal melting point of  $O_2$  is 54 K.

| Temperature (K) | Density (mol/L) |
|-----------------|-----------------|
| 60              | 40.1            |
| 70              | 38.6            |
| 80              | 37.2            |
| 90              | 35.6            |
| 100             | 0.123           |
| 120             | 0.102           |
| 140             | 0.087           |

- (a) Over what temperature range is  $O_2$  a solid? (b) Over what temperature range is  $O_2$  a liquid? (c) Over what temperature range in the table is  $O_2$  a gas? (d) Estimate the normal boiling point of  $O_2$ . (e) What intermolecular forces are operative in  $O_2$ ?
- 11.75** Suppose you have two colorless molecular liquids, one boiling at  $-84^\circ\text{C}$ , the other at  $34^\circ\text{C}$ , and both at atmospheric pressure. Which of the following statements is correct? For each statement that is not correct, modify the statement so that it is correct. (a) The higher-boiling liquid has greater total intermolecular forces than the lower-boiling liquid. (b) The lower-boiling liquid must consist of nonpolar molecules. (c) The lower-boiling liquid has a lower molecular weight than the higher-boiling liquid. (d) The two liquids have identical vapor pressures at their normal boiling points. (e) At  $-84^\circ\text{C}$  both liquids have vapor pressures of 760 mm Hg.
- 11.76** Two isomers of the planar compound 1,2-dichloroethylene are shown here.

- (a) Which of the two isomers will have the stronger dipole-dipole forces? (b) One isomer has a boiling point of  $60.3^\circ\text{C}$  and the other  $47.5^\circ\text{C}$ . Which isomer has which boiling point?
- 11.77** The table below shows some physical properties of halogenated liquids.

| Liquid                   | Experimental Dipole Moment (D) | Normal Boiling Point ( $^\circ\text{C}$ ) |
|--------------------------|--------------------------------|---|
| $\text{CH}_2\text{F}_2$  | 1.93                           | $-52$                                     |
| $\text{CH}_2\text{Cl}_2$ | 1.60                           | 40  |
| $\text{CH}_2\text{Br}_2$ | 1.43                           | 97  |

Which of the following statements best explains these data? (a) The larger the dipole moment, the stronger the intermolecular forces, and therefore the boiling point is lowest for the molecule with the largest dipole moment. (b) The dispersion forces increase from F to Cl to Br; since the boiling point also increases in this order, the dispersion forces must make a far greater contribution to intermolecular interactions than dipole-dipole interactions. (c) The trend in electronegativity is  $\text{F} > \text{Cl} > \text{Br}$ ; therefore, the most ionic compound ( $\text{CH}_2\text{F}_2$ ) has the lowest boiling point, and the most covalent compound ( $\text{CH}_2\text{Br}_2$ ) has the highest boiling point. (d) Boiling point increases with molecular weight for these nonpolar compounds.

- 11.78** The table below shows the normal boiling points of benzene and benzene derivatives.

| Compound  | Structure | Normal Boiling Point ( $^\circ\text{C}$ ) |
|---|-----------|---|
| $\text{C}_6\text{H}_6$ (benzene)                            |           | 80  |
| $\text{C}_6\text{H}_5\text{Cl}$ (chlorobenzene)             |           | 132                                       |
| $\text{C}_6\text{H}_5\text{Br}$ (bromobenzene)              |           | 156                                       |
| $\text{C}_6\text{H}_5\text{OH}$ (phenol, or hydroxybenzene) |           | 182                                       |

- (a) How many of these compounds exhibit dispersion interactions? (b) How many of these compounds exhibit dipole-dipole interactions? (c) How many of these compounds exhibit hydrogen bonding? (d) Why is the boiling point of bromobenzene higher than that of chlorobenzene? (e) Why is the boiling point of phenol the highest of all?
- 11.79** The DNA double helix (Figure 24.30) at the atomic level looks like a twisted ladder, where the “rungs” of the ladder consist of molecules that are hydrogen-bonded together. Sugar and phosphate groups make up the sides of the ladder. Shown are the structures of the adenine–thymine (AT) “base pair” and the guanine–cytosine (GC) base pair:

You can see that AT base pairs are held together by two hydrogen bonds and the GC base pairs are held together by three hydrogen bonds. Which base pair is more stable to heating? Why?

- 11.80** Ethylene glycol ( $\text{HOCH}_2\text{CH}_2\text{OH}$ ) and pentane ( $\text{C}_5\text{H}_{12}$ ) are both liquids at room temperature and room pressure, and have about the same molecular weight. (a) One of these liquids is much more viscous than the other. Which one do you predict is more viscous? (b) One of these liquids has a much lower normal boiling point ( $36.1^\circ\text{C}$ ) compared to the

other one (198 °C). Which liquid has the lower normal boiling point? (c) One of these liquids is the major component in antifreeze in automobile engines. Which liquid would you expect to be used as antifreeze? (d) One of these liquids is used as a “blowing agent” in the manufacture of polystyrene foam because it is so volatile. Which liquid would you expect to be used as a blowing agent?

**11.81** Use the normal boiling points

|   |          |
|---|----------|
| propane (C <sub>3</sub> H <sub>8</sub> )  | −42.1 °C |
| butane (C <sub>4</sub> H <sub>10</sub> )  | −0.5 °C  |
| pentane (C <sub>5</sub> H <sub>12</sub> ) | 36.1 °C  |
| hexane (C <sub>6</sub> H <sub>14</sub> )  | 68.7 °C  |
| heptane (C <sub>7</sub> H <sub>16</sub> ) | 98.4 °C  |

to estimate the normal boiling point of octane (C<sub>8</sub>H<sub>18</sub>). Explain the trend in the boiling points.

**11.82** One of the attractive features of ionic liquids is their low vapor pressure, which in turn tends to make them nonflammable. Why do you think ionic liquids have lower vapor pressures than most room-temperature molecular liquids?

**11.83** (a) When you exercise vigorously, you sweat. How does this help your body cool? (b) A flask of water is connected to a vacuum pump. A few moments after the pump is turned on, the water begins to boil. After a few minutes, the water begins to freeze. Explain why these processes occur.

**11.84** The following table gives the vapor pressure of hexafluorobenzene (C<sub>6</sub>F<sub>6</sub>) as a function of temperature:

| Temperature (K) | Vapor Pressure (torr) |
|-----------------|-----------------------|
| 280.0           | 32.42                 |
| 300.0           | 92.47                 |
| 320.0           | 225.1                 |
| 330.0           | 334.4                 |
| 340.0           | 482.9                 |

(a) By plotting these data in a suitable fashion, determine whether the Clausius–Clapeyron equation (Equation 11.1) is obeyed. If it is obeyed, use your plot to determine  $\Delta H_{\text{vap}}$  for C<sub>6</sub>F<sub>6</sub>. (b) Use these data to determine the boiling point of the compound.

**11.85** Suppose the vapor pressure of a substance is measured at two different temperatures. (a) By using the Clausius–Clapeyron equation (Equation 11.1) derive the following relationship between the vapor pressures,  $P_1$  and  $P_2$ , and the absolute temperatures at which they were measured,  $T_1$  and  $T_2$ :

$$\ln \frac{P_1}{P_2} = -\frac{\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$$

(b) Gasoline is a mixture of hydrocarbons, a component of which is octane (CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>3</sub>).

Octane has a vapor pressure of 13.95 torr at 25 °C and a vapor pressure of 144.78 torr at 75 °C. Use these data and the equation in part (a) to calculate the heat of vaporization of octane. (c) By using the equation in part (a) and the data given in part (b), calculate the normal boiling point of octane. Compare your answer to the one you obtained from Exercise 11.81. (d) Calculate the vapor pressure of octane at −30 °C.

**11.86** The following data present the temperatures at which certain vapor pressures are achieved for dichloromethane (CH<sub>2</sub>Cl<sub>2</sub>) and methyl iodide (CH<sub>3</sub>I):

| Vapor Pressure (torr)                        | 10.0  | 40.0  | 100.0 | 400.0 |
|--|-------|-------|-------|-------|
| $T$ for CH <sub>2</sub> Cl <sub>2</sub> (°C) | −43.3 | −22.3 | −6.3  | 24.1  |
| $T$ for CH <sub>3</sub> I (°C)               | −45.8 | −24.2 | −7.0  | 25.3  |

(a) Which of the two substances is expected to have the greater dipole–dipole forces? Which is expected to have the greater dispersion forces? Based on your answers, explain why it is difficult to predict which compound would be more volatile. (b) Which compound would you expect to have the higher boiling point? Check your answer in a reference book such as the *CRC Handbook of Chemistry and Physics*. (c) The order of volatility of these two substances changes as the temperature is increased. What quantity must be different for the two substances for this phenomenon to occur? (d) Substantiate your answer for part (c) by drawing an appropriate graph.

**11.87** Naphthalene (C<sub>10</sub>H<sub>8</sub>) is the main ingredient in traditional mothballs. Its normal melting point is 81 °C, its normal boiling point is 218 °C, and its triple point is 80 °C at 1000 Pa. Using the data, construct a phase diagram for naphthalene, labeling all the regions of your diagram.

**11.88** A watch with a liquid crystal display (LCD) does not function properly when it is exposed to low temperatures during a trip to Antarctica. Explain why the LCD might not function well at low temperature.

**11.89** A particular liquid crystalline substance has the phase diagram shown in the figure. By analogy with the phase diagram for a nonliquid crystalline substance, identify the phase present in each area.

## Integrative Exercises

**11.90** In Table 11.3, we saw that the viscosity of a series of hydrocarbons increased with molecular weight, doubling from the six-carbon molecule to the ten-carbon molecule. (a) The eight-carbon hydrocarbon, octane, has an isomer, isooctane. Would you predict that isooctane would have a larger or smaller viscosity than octane? Why? (b) Predict the relative order of boiling points of the hydrocarbons in Table 11.4, from lowest to highest. (c) The surface tension of

2,2,4-Trimethylpentane or isooctane

the hydrocarbon liquids in Table 11.4 does increase from hexane to decane, but only by a rather small amount (20% overall, compared to the doubling of viscosity). Which of the statements below is the most likely explanation for this phenomenon? (i) The flexibility of the molecules has a much larger effect on viscosity than on surface tension. (ii) Viscosity only depends on molecular weight, but surface tension depends on molecular weight and on intermolecular forces. (iii) Larger molecules can make larger liquid droplets and therefore have lower surface tension. (d) Nonane has a viscosity of  $7.11 \times 10^{-4}$  kg/m-s at 20 °C. *n*-octyl alcohol,  $\text{CH}_3(\text{CH}_2)_7\text{OH}$ , has almost the same molecular weight as nonane, but its viscosity is  $1.01 \times 10^{-2}$  kg/m-s at 20 °C. Which of the following statements is the most likely explanation for this phenomenon? (i) The stronger the intermolecular forces in a liquid, the smaller its viscosity. (ii) The stronger the intermolecular forces in a liquid, the larger its viscosity.

**11.91** Acetone [ $(\text{CH}_3)_2\text{CO}$ ] is widely used as an industrial solvent. (a) Draw the Lewis structure for the acetone molecule and predict the geometry around each carbon atom. (b) Is the acetone molecule polar or nonpolar? (c) What kinds of intermolecular attractive forces exist between acetone molecules? (d) 1-Propanol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ) has a molecular weight that is very similar to that of acetone, yet acetone boils at 56.5 °C and 1-propanol boils at 97.2 °C. Explain the difference.

**11.92** The table shown here lists the molar heats of vaporization for several organic compounds. Use specific examples from this list to illustrate how the heat of vaporization varies with (a) molar mass, (b) molecular shape, (c) molecular polarity, (d) hydrogen-bonding interactions. Explain these comparisons in terms of the nature of the intermolecular forces at work. (You may find it helpful to draw out the structural formula for each compound.)

| Compound  | Heat of Vaporization (kJ/mol) |
|---|-------------------------------|
| $\text{CH}_3\text{CH}_2\text{CH}_3$                       | 19.0                          |
| $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$ | 27.6                          |
| $\text{CH}_3\text{CHBrCH}_3$                              | 31.8                          |
| $\text{CH}_3\text{COCH}_3$                                | 32.0                          |
| $\text{CH}_3\text{CH}_2\text{CH}_2\text{Br}$              | 33.6                          |
| $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$              | 47.3                          |

**11.93** The vapor pressure of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) at 19 °C is 40.0 torr. A 1.00-g sample of ethanol is placed in a 2.00 L container at 19 °C. If the container is closed and the ethanol is allowed to reach equilibrium with its vapor, how many grams of liquid ethanol remain?

**11.94** Liquid butane ( $\text{C}_4\text{H}_{10}$ ) is stored in cylinders to be used as a fuel. The normal boiling point of butane is listed as  $-0.5$  °C. (a) Suppose the tank is standing in the sun and reaches a temperature of 35 °C. Would you expect the pressure in the tank to be greater or less than atmospheric pressure? How does the pressure within the tank depend on how much liquid butane is in it? (b) Suppose the valve to the tank is opened and a few liters of butane are allowed to escape rapidly. What do you expect would happen to the temperature of the remaining liquid butane in the tank? Explain. (c) How much heat must be added to vaporize 250 g of butane if its heat of vaporization is 21.3 kJ/mol? What volume does this much butane occupy at 755 torr and 35 °C?

**11.95** Using information in Appendices B and C, calculate the minimum grams of propane,  $\text{C}_3\text{H}_8(g)$ , that must be combusted to provide the energy necessary to convert 5.50 kg of ice at  $-20$  °C to liquid water at 75 °C.

**11.96** The vapor pressure of a volatile liquid can be determined by slowly bubbling a known volume of gas through it at a known temperature and pressure. In an experiment, 5.00 L of  $\text{N}_2$  gas is passed through 7.2146 g of liquid benzene ( $\text{C}_6\text{H}_6$ ) at 26.0 °C. The liquid remaining after the experiment weighs 5.1493 g. Assuming that the gas becomes saturated with benzene vapor and that the total gas volume and temperature remain constant, what is the vapor pressure of the benzene in torr?

**11.97** The relative humidity of a mixture of gases is the ratio of the partial pressure of water at the same temperature times 100%. If the relative humidity of the air is 58% and its temperature is 68 °F, how many molecules of water are present in a room measuring 12 ft  $\times$  10 ft  $\times$  8 ft?

## Design an Experiment

Intermolecular forces are very important for predicting the physical properties of molecular substances. Sometimes, however, it is difficult to explain or predict trends in these properties because all the possible intermolecular forces can be operating at the same time, and there is a wide range of energies for these interactions. Consider ammonia,  $\text{NH}_3$ . It is a gas at  $P = 1$  atm,  $T = 25$  °C. Ammonia can be liquefied at  $-33.5$  °C ( $P = 1$  atm). Methylamine,

$\text{CH}_3\text{NH}_2$ , is a derivative of ammonia and is also a gas at  $P = 1$  atm,  $T = 25$  °C. Methylamine can be liquefied at  $-6.4$  °C ( $P = 1$  atm).

Use these experimental data to determine which molecule has the stronger intermolecular attractive interactions, ammonia or methylamine; and suggest reasons for your conclusion. Based on your reasons, what other experiments could you do with these molecules, or related molecules, to test your hypothesis?

12

# SOLIDS AND MODERN MATERIALS

Modern devices like computers and cell phones are built from solids with very specific physical properties. For example, the integrated circuit that is at the heart of many electronic devices is built from semiconductors like silicon, metals like copper, and insulators like hafnium oxide.

Scientists and engineers turn almost exclusively to solids for materials used in many other technologies: *alloys* for magnets and airplane turbines, *semiconductors* for solar cells and light-emitting diodes, and *polymers* for packaging and biomedical applications. Chemists have contributed to the discovery and development of new materials either by inventing new substances or by developing the means to process natural materials to form substances that have specific electrical, magnetic, optical, catalytic, or mechanical properties. In this chapter, we explore the structures and properties of solids. As we do so, we will examine some of the solid materials used in modern technology.

◀ **QUANTUM DOT DISPLAYS** Quantum dots in the pixels of display screens in some models of HDTVs are a new technology in the marketplace. The optical properties of displays such as these are improved compared to previous generations of LCD displays. Quantum dots are semiconductor nanocrystals that have size-dependent properties in the 1–10 nm scale.

## WHAT'S AHEAD

- 12.1** ▶ **Classification of Solids** Examine the classification of solids according to the types of bonding interactions that hold the atoms together. This classification helps us make general predictions about the properties of solids.
- 12.2** ▶ **Structures of Solids** Learn that in *crystalline solids* the atoms are arranged in an orderly, repeating pattern but in *amorphous solids* this order is missing. Learn about *lattices* and *unit cells*, which define the repeating patterns that characterize crystalline solids.
- 12.3** ▶ **Metallic Solids** Examine the properties and structures of metals. Learn that many metals have structures in which the atoms pack together as closely as possible. Examine various types of alloys, materials that contain more than one element and display the characteristic properties of a metal.
- 12.4** ▶ **Metallic Bonding** Examine metallic bonding and how it is responsible for the properties of metals, in terms of two models—the *electron-sea model* and the *molecular-orbital model*. Learn how overlap of atomic orbitals gives rise to *bands* in metals.
- 12.5** ▶ **Ionic Solids** Examine the structures and properties of solids held together by the mutual attractions between cations and anions. Learn how the structures of ionic solids depend on the relative sizes of the ions and their stoichiometry.
- 12.6** ▶ **Molecular Solids** Examine solids that form when molecules are held together by weak intermolecular forces.
- 12.7** ▶ **Covalent-Network Solids** Learn about solids in which the atoms are held together by extended networks of covalent bonds. Learn how the electronic structure and properties of *semiconductors* differ from those of metals.
- 12.8** ▶ **Polymers** Learn about *polymers*—long chain-like molecules in which the motif of a small molecule is repeated many times over. Explore how both molecular shape and interactions between polymer chains affect the physical properties of polymers.
- 12.9** ▶ **Nanomaterials** Explore how the physical and chemical properties of materials change when their crystals become very small. These effects begin to occur when materials have sizes on the order of 1–100 nm. Learn about lower-dimensional forms of carbon—fullerenes, carbon nanotubes, and graphene.

## 12.1 | Classification of Solids

Solids can be as hard as diamond or as soft as wax. Some readily conduct electricity, whereas others do not. The shapes of some solids can easily be manipulated, while others are brittle and resistant to any change in shape. The physical properties as well as the structures of solids are dictated by the types of bonds that hold the atoms in place. We can classify solids according to those bonds (Figure 12.1).

**Metallic solids** are held together by a delocalized “sea” of collectively shared valence electrons. This form of bonding allows metals to conduct electricity. It is also responsible for the fact that most metals are relatively strong without being brittle. **Ionic solids** are held together by the mutual electrostatic attraction between cations and anions. Differences between ionic and metallic bonding make the electrical and mechanical properties of ionic solids very different from those of metals: Ionic solids do not conduct electricity well and are brittle. **Covalent-network solids** are held together by an extended network of covalent bonds. This type of bonding can result in materials that are extremely hard, like diamond, and it is also responsible for the unique properties of semiconductors. **Molecular solids** are held together by the intermolecular forces we studied in Chapter 11: dispersion forces, dipole–dipole interactions, and hydrogen bonds. Because these forces are relatively weak, molecular solids tend to be soft and have low melting points.

We will also consider two classes of solids that do not fall neatly into the preceding categories: polymers and nanomaterials. **Polymers** contain long chains of atoms (usually carbon), where the atoms within a given chain are connected by covalent bonds and adjacent chains are held to one another largely by weaker intermolecular forces. Polymers are normally stronger and have higher melting points than molecular solids, and they are more flexible than metallic, ionic, or covalent-network solids. **Nanomaterials** are solids in which the dimensions of individual crystals have been reduced to the order of 1–100 nm. As we will see, the properties of conventional materials change when their crystals become this small.

**Metallic solids**

Extended networks of atoms held together by metallic bonding (Cu, Fe)

**Ionic solids**

Extended networks of ions held together by cation–anion interactions (NaCl, MgO)

**Covalent-network solids**

Extended networks of atoms held together by covalent bonds (C, Si)

**Molecular solids**

Discrete molecules held together by intermolecular forces (HBr, H<sub>2</sub>O)

▲ Figure 12.1 Classification and examples of solids according to predominant bonding type.

## 12.2 | Structures of Solids

### Crystalline and Amorphous Solids

Solids contain large numbers of atoms. For example, a 1-carat diamond has a volume of  $57\text{ mm}^3$  and contains  $1.0 \times 10^{22}$  carbon atoms. How can we hope to describe such a large collection of atoms? Fortunately, the structures of many solids have patterns that repeat over and over in three dimensions. We can visualize the solid as being formed by stacking a large number of small, identical structural units, much like a wall can be built by stacking identical bricks.

Solids in which atoms are arranged in an orderly repeating pattern are called **crystalline solids**. These solids usually have flat surfaces, or *faces*, that make definite angles with one another. The orderly arrangements of atoms that produce these faces also cause the solids to have highly regular shapes (Figure 12.2). Examples of crystalline solids include sodium chloride, quartz, and diamond.

**Amorphous solids** (from the Greek words for “without form”) lack the order found in crystalline solids. At the atomic level the structures of amorphous solids are similar to the structures of liquids, but the molecules, atoms, and/or ions lack the freedom of motion they have in liquids. Amorphous solids do not have the well-defined faces and shapes of a crystal. Familiar amorphous solids are rubber, glass, and obsidian (volcanic glass).

### Unit Cells and Crystal Lattices

In a crystalline solid, there is a relatively small repeating unit, called a **unit cell**, that is made up of a unique arrangement of atoms and embodies the structure of the solid. The structure of the crystal can be built by stacking this unit over and over in all three dimensions. Thus, the structure of a crystalline solid is defined by (a) the size and shape of the unit cell and (b) the locations of atoms within the unit cell.

The geometrical pattern of points on which the unit cells are arranged is called a **crystal lattice**. The crystal lattice is, in effect, an abstract (that is, not real) scaffolding for the crystal structure. We can imagine forming the entire crystal structure by first building the scaffolding and then filling in each unit cell with the same atom or group of atoms.

Before describing the structures of solids, we need to understand the properties of crystal lattices. It is useful to begin with two-dimensional lattices because they are simpler to visualize than three-dimensional ones. Figure 12.3 shows a two-dimensional array of **lattice points**. Each lattice point has an identical environment. The positions of the lattice points are defined by the **lattice vectors**  $a$  and  $b$ . Beginning from any lattice point, it is possible to move to any other lattice point by adding together whole-number multiples of the two lattice vectors.\*

The parallelogram formed by the lattice vectors, the shaded region in Figure 12.3, defines the unit cell. In two dimensions the unit cells must *tile*, or fit together in space, in such a way that they completely cover the area of the lattice with no gaps. In three dimensions, the unit cells must stack together to fill all space.

In a two-dimensional lattice, the unit cells can take only one of the five shapes shown in Figure 12.4. The most general type of lattice is the *oblique lattice*. In this lattice, the lattice vectors are of different lengths and the angle  $\gamma$  between them is of arbitrary size, which makes the unit cell an arbitrarily shaped parallelogram. The *square lattice*, *rectangular lattice*, *hexagonal lattice*,\*\* and *rhombic lattice* have a unique combination of  $\gamma$  angle and relationship between the lengths of lattice vectors  $a$  and  $b$  (shown in Figure 12.4). For a rhombic lattice an alternative unit cell can be drawn, a rectangle with lattice points on its corners and its center (shown in green in Figure 12.4). Because of this,

Iron pyrite ( $\text{FeS}_2$ ), a crystalline solid

Obsidian (ca. 70%  $\text{SiO}_2$ ), an amorphous solid

▲ **Figure 12.2** Examples of crystalline and amorphous solids. The atoms in crystalline solids repeat in an orderly, periodic fashion that leads to well-defined faces at the macroscopic level. This order is lacking in amorphous solids like obsidian (volcanic glass).

▲ **Figure 12.3** A crystalline lattice in two dimensions. An infinite array of lattice points is generated by adding together the lattice vectors  $a$  and  $b$ . The unit cell is a parallelogram defined by the lattice vectors.

\*A vector is a quantity involving both a direction and a magnitude. The magnitudes of the vectors in Figure 12.3 are indicated by their lengths, and their directions are indicated by the arrowheads.

\*\*You may wonder why the hexagonal unit cell is not shaped like a hexagon. Remember that the unit cell is by definition a *parallelogram* whose size and shape are defined by the lattice vectors  $a$  and  $b$ .

▲ **Figure 12.4** The five two-dimensional lattices. The primitive unit cell for each lattice is shaded in blue. For the rhombic lattice the centered rectangular unit cell is shaded in green. Unlike the primitive rhombic unit cell, the centered cell has two lattice points per unit cell.

### Go Figure

Why is there a centered rectangular lattice but not a centered square lattice?

▲ **Figure 12.5** Not all shapes tile space. Tiling means covering a surface entirely, which is impossible for some geometric shapes, as shown here for pentagons.

the rhombic lattice is commonly referred to as a *centered rectangular lattice*. The lattices in Figure 12.4 represent five basic shapes: squares, rectangles, hexagons, rhombuses (diamonds), and arbitrary parallelograms. Other polygons, such as pentagons, cannot cover space without leaving gaps, as Figure 12.5 shows.

To understand real crystals, we must consider three dimensions. A three-dimensional lattice is defined by *three* lattice vectors  $a$ ,  $b$ , and  $c$  (Figure 12.6). These lattice vectors define a unit cell that is a parallelepiped (a six-sided figure whose faces are all parallelograms) and is described by the lengths  $a$ ,  $b$ ,  $c$  of the cell edges and the angles  $\alpha$ ,  $\beta$ ,  $\gamma$  between these edges. There are seven possible shapes for a three-dimensional unit cell, as shown in Figure 12.6.

### Give It Some Thought

Imagine you generate a three-dimensional lattice by taking  $a$  and  $b$  vectors that form a two-dimensional square lattice. Then add a third vector,  $c$ , that is of different length and perpendicular to the first two. Which of the seven three-dimensional lattices results?

▲ **Figure 12.6** The seven three-dimensional primitive lattices.

If we place a lattice point at each corner of a unit cell, we get a **primitive lattice**. All seven lattices in Figure 12.6 are primitive lattices. It is also possible to generate what are called *centered lattices* by placing additional lattice points in specific locations in the unit cell. This is illustrated for a cubic lattice in Figure 12.7. A **body-centered cubic lattice** has one lattice point at the center of the unit cell in addition to the lattice points at the eight corners. A **face-centered cubic lattice** has one lattice point at the center of each of the six faces of the unit cell in addition to the lattice points at the eight corners. Centered lattices exist for other types of unit cells as well. For the crystals discussed in this chapter we need consider only the lattices shown in Figures 12.6 and 12.7.

## Filling the Unit Cell

The lattice by itself does not define a crystal structure. To generate a crystal structure, we need to associate an atom or group of atoms with each lattice point. In the simplest case, the crystal structure consists of identical atoms, and each atom lies directly on a lattice point. When this happens, the crystal structure and the lattice points have identical patterns. Many metallic elements adopt such structures, as we will see in Section 12.3. Only for solids in which all the atoms are identical can this occur; in other words, *only elements* can form structures of this type. For compounds, even if we were to put an atom on every lattice point, the points would not be identical because the atoms are not all the same.

In most crystals, the atoms are not exactly coincident with the lattice points. Instead, a group of atoms, called a **motif**, is associated with each lattice point. The unit cell contains a specific motif of atoms, and the crystal structure is built up by repeating the unit cell over and over. This process is illustrated in Figure 12.8 for a two-dimensional crystal based on a hexagonal unit cell and a two-carbon-atom motif. The resulting infinite two-dimensional honeycomb structure is a two-dimensional crystal called *graphene*, a material that has so many interesting properties that its modern discoverers won the Nobel Prize in Physics in 2010. Each carbon atom is covalently bonded to three neighboring carbon atoms in what amounts to an infinite sheet of interconnected hexagonal rings.

The crystal structure of graphene illustrates two important characteristics of crystals. First, we see that no atoms lie on the lattice points. While most of the structures we discuss in this chapter do have atoms on the lattice points, there are many examples, like graphene, where this is not the case. Thus, to build up a structure you must know the location and orientation of the atoms in the motif with respect to the lattice points. Second, we see that bonds can be formed between atoms in neighboring unit cells and the bonds between atoms need not be parallel to the lattice vectors.

## A CLOSER LOOK X-ray Diffraction

When light waves pass through a narrow slit, they are scattered in such a way that the wave seems to spread out. This physical phenomenon is called *diffraction*. When light passes through many evenly spaced narrow slits (a *diffraction grating*), the scattered waves interact to form a series of bright and dark bands, known as a diffraction pattern. The bright bands correspond to constructive overlapping of the light waves, and the dark bands correspond to destructive overlapping of the light waves. [∞](#) (Section 9.8, “Phases in Atomic and Molecular Orbitals”) The most effective diffraction of light occurs when the wavelength of the light and the width of the slits are similar in magnitude.

The spacing of the layers of atoms in solid crystals is usually about 2–20 Å. The wavelengths of X rays are also in this range. Thus, a crystal can serve as an effective diffraction grating for X rays. X-ray diffraction results from the scattering of X rays by a regular arrangement of atoms, molecules, or ions. Much of what we know about crystal structures has been obtained by looking at the diffraction patterns that result when X rays pass through a crystal, a technique known as *X-ray crystallography*. As shown in [Figure 12.9](#) a monochromatic beam of X rays is passed through a crystal. The diffraction pattern that results is recorded. For many years the diffracted X rays were detected by photographic film. Today, crystallographers use an *array detector*, a

device analogous to that used in digital cameras, to capture and measure the intensities of the diffracted rays.

The pattern of spots on the detector in [Figure 12.9](#) depends on the particular arrangement of atoms in the crystal. The spacing and symmetry of the bright spots, where constructive interference occurs, provide information about the size and shape of the unit cell. The intensities of the spots provide information that can be used to determine the locations of the atoms within the unit cell. When combined, these two pieces of information give the atomic structure that defines the crystal.

X-ray crystallography is used extensively to determine the structures of molecules in crystals. The instruments used to measure X-ray diffraction, known as *X-ray diffractometers*, are now computer controlled, making the collection of diffraction data highly automated. The diffraction pattern of a crystal can be determined very accurately and quickly (sometimes in a matter of hours), even though thousands of diffraction spots are measured. Computer programs are then used to analyze the diffraction data and determine the arrangement and structure of the molecules in the crystal. X-ray diffraction is an important technique in industries ranging from steel and cement manufacture to pharmaceuticals.

**Related Exercises:** 12.113–12.115

▲ **Figure 12.9** Diffraction of X rays by a crystal. A monochromatic X-ray beam is passed through a crystal. The X rays are diffracted, and the resulting interference pattern is recorded. The crystal is rotated and another diffraction pattern recorded. Analysis of many diffraction patterns gives the positions of the atoms in the crystal.

## 12.3 | Metallic Solids

**Metallic solids**, also simply called *metals*, consist entirely of metal atoms. The bonding in metals is too strong to be due to dispersion forces, and yet there are not enough valence electrons to form covalent bonds between atoms. The bonding, called *metallic bonding*, happens because the valence electrons are *delocalized* throughout the entire solid. That is, the valence electrons are not associated with specific atoms or bonds but are spread throughout the solid. In fact, we can visualize a metal as an array of positive ions immersed in a “sea” of delocalized valence electrons.

The chemical bonding in metals is reflected in their properties. You have probably held a length of copper wire or an iron bolt. Perhaps you have even seen the surface of a freshly cut piece of sodium metal. These substances, though distinct from one another, share certain similarities that enable us to classify them as metallic. A clean metal surface has a characteristic luster. Metals have a characteristic cold feeling when you touch them, related to their high thermal conductivity (ability to conduct heat). Metals also have high electrical conductivity, which means that electrically charged particles flow easily through them. The thermal conductivity of a metal usually parallels its electrical conductivity. Silver and copper, for example, which possess the highest electrical conductivities among the elements, also possess the highest thermal conductivities.

Most metals are *malleable*, which means that they can be hammered into thin sheets, and *ductile*, which means that they can be drawn into wires (Figure 12.10). These properties indicate that the atoms are capable of slipping past one another. Ionic and covalent-network solids do not exhibit such behavior; they are typically brittle.

▲ **Figure 12.10** Malleability and ductility. Gold leaf demonstrates the characteristic malleability of metals, and copper wire demonstrates their ductility.

### Give It Some Thought

Atoms in metals easily slip past one another as mechanical force is applied; can you think of why this would not be true for ionic solids?

## The Structures of Metallic Solids

The crystal structures of many metals are simple and can be generated by placing a single atom on each lattice point. The structures corresponding to the three cubic lattices are shown in Figure 12.11. Metals with a primitive cubic structure are rare, one of the few examples being the radioactive element polonium. Body-centered cubic metals include iron, chromium, sodium, and tungsten. Examples of face-centered cubic metals include aluminum, lead, copper, silver, and gold.

▲ **Figure 12.11** The structures of (a) primitive cubic, (b) body-centered cubic, and (c) face-centered cubic metals. Each structure can be generated by the combination of a single-atom motif and the appropriate lattice. (d) Corner atoms (one shown in red) are shared among eight neighboring cubic unit cells.

### Go Figure

Which one of these unit cells would you expect to represent the densest packing of spheres?

(a) Primitive cubic metal  
1 atom per unit cell

(b) Body-centered cubic metal  
2 atoms per unit cell

(c) Face-centered cubic metal  
4 atoms per unit cell

**TABLE 12.1** Fraction of Any Atom as a Function of Location within the Unit Cell\*

| Atom Location | Number of Unit Cells Sharing Atom | Fraction of Atom within Unit Cell |
|---------------|-----------------------------------|-----------------------------------|
| Corner        | 8                                 | 1/8 or 12.5%                      |
| Edge          | 4                                 | 1/4 or 25%                        |
| Face          | 2                                 | 1/2 or 50%                        |
| Anywhere else | 1                                 | 1 or 100%                         |

\*It is only the position of the center of the atom that matters. Atoms that reside near the boundary of the unit cell but not on a corner, edge, or face are counted as residing 100% within the unit cell.

Notice in the bottom row of Figure 12.11 that the atoms on the corners and faces of a unit cell do not lie wholly within the unit cell. These corner and face atoms are shared by neighboring unit cells. An atom that sits at the corner of a unit cell is shared among eight unit cells, and only  $1/8$  of the atom is in one particular unit cell. Because a cube has eight corners, each primitive cubic unit cell contains  $(1/8) \times 8 = 1$  atom, as shown in Figure 12.12(a). Similarly, each body-centered cubic unit cell [Figure 12.12(b)] contains two atoms,  $(1/8) \times 8 = 1$  from the corners and 1 at the center of the unit cell. Atoms that lie on the face of a unit cell, as they do in a face-centered cubic metal, are shared by two unit cells so that only one-half of the atom belongs to each unit cell. Therefore, a face-centered cubic unit cell [Figure 12.12(c)] contains four atoms,  $(1/8) \times 8 = 1$  atom from the corners and  $(1/2) \times 6 = 3$  atoms from the faces.

Table 12.1 summarizes how the fractional part of each atom that resides within a unit cell depends on the atom's location within the cell.

### Close Packing

The shortage of valence electrons and the fact that they are collectively shared make it favorable for the atoms in a metal to pack together closely. Because we can consider the shape of an atom to be a sphere, we can understand the structures of metals by considering how spheres pack. The most efficient way to pack one layer of equal-sized spheres is to surround each sphere by six neighbors, as shown at the top of Figure 12.13. To form a three-dimensional structure, we need to stack additional layers on top of this base layer. To maximize packing efficiency, the second layer of spheres must sit in the depressions formed by the spheres in the first layer. We can either put the next layer of atoms into the depressions marked by the yellow dot or the depressions marked by the red dot (realizing that the spheres are too large to simultaneously fill both sets of depressions). For the sake of discussion we arbitrarily put the second layer in the yellow depressions.

For the third layer, we have two choices for where to place the spheres. One possibility is to put the third layer in the depressions that lie directly over the spheres in the first layer. This is done on the left-hand side of Figure 12.13, as shown by the dashed red lines in the side view. Continuing with this pattern, the fourth layer would lie directly over the spheres in the second layer, leading to the ABAB stacking pattern seen on the left, which is called **hexagonal close packing** (hcp). Alternatively, the third-layer spheres could lie directly over the depressions that were marked with red dots in the first layer. In this arrangement, the spheres in the third layer do not sit directly above the spheres in either of the first two layers, as shown by the dashed red lines on the lower right-hand side of Figure 12.13. If this sequence is repeated in subsequent layers, we derive an ABCABC stacking pattern shown on the right known as **cubic close packing** (ccp). In both hexagonal close packing and cubic close packing, each sphere has 12 equidistant nearest neighbors: six neighbors in the same layer, three from the layer above, and three from the layer below. We say that each sphere has a **coordination number** of 12. The coordination number is the number of atoms immediately surrounding a given atom in a crystal structure.

## Go Figure

What type of two-dimensional lattice describes the structure of a single layer of close-packed atoms?

▲ **Figure 12.13** Close packing of equal-sized spheres. Hexagonal (left) close packing and cubic (right) close packing are equally efficient ways of packing spheres. The red and yellow dots indicate the positions of depressions between atoms.

► **Figure 12.14** The unit cells for (a) a hexagonal close-packed metal and (b) a cubic close-packed metal. The solid lines indicate the unit cell boundaries. Colors are used to distinguish one layer of atoms from another.

The extended structure of a hexagonal close-packed metal is shown in **Figure 12.14(a)**. There are two atoms in the primitive hexagonal unit cell, one from each layer. Neither atom sits directly on the lattice points, which are located at the corners of the unit cell. The presence of two atoms in the unit cell is consistent with the two-layer ABAB stacking sequence associated with hcp packing.

Although it is not immediately obvious, the structure that results from cubic close packing possesses a unit cell that is identical to the face-centered cubic unit cell we encountered earlier [Figure 12.11(c)]. The relationship between the ABC layer stacking and the face-centered cubic unit cell is shown in **Figure 12.14(b)**. In this figure, we see that the layers stack perpendicular to the body diagonal of the cubic unit cell.

## Sample Exercise 12.1

### Calculating Packing Efficiency

It is not possible to pack spheres together without leaving some void spaces between the spheres. *Packing efficiency* is the fraction of space in a crystal that is actually occupied by atoms. Determine the packing efficiency of a face-centered cubic metal.

#### SOLUTION

**Analyze** We must determine the volume taken up by the atoms that reside in the unit cell and divide this number by the volume of the unit cell.

**Plan** We can calculate the volume taken up by atoms by multiplying the number of atoms per unit cell by the volume of a sphere,  $4\pi r^3/3$ . To determine the volume of the unit cell, we must first identify the direction along which the atoms touch each other. We can then use geometry to express the length of the cubic unit cell edge,  $a$ , in terms of the radius of the atoms. Once we know the edge length, the cell volume is simply  $a^3$ .

**Solve** As shown in Figure 12.12, a face-centered cubic metal has four atoms per unit cell. Therefore, the volume occupied by the atoms is

$$\text{Occupied volume} = 4 \times \left( \frac{4\pi r^3}{3} \right) = \frac{16\pi r^3}{3}$$

For a face-centered cubic metal, the atoms touch along the diagonal of a face of the unit cell:

Therefore, a diagonal across a face of the unit cell is equal to four times the atomic radius,  $r$ . Using simple trigonometry, and the identity  $\cos(45^\circ) = \sqrt{2}/2$ , we can show that

$$a = 4r \cos(45^\circ) = 4r(\sqrt{2}/2) = (2\sqrt{2})r$$

Finally, we calculate the packing efficiency by dividing the volume occupied by atoms by the volume of the cubic unit cell,  $a^3$ :

$$\begin{aligned}\text{Packing efficiency} &= \frac{\text{volume of atoms}}{\text{volume of unit cell}} = \frac{(\frac{16}{3})\pi r^3}{(2\sqrt{2})^3 r^3} \\ &= 0.74 \text{ or } 74\%\end{aligned}$$

### Practice Exercise 1

Consider the two-dimensional square lattice of Figure 12.4. The “packing efficiency” for a two-dimensional structure would be the area of the atoms divided by the area of the unit cell, times 100%. What is the packing efficiency for a square lattice for atoms of radius  $a/2$  that are centered at the lattice points?

(a) 3.14% (b) 15.7% (c) 31.8% (d) 74.0% (e) 78.5%

### Practice Exercise 2

Determine the packing efficiency by calculating the fraction of space occupied by atoms in a body-centered cubic metal.

### Give It Some Thought

For metallic structures, does the packing efficiency (see Sample Exercise 12.1) increase or decrease as the number of nearest neighbors (the coordination number) decreases?

## Alloys

An **alloy** is a material that contains more than one element and has the characteristic properties of a metal. The alloying of metals is of great importance because it is one of the primary ways of modifying the properties of pure metallic elements. Nearly all the common uses of iron, for example, involve alloy compositions (for example, stainless steel). Bronze is formed by alloying copper and tin, while brass is an alloy of copper and zinc. Pure gold is too soft to be used in jewelry, but alloys of gold are much harder (see “Chemistry Put to Work: Alloys of Gold”). Other common alloys are described in [Table 12.2](#).

Alloys can be divided into four categories: substitutional alloys, interstitial alloys, heterogeneous alloys, and intermetallic compounds. Substitutional and interstitial alloys are both homogeneous mixtures in which components are dispersed randomly and uniformly ([Figure 12.15](#)). [Section 1.2](#) Solids that form homogeneous mixtures are called solid solutions. When atoms of the solute in a solid solution occupy positions normally occupied by a solvent atom, we have a **substitutional alloy**. When the solute atoms occupy interstitial positions in the “holes” between solvent atoms, we have an **interstitial alloy** ([Figure 12.15](#)).

Substitutional alloys are formed when the two metallic components have similar atomic radii and chemical-bonding characteristics. For example, silver and gold form such an alloy over the entire range of possible compositions. When two metals differ in radii by more than about 15%, solubility is generally more limited.

For an interstitial alloy to form, the solute atoms must have a much smaller bonding atomic radius than the solvent atoms. Typically, the interstitial element is a non-metal that makes covalent bonds to the neighboring metal atoms. The presence of the

**TABLE 12.2** Some Common Alloys

| Name             | Primary Element | Typical Composition (by Mass)      | Properties                             | Uses                                    |
|------------------|-----------------|------------------------------------|--|---|
| Wood's metal     | Bismuth         | 50% Bi, 25% Pb, 12.5% Sn, 12.5% Cd | Low melting point (70 °C)              | Fuse plugs, automatic sprinklers        |
| Yellow brass     | Copper          | 67% Cu, 33% Zn                     | Ductile, takes polish                  | Hardware items                          |
| Bronze           | Copper          | 88% Cu, 12% Sn                     | Tough and chemically stable in dry air | Important alloy for early civilizations |
| Stainless steel  | Iron            | 80.6% Fe, 0.4% C, 18% Cr, 1% Ni    | Resists corrosion                      | Cookware, surgical instruments          |
| Plumber's solder | Lead            | 67% Pb, 33% Sn                     | Low melting point (275 °C)             | Soldering joints                        |
| Sterling silver  | Silver          | 92.5% Ag, 7.5% Cu                  | Bright surface                         | Tableware                               |
| Dental amalgam   | Silver          | 70% Ag, 18% Sn, 10% Cu, 2% Hg      | Easily worked                          | Dental fillings                         |
| Pewter           | Tin             | 92% Sn, 6% Sb, 2% Cu               | Low melting point (230 °C)             | Dishes, jewelry                         |

## Go Figure

What determines which species in a solid solution is the solute and which is the solvent?

▲ **Figure 12.15** The distribution of solute and solvent atoms in a substitutional alloy and an interstitial alloy. Both types of alloys are solid solutions and, therefore, homogeneous mixtures.

extra bonds provided by the interstitial component causes the metal lattice to become harder, stronger, and less ductile. For example, steel, which is much harder and stronger than pure iron, is an alloy of iron that contains up to 3% carbon. Other elements may be added to form *alloy steels*. Vanadium and chromium may be added to impart strength, for instance, and to increase resistance to fatigue and corrosion.

## Give It Some Thought

Would you expect the alloy  $\text{PdB}_{0.15}$  to be a substitutional alloy or an interstitial alloy?

One of the most important iron alloys is stainless steel, which contains about 0.4% carbon, 18% chromium, and 1% nickel. The ratio of elements present in the steel may vary over a wide range, imparting a variety of specific physical and chemical properties to the materials.

In a **heterogeneous alloy**, the components are not dispersed uniformly. For example, the heterogeneous alloy pearlite contains two phases (**Figure 12.16**). One phase is essentially pure body-centered cubic iron, and the other is the compound  $\text{Fe}_3\text{C}$ , known as cementite. In general, the properties of heterogeneous alloys depend on both the composition and the manner in which the solid is formed from the molten mixture. The properties of a heterogeneous alloy formed by rapid cooling of a molten mixture, for example, are distinctly different from the properties of an alloy formed by slow cooling of the same mixture.

**Intermetallic compounds** are compounds rather than mixtures. Because they are compounds, they have definite properties and their composition cannot be varied. Furthermore, the different types of atoms in an intermetallic compound are ordered rather than randomly distributed. The ordering of atoms in an intermetallic compound generally leads to better structural stability and higher melting points than what is observed in the constituent metals. These features can be attractive for high-temperature applications. On the negative side, intermetallic compounds are often more brittle than substitutional alloys.

► **Figure 12.16** Microscopic view of the structure of the heterogeneous alloy pearlite. The dark regions are body-centered cubic iron metal, and the lighter regions are cementite,  $\text{Fe}_3\text{C}$ .

## Go Figure

In the unit cell drawing on the right, why do we see eight Sm atoms and nine Co atoms if the empirical formula is  $\text{SmCo}_5$ ?

▲ **Figure 12.17** Three examples of intermetallic compounds.

Intermetallic compounds play many important roles in modern society. The intermetallic compound  $\text{Ni}_3\text{Al}$  is a major component of jet aircraft engines because of its strength at high temperature and its low density. Razor blades are often coated with  $\text{Cr}_3\text{Pt}$ , which adds hardness, allowing the blade to stay sharp longer. Both compounds have the structure shown on the left-hand side of **Figure 12.17**. The compound  $\text{Nb}_3\text{Sn}$ , also shown in **Figure 12.17**, is a superconductor, a substance that, when cooled below a critical temperature, conducts electricity with no resistance. In the case of  $\text{Nb}_3\text{Sn}$  superconductivity is observed only when the temperature falls below 18 K. Superconductors are used in the magnets in MRI scanners widely employed for medical imaging. (Section 6.7, “Nuclear Spin and Magnetic Resonance Imaging”) The need to keep the magnets cooled to such a low temperature is part of the reason why MRI devices are expensive to operate. The hexagonal intermetallic compound  $\text{SmCo}_5$ , shown on the right-hand side of **Figure 12.17**, is used to make the permanent magnets found in lightweight headsets and high-fidelity speakers. A related compound with the same structure,  $\text{LaNi}_5$ , is used as the anode in nickel-metal hydride batteries.

## CHEMISTRY PUT TO WORK Alloys of Gold

Gold has long been a metal of choice for decorative objects, jewelry, and coins. The popularity of gold is driven by its unusual color (for a metal), its resistance to many chemical reactions, and the fact that it can easily be worked. However, pure gold is too soft for many applications, including jewelry. To increase its strength and hardness, as well as to modify its color, gold is often alloyed with other metals. In the jewelry trade pure gold is termed 24 karat. The karat number decreases as the mass percent of gold decreases. The most common alloys used in jewelry are 14 karat, which is  $(14/24) \times 100 = 58\%$  gold, and 18 karat, which is  $(18/24) \times 100 = 75\%$  gold.

The color of gold varies depending on the metals it is alloyed with. Gold is typically alloyed with silver and/or copper. All three elements crystallize with a face-centered cubic structure. The fact that all three elements have similar radii (Au and Ag are nearly the same size; Cu is roughly 11% smaller) and crystallize with the same type of structure make it possible to form substitutional alloys with nearly any composition. The variations in color of these alloys as a function of composition are shown in **Figure 12.18**. Gold alloyed with equal parts silver and copper (blue dot) takes on the golden yellow color we associate with 18-karat gold jewelry. Red (14-karat) or rose gold is a copper-rich alloy (red dot). Silver-rich alloys take on a greenish hue, eventually giving way to silvery-white colors as silver becomes the majority constituent.

## Go Figure

Which of these drawings represent molecules?

▲ Figure 12.19 Bonding in period 3 elements.

## 12.4 | Metallic Bonding

Consider the elements of the third period of the periodic table (Na–Ar). Argon with eight valence electrons has a complete octet; as a result it does not form any bonds. Chlorine, sulfur, and phosphorus form molecules ( $\text{Cl}_2$ ,  $\text{S}_8$ , and  $\text{P}_4$ ) in which the atoms make one, two, and three bonds, respectively (Figure 12.19). Silicon forms an extended network solid in which each atom is bonded to four equidistant neighbors. Each of these elements forms  $8 - N$  bonds, where  $N$  is the number of valence electrons. This behavior can easily be understood through the application of the octet rule.

If the  $8 - N$  trend continued as we move left across the periodic table, we would expect aluminum (three valence electrons) to form five bonds. Like many other metals, however, aluminum adopts a close-packed structure with 12 nearest neighbors. Magnesium and sodium also adopt metallic structures. What is responsible for this abrupt change in the preferred bonding mechanism? The answer, as noted earlier, is that metals do not have enough valence-shell electrons to satisfy their bonding requirements by forming localized electron-pair bonds. In response to this deficiency, the valence electrons are collectively shared. A structure in which the atoms are close-packed facilitates this delocalized sharing of electrons.

▲ Figure 12.20 Electron-sea model of metallic bonding. The valence electrons delocalize to form a sea of mobile electrons that surrounds and binds together an extended array of metal ions.

### Electron-Sea Model

A simple model that accounts for some of the most important characteristics of metals is the **electron-sea model**, which pictures the metal as an array of metal cations in a “sea” of valence electrons (Figure 12.20). The electrons are confined to the metal by electrostatic attractions to the cations, and they are uniformly distributed throughout the structure. The electrons are mobile, however, and no individual electron is confined to any particular metal ion. When a voltage is applied to a metal wire, the electrons, being negatively charged, flow through the metal toward the positively charged end of the wire.

The high thermal conductivity of metals is also accounted for by the presence of mobile electrons. The movement of electrons in response to temperature gradients permits ready transfer of kinetic energy throughout the solid.

The ability of metals to deform (their malleability and ductility) can be explained by the fact that metal atoms form bonds to many neighbors. Changes in the positions of the atoms brought about in reshaping the metal are partly accommodated by a redistribution of electrons.

## Molecular Orbital Model

Although the electron-sea model works surprisingly well given its simplicity, it does not adequately explain many properties of metals. According to the model, for example, the strength of bonding between metal atoms should steadily increase as the number of valence electrons increases, resulting in a corresponding increase in the melting points. However, elements near the middle of the transition metal series, rather than those at the end, have the highest melting points in their respective periods (Figure 12.21). This trend implies that the strength of metallic bonding first increases with increasing number of electrons and then decreases. Similar trends are seen in other physical properties of the metals, such as the boiling point, heat of fusion, and hardness.

To obtain a more accurate picture of the bonding in metals, we must turn to molecular orbital theory. In Sections 9.7 and 9.8, we learned how molecular orbitals are created from the overlap of atomic orbitals. Let's briefly review some of the rules of molecular orbital theory:

1. Atomic orbitals combine to make molecular orbitals that can extend over the entire molecule.
2. A molecular orbital can contain zero, one, or two electrons.
3. The number of molecular orbitals in a molecule equals the number of atomic orbitals that combine to form molecular orbitals.
4. Adding electrons to a bonding molecular orbital strengthens bonding, while adding electrons to antibonding molecular orbitals weakens bonding.

The electronic structures of crystalline solids and small molecules have similarities as well as differences. To illustrate, consider how the molecular orbital diagram for a chain of lithium atoms changes as we increase the length of the chain (Figure 12.22).

### Go Figure

Which element in each period has the highest melting point? In each case, is the element you named at the beginning, middle, or end of its period?

▲ Figure 12.21 The melting points of metals from periods 4, 5, and 6.

### Go Figure

How does the energy spacing between molecular orbitals change as the number of atoms in the chain increases?

▲ Figure 12.22 Discrete energy levels in individual molecules become continuous energy bands in a solid. Occupied orbitals are shaded blue, and empty orbitals pink.

Each lithium atom contains a half-filled  $2s$  orbital in its valence shell. The molecular-orbital diagram for  $\text{Li}_2$  is analogous to that of an  $\text{H}_2$  molecule: one filled bonding molecular orbital and one empty antibonding molecular orbital with a nodal plane between the atoms.  (Section 9.7) For  $\text{Li}_4$ , there are four molecular orbitals, ranging from the lowest-energy orbital, where the orbital interactions are completely bonding (zero nodal planes), to the highest-energy orbital, where all interactions are antibonding (three nodal planes).

As the length of the chain increases, the number of molecular orbitals increases. Regardless of chain length, the lowest-energy orbitals are always the most bonding and the highest-energy orbitals always the most antibonding. Furthermore, because each lithium atom has only one valence shell atomic orbital, the number of molecular orbitals is equal to the number of lithium atoms in the chain. Because each lithium atom has one valence electron, half of the molecular orbitals are fully occupied and the other half are empty, regardless of chain length.\*

**Electronic Band Structure** If the chain becomes very long, there are so many molecular orbitals that the energy separation between them becomes vanishingly small. As the chain length goes to infinity, the allowed energy states become a continuous **band**. For a crystal large enough to see with the eye (or even an optical microscope), the number of atoms is extremely large. Consequently, the electronic structure of the crystal is like that of the infinite chain, consisting of bands, as shown on the right-hand side of Figure 12.22.

The electronic structures of most metals are more complicated than those shown in Figure 12.22 because we have to consider more than one type of atomic orbital on each atom. Because each type of orbital can give rise to its own band, the electronic structure of a solid usually consists of a series of bands. The electronic structure of a bulk solid is referred to as a **band structure**.

The band structure of a typical metal is shown schematically in Figure 12.23. The electron filling depicted corresponds to nickel metal, but the basic features of other

### Go Figure

If the metal were potassium rather than nickel, which bands— $4s$ ,  $4p$ , and/or  $3d$ —would be partially occupied?

▲ Figure 12.23 The electronic band structure of nickel.

\*This is strictly true only for chains with an even number of atoms.

metals are similar. The electron configuration of a nickel atom is  $[\text{Ar}]4s^23d^8$ , as shown on the left side of the figure. The energy bands that form from each of these orbitals are shown on the right side. The  $4s$ ,  $4p$ , and  $3d$  orbitals are treated independently, each giving rise to a band of molecular orbitals. In practice, these overlapping bands are not completely independent of each other, but for our purposes this simplification is reasonable.

The  $4s$ ,  $4p$ , and  $3d$  bands differ from one another in the energy range they span (represented by the heights of the rectangles on the right side of Figure 12.23) and in the number of electrons they can hold (represented by the area of the rectangles). The  $4s$ ,  $4p$ , and  $3d$  bands can hold 2, 6, and 10 electrons per atom, respectively, corresponding to two per orbital, as dictated by the Pauli exclusion principle. [∞ \(Section 6.7\)](#) The energy range spanned by the  $3d$  band is smaller than the range spanned by the  $4s$  and  $4p$  bands because the  $3d$  orbitals are smaller and, therefore, overlap with orbitals on neighboring atoms less effectively.

Many properties of metals can be understood from Figure 12.23. We can think of the energy band as a partially filled container for electrons. The incomplete filling of the energy band gives rise to characteristic metallic properties. The electrons in orbitals near the top of the occupied levels require very little energy input to be “promoted” to higher-energy orbitals that are unoccupied. Under the influence of any source of excitation, such as an applied electrical potential or an input of thermal energy, electrons move into previously vacant levels and are thus freed to move through the lattice, giving rise to electrical and thermal conductivity.

Without the overlap of energy bands, the periodic properties of metals could not be explained. In the absence of the  $d$ - and  $p$ -bands, we would expect the  $s$ -band to be half-filled for the alkali metals (group 1A) and completely filled for the alkaline-earth metals (group 2A). If that were true, metals like magnesium, calcium, and strontium would not be good electrical and thermal conductors, in disagreement with experimental observations.

While the conductivity of metals can be qualitatively understood using either the electron-sea model or the molecular orbital model, many physical properties of transition metals, such as the melting points plotted in Figure 12.21, can be explained only with the latter model. The molecular orbital model predicts that bonding first becomes stronger as the number of valence electrons increases and the bonding orbitals are increasingly populated. Upon moving past the middle elements of the transition metal series, the bonds grow weaker as electrons populate antibonding orbitals. Strong bonds between atoms lead to metals with higher melting and boiling points, higher heats of fusion, higher hardness, and so forth.

### Give It Some Thought

Which element, W or Au, has the greater number of electrons in antibonding orbitals? Which one would you expect to have the higher melting point?

## 12.5 | Ionic Solids

**Ionic solids** are held together by the electrostatic attraction between cations and anions: ionic bonds. [∞ \(Section 8.2\)](#) The high melting and boiling points of ionic compounds are a testament to the strength of the ionic bonds. The strength of an ionic bond depends on the charges and sizes of the ions. As discussed in Chapters 8 and 11, the attractions between cations and anions increase as the charges of the ions increase. Thus NaCl, where the ions have charges of  $1+$  and  $1-$ , melts at  $801^\circ\text{C}$ , whereas MgO, where the ions have charges of  $2+$  and  $2-$ , melts at  $2852^\circ\text{C}$ . The interactions between cations and anions also increase as the ions get smaller, as we see from the melting points of the alkali metal halides in [Table 12.3](#). These trends mirror the trends in lattice enthalpy discussed in Section 8.2.

### Go Figure

Why don't metals cleave in the way depicted here for ionic substances?

1 A shear stress is applied to an ionic crystal.

2 Planes of atoms slide in response to stress.

3 Repulsive interactions between ions of like charge lead to separation of the layers.

(a)

(b)

▲ **Figure 12.24 Brittleness and faceting in ionic crystals.** (a) When a shear stress (blue arrows) is applied to an ionic solid, the crystal separates along a plane of atoms as shown. (b) This property of ionic crystals is used to facet gemstones, such as rubies.

**TABLE 12.3 Properties of the Alkali Metal Halides**

| Compound | Cation–Anion Distance (Å) | Lattice Enthalpy (kJ/mol) | Melting Point (°C) |
|----------|---------------------------|---------------------------|--------------------|
| LiF      | 2.01                      | 1030                      | 845                |
| NaCl     | 2.83                      | 788                       | 801                |
| KBr      | 3.30                      | 671                       | 734                |
| RbI      | 3.67                      | 632                       | 674                |

Although ionic and metallic solids both have high melting and boiling points, the differences between ionic and metallic bonding are responsible for important differences in their properties. Because the valence electrons in ionic compounds are confined to the anions, rather than being delocalized, ionic compounds are typically electrical insulators. They tend to be brittle, a property explained by repulsive interactions between ions of like charge. When stress is applied to an ionic solid, as in **Figure 12.24**, the planes of atoms, which before the stress were arranged with cations next to anions, shift so that the alignment becomes cation–cation, anion–anion. The resulting repulsive interaction causes the planes to split away from each other, a property that lends itself to the carving of certain gemstones (such as ruby, composed principally of  $\text{Al}_2\text{O}_3$ ).

### Structures of Ionic Solids

Like metallic solids, ionic solids tend to adopt structures with symmetric, close-packed arrangements of atoms. However, important differences arise because we now have to pack together spheres that have different radii and opposite charges. Because cations are often considerably smaller than anions (see **Section 7.3**), the coordination numbers in ionic compounds are smaller than those in close-packed metals. Even if the anions and cations were the same size, the close-packed arrangements seen in metals cannot be replicated without letting ions of like charge come in contact with each other. The repulsions between ions of the same type make such arrangements unfavorable. The most favorable structures are those where the cation–anion distances are as close as those permitted by ionic radii, but the anion–anion and cation–cation distances are maximized.

### Give It Some Thought

Is it possible for all atoms in an ionic compound to lie on the lattice points as they do in the metallic structures shown in **Figure 12.11**?

Three common ionic structure types are shown in **Figure 12.25**. The cesium chloride ( $\text{CsCl}$ ) structure is based on a primitive cubic lattice. Anions sit on the lattice points at the corners of the unit cell, and a cation sits at the center of each cell. (Remember, there is no lattice point inside a primitive unit cell.) With this arrangement, both cations and anions are surrounded by a cube of eight ions of the opposite type.

The sodium chloride ( $\text{NaCl}$ ; also called the rock salt structure) and zinc blende ( $\text{ZnS}$ ) structures are based on a face-centered cubic lattice. In both structures the anions sit on the lattice points that lie on the corners and faces of the unit cell, but the two-atom motif is slightly different for the two structures. In  $\text{NaCl}$  the  $\text{Na}^+$  ions are displaced from the  $\text{Cl}^-$  ions along the edge of the unit cell, whereas in  $\text{ZnS}$  the  $\text{Zn}^{2+}$  ions are displaced from the  $\text{S}^{2-}$  ions along the body diagonal of the unit cell. This difference leads to different coordination numbers. In sodium chloride, each cation and each anion are surrounded by six ions of the opposite type, leading to an octahedral coordination environment. In zinc blende, each cation and each anion are surrounded by four ions of the opposite type, leading to a tetrahedral coordination geometry. The cation coordination environments can be seen in **Figure 12.26**.

## Go Figure

Do the anions touch each other in any of these three structures? If not, which ions do touch each other?

▲ **Figure 12.25** The structures of CsCl, NaCl, and ZnS. Each structure type can be generated by the combination of a two-atom motif and the appropriate lattice.

|                            | CsCl | NaCl | ZnS  |
|----------------------------|------|------|------|
| Cation radius, $r_+$ (Å)   | 1.81 | 1.16 | 0.88 |
| Anion radius, $r_-$ (Å)    | 1.67 | 1.67 | 1.70 |
| $r_+/r_-$                  | 1.08 | 0.69 | 0.52 |
| Cation coordination number | 8    | 6    | 4    |
| Anion coordination number  | 8    | 6    | 4    |

▲ **Figure 12.26** Coordination environments in CsCl, NaCl, and ZnS. The sizes of the ions have been reduced to show the coordination environments clearly.

## Go Figure

How many cations are there per unit cell for each of these structures?  
How many anions per unit cell?

▲ **Figure 12.27** Coordination numbers depend on stoichiometry. The sizes of the ions have been reduced to show the coordination environments clearly.

For a given ionic compound, we might ask which type of structure is most favorable. A number of factors come into play, but two of the most important are the relative sizes of the ions and the stoichiometry. Consider first ion size. Notice in Figure 12.26 that the coordination number changes from 8 to 6 to 4 on moving from CsCl to NaCl to ZnS. This trend is driven in part by the fact that for these three compounds the ionic radius of the cation gets smaller while the ionic radius of the anion changes very little. When the cation and anion are similar in size, a large coordination number is favored and the CsCl structure is often realized. As the relative size of the cation gets smaller, eventually it is no longer possible to maintain the cation–anion contacts and simultaneously keep the anions from touching each other. When this occurs, the coordination number drops from 8 to 6, and the sodium chloride structure becomes more favorable. As the cation size decreases further, eventually the coordination number must be reduced again, this time from 6 to 4, and the zinc blende structure becomes favored. Remember that, in ionic crystals, ions of opposite charge touch each other but ions of the same charge should not touch.

The relative number of cations and anions also helps determine the most stable structure type. All the structures in Figure 12.26 have equal numbers of cations and anions. These structure types (cesium chloride, sodium chloride, zinc blende) can be realized only for ionic compounds in which the number of cations and anions is equal. When this is not the case, other crystal structures must result. As an example, consider NaF, MgF<sub>2</sub>, and ScF<sub>3</sub> (Figure 12.27). Sodium fluoride has the sodium chloride structure with a coordination number of 6 for both cation and anion, as you might expect since NaF and NaCl are quite similar. Magnesium fluoride, however, has two anions for every cation, resulting in a tetragonal crystal structure called the *rutile structure*. The cation coordination number is still 6, but the fluoride coordination number is now only 3. In the scandium fluoride structure, there are three anions for every cation; the cation coordination number is still 6, but the fluoride coordination number has dropped to 2. As the cation/anion ratio goes down, there are fewer cations to surround each anion, and so the anion coordination number must decrease. The empirical formula of an ionic compound can be described quantitatively by the relationship

$$\frac{\text{Number of cations per formula unit}}{\text{Number of anions per formula unit}} = \frac{\text{anion coordination number}}{\text{cation coordination number}} \quad [12.1]$$

## Give It Some Thought

In the crystal structure of potassium oxide, the oxide ions are coordinated by eight potassium ions. What is the coordination number of potassium?

## Sample Exercise 12.2

## Calculating the Density of an Ionic Solid

Rubidium iodide crystallizes with the same structure as sodium chloride. (a) How many iodide ions are there per unit cell? (b) How many rubidium ions are there per unit cell? (c) Use the ionic radii and molar masses of  $\text{Rb}^+$  ( $1.66 \text{ \AA}$ ,  $85.47 \text{ g/mol}$ ) and  $\text{I}^-$  ( $2.06 \text{ \AA}$ ,  $126.90 \text{ g/mol}$ ) to estimate the density of rubidium iodide in  $\text{g/cm}^3$ .

## SOLUTION

## Analyze and Plan

- (a) We need to count the number of anions in the unit cell of the sodium chloride structure, remembering that ions on the corners, edges, and faces of the unit cell are only partially inside the unit cell.
- (b) We can apply the same approach to determine the number of cations in the unit cell. We can double-check our answer by writing the empirical formula to make sure the charges of the cations and anions are balanced.
- (c) Because density is an intensive property, the density of the unit cell is the same as the density of a bulk crystal. To calculate the density we must divide the mass of the atoms per unit cell by the volume of the unit cell. To determine the volume of the unit cell, we need to estimate the length of the unit cell edge by first identifying the direction along which the ions touch and then using ionic radii to estimate the length. Once we have the length of the unit cell edge, we can cube it to determine its volume.

## Solve

- (a) The crystal structure of rubidium iodide looks just like NaCl with  $\text{Rb}^+$  ions replacing  $\text{Na}^+$  and  $\text{I}^-$  ions replacing  $\text{Cl}^-$ . From the views of the NaCl structure in Figures 12.25 and 12.26, we see that there is an anion at each corner of the unit cell and at the center of each face. From Table 12.1 we see that the ions sitting on the corners are equally shared by eight unit cells ( $\frac{1}{8}$  ion per unit cell), while those ions sitting on the faces are equally shared by two unit cells ( $\frac{1}{2}$  ion per unit cell). A cube has eight corners and six faces, so the total number of  $\text{I}^-$  ions is  $8(\frac{1}{8}) + 6(\frac{1}{2}) = 4$  per unit cell.
- (b) Using the same approach for the rubidium cations, we see that there is a rubidium ion on each edge and one at the center of the unit cell. Using Table 12.1 again, we see that the ions sitting on the edges are equally shared by four unit cells ( $\frac{1}{4}$  ion per unit cell), whereas the cation at the center of the unit cell is not shared. A cube has 12 edges, so the total number of rubidium ions is  $12(\frac{1}{4}) + 1 = 4$ . This answer makes sense because the number of  $\text{Rb}^+$  ions must be the same as the number of  $\text{I}^-$  ions to maintain charge balance.
- (c) In ionic compounds, cations and anions touch each other. In RbI the cations and anions touch along the edge of the unit cell as shown in the following figure.

The length of the unit cell edge is equal to  $r(\text{I}^-) + 2r(\text{Rb}^+) + r(\text{I}^-) = 2r(\text{I}^-) + 2r(\text{Rb}^+)$ . Plugging in the ionic radii we get  $2(2.06 \text{ \AA}) + 2(1.66 \text{ \AA}) = 7.44 \text{ \AA}$ . The volume of a cubic unit cell is just the edge length cubed. Converting from  $\text{\AA}$  to cm and cubing we get

$$\text{Volume} = (7.44 \times 10^{-8} \text{ cm})^3 = 4.12 \times 10^{-22} \text{ cm}^3.$$

From parts (a) and (b) we know that there are four rubidium and four iodide ions per unit cell. Using this result and the molar masses, we can calculate the mass per unit cell

$$\text{Mass} = \frac{4(85.47 \text{ g/mol}) + 4(126.90 \text{ g/mol})}{6.022 \times 10^{23} \text{ mol}^{-1}} = 1.411 \times 10^{-21} \text{ g}$$

The density is the mass per unit cell divided by the volume of a unit cell

$$\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{1.411 \times 10^{-21} \text{ g}}{4.12 \times 10^{-22} \text{ cm}^3} = 3.43 \text{ g/cm}^3$$

**Check** The densities of most solids fall between the density of lithium ( $0.5 \text{ g/cm}^3$ ) and that of iridium ( $22.6 \text{ g/cm}^3$ ), so this value is reasonable.

## Practice Exercise 1

Given the ionic radii and molar masses of  $\text{Sc}^{3+}$  ( $0.88 \text{ \AA}$ ,  $45.0 \text{ g/mol}$ ) and  $\text{F}^-$  ( $1.19 \text{ \AA}$ ,  $19.0 \text{ g/mol}$ ), what value do you estimate for the density of  $\text{ScF}_3$ , whose structure is shown in Figure 12.27?

- (a)  $5.99 \text{ g/cm}^3$   
 (b)  $1.44 \times 10^{24} \text{ g/mol}$   
 (c)  $19.1 \text{ g/cm}^3$   
 (d)  $2.39 \text{ g/cm}^3$   
 (e)  $5.72 \text{ g/cm}^3$

## Practice Exercise 2

Estimate the length of the cubic unit cell edge and the density of CsCl (Figure 12.25) from the ionic radii of cesium,  $1.81 \text{ \AA}$ , and chloride,  $1.67 \text{ \AA}$ . (Hint: Ions in CsCl touch along the body diagonal, a vector running from one corner of a cube through the body center to the opposite corner. Using trigonometry it can be shown that the body diagonal of a cube is  $\sqrt{3}$  times longer than the edge.)

## 12.6 | Molecular Solids

**Molecular solids** consist of atoms or neutral molecules held together by dipole–dipole forces, dispersion forces, and/or hydrogen bonds. Because these intermolecular forces are weak, molecular solids are soft and have relatively low melting points (usually below 200 °C). Most substances that are gases or liquids at room temperature form molecular solids at low temperature. Examples include Ar, H<sub>2</sub>O, and CO<sub>2</sub>.

The properties of molecular solids depend in large part on the strengths of the forces between molecules. Consider, for example, the properties of sucrose (table sugar, C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>). Each sucrose molecule has eight —OH groups, which allow for the formation of multiple hydrogen bonds. Consequently, sucrose exists as a crystalline solid at room temperature, and its melting point, 184 °C, is relatively high for a molecular solid.

Molecular shape is also important because it dictates how efficiently molecules pack together in three dimensions. Benzene (C<sub>6</sub>H<sub>6</sub>), for example, is a highly symmetrical planar molecule.  (Section 8.6) It has a higher melting point than toluene, a compound in which one of the hydrogen atoms of benzene has been replaced by a CH<sub>3</sub> group (Figure 12.28). The lower symmetry of toluene molecules prevents them from packing in a crystal as efficiently as benzene molecules. As a result, the intermolecular forces that depend on close contact are not as effective and the melting point is lower. In contrast, the boiling point of toluene is *higher* than that of benzene, indicating that the intermolecular attractive forces are larger in liquid toluene than in liquid benzene. The melting and boiling points of phenol, another substituted benzene shown in Figure 12.28, are higher than those of benzene because the OH group of phenol can form hydrogen bonds.

### Go Figure

In which substance, benzene or toluene, are the intermolecular forces stronger? In which substance do the molecules pack more efficiently?

|                    |  |   |   |
|--------------------|--|---|---|
|                    |  |  |  |
|                    | Benzene  | Toluene   | Phenol  |
| Melting point (°C) | 5  | −95   | 43  |
| Boiling point (°C) | 80   | 111   | 182   |

▲ Figure 12.28 Melting and boiling points for benzene, toluene, and phenol.

## 12.7 | Covalent-Network Solids

**Covalent-network solids** consist of atoms held together in large networks by covalent bonds. Because covalent bonds are much stronger than intermolecular forces, these solids are much harder and have higher melting points than molecular solids. Diamond and graphite, two allotropes of carbon, are two of the most familiar covalent-network solids. Other examples are silicon, germanium, quartz (SiO<sub>2</sub>), silicon carbide (SiC), and boron nitride (BN). In all cases, the bonding between atoms is either completely covalent or more covalent than ionic.

In diamond, each carbon atom is bonded tetrahedrally to four other carbon atoms (Figure 12.29). The structure of diamond can be derived from the zinc blende structure (Figure 12.26) if carbon atoms replace both the zinc and sulfide ions. The carbon atoms are *sp*<sup>3</sup>-hybridized and held together by strong carbon–carbon single covalent bonds. The strength and directionality of these bonds make diamond the hardest known material. For this reason, industrial-grade diamonds are employed in saw blades used for the most demanding cutting jobs. The stiff, interconnected bond network also explains why

◀ **Figure 12.29** The structures of (a) diamond and (b) graphite.

diamond is one of the best-known thermal conductors, yet is not electrically conductive. Diamond has a high melting point, 3550 °C.

In graphite, [Figure 12.29(b)], the carbon atoms form covalently bonded layers that are held together by intermolecular forces. The layers in graphite are the same as those in the graphene sheet shown in Figure 12.8. Graphite has a hexagonal unit cell containing two layers offset so that the carbon atoms in a given layer sit over the middle of the hexagons of the layer below. Each carbon is covalently bonded to three other carbons in the same layer to form interconnected hexagonal rings. The distance between adjacent carbon atoms in the plane, 1.42 Å, is very close to the C—C distance in benzene, 1.395 Å. In fact, the bonding resembles that of benzene, with delocalized  $\pi$  bonds extending over the layers. ∞ (Section 9.6) Electrons move freely through the delocalized orbitals, making graphite a good electrical conductor along the layers. (In fact, graphite is used as a conducting electrode in batteries.) These  $sp^2$ -hybridized sheets of carbon atoms are separated by 3.35 Å from one another, and the sheets are held together only by dispersion forces. Thus, the layers readily slide past one another when rubbed, giving graphite a greasy feel. This tendency is enhanced when impurity atoms are trapped between the layers, as is typically the case in commercial forms of the material.

Graphite is used as a lubricant and as the “lead” in pencils. The enormous differences in physical properties of graphite and diamond—both of which are pure carbon—arise from differences in their three-dimensional structure and bonding.

## Semiconductors

Metals conduct electricity extremely well. Many solids, however, conduct electricity somewhat, but nowhere near as well as metals, which is why such materials are called **semiconductors**. Two examples of semiconductors are silicon and germanium, which lie immediately below carbon in the periodic table. Like carbon, each of these elements has four valence electrons, just the right number to satisfy the octet rule by forming single covalent bonds with four neighbors. Hence, silicon and germanium, as well as the gray form of tin, crystallize with the same infinite network of covalent bonds as diamond.

When atomic  $s$  and  $p$  orbitals overlap, they form bonding molecular orbitals and antibonding molecular orbitals. Each pair of  $s$  orbitals overlaps to give one bonding and one antibonding molecular orbital, whereas the  $p$  orbitals overlap to give three bonding and three antibonding molecular orbitals. ∞ (Section 9.8) The extended network of bonds leads to the formation of the same type of bands we saw for metals in Section 12.4. However, unlike metals, in semiconductors an energy gap develops between the filled and empty states, much like the energy gap between bonding and antibonding orbitals. ∞ (Section 9.6) The band that forms from bonding molecular orbitals is called the

## Go Figure

If you draw a second diagram next to this one to represent an insulator, what aspect of the second diagram would be different?

▲ **Figure 12.30** The electronic band structure of semiconductors that have the diamond crystal structure.

**valence band**, and the band that forms the antibonding orbitals is called the **conduction band** (Figure 12.30). In a semiconductor, the valence band is filled with electrons and the conduction band is empty. These two bands are separated by the energy **band gap**  $E_g$ . In the semiconductor community, energies are given in electron volts (eV);  $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ . Band gaps greater than  $\sim 3.5 \text{ eV}$  are so large that the material is not a semiconductor; it is an **insulator** and does not conduct electricity.

Semiconductors can be divided into two classes: elemental semiconductors, which contain only one type of atom, and compound semiconductors, which contain two or more elements. The elemental semiconductors all come from group 4A. As we move down the periodic table, bond distances increase, which decreases orbital overlap. This decrease in overlap reduces the energy difference between the top of the valence band and the bottom of the conduction band. As a result, the band gap decreases on going from diamond (5.5 eV, an insulator) to silicon (1.11 eV) to germanium (0.67 eV) to gray tin (0.08 eV). In the heaviest group 4A element, lead, the band gap collapses altogether. As a result, lead has the structure and properties of a metal.

Compound semiconductors maintain the same *average* valence electron count as elemental semiconductors—four per atom. For example, in gallium arsenide, GaAs, each Ga atom contributes three electrons and each As atom contributes five, which averages out to four per atom—the same number as in silicon or germanium. Hence, GaAs is a semiconductor. Other examples are InP, where indium contributes three valence electrons and phosphorus contributes five, and CdTe, where cadmium provides two valence electrons and tellurium contributes six. In both cases, the average is again four valence electrons per atom. GaAs, InP, and CdTe all crystallize with a zinc blende structure.

The band gap of a compound semiconductor tends to increase as the difference in group numbers increases. For example,  $E_g = 0.67 \text{ eV}$  in Ge, but  $E_g = 1.43 \text{ eV}$  in GaAs. If we increase the difference in group number to four, as in ZnSe (groups 2B and 6A), the band gap increases to 2.70 eV. This progression is a result of the transition from pure covalent bonding in elemental semiconductors to polar covalent bonding in compound semiconductors. As the difference in electronegativity of the elements increases, the bonding becomes more polar and the band gap increases.

**TABLE 12.4 Band Gaps of Select Elemental and Compound Semiconductors**

| Material        | Structure Type | $E_g$ , eV <sup>†</sup> |
|-----------------|----------------|-------------------------|
| Si              | Diamond        | 1.11                    |
| AlP             | Zinc blende    | 2.43                    |

| GaAs            | Zinc blende    | 1.43                    |
| ZnSe            | Zinc blende    | 2.58                    |
| Sn <sup>‡</sup> | Diamond        | 0.08                    |
| InSb            | Zinc blende    | 0.18                    |
| CdTe            | Zinc blende    | 1.50                    |

|          |          |          |          |          |
|----------|----------|----------|----------|----------|
|          | 13<br>Al | 14<br>Si | 15<br>P  |          |
| 30<br>Zn | 31<br>Ga | 32<br>Ge | 33<br>As | 34<br>Se |
| 48<br>Cd | 49<br>In | 50<br>Sn | 51<br>Sb | 52<br>Te |

<sup>†</sup> Band gap energies are room temperature values,  $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ .

<sup>‡</sup> These data are for gray tin, the semiconducting allotrope of tin. The other allotrope, white tin, is a metal.

Electrical engineers manipulate both the orbital overlap and the bond polarity to control the band gaps of compound semiconductors for use in a wide range of electrical and optical devices. The band gaps of several elemental and compound semiconductors are given in [Table 12.4](#).

### Sample Exercise 12.3

#### Qualitative Comparison of Semiconductor Band Gaps

Will GaP have a larger or smaller band gap than ZnS? Will it have a larger or smaller band gap than GaN?

#### SOLUTION

**Analyze** The size of the band gap depends on the vertical and horizontal positions of the elements in the periodic table. The band gap will increase when either of the following conditions is met: (1) The elements are located higher up in the periodic table, where enhanced orbital overlap leads to a larger splitting between bonding and antibonding orbital energies, or (2) the horizontal separation between the elements increases, which leads to an increase in the electronegativity difference and bond polarity.

**Plan** We must look at the periodic table and compare the relative positions of the elements in each case.

**Solve** Gallium is in the fourth period and group 3A. Phosphorus is in the third period and group 5A. Zinc and sulfur are in the same periods as gallium and phosphorus, respectively. However, zinc, in group 2B, is one element to the left of gallium; sulfur in group 6A is one element to the right of phosphorus. Thus, we would expect the electronegativity difference to be larger for ZnS, which should result in ZnS having a larger band gap than GaP.

For both GaP and GaN the more electropositive element is gallium. So we need only compare the positions of the more

electronegative elements, P and N. Nitrogen is located above phosphorus in group 5A. Therefore, based on increased orbital overlap, we would expect GaN to have a larger band gap than GaP.

**Check** External references show that the band gap of GaP is 2.26 eV, ZnS is 3.6 eV, and GaN is 3.4 eV.

#### ► Practice Exercise 1

Which of these statements is false?

- (a) As you go down column 4A in the periodic table, the elemental solids become more electrically conducting. (b) As you go down column 4A in the periodic table, the band gaps of the elemental solids decrease. (c) The valence electron count for a compound semiconductor averages out to four per atom. (d) Band gap energies of semiconductors range from ~0.1 to 3.5 eV. (e) In general, the more polar the bonds are in compound semiconductors, the smaller the band gap.

#### ► Practice Exercise 2

Will ZnSe have a larger or smaller band gap than ZnS?

## Semiconductor Doping

The electrical conductivity of a semiconductor is influenced by the presence of small numbers of impurity atoms. The process of adding controlled amounts of impurity atoms to a material is known as **doping**. Consider what happens when a few phosphorus atoms (known as dopants) replace silicon atoms in a silicon crystal. In pure Si, all of

the valence-band molecular orbitals are filled and all of the conduction-band molecular orbitals are empty, as **Figure 12.31(a)** shows. Because phosphorus has five valence electrons but silicon has only four, the “extra” electrons that come with the dopant phosphorus atoms are forced to occupy the conduction band [Figure 12.31(b)]. The doped material is called an *n-type* semiconductor, *n* signifying that the number of *negatively* charged electrons in the conduction band has increased. These extra electrons can move very easily in the conduction band. Thus, just a few parts per million (ppm) of phosphorus in silicon can increase silicon’s intrinsic conductivity by a factor of a million!

The dramatic change in conductivity in response to the addition of a trace amount of a dopant means that extreme care must be taken to control the impurities in semiconductors. The semiconductor industry uses “nine-nines” silicon to make integrated circuits; what this means is that Si must be 99.99999999% pure (nine nines after the decimal place) to be technologically useful! Doping provides an opportunity for controlling the electrical conductivity through precise control of the type and concentration of dopants.

It is also possible to dope semiconductors with atoms that have fewer valence electrons than the host material. Consider what happens when a few aluminum atoms replace silicon atoms in a silicon crystal. Aluminum has only three valence electrons compared to silicon’s four. Thus, there are electron vacancies, known as **holes**, in the valence band when silicon is doped with aluminum [Figure 12.31(c)]. Since the negatively charged electron is not there, the hole can be thought of as having a positive charge. Any adjacent electron that jumps into the hole leaves behind a new hole. Thus, the positive hole moves about in the lattice like a particle.\* A material like this is called a *p-type* semiconductor, *p* signifying that the number of *positive* holes in the material has increased.

As with n-type conductivity, p-type dopant levels of only parts per million can lead to a millionfold increase in conductivity—but in this case, the holes in the valence band are doing the conduction [Figure 12.31(c)].

The junction of an n-type semiconductor with a p-type semiconductor forms the basis for diodes, transistors, solar cells, and other devices.

\*This movement is analogous to watching people changing seats in a classroom; you can watch the people (electrons) move about the seats (atoms), or you can watch the empty seats (holes) “move.”

## Sample Exercise 12.4

### Identifying Types of Semiconductors

Which of the following elements, if doped into silicon, would yield an n-type semiconductor: Ga, As, or C?

### SOLUTION

**Analyze** An n-type semiconductor means that the dopant atoms must have more valence electrons than the host material. Silicon is the host material in this case.

**Plan** We must look at the periodic table and determine the number of valence electrons associated with Si, Ga, As, and C. The elements with more valence electrons than silicon are the ones that will produce an n-type material upon doping.

**Solve** Si is in column 4A, and so has four valence electrons. Ga is in column 3A, and so has three valence electrons. As is in column 5A, and so has five valence electrons; C is in column 4A, and so has four valence electrons. Therefore, As, if doped into silicon, would yield an n-type semiconductor.

### Practice Exercise 1

Which of these doped semiconductors would yield a p-type material? (These choices are written as host atom:dopant atom.)

(a) Ge:P (b) Si:Ge (c) Si:Al (d) Ge:S (e) Si:N

### Practice Exercise 2

Compound semiconductors can be doped to make n-type and p-type materials, but the scientist has to make sure that the proper atoms are substituted. For example, if Ge were doped into GaAs, Ge could substitute for Ga, making an n-type semiconductor; but if Ge substituted for As, the material would be p-type. Suggest a way to dope CdSe to create a p-type material.

## CHEMISTRY PUT TO WORK Solid-State Lighting

Artificial lighting is so widespread we take it for granted. Major savings in energy would be realized if incandescent lights could be replaced by light-emitting diodes (LEDs). Because LEDs are made from semiconductors, this is an appropriate place to take a closer look at the operation of an LED.

The heart of an LED is a p-n diode, which is formed by bringing an n-type semiconductor into contact with a p-type semiconductor. In the junction where they meet, there are very few electrons or holes to carry the charge across the interface between them, and the

conductivity decreases. When an appropriate voltage is applied, electrons are driven from the conduction band of the n-doped side into the junction, where they meet holes that have been driven from the valence band of the p-doped side. The electrons fall into the empty holes, and their energy is converted into light whose photons have energy equal to the band gap (Figure 12.32). In this way electrical energy is converted into optical energy.

Because the wavelength of light that is emitted depends on the band gap of the semiconductor, the color of light produced by the LED can be controlled by appropriate choice of semiconductor. Most red LEDs are made of a mixture of GaP and GaAs. The band gap of GaP is 2.26 eV ( $3.62 \times 10^{-19}$  J), which corresponds to a green photon with a wavelength of 549 nm, while GaAs has a band gap of 1.43 eV ( $2.29 \times 10^{-19}$  J), which corresponds to an infrared photon with a wavelength of 867 nm. (Sections 6.1 and 6.2) By forming solid solutions of these two compounds, with stoichiometries of  $\text{GaP}_{1-x}\text{As}_x$ , the band gap can be adjusted to any intermediate value. Thus,  $\text{GaP}_{1-x}\text{As}_x$  is the solid solution of choice for red, orange, and yellow LEDs. Green LEDs are made from mixtures of GaP and AlP ( $E_g = 2.43$  eV,  $\lambda = 510$  nm).

Red LEDs have been in the market for decades, but to make white light, an efficient blue LED was needed. The first prototype bright blue LED was demonstrated in a Japanese laboratory in 1993. In 2010, less than 20 years later, over \$10 billion worth of blue LEDs were sold worldwide. The blue LEDs are based on combinations of GaN ( $E_g = 3.4$  eV,  $\lambda = 365$  nm) and InN ( $E_g = 2.4$  eV,  $\lambda = 517$  nm). Many colors of LEDs are now available and are used in everything from barcode

▲ **Figure 12.32** Light-emitting diodes. The heart of a light-emitting diode is a p-n junction in which an applied voltage drives electrons and holes together, where they combine and give off light.

Continued

▲ Figure 12.33 LEDs are all around us.

scanners to traffic lights (Figure 12.33). Because the light emission results from semiconductor structures that can be made extremely small and because they emit little heat, LEDs are replacing standard incandescent and fluorescence light bulbs in many applications.

**Related Exercises:** 12.73–12.76

## 12.8 | Polymers

In nature we find many substances of very high molecular weight, running up to millions of amu, that make up much of the structure of living organisms and tissues. Some examples are starch and cellulose, which abound in plants, as well as proteins, which are found in both plants and animals. In 1827 Jöns Jakob Berzelius coined the word **polymer** (from the Greek *polys*, “many,” and *meros*, “parts”) to denote molecular substances of high molecular weight formed by the *polymerization* (joining together) of **monomers**, molecules with low molecular weight.

Historically, natural polymers, such as wool, leather, silk, and natural rubber, were processed into usable materials. During the past 70 years or so, chemists have learned to form synthetic polymers by polymerizing monomers through controlled chemical reactions. A great many of these synthetic polymers have a backbone of carbon–carbon bonds because carbon atoms have an exceptional ability to form strong stable bonds with one another.

**Plastics** are polymeric solids that can be formed into various shapes, usually by the application of heat and pressure. There are several types of plastics.

**Thermoplastics** can be reshaped. For example, plastic milk containers are made from the thermoplastic polymer *polyethylene*. These containers can be melted down and the polymer recycled for some other use. Over two million tons of plastic are recycled every year in the United States. If you look at the bottom of a plastic container, you are likely to see a recycle symbol containing a number, as shown in Figure 12.34. The number and the letter abbreviation below it indicate the kind of polymer from which the container is made, as summarized in Table 12.5. These symbols make it possible to sort containers by composition. In general, the lower the number, the greater the ease with which the material can be recycled.

Unlike a thermoplastic, a **thermosetting plastic** (also called a *thermoset*) is shaped through irreversible chemical processes and, therefore, cannot be reshaped readily. Vulcanized rubber and polyurethanes found in commercial products including insulating foams and mattresses are familiar examples of thermosetting plastics.

Another type of plastic is the **elastomer**, which is a material that exhibits rubbery or elastic behavior. When subjected to stretching or bending, an elastomer regains its original shape upon removal of the distorting force, if it has not been distorted beyond some elastic limit. Rubber is the most familiar example of an elastomer.

▲ Figure 12.34 Recycling symbols. Most plastic containers manufactured today carry a recycling symbol indicating the type of polymer used to make the container and the polymer’s suitability for recycling.

**TABLE 12.5 Categories Used for Recycling Polymeric Materials in the United States**

| Number | Abbreviation | Polymer                    |
|--------|--------------|----------------------------|
| 1      | PET or PETE  | Polyethylene terephthalate |
| 2      | HDPE         | High-density polyethylene  |
| 3      | PVC          | Polyvinyl chloride         |
| 4      | LDPE         | Low-density polyethylene   |
| 5      | PP           | Polypropylene              |
| 6      | PS           | Polystyrene                |
| 7      | None         | Other                      |

▲ **Figure 12.35** The polymerization of ethylene monomers to make the polymer polyethylene.

Some polymers, such as nylon and polyesters, both of which are thermosetting plastics, can be formed into fibers that, like hair, are very long relative to their cross-sectional area. These fibers can be woven into fabrics and cords and fashioned into clothing, tire cord, and other useful objects.

## Making Polymers

A good example of a polymerization reaction is the formation of polyethylene from ethylene molecules (**Figure 12.35**). In this reaction, the double bond in each ethylene molecule “opens up,” and two of the electrons originally in this bond are used to form new C—C single bonds with two other ethylene molecules. This type of polymerization, in which monomers are coupled through their multiple bonds, is called **addition polymerization**.

We can write the equation for the polymerization reaction as follows:

Here  $n$  represents the large number—ranging from hundreds to many thousands—of monomer molecules (ethylene in this case) that react to form one polymer molecule. Within the polymer, a repeat unit (the unit shown in brackets in the previous equation) appears over and over along the entire chain. The ends of the chain are capped by carbon-hydrogen bonds or by some other bond, so that the end carbons have four bonds.

Polyethylene is an important material; its annual production exceeds 190 billion pounds each year. Although its composition is simple, the polymer is not easy to make. The right manufacturing conditions were identified only after many years of research. Today many forms of polyethylene, varying widely in physical properties, are known.

Polymers of other chemical compositions provide still greater variety in physical and chemical properties. **Table 12.6** lists several other common polymers obtained by addition polymerization.

A second general reaction used to synthesize commercially important polymers is **condensation polymerization**. In a condensation reaction two molecules are joined to form a larger molecule by elimination of a small molecule, such as  $\text{H}_2\text{O}$ . For example, an amine (a compound containing  $-\text{NH}_2$ ) reacts with a carboxylic acid (a compound containing  $-\text{COOH}$ ) to form a bond between N and C plus an  $\text{H}_2\text{O}$  molecule (**Figure 12.36**).

Polymers formed from two different monomers are called **copolymers**. In the formation of many nylons, a *diamine*, a compound with the  $-\text{NH}_2$  group at each end, is reacted with a *diacid*, a compound with the  $-\text{COOH}$  group at each end. For example, the copolymer nylon 6,6 is formed when a diamine that has six carbon atoms and an amino group on each end is reacted with adipic acid, which also has six carbon atoms

TABLE 12.6 Polymers of Commercial Importance

| Polymer                                  | Structure   | Uses  |
|--|---|---|
| <b>Addition Polymers</b>                 |   |   |
| Polyethylene                             | $\text{-(CH}_2\text{—CH}_2\text{)}_n$   | Films, packaging, bottles   |
| Polypropylene                            | $\left[ \begin{array}{c} \text{CH}_2\text{—CH} \\   \\ \text{CH}_3 \end{array} \right]_n$   | Kitchenware, fibers, appliances   |
| Polystyrene                              | $\left[ \begin{array}{c} \text{CH}_2\text{—CH} \\   \\ \text{C}_6\text{H}_5 \end{array} \right]_n$  | Packaging, disposable food containers, insulation   |
| Polyvinyl chloride (PVC)                 | $\left[ \begin{array}{c} \text{CH}_2\text{—CH} \\   \\ \text{Cl} \end{array} \right]_n$   | Pipe fittings, plumbing   |
| <b>Condensation Polymers</b>             |   |   |
| Polyurethane                             | $\left[ \text{NH—R—NH—}\overset{\text{O}}{\parallel}\text{C—O—R'—O—}\overset{\text{O}}{\parallel}\text{C} \right]_n$ <p><math>\text{R, R' = —CH}_2\text{—CH}_2\text{— (for example)}</math></p> | “Foam” furniture stuffing, spray-on insulation, automotive parts, footwear, water-protective coatings |
| Polyethylene terephthalate (a polyester) | $\left[ \text{O—CH}_2\text{—CH}_2\text{—O—}\overset{\text{O}}{\parallel}\text{C—C}_6\text{H}_4\text{—}\overset{\text{O}}{\parallel}\text{C} \right]_n$  | Tire cord, magnetic tape, apparel, soft-drink bottles   |
| Nylon 6,6                                | $\left[ \text{NH—(CH}_2\text{)}_6\text{—NH—}\overset{\text{O}}{\parallel}\text{C—(CH}_2\text{)}_4\text{—}\overset{\text{O}}{\parallel}\text{C} \right]_n$                                       | Home furnishings, apparel, carpet, fishing line, toothbrush bristles                                  |
| Polycarbonate                            | $\left[ \text{O—C}_6\text{H}_4\text{—C(CH}_3\text{)}_2\text{—C}_6\text{H}_4\text{—O—}\overset{\text{O}}{\parallel}\text{C} \right]_n$   | Shatterproof eyeglass lenses, CDs, DVDs, bulletproof windows, greenhouses                             |

(Figure 12.37). A condensation reaction occurs on each end of the diamine and the acid. Water is released, and N—C bonds are formed between molecules.

Table 12.6 lists nylon 6,6 and some other common polymers obtained by condensation polymerization. Notice that these polymers have backbones containing N or O atoms as well as C atoms.

## CHEMISTRY PUT TO WORK Modern Materials in the Automobile

There are over a billion motor vehicles in the world. Improvement in the fundamental understanding of the structure and properties of materials has enabled the development of motor vehicles that are safer, more powerful, more comfortable, and more fuel efficient. Let's take a look at some of these modern materials (**Figure 12.38**).

Metals and metal alloys are incorporated into many parts of an automobile. For example, aluminum is the primary component of the radiator, intake manifold, and engine block. Steel is typically the material used for the frame and body. Stainless steel is utilized in mufflers, exhaust silencers, and catalytic converters. The inside

of the catalytic converter contains small particles of platinum group metals that are deposited onto a honeycomb-shaped structural ceramic. The ceramic is composed of the ionic solids alumina ( $\text{Al}_2\text{O}_3$ ) coated onto cordierite ( $\text{Mg}_2\text{Al}_4\text{Si}_5\text{O}_{18}$ ). Semiconducting oxides are used for the oxygen sensor to monitor the air/fuel ratio in the exhaust gases, which is controlled by the engine control computer that is based on silicon, a covalent network solid. Polymers are found in a motor vehicle too, with polyesters in seat covers and carpets, polycarbonate optical reflectors, and polypropylene in bumpers and car batteries.

▲ **Figure 12.38** Selected modern material components of an automobile.

▲ **Figure 12.39** A segment of a polyethylene chain. This segment consists of 28 carbon atoms. In commercial polyethylenes, the chain lengths range from about  $10^3$  to  $10^5$   $\text{CH}_2$  units.

▲ **Figure 12.40** Interactions between polymer chains. In the circled regions, the forces that operate between adjacent segments of the chains lead to ordering analogous to the ordering in crystals, though less regular.

### Give It Some Thought

Is this molecule a better starting material for an addition polymer or a condensation polymer?

## Structure and Physical Properties of Polymers

The simple structural formulas given for polyethylene and other polymers are deceptive. Because four bonds surround each carbon atom in polyethylene, the atoms are arranged in a tetrahedral fashion, so that the chain is not straight as we have depicted it. Furthermore, the atoms are relatively free to rotate around the  $\text{C}-\text{C}$  single bonds. Rather than being straight and rigid, therefore, the chains are flexible, folding readily (**Figure 12.39**). The flexibility in the molecular chains causes any material made of this polymer to be very flexible.

Both synthetic and natural polymers commonly consist of a collection of *macromolecules* (large molecules) of different molecular weights. Depending on the conditions of formation, the molecular weights may be distributed over a wide range or may be closely clustered around an average value. In part because of this distribution in molecular weights, polymers are largely amorphous (noncrystalline) materials. Rather than exhibiting a well-defined crystalline phase with a sharp melting point, polymers soften over a range of temperatures. They may, however, possess short-range order in some regions of the solid, with chains lined up in regular arrays as shown in **Figure 12.40**. The extent of such ordering is indicated by the degree of **crystallinity** of the polymer. Mechanical stretching or pulling to align the chains as the molten polymer is drawn through small holes can frequently enhance the crystallinity of a polymer. Intermolecular forces between the polymer chains hold the chains together in the ordered crystalline regions, making the polymer denser, harder, less soluble, and more resistant to heat. **Table 12.7** shows how the properties of polyethylene change as the degree of crystallinity increases.

The linear structure of polyethylene is conducive to intermolecular interactions that lead to crystallinity. However, the degree of crystallinity in polyethylene strongly depends on the average molecular weight. Polymerization results in a mixture of macromolecules with varying values of  $n$  (numbers of monomer molecules) and, hence, varying molecular weights. Low-density polyethylene (LDPE), used in forming films and sheets, has an average molecular weight in the range of  $10^4$  amu, has a density of less than  $0.94 \text{ g/cm}^3$ , and has substantial chain branching. That is, there are side chains off the main chain of the polymer. These side chains inhibit the formation of crystalline regions, reducing the density of the material. High-density polyethylene (HDPE), used to form bottles, drums, and pipes, has an average molecular weight in the range of  $10^6$  amu and has a density of  $0.94 \text{ g/cm}^3$  or higher. This form has fewer side chains and thus a higher degree of crystallinity.

**TABLE 12.7** Properties of Polyethylene as a Function of Crystallinity

| Properties                           | Crystallinity |      |      |      |      |
|--------------------------------------|---------------|------|------|------|------|
|                                      | 55%           | 62%  | 70%  | 77%  | 85%  |
| Melting point ( $^{\circ}\text{C}$ ) | 109           | 116  | 125  | 130  | 133  |
| Density ( $\text{g/cm}^3$ )          | 0.92          | 0.93 | 0.94 | 0.95 | 0.96 |
| Stiffness*                           | 25            | 47   | 75   | 120  | 165  |
| Yield stress*                        | 1700          | 2500 | 3300 | 4200 | 5100 |

\*These test results show that the mechanical strength of the polymer increases with increased crystallinity. The physical units for the stiffness test are  $\text{psi} \times 10^{-3}$  ( $\text{psi}$  = pounds per square inch); those for the yield stress test are  $\text{psi}$ . Discussion of the exact meaning and significance of these tests is beyond the scope of this text.

### Give It Some Thought

In copolymers made of ethylene and vinyl acetate monomers, melting point and degree of crystallinity decrease as the percentage of vinyl acetate increases. Suggest an explanation.

▲ **Figure 12.41** Cross-linking of polymer chains. The cross-linking groups (red) constrain the relative motions of the polymer chains, making the material harder and less flexible than when the cross-links are not present.

Polymers can be made stiffer by introducing chemical bonds between chains. Forming bonds between chains is called **cross-linking** (Figure 12.41). The greater the number of cross-links, the more rigid the polymer. Whereas thermoplastic materials consist of independent polymer chains, thermosetting plastics become cross-linked when heated; the cross-links allow them to hold their shapes.

An important example of cross-linking is the **vulcanization** of natural rubber, a process discovered by Charles Goodyear in 1839. Natural rubber is formed from a liquid resin derived from the inner bark of the *Hevea brasiliensis* tree. Chemically, it is a polymer of isoprene,  $\text{C}_5\text{H}_8$  (Figure 12.42). Because rotation about the carbon–carbon double bond does not readily occur, the orientation of the groups bound to the carbons is rigid. In natural rubber, the chain extensions are on the same side of the double bond, as shown in Figure 12.42(a).

Natural rubber is not a useful polymer because it is too soft and too chemically reactive. Goodyear accidentally discovered that adding sulfur and then heating the mixture make the rubber harder and reduce its susceptibility to oxidation and other chemical

▲ **Figure 12.42** Vulcanization of natural rubber. (a) Formation of polymeric natural rubber from the monomer isoprene. (b) Adding sulfur to rubber creates carbon–sulfur bonds and sulfur–atom links between chains.

▲ **Figure 12.43 Plastic electronics.**  
Flexible organic solar cells are made from conducting polymers.

degradation reactions. The sulfur changes rubber into a thermosetting polymer by cross-linking the polymer chains through reactions at some of the double bonds, as shown schematically in Figure 12.42(b). Cross-linking of about 5% of the double bonds creates a flexible, resilient rubber. When the rubber is stretched, the cross-links help prevent the chains from slipping, so that the rubber retains its elasticity. Because heating was an important step in his process, Goodyear named it after Vulcan, the Roman god of fire.

Most polymers contain  $sp^3$ -hybridized carbon atoms lacking delocalized  $\pi$  electrons (Section 9.6), so they are usually electrical insulators and are colorless (which implies a large band gap). However, if the backbone of the polymer has resonance (Sections 8.6 and 9.6), the electrons can become delocalized over long distances, which can lead to semiconducting behavior in the polymer. Such “plastic electronics” are of great current interest for lightweight and flexible organic solar cells, organic transistors, organic light-emitting diodes, and other devices that are based on carbon rather than inorganic semiconductors like silicon (Figure 12.43).

## 12.9 | Nanomaterials

The prefix *nano* means  $10^{-9}$ . (Section 1.4) When people speak of “nanotechnology,” they usually mean making devices that are on the 1–100-nm scale. It turns out that the properties of semiconductors and metals change in this size range. **Nanomaterials**—materials that have dimensions on the 1–100-nm scale—are under intense investigation in research laboratories around the world, and chemistry plays a central role in this investigation.

### Semiconductors on the Nanoscale

Figure 12.22 shows that, in small molecules, electrons occupy discrete molecular orbitals, whereas in macroscale solids the electrons occupy delocalized bands. At what point does a molecule get so large that it starts behaving as though it has delocalized bands rather than localized molecular orbitals? For semiconductors, both theory and experiment tell us that the answer is roughly at 1 to 10 nm (about 10–100 atoms across). The exact number depends on the specific semiconductor material. The equations of quantum mechanics that were used for electrons in atoms can be applied to electrons (and holes) in semiconductors to estimate the size where materials undergo a crossover from molecular orbitals to bands. Because these effects become important at 1 to 10 nm, semiconductor particles with diameters in this size range are called *quantum dots*.

One of the most spectacular effects of reducing the size of a semiconductor crystal is that the band gap changes substantially with size in the 1–10-nm range. As the particle gets smaller, the band gap gets larger, an effect observable by the naked eye, as shown in Figure 12.44. On the macro level, the semiconductor cadmium phosphide looks black because its band gap is small ( $E_g = 0.5$  eV), and it absorbs all wavelengths of visible light. As the crystals are made smaller, the material progressively changes color until it looks white! It looks white because now no visible light is absorbed. The band gap is so large that only high-energy ultraviolet light can excite electrons into the conduction band ( $E_g > 3.0$  eV).

Making quantum dots is most easily accomplished using chemical reactions in solution. For example, to make CdS, you can mix  $\text{Cd}(\text{NO}_3)_2$  and  $\text{Na}_2\text{S}$  in water. If you do not do anything else, you will precipitate large crystals of CdS. However, if you first add a negatively charged polymer to the water (such as polyphosphate,  $-(\text{OPO}_2^-)_n-$ ), the  $\text{Cd}^{2+}$  associates with the polymer, like tiny “meatballs” in the polymer “spaghetti.” When sulfide is added, CdS particles grow, but the polymer keeps them from forming large crystals. A great deal of fine-tuning of reaction conditions is necessary to produce nanocrystals that are of uniform size and shape.

As we learned in Section 12.7, some semiconductor devices can emit light when a voltage is applied. Another way to make semiconductors emit light is to illuminate

◀ **Figure 12.44**  $\text{Cd}_3\text{P}_2$  powders with different particle sizes. The arrow indicates decreasing particle size and a corresponding increase in the band gap energy, resulting in different colors.

them with light whose photons have energies larger than the energy of the band gap of the semiconductor, a process called *photoluminescence*. A valence-band electron absorbs a photon and is promoted to the conduction band. If the excited electron then falls back down into the hole it left in the valence band, it emits a photon having energy equal to the band gap energy. In the case of quantum dots, the band gap is tunable with the crystal size, and thus all the colors of the rainbow can be obtained from just one material, as shown for CdSe in **Figure 12.45**.

### Give It Some Thought

Large crystals of ZnS can show photoluminescence, emitting ultraviolet photons with energies equal to the band gap energy and a wavelength of 340 nm. Is it possible to shift the luminescence so that the emitted photons are in the visible region of the spectrum by making appropriately sized nanocrystals?

Quantum dots are being explored for applications ranging from electronics to lasers to medical imaging because they are very bright, very stable, and small enough to be taken up by living cells even after being coated with a biocompatible surface layer.

Semiconductors do not have to be shrunk to the nanoscale in all three dimensions to show new properties. They can be laid down in relatively large two-dimensional areas on a substrate but be only a few nanometers thick to make *quantum wells*. *Quantum wires*, in which the semiconductor wire diameter is only a few nanometers but its length is very long, have also been made by various chemical routes. In both quantum wells and quantum wires, measurements along the nanoscale dimension(s) show quantum behavior, but in the long dimension, the properties seem to be just like those of the bulk material.

## Metals on the Nanoscale

Metals also have unusual properties on the 1–100-nm-length scale. Fundamentally, this is because the mean free path  $\infty$  (Section 10.8) of an electron in a metal at room temperature is typically about 1–100 nm. So when the particle size of a metal is 100 nm or less, one might expect unusual effects because the “sea of electrons” encounters a “shore” (the surface of the particle).

### Go Figure

As the size of the quantum dots decreases, does the wavelength of the emitted light increase or decrease?

▲ **Figure 12.45** Photoluminescence depends on particle size at the nanoscale. When illuminated with ultraviolet light, these solutions, each containing nanoparticles of the semiconductor CdSe, emit light that corresponds to their respective band gap energies. The wavelength of the light emitted depends on the size of the CdSe nanoparticles.

## CHEMISTRY PUT TO WORK Microporous and Mesoporous Materials

**Macroporous** materials have pores that are visible to the naked eye. Examples include the everyday synthetic sponge [Figure 12.46(a)] and the honeycomb-like cordierite core of an automobile catalytic converter [Figure 12.46(b)], with pore sizes in the mm size range and the tens of  $\mu\text{m}$  size range, respectively. *Microporous* and *mesoporous* materials have much smaller pores that are not visible to the naked eye. **Microporous** solids have pores up to 2 nm in size, whereas **mesoporous** solids have pore sizes in the range 2 to 50 nm.

Microporous and mesoporous materials have a large surface area relative to their volume because of their numerous pores and cavities. **Nanomaterials**, on the other hand, have a large surface area relative to their volume because of their small particle size. The size-dependent properties of these materials has led researchers to investigate their fundamental science and application.

**Zeolites**, which occur naturally and can also be synthesized, are a class of aluminosilicates that have been known since 1756. There are several hundred types of microporous and mesoporous zeolites. These substances adopt a variety of structures with polyhedral cavities connected by tunnels that often resemble a honeycomb [Figure 12.46(c)]. The interior surfaces attract ions and molecules that weakly interact with the rigid framework of aluminum, silicon, and

oxygen atoms. Various pore and cavity sizes can be prepared by varying the chemical composition and synthesis method.

Zeolites may be synthesized with weakly interacting ions occupying the cavities. Upon exposure to ions that interact more strongly with the interior surfaces, there is a preferential exchange of weakly interacting ions for more strongly interacting ions. This effectively creates what we might think of as an ionic sponge. An example that illustrates this behavior is the use of a sodium zeolite to remove radioactive cesium ( $^{134}\text{Cs}$  and  $^{137}\text{Cs}$ ) from contaminated areas around the Fukushima Daiichi nuclear power plants in Japan, which were damaged by an earthquake and tsunami in 2011. The cesium ions are attracted into the cavities of the zeolite where an ion exchange occurs ( $\text{Cs}^+$  for  $\text{Na}^+$ ). Another example is treatment of water from wells that contain relatively high concentrations of calcium, magnesium, and iron ions—so-called hard water. Heated hard water can cause problems by forming deposits inside of pipes, reducing flow over time. Hard water can be “softened” by passing it through zeolites containing sodium ions that are replaced or exchanged for calcium ions in the hard water. Periodic flushing of the zeolite with an aqueous solution containing a high concentration of sodium ions removes the calcium ions and renews the zeolite for further use.

▲ **Figure 12.46** Porous materials. Sponges (a) and the core of an automobile catalytic converter (b) are macroporous. Zeolite ZSM-5 (c) is a microporous material with pore sizes near 0.5 nm.

Although it was not fully understood, people have known for hundreds of years that metals are different when they are very finely divided. Dating back to the Middle Ages, the makers of stained-glass windows knew that gold dispersed in molten glass made the glass a beautiful deep red (Figure 12.47). Much later, in 1857, Michael Faraday reported that dispersions of small gold particles could be made stable and were deeply colored—some of the original colloidal solutions that he made are still in the Royal Institution of Great Britain’s Faraday Museum in London (Figure 12.48).

Other physical and chemical properties of metallic nanoparticles are also different from the properties of the bulk materials. Gold particles less than 20 nm in diameter melt at a far lower temperature than bulk gold, for instance, and when the particles are

▲ **Figure 12.47** Stained glass window from the Chartres Cathedral in France. Gold nanoparticles are responsible for the red color in this window, which dates back to the twelfth century.

between 2 and 3 nm in diameter, gold is no longer a “noble,” unreactive metal; in this size range it becomes chemically reactive.

At nanoscale dimensions, silver has properties analogous to those of gold in its beautiful colors, although it is more reactive than gold. Currently, research laboratories around the world are showing great interest in taking advantage of the unusual optical properties of metal nanoparticles for applications in biomedical imaging and chemical detection.

## Carbon on the Nanoscale

We have seen that elemental carbon is quite versatile. In its bulk  $sp^3$ -hybridized solid-state form, it is diamond; in its bulk  $sp^2$ -hybridized solid-state form, it is graphite. Over the past three decades, scientists have discovered that  $sp^2$ -hybridized carbon can also form discrete molecules, one-dimensional nanoscale tubes, and two-dimensional nanoscale sheets. Each of these forms of carbon shows very interesting properties.

Until the mid-1980s, pure solid carbon was thought to exist in only two forms: the covalent-network solids diamond and graphite. In 1985, however, a group of researchers led by Richard Smalley and Robert Curl of Rice University and Harry Kroto of the University of Sussex, England, vaporized a sample of graphite with an intense pulse of laser light and used a stream of helium gas to carry the vaporized carbon into a mass spectrometer. ∞ (Section 2.4, “The Mass Spectrometer”) The mass spectrum showed peaks corresponding to clusters of carbon atoms, with a particularly strong peak corresponding to molecules composed of 60 carbon atoms,  $C_{60}$ .

Because  $C_{60}$  clusters were so preferentially formed, the group proposed a radically different form of carbon, namely, nearly spherical  $C_{60}$  molecules. They proposed that the carbon atoms of  $C_{60}$  form a “ball” with 32 faces, 12 of them pentagons and 20 hexagons (Figure 12.49), exactly like a soccer ball. The shape of this molecule is reminiscent of the geodesic dome invented by the U.S. engineer and philosopher R. Buckminster Fuller, so  $C_{60}$  was whimsically named “buckminsterfullerene,” or “buckyball” for short. Since the discovery of  $C_{60}$ , other related molecules made of pure carbon have been discovered. These molecules are now known as fullerenes.

Appreciable amounts of buckyball can be prepared by electrically evaporating graphite in an atmosphere of helium gas. About 14% of the resulting soot consists of  $C_{60}$  and a related molecule,  $C_{70}$ , which has a more elongated structure. The carbon-rich gases from which  $C_{60}$  and  $C_{70}$  condense also contain other fullerenes, mostly containing more carbon atoms, such as  $C_{76}$  and  $C_{84}$ . The smallest possible fullerene,  $C_{20}$ , was first detected in 2000. This small, ball-shaped molecule is much more reactive than the larger fullerenes. Because fullerenes are molecules, they dissolve in various organic solvents, whereas diamond and graphite do not. This solubility permits fullerenes to be separated from the other components of soot and even from one another. It also allows the study of their reactions in solution.

▲ **Figure 12.48** The solution of colloidal gold nanoparticles made by Michael Faraday in the 1850s. This is on display in the Royal Institution, London.

## Go Figure

How many bonds does each carbon atom in  $C_{60}$  make? Based on this observation, would you expect the bonding in  $C_{60}$  to be more like that in diamond or that in graphite?

▲ **Figure 12.49** Buckminsterfullerene,  $C_{60}$ . The molecule has a highly symmetric structure in which the 60 carbon atoms sit at the vertices of a truncated icosahedron. The bottom view shows only the bonds between carbon atoms.

▲ **Figure 12.50** Atomic models of carbon nanotubes. Left: “Armchair” nanotube, which shows metallic behavior. Right: “Zigzag” nanotube, which can be either semiconducting or metallic, depending on tube diameter.

▲ **Figure 12.51** A portion of a two-dimensional graphene sheet.

Soon after the discovery of  $C_{60}$ , chemists discovered carbon nanotubes (**Figure 12.50**). You can think of these as sheets of graphite rolled up and capped at one or both ends by half of a  $C_{60}$  molecule. Carbon nanotubes are made in a manner similar to that used to make  $C_{60}$ . They can be made in either *multiwall* or *single-walled* forms. Multiwall carbon nanotubes consist of tubes within tubes, nested together, whereas single-walled carbon nanotubes consist of single tubes. Single-walled carbon nanotubes can be 1000 nm long or even longer but are only about 1 nm in diameter. Depending on the diameter of the graphite sheet and how it is rolled up, carbon nanotubes can behave as either semiconductors or metals.

The fact that carbon nanotubes can be made either semiconducting or metallic without any doping is unique among solid-state materials, and laboratories worldwide are making and testing carbon-based electronic devices. Carbon nanotubes are also being explored for their mechanical properties. The carbon–carbon bonded framework of the nanotubes means that the imperfections that might appear in a metal nanowire of similar dimensions are nearly absent. Experiments on individual carbon nanotubes suggest that they are stronger than steel, if steel were the dimensions of a carbon nanotube. Carbon nanotubes have been spun into fibers with polymers, adding great strength and toughness to the composite material.

The two-dimensional form of carbon, graphene, is the most recent low-dimensional form of carbon to be experimentally isolated and studied. Although its properties had been the subject of theoretical predictions for over 60 years, it was not until 2004 that researchers at the University of Manchester in England isolated and identified individual sheets of carbon atoms with the honeycomb structure shown in **Figure 12.51**. Amazingly, the technique they used to isolate single-layer graphene was to successively peel away thin layers of graphite using adhesive tape. Individual layers of graphene were then transferred to a silicon wafer having a precisely defined overcoat of  $SiO_2$ . When a single layer of graphene is left on the wafer, an interference-like contrast pattern results that can be seen with an optical microscope. If not for this simple yet effective way to scan for individual graphene crystals, they would probably still remain undiscovered. Subsequently, it has been shown that graphene can be deposited on clean surfaces of other types of crystals. The scientists who led the effort at the University of Manchester, Andre Geim and Konstantin Novoselov, were awarded the 2010 Nobel Prize in Physics for their work.

The properties of graphene are remarkable. It is very strong and has a record thermal conductivity, topping carbon nanotubes in both categories. Graphene is a semimetal, which means its electronic structure is like that of a semiconductor in which the energy gap is exactly zero. The combination of graphene’s two-dimensional character and the fact that it is a semimetal allows the electrons to travel very long distances, up to  $0.3\ \mu\text{m}$ , without scattering from another electron, atom, or impurity. Graphene can sustain electrical current densities six orders of magnitude higher than those sustainable in copper. Even though it is only one atom thick, graphene can absorb 2.3% of sunlight that strikes it. Scientists are currently exploring ways to incorporate graphene in various technologies, including electronics, sensors, batteries, and solar cells.

## Sample Integrative Exercise

### Putting Concepts Together

Polymers that can conduct electricity are called *conducting polymers*. Some polymers can be made semiconducting; others can be nearly metallic. Polyacetylene is an example of a polymer that is a semiconductor. It can also be doped to increase its conductivity.

Polyacetylene is made from acetylene in a reaction that looks simple but is actually tricky to do:

- What is the hybridization of the carbon atoms, and the geometry around those atoms, in acetylene and in polyacetylene?
- Write a balanced equation to make polyacetylene from acetylene.

- (c) Acetylene is a gas at room temperature and pressure (298 K, 1.00 atm). How many grams of polyacetylene can you make from a 5.00-L vessel of acetylene gas at room temperature and room pressure? Assume that acetylene behaves ideally and that the polymerization reaction occurs with 100% yield.
- (d) Using the average bond enthalpies in Table 8.4, predict whether the formation of polyacetylene from acetylene is endothermic or exothermic.
- (e) A sample of polyacetylene absorbs light from 300 nm down to 650 nm. What is its band gap, in electron volts?

## SOLUTION

**Analyze** For part (a), we need to recall what we have learned about  $sp$ ,  $sp^2$ , and  $sp^3$  hybridization and geometry. (Section 9.5) For part (b), we need to write a balanced equation. For part (c), we need to use the ideal-gas equation. (Section 10.4) For part (d), we need to recall the definitions of endothermic and exothermic and how bond enthalpies can be used to predict overall reaction enthalpies. (Section 8.8) For part (e), we need to relate the absorption of light to the differences in energy levels between filled and empty states in a material. (Section 6.3)

**Plan** For part (a), we should draw out the chemical structures of the reactant and product. For part (b), we need to make sure the

equation is properly balanced. For part (c), we need to convert from liters of gas to moles of gas, using the ideal-gas equation ( $PV = nRT$ ); then we need to convert from moles of acetylene gas to moles of polyacetylene using the answer from part (b); finally, we can convert to grams of polyacetylene. For part (d), we need to recall that  $\Delta H_{\text{rxn}} = \sum(\text{bond enthalpies of bonds broken}) - \sum(\text{bond enthalpies of bonds formed})$ . (Section 8.8) For part (e), we need to realize that the lowest energy absorbed by a material will tell us its band gap  $E_g$  (for a semiconductor or insulator) and combine  $E = h\nu$  and  $c = \lambda\nu$  together ( $E = hc/\lambda$ ) to solve for  $E_g$ .

## Solve

- (a) Carbon usually forms four bonds. Thus, each C atom must have a single bond to H and a triple bond to the other C atom in acetylene. As a result, each C atom has two electron domains and must be  $sp$  hybridized. This  $sp$  hybridization also means that the  $\text{H}-\text{C}-\text{C}$  angles in acetylene are  $180^\circ$  and the molecule is linear. We can write out the partial structure of polyacetylene as follows:

Each carbon is identical but now has three bonding electron domains that surround it. Therefore, the hybridization of each carbon atom is  $sp^2$ , and each carbon has local trigonal planar geometry with  $120^\circ$  angles.

- (b) We can write:

Note that all atoms originally present in acetylene end up in the polyacetylene product.

- (c) We can use the ideal-gas equation as follows:

$$PV = nRT$$

$$(1.00 \text{ atm})(5.00 \text{ L}) = n(0.08206 \text{ L}\cdot\text{atm}/\text{K}\cdot\text{mol})(298 \text{ K})$$

$$n = 0.204 \text{ mol}$$

Acetylene has a molar mass of 26.0 g/mol; therefore, the mass of 0.204 mol is:

$$(0.204 \text{ mol})(26.0 \text{ g/mol}) = 5.32 \text{ g acetylene}$$

Note that from the answer to part (b), all the atoms in acetylene go into polyacetylene. Due to conservation of mass, then, the mass of polyacetylene produced must also be 5.32 g, if we assume 100% yield.

- (d) Let's consider the case for  $n = 1$ . We note that the reactant side of the equation in part (b) has one  $\text{C}\equiv\text{C}$  triple bond and two  $\text{C}-\text{H}$  single bonds. The product side of the equation in part (b) has one  $\text{C}=\text{C}$  double bond, one  $\text{C}-\text{C}$  single bond (to link to the adjacent monomer), and two  $\text{C}-\text{H}$  single bonds. Therefore, we are breaking one  $\text{C}\equiv\text{C}$  triple bond and are forming one  $\text{C}=\text{C}$  double bond and one  $\text{C}-\text{C}$  single bond. Accordingly, the enthalpy change for polyacetylene formation is:

Because  $\Delta H$  is a negative number, the reaction releases heat and is exothermic.

$$\begin{aligned} \Delta H_{\text{rxn}} &= (\text{C}\equiv\text{C enthalpy}) - (\text{C}=\text{C enthalpy}) - (\text{C}-\text{C enthalpy}) \\ &= (839 \text{ kJ/mol}) - (614 \text{ kJ/mol}) - (348 \text{ kJ/mol}) \\ &= -123 \text{ kJ/mol} \end{aligned}$$

- (e) The sample of polyacetylene absorbs many wavelengths of light, but the one we care about is the longest one, which corresponds to the lowest energy.

We recognize that this energy corresponds to the energy difference between the bottom of the conduction band and the top of the valence band, and so is equivalent to the band gap  $E_g$ . Now we have to convert the number to electron volts. Since  $1.602 \times 10^{-19} \text{ J} = 1 \text{ eV}$ , we find that:

$$E = hc/\lambda$$

$$\begin{aligned} &= (6.626 \times 10^{-34} \text{ J}\cdot\text{s})(3.00 \times 10^8 \text{ m}\cdot\text{s}^{-1})/(650 \times 10^{-9} \text{ m}) \\ &= 3.06 \times 10^{-19} \text{ J} \end{aligned}$$

$$E_g = 1.91 \text{ eV}$$

## Chapter Summary and Key Terms

### CLASSIFICATION OF SOLIDS (INTRODUCTION AND SECTION 12.1)

The structures and properties of solids can be classified according to the forces that hold the atoms together. **Metallic solids** are held together by a delocalized sea of collectively shared valence electrons. **Ionic solids** are held together by the mutual attraction between cations and anions. **Covalent-network solids** are held together by an extended network of covalent bonds. **Molecular solids** are held together by weak intermolecular forces. **Polymers** contain very long chains of atoms held together by covalent bonds. These chains are usually held to one another by weaker intermolecular forces. **Nanomaterials** are solids where the dimensions of individual crystals are on the order of 1–100 nm.

**STRUCTURES OF SOLIDS (SECTION 12.2)** In **crystalline solids**, particles are arranged in a regularly repeating pattern. In **amorphous solids**, however, particles show no long-range order. In a crystalline solid the smallest repeating unit is called a **unit cell**. All unit cells in a crystal contain an identical arrangement of atoms. The geometrical pattern of points on which the unit cells are arranged is called a **crystal lattice**. To generate a crystal structure a **motif**, which is an atom or group of atoms, is associated with each and every **lattice point**.

In two dimensions, the unit cell is a parallelogram whose size and shape are defined by two **lattice vectors** ( $a$  and  $b$ ). There are five **primitive lattices**, lattices in which the lattice points are located only at the corners of the unit cell: square, hexagonal, rectangular, rhombic, and oblique. In three dimensions the unit cell is a parallelepiped whose size and shape are defined by three lattice vectors ( $a$ ,  $b$ , and  $c$ ), and there are seven primitive lattices: cubic, tetragonal, hexagonal, rhombohedral, orthorhombic, monoclinic, and triclinic. Placing an additional lattice point at the center of a cubic unit cell leads to a **body-centered cubic lattice**, while placing an additional point at the center of each face of the unit cell leads to a **face-centered cubic lattice**.

**METALLIC SOLIDS (SECTION 12.3)** **Metallic solids** are typically good conductors of electricity and heat, *malleable*, which means that they can be hammered into thin sheets, and *ductile*, which means that they can be drawn into wires. Metals tend to form structures where the atoms are closely packed. Two related forms of close packing, **cubic close packing** and **hexagonal close packing**, are possible. In both, each atom has a **coordination number** of 12.

**Alloys** are materials that possess characteristic metallic properties and are composed of more than one element. The elements in an alloy can be distributed either homogeneously or heterogeneously. Alloys which contain homogeneous mixtures of elements can either be substitutional or interstitial alloys. In a **substitutional alloy** the atoms of the minority element(s) occupy positions normally occupied by atoms of the majority element. In an **interstitial alloy** atoms of the minority element(s), often smaller nonmetallic atoms, occupy interstitial positions that lie in the “holes” between atoms of the majority element. In a **heterogeneous alloy** the elements are not distributed uniformly; instead, two or more distinct phases with characteristic compositions are present. **Intermetallic compounds** are alloys that have a fixed composition and definite properties.

**METALLIC BONDING (SECTION 12.4)** The properties of metals can be accounted for in a qualitative way by the **electron-sea model**, in which the electrons are visualized as being free to move throughout the metal. In the molecular orbital model the valence atomic orbitals of the metal atoms interact to form energy **bands** that are incompletely filled by valence electrons. Consequently, the electronic structure of a bulk solid is referred to as a **band structure**. The orbitals that constitute the energy band are delocalized over the atoms of the metal, and their energies are closely spaced. In a metal the valence shell  $s$ ,  $p$ , and  $d$  orbitals form bands, and these bands overlap, resulting in one or more partially filled bands. Because the energy differences between orbitals *within a band* are extremely small, promoting

electrons to higher-energy orbitals requires very little energy. This gives rise to high electrical and thermal conductivity, as well as other characteristic metallic properties.

**IONIC SOLIDS (SECTION 12.5)** **Ionic solids** consist of cations and anions held together by electrostatic attractions. Because these interactions are quite strong, ionic compounds tend to have high melting points. The attractions become stronger as the charges of the ions increase and/or the sizes of the ions decrease. The presence of both attractive (cation–anion) and repulsive (cation–cation and anion–anion) interactions helps to explain why ionic compounds are brittle. Like metals, the structures of ionic compounds tend to be symmetric, but to minimize direct contact between ions of like charge, the coordination numbers (typically 4 to 8) are necessarily smaller than those seen in close-packed metals. The exact structure depends on the relative sizes of the ions and the cation-to-anion ratio in the empirical formula.

**MOLECULAR SOLIDS (SECTION 12.6)** **Molecular solids** consist of atoms or molecules held together by intermolecular forces. Because these forces are relatively weak, molecular solids tend to be soft and possess low melting points. The melting point depends on the strength of the intermolecular forces, as well as the efficiency with which the molecules can pack together.

**COVALENT-NETWORK SOLIDS (SECTION 12.7)** **Covalent-network solids** consist of atoms held together in large networks by covalent bonds. These solids are much harder and have higher melting points than molecular solids. Important examples include diamond, where the carbons are tetrahedrally coordinated to each other, and graphite, where the  $sp^2$ -hybridized carbon atoms form hexagonal layers. **Semiconductors** are solids that do conduct electricity, but to a far lesser extent than metals. **Insulators** do not conduct electricity at all.

Elemental semiconductors, like Si and Ge, as well as compound semiconductors, like GaAs, InP, and CdTe, are important examples of covalent-network solids. In a semiconductor the filled bonding molecular orbitals make up the **valence band**, while the empty antibonding molecular orbitals make up the **conduction band**. The valence and conduction bands are separated by an energy that is referred to as the **band gap**,  $E_g$ . The size of the band gap increases as the bond length decreases and as the difference in electronegativity between the two elements increases.

**Doping** semiconductors changes their ability to conduct electricity by orders of magnitude. An  $n$ -type semiconductor is one that is doped so that there are excess electrons in the conduction band; a  $p$ -type semiconductor is one that is doped so that there are missing electrons, which are called **holes**, in the valence band.

**POLYMERS (SECTION 12.8)** **Polymers** are molecules of high molecular weight formed by joining large numbers of small molecules called **monomers**. **Plastics** are materials that can be formed into various shapes, usually by the application of heat and pressure. **Thermoplastic** polymers can be reshaped, typically through heating, in contrast to **thermosetting plastics**, which are formed into objects through an irreversible chemical process and cannot readily be reshaped. An **elastomer** is a material that exhibits elastic behavior; that is, it returns to its original shape following stretching or bending.

In an **addition polymerization** reaction, the molecules form new linkages by opening existing  $\pi$  bonds. Polyethylene forms, for example, when the carbon–carbon double bonds of ethylene open up. In a **condensation polymerization** reaction, the monomers are joined by eliminating a small molecule between them. The various kinds of nylon are formed, for example, by removing a water molecule between an amine and a carboxylic acid. A polymer formed from two different monomers is called a **copolymer**.

Polymers are largely amorphous, but some materials possess a degree of **crystallinity**. For a given chemical composition, the crystallinity depends on the molecular weight and the degree of branching along the main polymer chain. Polymer properties are also strongly affected by **cross-linking**, in which short chains of atoms connect the long polymer chains. Rubber is cross-linked by short chains of sulfur atoms in a process called **vulcanization**.

**NANOMATERIALS (SECTION 12.9)** When one or more dimensions of a material become sufficiently small, generally smaller than 100 nm, the properties of the material change. Materials with dimensions on this length scale are called **nanomaterials**. Quantum dots are semiconductor particles with diameters of 1–10 nm. In this size range the

material's band gap energy becomes size-dependent. Metal nanoparticles have different chemical and physical properties in the 1–100-nm size range. Nanoparticles of gold, for example, are more reactive than bulk gold and no longer have a golden color. Nanoscience has produced a number of previously unknown forms of  $sp^2$ -hybridized carbon. Fullerenes, like  $C_{60}$ , are large molecules containing only carbon atoms. Carbon nanotubes are sheets of graphite rolled up. They can behave as either semiconductors or metals depending on how the sheet was rolled. Graphene, which is an isolated layer from graphite, is a two-dimensional form of carbon. These nanomaterials are being developed now for many applications in electronics, batteries, solar cells, and medicine.

## Learning Outcomes After studying this chapter, you should be able to:

- Classify solids based on their bonding/intermolecular forces and understand how differences in bonding relate to physical properties. (Section 12.1) *Related Exercises: 12.12–12.16*
- Describe the difference between crystalline and amorphous solids. (Section 12.2) *Related Exercises: 12.19, 12.20*
- Define and describe the relationships between unit cells, crystal lattice, lattice vectors, and lattice points. (Section 12.2) *Related Exercises: 12.21, 12.22*
- Explain why there are a limited number of lattices. Recognize the five two-dimensional and the seven three-dimensional primitive lattices. Describe the locations of lattice points for body-centered and face-centered lattices. (Section 12.2) *Related Exercises: 12.21, 12.22, 12.25–12.28*
- State the characteristics and properties of metals. (Section 12.3) *Related Exercises: 12.3, 12.31–12.33*
- Calculate the empirical formula and density of ionic and metallic solids from a picture of the unit cell. Estimate the length of a cubic unit cell from the radii of the atoms/ions present. (Sections 12.3 and 12.5) *Related Exercises: 12.34–12.37, 12.39, 12.40*
- Explain how homogeneous and heterogeneous alloys differ. Describe the differences between substitutional alloys, interstitial alloys, and intermetallic compounds. (Section 12.3) *Related Exercises: 12.41–12.46*
- Explain the electron-sea model of metallic bonding. (Section 12.4) *Related Exercise: 12.49*
- Use the molecular orbital model of metallic bonding to generate the electronic band structures of metals and qualitatively predict the trends in melting point, boiling point, and hardness of metals. (Section 12.4) *Related Exercises: 12.51, 12.55, 12.56*
- Predict the structures of ionic solids from their ionic radii and empirical formula. (Section 12.5) *Related Exercises: 12.63, 12.64*
- Predict the empirical formula from the structure of an ionic solid. (Section 12.5) *Related Exercises: 12.57, 12.58*
- Interpret melting point and boiling point data of molecular solids in terms of intermolecular forces and crystalline packing. (Section 12.6) *Related Exercise: 12.64*
- Identify the valence band, conduction band, and band gap, for semiconductors and insulators. (Section 12.7) *Related Exercise: 12.8*
- Account for the relative band gap energies of semiconductors in terms of periodic trends. Calculate the wavelength of a photon emitted from an LED given its band gap. (Section 12.7) *Related Exercises: 12.71, 12.72, 12.75–12.80*
- Predict how n-type and p-type doping can be used to control the conductivity of semiconductors. (Section 12.7) *Related Exercises: 12.73, 12.74*
- Define the terms monomer, plastic, thermoplastic, thermosetting plastic, elastomer, copolymers, and cross-linking. (Section 12.8) *Related Exercise: 12.81*
- Describe how polymers are formed from monomers and recognize the features of a molecule that allow it to react to form a polymer. Explain the differences between addition polymerization and condensation polymerization. (Section 12.8) *Related Exercises: 12.85–12.87*
- Explain how the interactions between polymer chains impact the physical properties of polymers. (Section 12.8) *Related Exercises: 12.91–12.94*
- Describe how the properties of bulk semiconductors and metals change as the size of the crystals decreases to the nanometer-length scale. (Section 12.9) *Related Exercises: 12.96, 12.97, 12.100*
- Describe the structures and unique properties of fullerenes, carbon nanotubes, and graphene. (Section 12.9) *Related Exercises: 12.101, 12.102*

## Key Equations

- $$\frac{\text{Number of cations per formula unit}}{\text{Number of anions per formula unit}} = \frac{\text{anion coordination number}}{\text{cation coordination number}} \quad [12.1]$$

Relationship between cation and anion coordination numbers and the empirical formula of an ionic compound

## Exercises

### Visualizing Concepts

- 12.1** Two solids are shown below. One is a semiconductor and one is an insulator. Which one is which? Explain your reasoning. [Sections 12.1, 12.7]

- 12.2** For each of the two-dimensional structures shown here (a) draw the unit cell, (b) determine the type of two-dimensional lattice (from Figure 12.4), and (c) determine how many of each type of circle (white or black) there are per unit cell. [Section 12.2]

(i)

(ii)

- 12.3** Shown here are sketches of two processes. Which of the processes refers to the ductility of metals and which refers to malleability of metals? [Section 12.3]

- 12.4** Which arrangement of atoms in a lattice represents close-packing? (Section 12.3)

(i)

(ii)

- 12.5** (a) What kind of packing arrangement is seen in the accompanying photo? (b) What is the coordination number of each cannonball in the interior of the stack? (c) What are the coordination numbers for the numbered cannonballs on the visible side of the stack? [Section 12.3]

- 12.6** Which arrangement of cations (yellow) and anions (blue) in a lattice is the more stable? Explain your reasoning. [Section 12.5]

- 12.7** Which of these molecular fragments would you expect to be more likely to give rise to electrical conductivity? Explain your reasoning. [Sections 12.6, 12.8]

- 12.8** The electronic structure of a doped semiconductor is shown here. (a) Which band, A or B, is the valence band? (b) Which band is the conduction band? (c) Which region of the diagram represents the band gap? (d) Which band consists of bonding molecular orbitals? (e) Is this an example of an n-type or p-type semiconductor? (f) If the semiconductor is germanium, which of the following elements could be the dopant: Ga, Si, or P? [Section 12.7]

- 12.9** Shown here are cartoons of two different polymers. Which of these polymers would you expect to be more crystalline? Which one would have the higher melting point? [Section 12.8]

- 12.10** The accompanying image shows photoluminescence from four different samples of CdTe nanocrystals, each embedded in a polymer matrix. The photoluminescence occurs because the samples are being irradiated by a UV light source. The nanocrystals in each vial have different average sizes. The sizes are 4.0, 3.5, 3.2, and 2.8 nm. (a) Which vial contains the 4.0-nm nanocrystals? (b) Which vial contains the 2.8-nm nanocrystals? (c) Crystals of CdTe that have sizes that are larger than approximately 100 nm have a band gap of 1.5 eV. What would be the wavelength and frequency of light emitted from these crystals? What type of light is this? [Sections 12.7 and 12.9]

### Classification of Solids (Section 12.1)

- 12.11** Covalent bonding occurs in both molecular and covalent-network solids. Which of the following statements best explains why these two kinds of solids differ so greatly in their hardness and melting points?
- The molecules in molecular solids have stronger covalent bonding than covalent-network solids do.
  - The molecules in molecular solids are held together by weak intermolecular interactions.
  - The atoms in covalent-network solids are more polarizable than those in molecular solids.
  - Molecular solids are denser than covalent-network solids.
- 12.12** Silicon is the fundamental component of integrated circuits. Si has the same structure as diamond. (a) Is Si a molecular, metallic, ionic, or covalent-network solid? (b) Silicon readily reacts to form silicon dioxide,  $\text{SiO}_2$ , which is quite hard and is insoluble in water. Is  $\text{SiO}_2$  most likely a molecular, metallic, ionic, or covalent-network solid?
- 12.13** What kinds of attractive forces exist between particles (atoms, molecules, or ions) in (a) molecular crystals, (b) covalent-network crystals, (c) ionic crystals, (d) and metallic crystals?
- 12.14** Which type (or types) of crystalline solid is characterized by each of the following? (a) High mobility of electrons throughout the solid; (b) softness, relatively low melting point; (c) high melting point and poor electrical conductivity; (d) network of covalent bonds.
- 12.15** Indicate the type of solid (molecular, metallic, ionic, or covalent-network) for each compound: (a)  $\text{CaSO}_4$ , (b) Pd, (c)  $\text{Ta}_2\text{O}_5$  (melting point, 1872 °C), (d) caffeine ( $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ ), (e) toluene ( $\text{C}_7\text{H}_8$ ), (f)  $\text{P}_4$ .
- 12.16** Indicate the type of solid (molecular, metallic, ionic, or covalent-network) for each compound: (a) InAs, (b) MgO, (c) HgS, (d) In, (e) HBr.

**12.17** You are given a gray substance that melts at  $700^{\circ}\text{C}$ ; the solid is a conductor of electricity and is insoluble in water. Which type of solid (molecular, metallic, covalent-network, or ionic) might this substance be?

**12.18** You are given a white substance that melts at  $100^{\circ}\text{C}$ . The substance is soluble in water. Neither the solid nor the solution is a conductor of electricity. Which type of solid (molecular, metallic, covalent-network, or ionic) might this substance be?

### Structures of Solids (Section 12.2)

**12.19** (a) Draw a picture that represents a crystalline solid at the atomic level. (b) Now draw a picture that represents an amorphous solid at the atomic level.

**12.20** Amorphous silica,  $\text{SiO}_2$ , has a density of about  $2.2\text{ g/cm}^3$ , whereas the density of crystalline quartz, another form of  $\text{SiO}_2$ , is  $2.65\text{ g/cm}^3$ . Which of the following statements is the best explanation for the difference in density?

- (a) Amorphous silica is a network-covalent solid, but quartz is metallic.
- (b) Amorphous silica crystallizes in a primitive cubic lattice.
- (c) Quartz is harder than amorphous silica.
- (d) Quartz must have a larger unit cell than amorphous silica.
- (e) The atoms in amorphous silica do not pack as efficiently in three dimensions as compared to the atoms in quartz.

**12.21** Two patterns of packing for two different circles of the same size are shown here. For each structure (a) draw the two-dimensional unit cell; (b) determine the angle between the lattice vectors,  $\gamma$ , and determine whether the lattice vectors are of the same length or of different lengths; and (c) determine the type of two-dimensional lattice (from Figure 12.4).

(i)

(ii)

**12.22** Two patterns of packing two different circles of the same size are shown here. For each structure (a) draw the two-dimensional unit cell; (b) determine the angle between the lattice vectors,  $\gamma$ , and determine whether the lattice vectors are of the same length or of different lengths; (c) determine the type of two-dimensional lattice (from Figure 12.4).

(i)

(ii)

**12.23** Imagine the primitive cubic lattice. Now imagine grabbing the top of it and stretching it straight up. All angles remain  $90^{\circ}$ . What kind of primitive lattice have you made?

**12.24** Imagine the primitive cubic lattice. Now imagine grabbing opposite corners and stretching it along the body diagonal while keeping the edge lengths equal. The three angles between the lattice vectors remain equal but are no longer  $90^{\circ}$ . What kind of primitive lattice have you made?

**12.25** Which of the three-dimensional primitive lattices has a unit cell where none of the internal angles is  $90^{\circ}$ ? (a) Orthorhombic, (b) hexagonal, (c) rhombohedral, (d) triclinic, (e) both rhombohedral and triclinic.

**12.26** Besides the cubic unit cell, which other unit cell(s) has edge lengths that are all equal to each other? (a) Orthorhombic, (b) hexagonal, (c) rhombohedral, (d) triclinic, (e) both rhombohedral and triclinic.

**12.27** What is the minimum number of atoms that could be contained in the unit cell of an element with a body-centered cubic lattice? (a) 1, (b) 2, (c) 3, (d) 4, (e) 5.

**12.28** What is the minimum number of atoms that could be contained in the unit cell of an element with a face-centered cubic lattice? (a) 1, (b) 2, (c) 3, (d) 4, (e) 5.

**12.29** The unit cell of nickel arsenide is shown here. (a) What type of lattice does this crystal possess? (b) What is the empirical formula?

**12.30** The unit cell of a compound containing potassium, aluminum, and fluorine is shown here. (a) What type of lattice does this crystal possess (all three lattice vectors are mutually perpendicular)? (b) What is the empirical formula?

### Metallic Solids (Section 12.3)

**12.31** The densities of the elements K, Ca, Sc, and Ti are 0.86, 1.5, 3.2, and 4.5 g/cm<sup>3</sup>, respectively. One of these elements crystallizes in a body-centered cubic structure; the other three crystallize in a face-centered cubic structure. Which one crystallizes in the body-centered cubic structure? Justify your answer.

**12.32** For each of these solids, state whether you would expect it to possess metallic properties: (a) TiCl<sub>4</sub>, (b) NiCo alloy, (c) W, (d) Ge, (e) ScN.

**12.33** Consider the unit cells shown here for three different structures that are commonly observed for metallic elements. (a) Which structure(s) corresponds to the densest packing of atoms? (b) Which structure(s) corresponds to the least dense packing of atoms?

**12.34** Sodium metal (atomic weight 22.99 g/mol) adopts a body-centered cubic structure with a density of 0.97 g/cm<sup>3</sup>. (a) Use this information and Avogadro's number ( $N_A = 6.022 \times 10^{23}$ /mol) to estimate the atomic radius of sodium. (b) If sodium didn't react so vigorously, it could float on water. Use the answer from part (a) to estimate the density of Na if its structure were that of a cubic close-packed metal. Would it still float on water?

**12.35** Iridium crystallizes in a face-centered cubic unit cell that has an edge length of 3.833 Å. (a) Calculate the atomic

radius of an iridium atom. (b) Calculate the density of iridium metal.

**12.36** Calcium crystallizes in a body-centered cubic structure at 467 °C. (a) How many Ca atoms are contained in each unit cell? (b) How many nearest neighbors does each Ca atom possess? (c) Estimate the length of the unit cell edge,  $a$ , from the atomic radius of calcium (1.97 Å). (d) Estimate the density of Ca metal at this temperature.

**12.37** Calcium crystallizes in a face-centered cubic unit cell at room temperature that has an edge length of 5.588 Å. (a) Calculate the atomic radius of a calcium atom. (b) Calculate the density of Ca metal at this temperature.

**12.38** Calculate the volume in Å<sup>3</sup> of each of the following types of cubic unit cells if it is composed of atoms with an atomic radius of 1.82 Å. (a) primitive (b) face-centered cubic.

**12.39** Aluminum metal crystallizes in a face-centered cubic unit cell. (a) How many aluminum atoms are in a unit cell? (b) What is the coordination number of each aluminum atom? (c) Estimate the length of the unit cell edge,  $a$ , from the atomic radius of aluminum (1.43 Å). (d) Calculate the density of aluminum metal.

**12.40** An element crystallizes in a face-centered cubic lattice. The edge of the unit cell is 4.078 Å, and the density of the crystal is 19.30 g/cm<sup>3</sup>. Calculate the atomic weight of the element and identify the element.

**12.41** Which of these statements about alloys and intermetallic compounds is false? (a) Bronze is an example of an alloy. (b) "Alloy" is just another word for "a chemical compound of fixed composition that is made of two or more metals." (c) Intermetallics are compounds of two or more metals that have a definite composition and are not considered alloys. (d) If you mix two metals together and, at the atomic level, they separate into two or more different compositional phases, you have created a heterogeneous alloy. (e) Alloys can be formed even if the atoms that comprise them are rather different in size.

**12.42** Determine if each statement is true or false: (a) Substitutional alloys are solid solutions, but interstitial alloys are heterogeneous alloys. (b) Substitutional alloys have "solute" atoms that replace "solvent" atoms in a lattice, but interstitial alloys have "solute" atoms that are in between the "solvent" atoms in a lattice. (c) The atomic radii of the atoms in a substitutional alloy are similar to each other, but in an interstitial alloy, the interstitial atoms are a lot smaller than the host lattice atoms.

**12.43** For each of the following alloy compositions, indicate whether you would expect it to be a substitutional alloy, an interstitial alloy, or an intermetallic compound:

(a) Fe<sub>0.97</sub>Si<sub>0.03</sub>, (b) Fe<sub>0.60</sub>Ni<sub>0.40</sub>, (c) SmCo<sub>5</sub>.

**12.44** For each of the following alloy compositions, indicate whether you would expect it to be a substitutional alloy, an interstitial alloy, or an intermetallic compound:

(a) Cu<sub>0.66</sub>Zn<sub>0.34</sub>, (b) Ag<sub>3</sub>Sn, (c) Ti<sub>0.99</sub>O<sub>0.01</sub>.

**12.45** Indicate whether each statement is true or false:

(a) Substitutional alloys tend to be more ductile than interstitial alloys.

(b) Interstitial alloys tend to form between elements with similar ionic radii.

(c) Nonmetallic elements are never found in alloys.

**12.46** Indicate whether each statement is true or false:

(a) Intermetallic compounds have a fixed composition.

(b) Copper is the majority component in both brass and bronze.

(c) In stainless steel, the chromium atoms occupy interstitial positions.

- 12.47** Which element or elements are alloyed with gold to make the following types of “colored gold” used in the jewelry industry? For each type, also indicate what type of alloy is formed: **(a)** white gold, **(b)** rose gold, **(c)** green gold.
- 12.48** An increase in temperature causes most metals to undergo *thermal expansion*, which means the volume of the metal increases upon heating. How does thermal expansion affect the unit cell length? What is the effect of an increase in temperature on the density of a metal?

### Metallic Bonding (Section 12.4)

- 12.49** State whether each sentence is true or false:
- Metals have high electrical conductivities because the electrons in the metal are delocalized.
  - Metals have high electrical conductivities because they are denser than other solids.
  - Metals have large thermal conductivities because they expand when heated.
  - Metals have small thermal conductivities because the delocalized electrons cannot easily transfer the kinetic energy imparted to the metal from heat.
- 12.50** Imagine that you have a metal bar sitting half in the sun and half in the dark. On a sunny day, the part of the metal that has been sitting in the sun feels hot. If you touch the part of the metal bar that has been sitting in the dark, will it feel hot or cold? Justify your answer in terms of thermal conductivity.
- 12.51** The molecular-orbital diagrams for two- and four-atom linear chains of lithium atoms are shown in Figure 12.22. Construct a molecular-orbital diagram for a chain containing six lithium atoms and use it to answer the following questions: **(a)** How many molecular orbitals are there in the diagram? **(b)** How many nodes are in the lowest-energy molecular orbital? **(c)** How many nodes are in the highest-energy molecular orbital? **(d)** How many nodes are in the highest-energy occupied molecular orbital (HOMO)? **(e)** How many nodes are in the lowest-energy unoccupied molecular orbital (LUMO)? **(f)** How does the HOMO–LUMO energy gap for this case compare to that of the four-atom case?
- 12.52** Repeat Exercise 12.51 for a linear chain of eight lithium atoms.
- 12.53** Which would you expect to be the more ductile element, **(a)** Ag or Mo, **(b)** Zn or Si? In each case explain your reasoning.
- 12.54** Which of the following statements does not follow from the fact that the alkali metals have relatively weak metal–metal bonding?
- The alkali metals are less dense than other metals.
  - The alkali metals are soft enough to be cut with a knife.
  - The alkali metals are more reactive than other metals.
  - The alkali metals have higher melting points than other metals.
  - The alkali metals have low ionization energies.
- 12.55** Arrange the following metals in increasing order of expected melting point: Mo, Zr, Y, Nb. Explain this trend in melting points.
- 12.56** For each of the following groups, which metal would you expect to have the highest melting point: **(a)** gold, rhenium, or cesium; **(b)** rubidium, molybdenum, or indium; **(c)** ruthenium, strontium, or cadmium?

### Ionic and Molecular Solids (Sections 12.5 and 12.6)

- 12.57** Tausonite, a mineral composed of Sr, O, and Ti, has the cubic unit cell shown in the drawing. **(a)** What is the empirical formula of this mineral? **(b)** How many oxygens are coordinated to titanium? **(c)** To see the full coordination environment of the other ions, we have to consider neighboring unit cells. How many oxygens are coordinated to strontium?

- 12.58** The unit cell of a compound containing Co and O has a unit cell shown below. The Co atoms are on the corners, and the O atoms are completely within the unit cell. What is the empirical formula of this compound? What is the oxidation state of the metal?

- 12.59** Alabandite is a mineral composed of manganese(II) sulfide (MnS). The mineral adopts the rock salt structure. The length of an edge of the MnS unit cell is 5.223 Å at 25 °C. Determine the density of MnS in g/cm<sup>3</sup>.
- 12.60** Clausthalite is a mineral composed of lead selenide (PbSe). The mineral adopts the rock salt structure. The density of PbSe at 25 °C is 8.27 g/cm<sup>3</sup>. Calculate the length of an edge of the PbSe unit cell.
- 12.61** A particular form of cinnabar (HgS) adopts the zinc blende structure. The length of the unit cell edge is 5.852 Å. **(a)** Calculate the density of HgS in this form. **(b)** The mineral tiemannite (HgSe) also forms a solid phase with the zinc blende structure. The length of the unit cell edge in this mineral is 6.085 Å. What accounts for the larger unit cell length in tiemannite? **(c)** Which of the two substances has the higher density? How do you account for the difference in densities?
- 12.62** At room temperature and pressure RbI crystallizes with the NaCl-type structure. **(a)** Use ionic radii to predict the length of the cubic unit cell edge. **(b)** Use this value to estimate the density. **(c)** At high pressure the structure transforms to one with a CsCl-type structure. **(c)** Use ionic radii to predict the length

of the cubic unit cell edge for the high-pressure form of RbI. **(d)** Use this value to estimate the density. How does this density compare with the density you calculated in part (b)?

**12.63** CuI, CsI, and NaI each adopt a different type of structure. The three different structures are those shown in Figure 12.26. **(a)** Use ionic radii,  $\text{Cs}^+$  ( $r = 1.81 \text{ \AA}$ ),  $\text{Na}^+$  ( $r = 1.16 \text{ \AA}$ ),  $\text{Cu}^+$  ( $r = 0.74 \text{ \AA}$ ), and,  $\text{I}^-$  ( $r = 2.06 \text{ \AA}$ ), to predict which compound will crystallize with which structure. **(b)** What is the coordination number of iodide in each of these structures?

**12.64** The rutile and fluorite structures, shown here (anions are colored green), are two of the most common structure types of ionic compounds where the cation to anion ratio is 1:2. **(a)** For  $\text{CaF}_2$  and  $\text{ZnF}_2$  use ionic radii,  $\text{Ca}^{2+}$  ( $r = 1.14 \text{ \AA}$ ),  $\text{Zn}^{2+}$  ( $r = 0.88 \text{ \AA}$ ), and  $\text{F}^-$  ( $r = 1.19 \text{ \AA}$ ), to predict which compound is more likely to crystallize with the fluorite structure and which with the rutile structure. **(b)** What are the coordination numbers of the cations and anions in each of these structures?

Rutile

Fluorite

**12.65** The coordination number for  $\text{Mg}^{2+}$  ion is usually six. Assuming this assumption holds, determine the anion coordination number in the following compounds: **(a)**  $\text{MgS}$ , **(b)**  $\text{MgF}_2$ , **(c)**  $\text{MgO}$ .

**12.66** The coordination number for the  $\text{Al}^{3+}$  ion is typically between four and six. Use the anion coordination number to determine the  $\text{Al}^{3+}$  coordination number in the following compounds: **(a)**  $\text{AlF}_3$  where the fluoride ions are two coordinate, **(b)**  $\text{Al}_2\text{O}_3$  where the oxygen ions are six coordinate, **(c)**  $\text{AlN}$  where the nitride ions are four coordinate.

**12.67** Classify each of the following statements as true or false:

- (a)** Although both molecular solids and covalent-network solids have covalent bonds, the melting points of molecular solids are much lower because their covalent bonds are much weaker.
- (b)** Other factors being equal, highly symmetric molecules tend to form solids with higher melting points than asymmetrically shaped molecules.

**12.68** Classify each of the following statements as true or false:

- (a)** For molecular solids, the melting point generally increases as the strengths of the covalent bonds increase.

- (b)** For molecular solids, the melting point generally increases as the strengths of the intermolecular forces increase.

## Covalent-Network Solids (Section 12.7)

**12.69** Both covalent-network solids and ionic solids can have melting points well in excess of room temperature, and both can be poor conductors of electricity in their pure form. However, in other ways their properties are quite different.

- (a)** Which type of solid is more likely to dissolve in water?
- (b)** Which type of solid can become a considerably better conductor of electricity via chemical substitution?

**12.70** Which of the following properties are typical characteristics of a covalent-network solid, a metallic solid, or both: **(a)** ductility, **(b)** hardness, **(c)** high melting point?

**12.71** For each of the following pairs of semiconductors, which one will have the larger band gap: **(a)**  $\text{CdS}$  or  $\text{CdTe}$ , **(b)**  $\text{GaN}$  or  $\text{InP}$ , **(c)**  $\text{GaAs}$  or  $\text{InAs}$ ?

**12.72** For each of the following pairs of semiconductors, which one will have the larger band gap: **(a)**  $\text{InP}$  or  $\text{InAs}$ , **(b)**  $\text{Ge}$  or  $\text{AlP}$ , **(c)**  $\text{AgI}$  or  $\text{CdTe}$ ?

**12.73** If you want to dope  $\text{GaAs}$  to make an n-type semiconductor with an element to replace Ga, which element(s) would you pick?

**12.74** If you want to dope  $\text{GaAs}$  to make a p-type semiconductor with an element to replace As, which element(s) would you pick?

**12.75** Silicon has a band gap of 1.1 eV at room temperature. **(a)** What wavelength of light would a photon of this energy correspond to? **(b)** Draw a vertical line at this wavelength in the figure shown, which shows the light output of the Sun as a function of wavelength. Does silicon absorb all, none, or a portion of the visible light that comes from the Sun? **(c)** You can estimate the portion of the overall solar spectrum that silicon absorbs by considering the area under the curve. If you call the area under the entire curve "100%," what approximate percentage of the area under the curve is absorbed by silicon?

**12.76** Cadmium telluride is an important material for solar cells. **(a)** What is the band gap of  $\text{CdTe}$ ? **(b)** What wavelength of light would a photon of this energy correspond to? **(c)** Draw a vertical line at this wavelength in the figure shown in Exercise 12.75, which shows the light output of the sun as a function of wavelength. **(d)** With respect to silicon, does  $\text{CdTe}$  absorb a larger or smaller portion of the solar spectrum?

- 12.77** The semiconductor CdSe has a band gap of 1.74 eV. What wavelength of light would be emitted from an LED made from CdSe? What region of the electromagnetic spectrum is this?
- 12.78** The first LEDs were made from GaAs, which has a band gap of 1.43 eV. What wavelength of light would be emitted from an LED made from GaAs? What region of the electromagnetic spectrum does this light correspond to: ultraviolet, visible, or infrared?
- 12.79** GaAs and GaP make solid solutions that have the same crystal structure as the parent materials, with As and P randomly distributed throughout the crystal.  $\text{GaP}_x\text{As}_{1-x}$  exists for any value of  $x$ . If we assume that the band gap varies linearly with composition between  $x = 0$  and  $x = 1$ , estimate the band gap for  $\text{GaP}_{0.5}\text{As}_{0.5}$ . (GaAs and GaP band gaps are 1.43 eV and 2.26 eV, respectively.) What wavelength of light does this correspond to?
- 12.80** Red light-emitting diodes are made from GaAs and GaP solid solutions,  $\text{GaP}_x\text{As}_{1-x}$  (see Exercise 12.79). The original red LEDs emitted light with a wavelength of 660 nm. If we assume that the band gap varies linearly with composition between  $x = 0$  and  $x = 1$ , estimate the composition (the value of  $x$ ) that is used in these LEDs.

## Polymers (Section 12.8)

- 12.81** (a) What is a monomer? (b) Which of these molecules can be used as a monomer: ethanol, ethene (also called ethylene), methane?
- 12.82** The molecular formula of *n*-decane is  $\text{CH}_3(\text{CH}_2)_8\text{CH}_3$ . Decane is not considered a polymer, whereas polyethylene is. What is the distinction?
- 12.83** State whether each of these numbers is a reasonable value for a polymer's molecular weight: 100 amu, 10,000 amu, 100,000 amu, 1,000,000 amu?
- 12.84** Indicate whether the following statement is true or false: For an addition polymerization, there are no by-products of the reaction (assuming 100% yield).
- 12.85** An ester is a compound formed by a condensation reaction between a carboxylic acid and an alcohol that eliminates a water molecule. Read the discussion of esters in Section 24.4 and then give an example of a reaction forming an ester. How might this kind of reaction be extended to form a polymer (a polyester)?
- 12.86** Write a balanced chemical equation for the formation of a polymer via a condensation reaction from the monomers succinic acid ( $\text{HOOCCH}_2\text{CH}_2\text{COOH}$ ) and ethylenediamine ( $\text{H}_2\text{NCH}_2\text{CH}_2\text{NH}_2$ ).
- 12.87** An addition polymerization forms the polymer originally used as Saran™ wrap. It has the following structure  $[-\text{CCl}_2-\text{CH}_2-]_n$ . Draw the structure of the monomer.
- 12.88** Write the chemical equation that represents the formation of

Chloroprene

- (b) polyacrylonitrile from acrylonitrile (polyacrylonitrile is used in home furnishings, craft yarns, clothing, and many other items).

- 12.89** The polymer Kevlar, a condensation polymer, is used as reinforcement in car tires, strings of archery bows, and as a component of bulletproof vests.

Draw the structures of the two monomers that yield Kevlar.

- 12.90** Proteins are naturally occurring polymers formed by condensation reactions of amino acids, which have the general structure

In this structure, —R represents —H, —CH<sub>3</sub>, or another group of atoms; there are 20 different natural amino acids, and each has one of 20 different R groups. (a) Draw the general structure of a protein formed by condensation polymerization of the generic amino acid shown here. (b) When only a few amino acids react to make a chain, the product is called a “peptide” rather than a protein; only when there are 50 amino acids or more in the chain would the molecule be called a protein. For three amino acids (distinguished by having three different R groups, R<sub>1</sub>, R<sub>2</sub>, and R<sub>3</sub>), draw the peptide that results from their condensation reactions. (c) The order in which the R groups exist in a peptide or protein has a huge influence on its biological activity. To distinguish different peptides and proteins, chemists call the first amino acid the one at the “N terminus” and the last one the one at the “C terminus.” From your drawing in part (b) you should be able to figure out what “N terminus” and “C terminus” mean. How many different peptides can be made from your three different amino acids?

- 12.91** (a) What molecular features make a polymer flexible? (b) If you cross-link a polymer, is it more flexible or less flexible than it was before?
- 12.92** What molecular structural features cause high-density polyethylene to be denser than low-density polyethylene?
- 12.93** If you want to make a polymer for plastic wrap, should you strive to make a polymer that has a high or low degree of crystallinity?
- 12.94** Indicate whether each statement is true or false:
- (a) Elastomers are rubbery solids.
  - (b) Thermosets cannot be reshaped.
  - (c) Thermoplastic polymers can be recycled.

## Nanomaterials (Section 12.9)

- 12.95** Explain why “bands” may not be the most accurate description of bonding in a solid when the solid has nanoscale dimensions.

**12.96** CdS has a band gap of 2.4 eV. If large crystals of CdS are illuminated with ultraviolet light, they emit light equal to the band gap energy. **(a)** What color is the emitted light? **(b)** Would appropriately sized CdS quantum dots be able to emit blue light? **(c)** What about red light?

**12.97** Indicate whether each statement is true or false:

- (a)** The band gap of a semiconductor decreases as the particle size decreases in the 1–10-nm range.
- (b)** The light that is emitted from a semiconductor, upon external stimulation, becomes longer in wavelength as the particle size of the semiconductor decreases.

**12.98** Indicate whether this statement is true or false:

If you want a semiconductor that emits blue light, you could either use a material that has a band gap corresponding to the energy of a blue photon or you could use a material that has a smaller band gap but make an appropriately sized nanoparticle of the same material.

**12.99** Gold adopts a face-centered cubic structure with a unit cell edge of 4.08 Å (Figure 12.11). How many gold atoms are there in a sphere that is 20 nm in diameter? Recall that the volume of a sphere is  $\frac{4}{3}\pi r^3$ .

**12.100** An ideal quantum dot for use in TVs does not contain any cadmium due to concerns about disposal. One potential material for this purpose is InP, which adopts the zinc

blende (ZnS) structure (face-centered cubic). The unit cell edge length is 5.869 Å. **(a)** If the quantum dot is shaped like a cube, how many of each type of atom are there in a cubic crystal with an edge length of 3.00 nm? 5.00 nm? **(b)** If one of the nanoparticles in part (a) emits blue light and the other emits orange light, which color is emitted by the crystal with the 3.00-nm edge length? With the 5.00-nm edge length?

**12.101** Which statement correctly describes a difference between graphene and graphite?

**(a)** Graphene is a molecule but graphite is not. **(b)** Graphene is a single sheet of carbon atoms and graphite contains many, and larger, sheets of carbon atoms. **(c)** Graphene is an insulator but graphite is a metal. **(d)** Graphite is pure carbon but graphene is not. **(e)** The carbons are  $sp^2$  hybridized in graphene but  $sp^3$  hybridized in graphite.

**12.102** What evidence supports the notion that buckyballs are actual molecules and not extended materials?

- (a)** Buckyballs are made of carbon.
- (b)** Buckyballs have a well-defined atomic structure and molecular weight.
- (c)** Buckyballs have a well-defined melting point.
- (d)** Buckyballs are semiconductors.
- (e)** More than one of the previous choices.

## Additional Exercises

**[12.103]** Selected chlorides have the following melting points: NaCl (801 °C),  $MgCl_2$  (714 °C),  $PCl_3$  (−94 °C),  $SiCl_4$  (−121 °C) **(a)** For each compound, indicate what type its solid form is (molecular, metallic, ionic, or covalent-network). **(b)** Predict which of the following compounds has a higher melting point:  $CaCl_2$  or  $SiCl_4$ .

**[12.104]** A face-centered tetragonal lattice is not one of the 14 three-dimensional lattices. Show that a face-centered tetragonal unit cell can be redefined as a body-centered tetragonal lattice with a smaller unit cell.

**[12.105]** Imagine the primitive cubic lattice. Now imagine pushing on top of it, straight down. Next, stretch another face by pulling it to the right. All angles remain 90°. What kind of primitive lattice have you made?

**12.106** Pure iron crystallizes in a body-centered cubic structure, but small amounts of impurities can stabilize a face-centered cubic structure. Which form of iron has a higher density?

**[12.107]** Introduction of carbon into a metallic lattice generally results in a harder, less ductile substance with lower electrical and thermal conductivities. Explain why this might be so.

**12.108**  $Ni_3Al$  is used in the turbines of aircraft engines because of its strength and low density. Nickel metal has a cubic close-packed structure with a face-centered cubic unit cell, while  $Ni_3Al$  has the ordered cubic structure shown in Figure 12.17. The length of the cubic unit cell edge is 3.53 Å for nickel and 3.56 Å for  $Ni_3Al$ . Use these data to calculate and compare the densities of these two materials.

**12.109** For each of the intermetallic compounds shown in Figure 12.17 determine the number of each type of

atom in the unit cell. Do your answers correspond to the ratios expected from the empirical formulas:  $Ni_3Al$ ,  $Nb_3Sn$ , and  $SmCo_5$ ?

**12.110** What type of lattice—primitive cubic, body-centered cubic, or face-centered cubic—does each of the following structure types possess: **(a)** CsCl, **(b)** Au, **(c)** NaCl, **(d)** Po, **(e)** ZnS?

**12.111** Cinnabar (HgS) was utilized as a pigment known as vermilion. It has a band gap of 2.20 eV near room temperature for the bulk solid. What wavelength of light (in nm) would a photon of this energy correspond to?

**[12.112]** The electrical conductivity of aluminum is approximately  $10^9$  times greater than that of its neighbor in the periodic table, silicon. Aluminum has a face-centered cubic structure, and silicon has the diamond structure. A classmate of yours tells you that density is the reason aluminum is a metal but silicon is not; therefore, if you were to put silicon under high pressure, it too would act like a metal. Discuss this idea with your classmates, looking up data about Al and Si as needed.

**12.113** Silicon carbide, SiC, has the three-dimensional structure shown in the figure.

(a) Name another compound that has the same structure. (b) Would you expect the bonding in SiC to be predominantly ionic, metallic, or covalent? (c) How do the bonding and structure of SiC lead to its high thermal stability (to 2700 °C) and exceptional hardness?

- [12.114] Energy bands are considered continuous due to the large number of closely spaced energy levels. The range of energy levels in a crystal of copper is approximately  $1 \times 10^{-19}$  J. Assuming equal spacing between levels, the spacing between energy levels may be approximated by dividing the range of energies by the number of atoms in the crystal. (a) How many copper atoms are in a piece of copper metal in the shape of a cube with edge length 0.5 mm? The density of copper is 8.96 g/cm<sup>3</sup>. (b) Determine the average spacing in J between energy levels in the copper metal in part (a). (c) Is this spacing larger, substantially smaller, or about the same as the  $1 \times 10^{-18}$  J separation between energy levels in a hydrogen atom?

- [12.115] Unlike metals, semiconductors increase their conductivity as you heat them (up to a point). Suggest an explanation.

- 12.116 Sodium oxide (Na<sub>2</sub>O) adopts a cubic structure with Na atoms represented by green spheres and O atoms by red spheres.

- (a) How many atoms of each type are there in the unit cell?  
 (b) Determine the coordination number and describe the shape of the coordination environment for the sodium ion.  
 (c) The unit cell edge length is 5.550 Å. Determine the density of Na<sub>2</sub>O.

- 12.117 Teflon is a polymer formed by the polymerization of F<sub>2</sub>C=CF<sub>2</sub>. (a) Draw the structure of a section of this polymer. (b) What type of polymerization reaction is required to form Teflon?

- 12.118 Hydrogen bonding between polyamide chains plays an important role in determining the properties of a nylon such as nylon 6,6 (Table 12.6). Draw the structural formulas for two adjacent chains of nylon 6,6 and show where hydrogen-bonding interactions could occur between them.

- 12.119 Explain why X rays can be used to measure atomic distances in crystals but visible light cannot be used for this purpose.

- 12.120 In their study of X-ray diffraction, William and Lawrence Bragg determined that the relationship among the wavelength of the radiation ( $\lambda$ ), the angle at which the radiation is diffracted ( $\theta$ ), and the distance between planes of atoms in the crystal that cause the diffraction ( $d$ ) is given by  $n\lambda = 2d \sin \theta$ . X rays from a copper X-ray tube that have a wavelength of 1.54 Å are diffracted at an angle of 14.22 degrees by crystalline silicon. Using the Bragg equation, calculate the distance between the planes of atoms responsible for diffraction in this crystal, assuming  $n = 1$  (first-order diffraction).

- 12.121 Germanium has the same structure as silicon, but the unit cell size is different because Ge and Si atoms are not the same size. If you were to repeat the experiment described in the previous problem but replace the Si crystal with a Ge crystal, would you expect the X rays to be diffracted at a larger or smaller angle  $\theta$ ?

- [12.122] (a) The density of diamond is 3.5 g/cm<sup>3</sup>, and that of graphite is 2.3 g/cm<sup>3</sup>. Based on the structure of buckminsterfullerene, what would you expect its density to be relative to these other forms of carbon? (b) X-ray diffraction studies of buckminsterfullerene show that it has a face-centered cubic lattice of C<sub>60</sub> molecules. The length of an edge of the unit cell is 14.2 Å. Calculate the density of buckminsterfullerene.

- 12.123 When you shine light of band gap energy or higher on a semiconductor and promote electrons from the valence band to the conduction band, do you expect the conductivity of the semiconductor to (a) remain unchanged, (b) increase, or (c) decrease?

## Integrative Exercises

- 12.124 The karat scale used to describe gold alloys is based on mass percentages. (a) If an alloy is formed that is 50 mol% silver and 50 mol% gold, what is the karat number of the alloy? Use Figure 12.18 to estimate the color of this alloy. (b) If an alloy is formed that is 50 mol% copper and 50 mol% gold, what is the karat number of the alloy? What is the color of this alloy?

- 12.125 Spinel is a mineral that contains 37.9% Al, 17.1% Mg, and 45.0% O, by mass, and has a density of 3.57 g/cm<sup>3</sup>. The unit cell is cubic with an edge length of 8.09 Å. How many atoms of each type are in the unit cell?

- 12.126 (a) What are the C—C—C bond angles in diamond? (b) What are they in graphite (in one sheet)? (c) What atomic orbitals are involved in the stacking of graphite sheets with each other?

- [12.127] Employing the bond enthalpy values listed in Table 8.4, estimate the molar enthalpy change occurring upon (a) polymerization of ethylene, (b) formation of nylon 6,6, (c) formation of polyethylene terephthalate (PET).

- [12.128] Although polyethylene can twist and turn in random ways, the most stable form is a linear one with the carbon backbone oriented as shown in the following figure:

The solid wedges in the figure indicate bonds from carbon that come out of the plane of the page; the dashed wedges indicate bonds that lie behind the plane of the page.

- (a) What is the hybridization of orbitals at each carbon atom? What angles do you expect between the bonds?
- (b) Now imagine that the polymer is polypropylene rather than polyethylene. Draw structures for polypropylene in which (i) the  $\text{CH}_3$  groups all lie on the same side of the plane of the paper (this form is called isotactic polypropylene), (ii) the  $\text{CH}_3$  groups lie on alternating sides of the plane (syndiotactic polypropylene), or (iii) the  $\text{CH}_3$  groups are randomly distributed on either side (atactic polypropylene). Which of these forms would you expect to have the highest crystallinity and melting point, and which the lowest? Explain in terms of intermolecular interactions and molecular shapes.
- (c) Polypropylene fibers have been employed in athletic wear. The product is said to be superior to cotton or polyester clothing in wicking moisture away from the body through the fabric to the outside. Explain the difference between polypropylene and polyester or cotton (which has many  $-\text{OH}$  groups along the molecular chain) in terms of intermolecular interactions with water.

**12.129** (a) In polyvinyl chloride shown in Table 12.6, which bonds have the lowest average bond enthalpy?

(b) When subjected to high pressure and heated, polyvinyl chloride converts to diamond. During this transformation which bonds are most likely to break first? (c) Employing the values of average bond enthalpy in Table 8.3, estimate the overall enthalpy change for converting PVC to diamond.

**[12.130]** Silicon has the diamond structure with a unit cell edge length of  $5.43 \text{ \AA}$  and eight atoms per unit cell. (a) How many silicon atoms are there in  $1 \text{ cm}^3$  of material? (b) Suppose you dope that  $1 \text{ cm}^3$  sample of silicon with 1 ppm of phosphorus that will increase the conductivity by a factor of a million. How many milligrams of phosphorus are required?

**12.131** One method to synthesize ionic solids is by the heating of two reactants at high temperatures. Consider the reaction of  $\text{FeO}$  with  $\text{TiO}_2$  to form  $\text{FeTiO}_3$ . Determine the amount of each of the two reactants to prepare  $2.500 \text{ g FeTiO}_3$ , assuming the reaction goes to completion.

- (a) Write a balanced chemical reaction.
- (b) Calculate the formula weight of  $\text{FeTiO}_3$ .
- (c) Determine the moles of  $\text{FeTiO}_3$ .

**12.132** Look up the diameter of a silicon atom, in  $\text{\AA}$ . The latest semiconductor chips have fabricated lines as small as  $14 \text{ nm}$ . How many silicon atoms does this correspond to?

## Design an Experiment

Polymers were commercially made by the DuPont Company starting in the late 1920s. At that time, some chemists still could not believe that polymers were molecules; they thought covalent bonding would not “last” for millions of atoms, and that polymers were

really clumps of molecules held together by weak intermolecular forces. Design an experiment to demonstrate that polymers really are large molecules and not little clumps of small molecules that are held together by weak intermolecular forces.

13

# PROPERTIES OF SOLUTIONS

In Chapters 10, 11, and 12, we explored the properties of pure gases, liquids, and solids. However, the matter that we encounter in our daily lives, such as soda, air, and glass, are frequently mixtures. In this chapter, we examine homogeneous mixtures.

As we noted in the earlier chapters, homogeneous mixtures are called *solutions*.  (Sections 1.2 and 4.1)

When we think of solutions, we usually think of liquids, like those in this chapter's opening photograph. Solutions, however, can also be solids or gases. For example, sterling silver is a homogeneous mixture of about 7% copper in silver and so is a solid solution. The air we breathe is a homogeneous mixture of several gases, making air a gaseous solution. However, because liquid solutions are the most common, we focus our attention on them in this chapter.

Each substance in a solution is a *component* of the solution. As we saw in Chapter 4, the *solvent* is normally the component present in the greatest amount, and all the other components are called *solutes*. In this chapter, we compare the physical properties of solutions with the properties of the components in their pure form. We will be particularly concerned with aqueous solutions, which contain water as the solvent and either a gas, liquid, or solid as a solute.

◀ **COLORED FLOW.** This microfluidic chip is similar to the one used in many medical diagnostic laboratories. The colored dye solutions are used to test the flow in each channel for proper functioning.

## WHAT'S AHEAD

- 13.1** ▶ **The Solution Process** Explore what happens at the molecular level when one substance dissolves into another; intermolecular forces are key. Two important aspects of the solution process are the natural tendency of particles to mix and the accompanying changes in energy.
- 13.2** ▶ **Saturated Solutions and Solubility** Learn that when a saturated solution is in contact with undissolved solute, the dissolved and undissolved solutes are in dynamic equilibrium. The *solubility* of a substance in a particular solvent is defined as the amount of the substance required to make a saturated solution.
- 13.3** ▶ **Factors Affecting Solubility** Describe the major factors affecting solubility: the kinds of intermolecular forces between solvent and solute molecules, and temperature. Most solids are more soluble in water at higher temperatures, whereas gases are less soluble in water at higher temperatures. The solubility of gases in a liquid increases with increasing pressure.
- 13.4** ▶ **Expressing Solution Concentration** Examine the common ways of expressing the concentration of a solute in a solvent: *mass percentage*, *mole fraction*, *molarity*, and *molality*.
- 13.5** ▶ **Colligative Properties** Observe that some physical properties of solutions depend only on the concentration of the solute and not its identity. These *colligative properties* include vapor-pressure lowering, boiling-point elevation, and freezing-point depression, as well as *osmotic pressure*.
- 13.6** ▶ **Colloids** Investigate colloids, mixtures that are not true solutions but consist of a solute-like phase (the dispersed phase) and a solvent-like phase (the dispersion medium). The dispersed phase consists of particles larger than typical molecular sizes.

## 13.1 | The Solution Process

A solution is formed when one substance disperses uniformly throughout another. The ability of substances to form solutions depends on two factors: (1) the natural tendency of substances to mix and spread into larger volumes when not restrained in some way and (2) the types of intermolecular interactions involved in the solution process.

### The Natural Tendency toward Mixing

Suppose we have  $\text{O}_2(\text{g})$  and  $\text{Ar}(\text{g})$  separated by a barrier, as in [Figure 13.1](#). If the barrier is removed, the gases mix to form a solution. The molecules experience very little intermolecular interactions and behave like ideal gas particles. As a result, their molecular motion causes them to spread through the larger volume, and a gaseous solution is formed.

The mixing of gases is a *spontaneous* process, meaning it occurs of its own accord without any input of energy from outside the system. When the molecules mix and become more randomly distributed, there is an increase in a thermodynamic quantity called *entropy*. Entropy will be defined more rigorously in Chapter 19; but for now, we can consider that the entropy of a system increases if its degree of disorder increases, or if its energy becomes dispersed over a greater number of particles. Therefore, the mixing of gases we just described increases the entropy of the system. The enthalpy of the system, however, changes little upon gas mixing because there are few intermolecular interactions between the gas particles. All of the intermolecular forces (dispersion forces, dipole–dipole interactions, hydrogen bonding) and their corresponding energies are part of the enthalpy of the system. Decreasing the enthalpy of the system would correspond to increasing favorable intermolecular interactions between gas particles. Furthermore, the balance between increasing the entropy and decreasing the enthalpy of a system is what determines whether a process is spontaneous. Thus, the *formation of solutions is favored by the increase in entropy that accompanies mixing*.

When molecules of different types are brought together, mixing occurs spontaneously unless the molecules are restrained either by sufficiently strong intermolecular forces or by physical barriers. Thus, gases spontaneously mix unless restrained by their containers because with gases intermolecular forces are too weak to restrain the molecules. However, when the solvent or solute is a solid or liquid, intermolecular forces become important in determining whether a solution forms. For example, although ionic bonds hold sodium and chloride ions together in solid sodium chloride  $\infty$  ([Section 8.2](#)), the solid dissolves in water because of the compensating strength of the attractive forces

#### Go Figure

What aspect of the kinetic theory of gases tells us that the gases will mix?

▲ **Figure 13.1** Spontaneous mixing of two gases to form a homogeneous mixture (a solution).

between the ions and water molecules. Sodium chloride does not dissolve in gasoline, however, because the intermolecular forces between the ions and the gasoline molecules are too weak.

### Give It Some Thought

If you put a drop of food coloring in water and watch the drop disperse, is entropy increasing or decreasing?

## The Effect of Intermolecular Forces on Solution Formation

Any of the intermolecular forces discussed in Chapter 11 can operate between solute and solvent particles in a solution. These forces are summarized in **Figure 13.2**. Dispersion forces, for example, dominate when one nonpolar substance, such as  $C_7H_{16}$ , dissolves in another, such as  $C_5H_{12}$ , and ion–dipole forces dominate in solutions of ionic substances in water.

Three kinds of intermolecular interactions are involved in solution formation:

1. *Solute–solute* interactions between solute particles must be overcome to disperse the solute particles through the solvent.
2. *Solvent–solvent* interactions between solvent particles must be overcome to make room for the solute particles in the solvent.
3. *Solvent–solute* interactions between the solvent and solute particles occur as the particles mix.

The extent to which one substance is able to dissolve in another depends on the relative magnitudes of these three types of interactions. Solutions form when the magnitudes of the solvent–solute interactions are either comparable to or greater than the solute–solute and solvent–solvent interactions. For example, heptane ( $C_7H_{16}$ ) and pentane ( $C_5H_{12}$ ) dissolve in each other in all proportions. For this discussion, we can arbitrarily call heptane the solvent and pentane the solute. Both substances are nonpolar, and the magnitudes of the solvent–solute interactions (attractive dispersion forces) are comparable to the solute–solute and the solvent–solvent interactions. Thus, no forces impede mixing, and the tendency to mix (increase entropy) causes the solution to form spontaneously.

An everyday example of solution formation occurs when you dissolve salt in water. Solid NaCl dissolves readily in water because the attractive solvent–solute interactions between the polar  $H_2O$  molecules and the ions are strong enough to overcome the attractive solute–solute interactions between ions in the  $NaCl(s)$  and the attractive solvent–solvent interactions between  $H_2O$  molecules. When NaCl is added to water

### Go Figure

Which atom in water points toward  $Na^+$  in the ion–dipole interaction? Why?

#### Dispersion

Heptane ( $C_7H_{16}$ )      Pentane ( $C_5H_{12}$ )

#### Dipole–dipole

Chloroform ( $CHCl_3$ )

#### Hydrogen bond

Ethanol ( $C_2H_5OH$ )

Water ( $H_2O$ )

#### Ion–dipole

**Figure 13.2** Intermolecular interactions involved in solutions.

▲ **Figure 13.3** Dissolution of the ionic solid NaCl in water.

(**Figure 13.3**), the water molecules orient themselves on the surface of the NaCl crystals with the positive end of the water dipole oriented toward  $\text{Cl}^-$  ions and the negative end oriented toward  $\text{Na}^+$  ions. These ion-dipole attractions are strong enough to pull the surface ions away from the solid, thus overcoming the solute-solute interactions. For the solid to dissolve, some solvent-solvent interactions must also be overcome to create room for the ions to “fit” among all the water molecules.

Once separated from the solid, the  $\text{Na}^+$  and  $\text{Cl}^-$  ions are surrounded by water molecules. Interactions such as this between solute and solvent molecules are known as **solvation**. When the solvent is water, the interactions are referred to as **hydration**.

### Give It Some Thought

Why doesn't NaCl dissolve in nonpolar solvents such as hexane,  $\text{C}_6\text{H}_{14}$ ?

## Energetics of Solution Formation

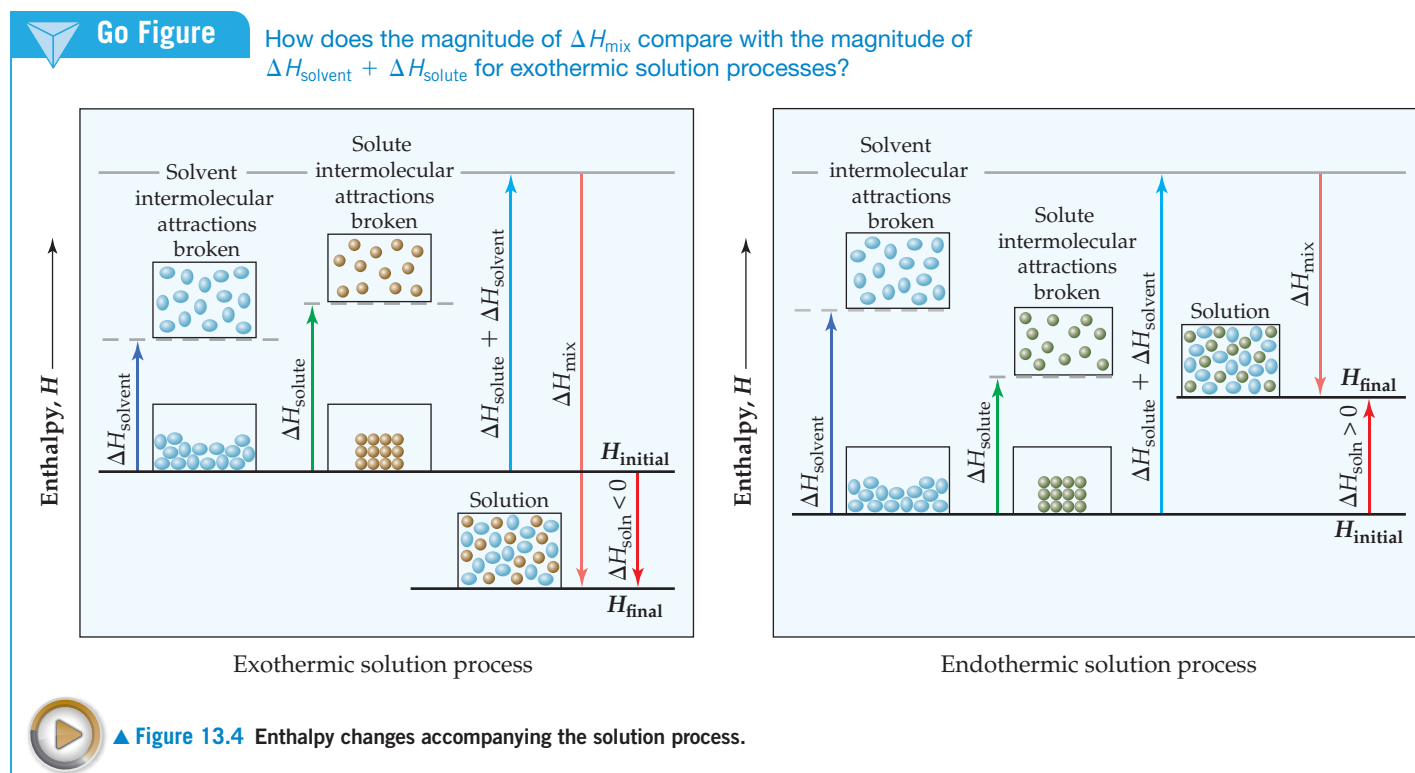

Solution processes are typically accompanied by changes in enthalpy. For example, when NaCl dissolves in water, the process is slightly endothermic,  $\Delta H_{\text{soln}} = 3.9 \text{ kJ/mol}$ . We can use Hess's law to analyze how the solute-solute, solvent-solvent, and solute-solvent interactions influence the enthalpy of solution. [∞ \(Section 5.6\)](#)

We can imagine the solution process as having three components, each with an associated enthalpy change: A cluster of  $n$  solute particles must separate from one another ( $\Delta H_{\text{solute}}$ ), a cluster of  $m$  solvent particles separate from one another ( $\Delta H_{\text{solvent}}$ ), and these solute and solvent particles mix ( $\Delta H_{\text{mix}}$ ).

- |  |   |
|--|---|
| 1. $(\text{solute})_n \rightleftharpoons n \text{ solute}$                     | $\Delta H_{\text{solute}}$  |
| 2. $(\text{solvent})_m \rightleftharpoons m \text{ solvent}$                   | $\Delta H_{\text{solvent}}$   |
| 3. $n \text{ solute} + m \text{ solvent} \rightleftharpoons \text{solution}$   | $\Delta H_{\text{mix}}$   |
| 4. $(\text{solute})_n + (\text{solvent})_m \rightleftharpoons \text{solution}$ | $\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{solvent}} + \Delta H_{\text{mix}}$ |

As seen above, the overall enthalpy change,  $\Delta H_{\text{soln}}$ , is the sum of the three steps:

$$\Delta H_{\text{soln}} = \Delta H_{\text{solute}} + \Delta H_{\text{solvent}} + \Delta H_{\text{mix}} \quad [13.1]$$

Separation of the solute particles from one another always requires an input of energy to overcome their attractive interactions. The process is therefore endothermic ( $\Delta H_{\text{solute}} > 0$ ). Likewise, separation of solvent molecules to accommodate the solute always requires energy ( $\Delta H_{\text{solvent}} > 0$ ). The third component, which arises from the attractive interactions between solute particles and solvent particles, is always exothermic ( $\Delta H_{\text{mix}} < 0$ ).

The three enthalpy terms in Equation 13.1 can be added together to give either a negative or a positive sum, depending on the actual numbers for the system being considered (**Figure 13.4**). Thus, the formation of a solution can be either exothermic or endothermic. For example, when magnesium sulfate ( $\text{MgSO}_4$ ) is added to water, the solution process is exothermic:  $\Delta H_{\text{soln}} = -91.2 \text{ kJ/mol}$ . In contrast, the dissolution of ammonium nitrate ( $\text{NH}_4\text{NO}_3$ ) is endothermic:  $\Delta H_{\text{soln}} = 26.4 \text{ kJ/mol}$ . These particular salts are the main components in the instant heat packs and ice packs used to treat athletic injuries (**Figure 13.5**). The packs consist of a pouch of water and the solid salt sealed off from the water— $\text{MgSO}_4(s)$  for hot packs and  $\text{NH}_4\text{NO}_3(s)$  for cold packs. When the pack is squeezed, the seal separating the solid from the water is broken and a solution forms, either increasing or decreasing the temperature. This means that a freshly made solution of  $\text{MgSO}_4$  in water feels warm and a freshly made solution of  $\text{NH}_4\text{NO}_3$  feels cold.

The enthalpy change for a process can provide insight into the extent to which the process occurs. ∞ (Section 5.4) Exothermic processes tend to proceed spontaneously. On the other hand, if  $\Delta H_{\text{soln}}$  is too endothermic, the solute might not dissolve to any significant extent in the chosen solvent. Thus, for solutions to form, the solvent-solute interaction must be strong enough to make  $\Delta H_{\text{mix}}$  comparable in magnitude to  $\Delta H_{\text{solute}} + \Delta H_{\text{solvent}}$ . This fact further explains why ionic solutes do not dissolve in nonpolar solvents. The nonpolar solvent molecules experience only weak attractive interactions with the ions, and these interactions do not compensate for the energies required to separate the ions from one another.

By similar reasoning, a polar liquid solute, such as water, does not dissolve in a nonpolar liquid solvent, such as octane ( $\text{C}_8\text{H}_{18}$ ). The water molecules experience strong hydrogen-bonding interactions with one another ∞ (Section 11.2)—attractive forces that must be overcome if the water molecules are to be dispersed throughout the octane solvent. The energy required to separate the  $\text{H}_2\text{O}$  molecules from one another is not recovered in the form of attractive interactions between the  $\text{H}_2\text{O}$  and  $\text{C}_8\text{H}_{18}$  molecules.

▲ **Figure 13.5** Magnesium sulfate instant hot pack.

## Give It Some Thought

- Label the following processes as exothermic or endothermic:
- (a) breaking solvent–solvent interactions to form separated particles
  - (b) forming solvent–solute interactions from separated particles

## Solution Formation and Chemical Reactions

In discussing solutions, we must be careful to distinguish the physical process of solution formation from chemical reactions that lead to a solution. For example, nickel metal dissolves on contact with an aqueous hydrochloric acid solution because the following reaction occurs:

In this instance, one of the resulting solutes is not Ni metal but rather its salt  $\text{NiCl}_2$ . If the solution is evaporated to dryness,  $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}(s)$  is recovered (Figure 13.6). Compounds such as  $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}(s)$  that have a defined number of water molecules in the crystal lattice are known as *hydrates*. When  $\text{NaCl}(s)$  is dissolved in water, on the other hand, no chemical reaction occurs. If the solution is evaporated to dryness,  $\text{NaCl}$  is recovered. Our focus throughout this chapter is on solutions from which the solute can be recovered unchanged from the solution.

## 13.2 | Saturated Solutions and Solubility

As a solid solute begins to dissolve in a solvent, the concentration of solute particles in solution increases, increasing the chances that some solute particles will collide with the surface of the solid and reattach. This process, which is the opposite of the solution process, is called **crystallization**. Thus, two opposing processes occur in a solution in contact with undissolved solute. This situation is represented in this chemical equation:

When the rates of these opposing processes become equal, a *dynamic equilibrium* is established, and there is no further increase in the amount of solute in solution. ∞ (Section 4.1)

Nickel metal and hydrochloric acid

Nickel reacts with hydrochloric acid, forming  $\text{NiCl}_2(aq)$  and  $\text{H}_2(g)$ . The solution is of  $\text{NiCl}_2$ , not Ni metal

$\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}(s)$  remains when solvent evaporated

▲ **Figure 13.6** The reaction between nickel metal and hydrochloric acid is *not* a simple dissolution. The product is  $\text{NiCl}_2 \cdot 6 \text{H}_2\text{O}(s)$ , nickel(II) chloride hexahydrate, which has exactly 6 waters of hydration in the crystal lattice for every nickel ion.

A solution that is in equilibrium with undissolved solute is **saturated**. Additional solute will not dissolve if added to a saturated solution. The amount of solute needed to form a saturated solution in a given quantity of solvent is known as the **solubility** of that solute. That is,

*the solubility of a particular solute in a particular solvent is the maximum amount of the solute that can dissolve in a given amount of the solvent at a specified temperature, assuming that excess solute is present.*

For example, the solubility of NaCl in water at 0 °C is 35.7 g per 100 mL of water. This is the maximum amount of NaCl that can be dissolved in water to give a stable equilibrium solution at that temperature.

If we dissolve less solute than the amount needed to form a saturated solution, the solution is **unsaturated**. Thus, a solution containing 10.0 g of NaCl per 100 mL of water at 0 °C is unsaturated because it has the capacity to dissolve more solute.

Under suitable conditions, it is possible to form solutions that contain a greater amount of solute than needed to form a saturated solution. Such solutions are **supersaturated**. For example, when a saturated solution of sodium acetate is made at a high temperature and then slowly cooled, all of the solute may remain dissolved even though its solubility decreases as the temperature decreases. Because the solute in a supersaturated solution is present in a concentration higher than the equilibrium concentration, supersaturated solutions are unstable with respect to crystallization of the solute. For crystallization to occur, however, the solute particles must arrange themselves properly to form crystals. The addition of a small crystal of the solute (a seed crystal) provides a template for crystallization of the excess solute, leading to a saturated solution in contact with excess solid (Figure 13.7).

### Give It Some Thought

What happens if a solute is added to a saturated solution?

### Go Figure

How many grams of sodium acetate are in solution in the third beaker?

Amount of sodium acetate dissolved is greater than its solubility at this temperature.

1 Seed crystal of sodium acetate is added to supersaturated solution.

2 Excess sodium acetate starts to crystallize from solution.

3 Solution is saturated and excess solute has crystallized.

▲ **Figure 13.7** Precipitation from a supersaturated sodium acetate solution. The solution on the left was formed by dissolving about 170 g of the salt in 100 mL of water at 100 °C and then slowly cooling it to 20 °C. Because the solubility of sodium acetate in water at 20 °C is 46 g per 100 mL of water, the solution is supersaturated. Addition of a sodium acetate crystal causes the excess solute to crystallize from solution.

**TABLE 13.1** Solubilities of Gases in Water at 20 °C, at 1 atm Gas Pressure

| Gas            | Molar Mass (g/mol) | Solubility (M)        |
|----------------|--------------------|-----------------------|
| N <sub>2</sub> | 28.0               | $0.69 \times 10^{-3}$ |
| O <sub>2</sub> | 32.0               | $1.38 \times 10^{-3}$ |
| Ar             | 39.9               | $1.50 \times 10^{-3}$ |
| Kr             | 83.8               | $2.79 \times 10^{-3}$ |

## 13.3 | Factors Affecting Solubility

The extent to which one substance dissolves in another depends on the nature of both substances. [∞ \(Section 13.1\)](#) It also depends on temperature and, at least for gases, on pressure.

### Solute–Solvent Interactions

The natural tendency of substances to mix and the various interactions among solute and solvent particles are all involved in determining solubilities. Nevertheless, insight into variations in solubility can often be gained by focusing on the interaction between the solute and solvent. The data in [Table 13.1](#) show that the solubilities of various gases in water increase with increasing molecular mass. The attractive forces between the gas molecules and solvent molecules are mainly dispersion forces, which increase with increasing size and molecular mass. [∞ \(Section 11.2\)](#) Thus, the data indicate that the solubilities of gases in water increase as the attraction between solute (gas) and solvent (water) increases. In general, when other factors are comparable, *the stronger the attractions between solute and solvent molecules, the greater the solubility of the solute in that solvent.*

Because of favorable dipole–dipole attractions between polar solvent molecules and polar solute molecules, *polar liquids tend to dissolve in polar solvents.* Water is both polar and able to form hydrogen bonds. [∞ \(Section 11.2\)](#) Thus, polar molecules, especially those that can form hydrogen bonds with water molecules, tend to be soluble in water. For example, acetone, a polar molecule with the structural formula shown below, mixes in all proportions with water. Acetone has a strongly polar C=O bond and pairs of nonbonding electrons on the O atom that can form hydrogen bonds with water.

Acetone

Liquids that mix in all proportions, such as acetone and water, are **miscible**, whereas those that do not dissolve in one another are **immiscible**. Gasoline, which is a mixture of hydrocarbons, is immiscible with water. Hydrocarbons are nonpolar substances because of several factors: The C—C bonds are nonpolar, the C—H bonds are nearly nonpolar, and the molecules are symmetrical enough to cancel much of the weak C—H bond dipoles. The attraction between the polar water molecules and the nonpolar hydrocarbon molecules is not sufficiently strong to allow the formation of a solution. *Nonpolar liquids tend to be insoluble in polar liquids*, as [Figure 13.8](#) shows for hexane (C<sub>6</sub>H<sub>14</sub>) and water.

Many organic compounds have polar groups attached to a nonpolar framework of carbon and hydrogen atoms. For example, the series of organic compounds in [Table 13.2](#) all contain the polar OH group. Organic compounds with this molecular feature are called *alcohols*. The O—H bond is able to form hydrogen bonds. For example, ethanol (CH<sub>3</sub>CH<sub>2</sub>OH) molecules can form hydrogen bonds with water molecules as well as with each other ([Figure 13.9](#)). As a result, the solute–solute, solvent–solvent, and solute–solvent forces are not greatly different in a mixture of CH<sub>3</sub>CH<sub>2</sub>OH and H<sub>2</sub>O. No major change occurs in the environments of the molecules as they are mixed. Therefore, the increased entropy when the components mix plays a significant role in solution formation, and ethanol is completely miscible with water.

Notice in [Table 13.2](#) that the number of carbon atoms in an alcohol affects its solubility in water. As this number increases, the polar OH group becomes an even smaller part of the molecule, and the molecule behaves more like a hydrocarbon. The solubility

▲ **Figure 13.8** Hexane, a hydrocarbon, is immiscible with water. Hexane is the top layer because it is less dense than water.

**TABLE 13.2 Solubilities of Some Alcohols in Water and in Hexane\***

| Alcohol  | Solubility in H <sub>2</sub> O | Solubility in C <sub>6</sub> H <sub>14</sub> |
|--|--------------------------------|--|
| CH <sub>3</sub> OH (methanol)  | ∞                              | 0.12   |
| CH <sub>3</sub> CH <sub>2</sub> OH (ethanol)   | ∞                              | ∞  |
| CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> OH (propanol)  | ∞                              | ∞  |
| CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH (butanol)                                 | 0.11                           | ∞  |
| CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH (pentanol)                | 0.030                          | ∞  |
| CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH (hexanol) | 0.0058                         | ∞  |

\*Expressed in mol alcohol/100 g solvent at 20 °C. The infinity symbol (∞) indicates that the alcohol is completely miscible with the solvent.

▲ **Figure 13.9** Hydrogen bonding involving OH groups.

of the alcohol in water decreases correspondingly. On the other hand, the solubility of alcohols in a nonpolar solvent like hexane (C<sub>6</sub>H<sub>14</sub>) increases as the nonpolar hydrocarbon chain lengths.

One way to enhance the solubility of a substance in water is to increase the number of polar groups the substance contains. For example, increasing the number of OH groups in a solute increases the extent of hydrogen bonding between that solute and water, thereby increasing solubility. Glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>, **Figure 13.10**) has five OH groups on a six-carbon framework, which makes the molecule very soluble in water: 830 g dissolves in 1.00 L of water at 17.5 °C. In contrast, cyclohexane (C<sub>6</sub>H<sub>12</sub>), which has a similar structure to glucose but with all of the OH groups replaced by H, is essentially insoluble in water (only 55 mg of cyclohexane can dissolve in 1.00 L of water at 25 °C).

Over years of study, examination of different solvent–solute combinations has led to an important generalization:

*Substances with similar intermolecular attractive forces tend to be soluble in one another.*

▲ **Figure 13.10** The correlation of molecular structure with solubility.

## CHEMISTRY AND LIFE Fat-Soluble and Water-Soluble Vitamins

Vitamins have unique chemical structures that affect their solubilities in different parts of the human body. Vitamin C and the B vitamins are soluble in water, for example, whereas vitamins A, D, E, and K are soluble in nonpolar solvents and in fatty tissue (which is nonpolar). Because of their water solubility, vitamins B and C are not stored to any appreciable extent in the body, and so foods containing these vitamins should be included in the daily diet. In contrast, the fat-soluble vitamins are stored in sufficient quantities to keep vitamin-deficiency diseases from appearing even after a person has subsisted for a long period on a vitamin-deficient diet.

That some vitamins are soluble in water and others are not can be explained in terms of their structures. Notice in **Figure 13.11** that vitamin A (retinol) is an alcohol with a very long carbon chain. Because the OH group is such a small part of the molecule, the molecule resembles the long-chain alcohols listed in Table 13.2. This vitamin is nearly nonpolar. In contrast, the vitamin C molecule is smaller and has several OH groups that can form hydrogen bonds with water, somewhat like glucose.

**Related Exercises:** 13.7, 13.48

*Continued*

▲ Figure 13.11 The molecular structures of vitamins A and C.

This generalization is often simply stated as “*like dissolves like*.” Nonpolar substances are more likely to be soluble in nonpolar solvents; ionic and polar solutes are more likely to be soluble in polar solvents. Network solids such as diamond and quartz are not soluble in either polar or nonpolar solvents because of the strong bonding within the solid.

### Give It Some Thought

Suppose the hydrogens on the OH groups in glucose (Figure 13.10) were replaced with methyl groups, CH<sub>3</sub>. Would you expect the water solubility of the resulting molecule to be higher than, lower than, or about the same as glucose?

## Pressure Effects

The solubilities of solids and liquids are not appreciably affected by pressure, whereas *the solubility of a gas in any solvent is increased as the partial pressure of the gas above the solvent increases*. We can understand the effect of pressure on gas solubility by considering

## Sample Exercise 13.1

### Predicting Solubility Patterns

Predict whether each of the following substances is more likely to dissolve in the nonpolar solvent carbon tetrachloride (CCl<sub>4</sub>) or in water: C<sub>7</sub>H<sub>16</sub>, Na<sub>2</sub>SO<sub>4</sub>, HCl, and I<sub>2</sub>.

### SOLUTION

**Analyze** We are given two solvents, one that is nonpolar (CCl<sub>4</sub>) and the other that is polar (H<sub>2</sub>O), and asked to determine which will be the better solvent for each solute listed.

**Plan** By examining the formulas of the solutes, we can predict whether they are ionic or molecular. For those that are molecular, we can predict whether they are polar or nonpolar. We can then apply the idea that the nonpolar solvent will be better for the nonpolar solutes, whereas the polar solvent will be better for the ionic and polar solutes.

**Solve** C<sub>7</sub>H<sub>16</sub> is a hydrocarbon, so it is molecular and nonpolar. Na<sub>2</sub>SO<sub>4</sub>, a compound containing a metal and nonmetals, is ionic.

HCl, a diatomic molecule containing two nonmetals that differ in electronegativity, is polar. I<sub>2</sub>, a diatomic molecule with atoms of equal electronegativity, is nonpolar. We would therefore predict that C<sub>7</sub>H<sub>16</sub> and I<sub>2</sub> (the nonpolar solutes) would be more soluble in the nonpolar CCl<sub>4</sub> than in polar H<sub>2</sub>O, whereas water would be the better solvent for Na<sub>2</sub>SO<sub>4</sub> and HCl (the ionic and polar covalent solutes).

### Practice Exercise 1

Which of the following solvents will best dissolve wax, which is a complex mixture of compounds that mostly are CH<sub>3</sub>–CH<sub>2</sub>–CH<sub>2</sub>–CH<sub>2</sub>–CH<sub>2</sub>–?

### Practice Exercise 2

Arrange the following substances in order of increasing solubility in water:

**Figure 13.12**, which shows carbon dioxide gas distributed between the gas and solution phases. When equilibrium is established, the rate at which gas molecules enter the solution equals the rate at which solute molecules escape from the solution to enter the gas phase. The equal number of up and down arrows in the left container in Figure 13.12 represent these opposing processes.

Now suppose we exert greater pressure on the piston and compress the gas above the solution, as shown in the middle container in Figure 13.12. If we reduce the gas volume to half its original value, the pressure of the gas increases to about twice its original value. As a result of this pressure increase, the rate at which gas molecules strike the liquid surface and enter the solution phase increases. Thus, the solubility of the gas in the solution increases until equilibrium is again established; that is, solubility increases until the rate at which gas molecules enter the solution equals the rate at which they

### Go Figure

If the partial pressure of a gas over a solution is doubled, how has the concentration of gas in the solution changed after equilibrium is restored?

▲ **Figure 13.12** Effect of pressure on gas solubility.

### Go Figure

Does the gas with the largest molar mass have the highest or lowest solubility in water?

▲ **Figure 13.13** The solubility of a gas in water is directly proportional to the partial pressure of the gas. The solubilities are in millimoles of gas per liter of solution.

escape from the solution. Thus, *the solubility of a gas in a liquid solvent increases in direct proportion to the partial pressure of the gas above the solution* (Figure 13.13).

The relationship between pressure and gas solubility is expressed by **Henry's law**:

$$S_g = kP_g \quad [13.4]$$

Here,  $S_g$  is the solubility of the gas in the solvent (usually expressed as molarity),  $P_g$  is the partial pressure of the gas over the solution, and  $k$  is a proportionality constant known as the *Henry's law constant*. The value of this constant depends on the solute, solvent, and temperature. As an example, the solubility of  $N_2$  gas in water at 25 °C and 0.78 atm pressure is  $4.75 \times 10^{-4} M$ . The Henry's law constant for  $N_2$  in 25 °C water is thus  $(4.75 \times 10^{-4} \text{ mol/L}) / (0.78 \text{ atm}) = 6.1 \times 10^{-4} \text{ mol/L}\cdot\text{atm}$ . If the partial pressure of  $N_2$  is doubled, Henry's law predicts that the solubility in water at 25 °C also doubles to  $9.50 \times 10^{-4} M$ .

Bottlers use the effect of pressure on solubility in producing carbonated beverages, which are bottled under a carbon dioxide pressure greater than 1 atm. When the bottles are opened to the air, the partial pressure of  $CO_2$  above the solution decreases. Hence, the solubility of  $CO_2$  decreases, and  $CO_2(g)$  escapes from the solution as bubbles (Figure 13.14).

▲ **Figure 13.14** Gas solubility decreases as pressure decreases.  $CO_2$  bubbles out of solution when a carbonated beverage is opened because the  $CO_2$  partial pressure above the solution is reduced.

## Sample Exercise 13.2

### A Henry's Law Calculation

Calculate the concentration of  $CO_2$  in a soft drink that is bottled with a partial pressure of  $CO_2$  of 4.0 atm over the liquid at 25 °C. The Henry's law constant for  $CO_2$  in water at this temperature is  $3.4 \times 10^{-2} \text{ mol/L}\cdot\text{atm}$ .

### SOLUTION

**Analyze** We are given the partial pressure of  $CO_2$ ,  $P_{CO_2}$ , and the Henry's law constant,  $k$ , and asked to calculate the concentration of  $CO_2$  in the solution.

**Plan** With the information given, we can use Henry's law, Equation 13.4, to calculate the solubility,  $S_{CO_2}$ .

**Solve**  $S_{CO_2} = kP_{CO_2} = (3.4 \times 10^{-2} \text{ mol/L}\cdot\text{atm})(4.0 \text{ atm})$   
 $= 0.14 \text{ mol/L} = 0.14 M$

**Check** The units are correct for solubility, and the answer has two significant figures consistent with both the partial pressure of  $CO_2$  and the value of the Henry's law constant.

### Practice Exercise 1

You double the partial pressure of a gas over a liquid at constant temperature. Which of these statements is then true?

- The Henry's law constant is doubled.
- The Henry's law constant is decreased by half.
- There are half as many gas molecules in the liquid.
- There are twice as many gas molecules in the liquid.
- There is no change in the number of gas molecules in the liquid.

### Practice Exercise 2

Calculate the concentration of  $CO_2$  in a soft drink after the bottle is opened and the solution equilibrates at 25 °C under a  $CO_2$  partial pressure of  $3.0 \times 10^{-4} \text{ atm}$ .

## Go Figure

How does the solubility of KCl at 80 °C compare with that of NaCl at the same temperature?

▲ **Figure 13.15** Solubilities of some ionic compounds in water as a function of temperature.

## Go Figure

Between which two gases would you expect  $N_2$  to fit on this graph?

▲ **Figure 13.16** Solubilities of four gases in water as a function of temperature. The solubilities are in millimoles per liter of solution, for a constant total pressure of 1 atm in the gas phase.

## Temperature Effects

The solubility of most solid solutes in water increases as the solution temperature increases, as **Figure 13.15** shows. There are exceptions to this rule, however, as seen for  $Ce_2(SO_4)_3$ , whose solubility curve slopes downward with increasing temperature.

In contrast to solid solutes, the solubility of gases in water decreases with increasing temperature (**Figure 13.16**). If a glass of cold tap water is warmed, you can see bubbles on the inside of the glass because some of the dissolved air comes out of solution.

Similarly, as carbonated beverages are allowed to warm, the solubility of  $CO_2$  decreases, and  $CO_2(g)$  escapes from the solution.

## CHEMISTRY AND LIFE Blood Gases and Deep-Sea Diving

Because gas solubility increases with increasing pressure, divers who breathe compressed air (**Figure 13.17**) must be concerned about the solubility of gases in their blood. Although the gases are not very soluble at sea level, their solubilities can be appreciable at deep levels where their partial pressures are greater. Thus, divers must ascend slowly to prevent dissolved gases from being released rapidly from solution and forming bubbles in the blood and other fluids in the body. These bubbles affect nerve impulses and cause decompression sickness, or “the bends,” which is a painful and potentially fatal condition. Nitrogen is the main problem because it is the most abundant gas in air and because it can be removed from the body only through the respiratory system. Oxygen, in contrast, is consumed in metabolism.

Deep-sea divers sometimes substitute helium for nitrogen in the air they breathe because helium has a much lower solubility in biological fluids than  $N_2$ . For example, divers working at a depth of 100 ft experience a pressure of about 4 atm. At this pressure, a mixture of 95% helium and 5% oxygen gives an oxygen partial pressure of about 0.2 atm, which is the partial pressure of oxygen in normal air at 1 atm.

▲ **Figure 13.17** Gas solubility increases as pressure increases. Divers who use compressed gases must be concerned about the solubility of the gases in their blood.

If the oxygen partial pressure becomes too great, the urge to breathe is reduced,  $CO_2$  is not removed from the body, and  $CO_2$  poisoning occurs. At excessive concentrations in the body, carbon dioxide acts as a neurotoxin, interfering with nerve conduction and transmission.

**Related Exercises:** 13.59, 13.60, 13.107

If you think about it, you can rationalize why the solubilities of gases and ionic solids in water respond differently to temperature. As you heat an aqueous solution that contains a gas, you give enough energy to the gas particles for them to escape from the solution and go into the gas phase. Thus, increasing temperature reduces the solubility of the gas. On the other hand, if you heat up a mixture of water and an ionic solid, you give energy to the solid so it can break into its constituent ions that are then hydrated by water. Thus, increasing temperature increases the solubility of the ionic solid.

## 13.4 | Expressing Solution Concentration

The concentration of a solution can be expressed either qualitatively or quantitatively. The terms *dilute* and *concentrated* are used to describe a solution qualitatively. A solution with a relatively small concentration of solute is said to be dilute; one with a large concentration is said to be concentrated. Chemists use various ways to express concentration quantitatively, and we examine several of these next.

### Mass Percentage, ppm, and ppb

One of the simplest quantitative expressions of concentration is the **mass percentage** of a component in a solution, given by

$$\text{Mass \% of component} = \frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 100 \quad [13.5]$$

Because *percent* means “per hundred,” a solution of hydrochloric acid that is 36% HCl by mass contains 36 g of HCl for each 100 g of solution.

We often express the concentration of very dilute solutions in **parts per million (ppm)** or **parts per billion (ppb)**. These quantities are similar to mass percentage but use  $10^6$  (a million) or  $10^9$  (a billion), respectively, in place of 100, as a multiplier for the ratio of the mass of solute to the mass of solution. Thus, parts per million is defined as

$$\text{ppm of component} = \frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 10^6 \quad [13.6]$$

A solution whose solute concentration is 1 ppm contains 1 g of solute for each million ( $10^6$ ) grams of solution or, equivalently, 1 mg of solute per kilogram of solution. Because the density of water is 1 g/mL, 1 kg of a dilute aqueous solution has a volume very close to 1 L. Thus, 1 ppm also corresponds to 1 mg of solute per liter of aqueous solution.

The acceptable maximum concentrations of toxic or carcinogenic substances in the environment are often expressed in ppm or ppb. For example, the maximum allowable concentration of arsenic in drinking water in the United States is 0.010 ppm; that is, 0.010 mg of arsenic per liter of water. This concentration corresponds to 10 ppb.

#### Give It Some Thought

A solution of  $\text{SO}_2$  in water contains 0.00023 g of  $\text{SO}_2$  per liter of solution. What is the concentration of  $\text{SO}_2$  in ppm? In ppb?

### Sample Exercise 13.3

#### Calculation of Mass-Related Concentrations

- A solution is made by dissolving 13.5 g of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 0.100 kg of water. What is the mass percentage of solute in this solution?
- A 2.5-g sample of groundwater was found to contain  $5.4 \mu\text{g}$  of  $\text{Zn}^{2+}$ . What is the concentration of  $\text{Zn}^{2+}$  in parts per million?

**SOLUTION**

**(a) Analyze** We are given the number of grams of solute (13.5 g) and the number of grams of solvent (0.100 kg = 100 g). From this, we must calculate the mass percentage of solute.

**Plan** We can calculate the mass percentage by using Equation 13.5. The mass of the solution is the sum of the mass of solute (glucose) and the mass of solvent (water).

$$\begin{aligned}\text{Solve Mass \% of glucose} &= \frac{\text{mass glucose}}{\text{mass soln}} \times 100 \\ &= \frac{13.5 \text{ g}}{(13.5 + 100) \text{ g}} \times 100 = 11.9\%\end{aligned}$$

**Comment** The mass percentage of water in this solution is  $(100 - 11.9)\% = 88.1\%$ .

**(b) Analyze** In this case we are given the number of micrograms of solute. Because  $1 \mu\text{g}$  is  $1 \times 10^{-6} \text{ g}$ ,  $5.4 \mu\text{g} = 5.4 \times 10^{-6} \text{ g}$ .

**Plan** We calculate the parts per million using Equation 13.6.

$$\begin{aligned}\text{Solve ppm} &= \frac{\text{mass of solute}}{\text{mass of soln}} \times 10^6 \\ &= \frac{5.4 \times 10^{-6} \text{ g}}{2.5 \text{ g}} \times 10^6 = 2.2 \text{ ppm}\end{aligned}$$

**► Practice Exercise 1**

Calculate the mass percentage of NaCl in a solution containing 1.50 g of NaCl in 50.0 g of water.

(a) 0.0291% (b) 0.0300% (c) 0.0513% (d) 2.91% (e) 3.00%

**► Practice Exercise 2**

A commercial bleaching solution contains 3.62% by mass of sodium hypochlorite, NaOCl. What is the mass of NaOCl in a bottle containing 2.50 kg of bleaching solution?

**Mole Fraction, Molarity, and Molality**

Concentration expressions are often based on the number of moles of one or more components of the solution. Recall from Section 10.6 that the *mole fraction* of a component of a solution is given by

$$\text{Mole fraction of component} = \frac{\text{moles of component}}{\text{total moles of all components}} \quad [13.7]$$

The symbol  $X$  is commonly used for mole fraction, with a subscript to indicate the component of interest. For example, the mole fraction of HCl in a hydrochloric acid solution is represented as  $X_{\text{HCl}}$ . Thus, if a solution contains 1.00 mol of HCl (36.5 g) and 8.00 mol of water (144 g), the mole fraction of HCl is  $X_{\text{HCl}} = (1.00 \text{ mol}) / (1.00 \text{ mol} + 8.00 \text{ mol}) = 0.111$ . Mole fractions have no units because the units in the numerator and the denominator cancel. The sum of the mole fractions of all components of a solution must equal 1. Thus, in the aqueous HCl solution,  $X_{\text{H}_2\text{O}} = 1.000 - 0.111 = 0.889$ . Mole fractions are very useful when dealing with gases, as we saw in Section 10.6, but have limited use when dealing with liquid solutions.

Recall from Section 4.5 that the *molarity* ( $M$ ) of a solute in a solution is defined as

$$\text{Molarity} = \frac{\text{moles of solute}}{\text{liters of soln}} \quad [13.8]$$

For example, if you dissolve 0.500 mol of  $\text{Na}_2\text{CO}_3$  in enough water to form 0.250 L of solution, the molarity of  $\text{Na}_2\text{CO}_3$  in the solution is  $(0.500 \text{ mol}) / (0.250 \text{ L}) = 2.00 \text{ M}$ . Molarity is especially useful for relating the volume of a solution to the quantity of solute contained in that volume, as we saw in our discussions of titrations. [∞∞ \(Section 4.6\)](#)

The **molality** of a solution, denoted  $m$ , is a concentration unit that is also based on moles of solute. Molality equals the number of moles of solute per kilogram of solvent:

$$\text{Molality} = \frac{\text{moles of solute}}{\text{kilograms of solvent}} \quad [13.9]$$

Thus, if you form a solution by mixing 0.200 mol of NaOH (8.00 g) and 0.500 kg of water (500 g), the concentration of the solution is  $(0.200 \text{ mol}) / (0.500 \text{ kg}) = 0.400 \text{ m}$  (that is, 0.400 molal) in NaOH.

The definitions of molarity and molality are similar enough that they can be easily confused.

- Molarity depends on the *volume of solution*.
- Molality depends on the *mass of solvent*.

When water is the solvent, the molality and molarity of dilute solutions are numerically about the same because 1 kg of solvent is nearly the same as 1 kg of solution, and 1 kg of the solution has a volume of about 1 L.

The molality of a given solution does not vary with temperature because masses do not vary with temperature. The molarity of the solution does change with temperature, however, because the volume of the solution expands or contracts with temperature. Thus, molality is often the concentration unit of choice when a solution is to be used over a range of temperatures.

### Give It Some Thought

If an aqueous solution is very dilute, will its molality be greater than its molarity, nearly the same as its molarity, or smaller than its molarity?

## Sample Exercise 13.4

### Calculation of Molality

A solution is made by dissolving 4.35 g of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 25.0 mL of water at 25 °C. Calculate the molality of glucose in the solution. Water has a density of 1.00 g/mL.

### SOLUTION

**Analyze** We are asked to calculate a solution concentration in units of molality. To do this, we must determine the number of moles of solute (glucose) and the number of kilograms of solvent (water).

**Plan** We use the molar mass of  $\text{C}_6\text{H}_{12}\text{O}_6$  to convert grams of glucose to moles. We use the density of water to convert milliliters of water to kilograms. The molality equals the number of moles of solute (glucose) divided by the number of kilograms of solvent (water).

### Solve

Use the molar mass of glucose, 180.2 g/mol, to convert grams to moles:

$$\text{Mol C}_6\text{H}_{12}\text{O}_6 = (4.35 \text{ g C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.2 \text{ g C}_6\text{H}_{12}\text{O}_6} \right) = 0.0241 \text{ mol C}_6\text{H}_{12}\text{O}_6$$

Because water has a density of 1.00 g/mL, the mass of the solvent is:

$$(25.0 \text{ mL})(1.00 \text{ g/mL}) = 25.0 \text{ g} = 0.0250 \text{ kg}$$

Finally, use Equation 13.9 to obtain the molality:

$$\text{Molality of C}_6\text{H}_{12}\text{O}_6 = \frac{0.0241 \text{ mol C}_6\text{H}_{12}\text{O}_6}{0.0250 \text{ kg H}_2\text{O}} = 0.964 \text{ m}$$

### Practice Exercise 1

Suppose you take a solution and add more solvent, so that the original mass of solvent is doubled. You take this new solution and add more solute, so that the original mass of the solute is doubled. What happens to the molality of the final solution, compared to the original molality?

- (a) It is doubled.
- (b) It is decreased by half.
- (c) It is unchanged.

- (d) It will increase or decrease depending on the molar mass of the solute.
- (e) There is no way to tell without knowing the molar mass of the solute.

### Practice Exercise 2

What is the molality of a solution made by dissolving 36.5 g of naphthalene ( $\text{C}_{10}\text{H}_8$ ) in 425 g of toluene ( $\text{C}_7\text{H}_8$ )?

## Converting Concentration Units

If you follow the dimensional analysis techniques you learned in Chapter 1, you can convert between concentration units, as shown in Sample Exercise 13.5. To convert between molality and molarity, the density of the solution will be needed, as in Sample Exercise 13.6.

## Sample Exercise 13.5

### Calculation of Mole Fraction and Molality

An aqueous solution of hydrochloric acid contains 36% HCl by mass. (a) Calculate the mole fraction of HCl in the solution. (b) Calculate the molality of HCl in the solution.

### SOLUTION

**Analyze** We are asked to calculate the concentration of the solute, HCl, in two related concentration units, given only the percentage by mass of the solute in the solution.

**Plan** In converting concentration units based on the mass or moles of solute and solvent (mass percentage, mole fraction, and molality), it is useful to assume a certain total mass of

solution. Let's assume that there is exactly 100 g of solution. Because the solution is 36% HCl, it contains 36 g of HCl and  $(100 - 36) \text{ g} = 64 \text{ g}$  of  $\text{H}_2\text{O}$ . We must convert grams of solute

(HCl) to moles to calculate either mole fraction or molality. We must convert grams of solvent ( $\text{H}_2\text{O}$ ) to moles to calculate mole fractions and to kilograms to calculate molality.

### Solve

- (a) To calculate the mole fraction of HCl, we convert the masses of HCl and  $\text{H}_2\text{O}$  to moles and then use Equation 13.7:

$$\text{Moles HCl} = (36 \text{ g HCl}) \left( \frac{1 \text{ mol HCl}}{36.5 \text{ g HCl}} \right) = 0.99 \text{ mol HCl}$$

$$\text{Moles H}_2\text{O} = (64 \text{ g H}_2\text{O}) \left( \frac{1 \text{ mol H}_2\text{O}}{18 \text{ g H}_2\text{O}} \right) = 3.6 \text{ mol H}_2\text{O}$$

$$X_{\text{HCl}} = \frac{\text{moles HCl}}{\text{moles H}_2\text{O} + \text{moles HCl}} = \frac{0.99}{3.6 + 0.99} = \frac{0.99}{4.6} = 0.22$$

- (b) To calculate the molality of HCl in the solution, we use Equation 13.9. We calculated the number of moles of HCl in part (a), and the mass of solvent is  $64 \text{ g} = 0.064 \text{ kg}$ :

$$\text{Molality of HCl} = \frac{0.99 \text{ mol HCl}}{0.064 \text{ kg H}_2\text{O}} = 15 \text{ m}$$

Notice that we can't readily calculate the molarity of the solution because we don't know the volume of the 100 g of solution.

### Practice Exercise 1

The solubility of oxygen gas in water at  $40^\circ\text{C}$  is 1.0 mmol per liter of solution. What is this concentration in units of mole fraction?

- (a)  $1.00 \times 10^{-6}$  (b)  $1.80 \times 10^{-5}$  (c)  $1.00 \times 10^{-2}$   
(d)  $1.80 \times 10^{-2}$  (e)  $5.55 \times 10^{-2}$

### Practice Exercise 2

A commercial bleach solution contains 3.62% by mass of NaOCl in water. Calculate (a) the mole fraction and (b) the molality of NaOCl in the solution.

## Sample Exercise 13.6

### Calculation of Molarity Using the Density of the Solution

A solution with a density of  $0.876 \text{ g/mL}$  contains  $5.0 \text{ g}$  of toluene ( $\text{C}_7\text{H}_8$ ) and  $225 \text{ g}$  of benzene. Calculate the molarity of the solution.

### SOLUTION

**Analyze** Our goal is to calculate the molarity of a solution, given the masses of solute ( $5.0 \text{ g}$ ) and solvent ( $225 \text{ g}$ ) and the density of the solution ( $0.876 \text{ g/mL}$ ).

**Plan** The molarity of a solution is the number of moles of solute divided by the number of liters of solution (Equation 13.8). The number of moles of solute ( $\text{C}_7\text{H}_8$ ) is calculated from the number of grams of solute and its molar mass. The volume of the solution is obtained from the mass of the solution (mass of solution = mass of solute + mass of solvent =  $5.0 \text{ g} + 225 \text{ g} = 230 \text{ g}$ ) and its density.

### Solve

The number of moles of solute is:

$$\text{Moles C}_7\text{H}_8 = (5.0 \text{ g C}_7\text{H}_8) \left( \frac{1 \text{ mol C}_7\text{H}_8}{92 \text{ g C}_7\text{H}_8} \right) = 0.054 \text{ mol}$$

The density of the solution is used to convert the mass of the solution to its volume:

$$\text{Milliliters soln} = (230 \text{ g}) \left( \frac{1 \text{ mL}}{0.876 \text{ g}} \right) = 263 \text{ mL}$$

Molarity is moles of solute per liter of solution:

$$\text{Molarity} = \left( \frac{\text{moles C}_7\text{H}_8}{\text{liter soln}} \right) = \left( \frac{0.054 \text{ mol C}_7\text{H}_8}{263 \text{ mL soln}} \right) \left( \frac{1000 \text{ mL soln}}{1 \text{ L soln}} \right) = 0.21 \text{ M}$$

**Check** The magnitude of our answer is reasonable. Rounding moles to 0.05 and liters to 0.25 gives a molarity of  $(0.05 \text{ mol})/(0.25 \text{ L}) = 0.2 \text{ M}$ .

The units for our answer ( $\text{mol/L}$ ) are correct, and the answer, 0.21, has two significant figures, corresponding to the number of significant figures in the mass of solute (2).

**Comment** Because the mass of the solvent (0.225 kg) and the volume of the solution (0.263) are similar in magnitude, the molarity and molality are also similar in magnitude:  $(0.054 \text{ mol C}_7\text{H}_8)/(0.225 \text{ kg solvent}) = 0.24 \text{ m}$ .

### Practice Exercise 1

Maple syrup has a density of  $1.325 \text{ g/mL}$ , and  $100.00 \text{ g}$  of maple syrup contains  $67 \text{ mg}$  of calcium in the form of  $\text{Ca}^{2+}$  ions. What is the molarity of calcium in maple syrup?

- (a)  $0.017 \text{ M}$  (b)  $0.022 \text{ M}$  (c)  $0.89 \text{ M}$  (d)  $12.6 \text{ M}$  (e)  $45.4 \text{ M}$

### Practice Exercise 2

A solution containing equal masses of glycerol ( $\text{C}_3\text{H}_8\text{O}_3$ ) and water has a density of  $1.10 \text{ g/mL}$ . Calculate (a) the molality of glycerol, (b) the mole fraction of glycerol, (c) the molarity of glycerol in the solution.

## 13.5 | Colligative Properties

Some physical properties of solutions differ in important ways from those of the pure solvent. For example, pure water freezes at 0 °C, but aqueous solutions freeze at lower temperatures. We apply this behavior when we add ethylene glycol antifreeze to a car's radiator to lower the freezing point of the solution. The added solute also raises the boiling point of the solution above that of pure water, making it possible to operate the engine at a higher temperature.

Lowering of the freezing point and raising of the boiling point are physical properties of solutions that depend on the *quantity* (concentration) but not on the *kind* or *identity* of the solute particles. Such properties are called **colligative properties**. (*Colligative* means “depending on the collection”; colligative properties depend on the collective effect of the number of solute particles.)

In addition to freezing-point lowering and boiling-point raising, two other important colligative properties are vapor–pressure lowering and osmotic pressure. As we examine each one, notice how solute concentration quantitatively affects the property.

### Vapor–Pressure Lowering

A liquid in a closed container establishes equilibrium with its vapor.  (Section 11.5) The *vapor pressure* is the pressure exerted by the vapor when it is at equilibrium with the liquid (that is, when the rate of vaporization equals the rate of condensation). A substance that has no measurable vapor pressure is *nonvolatile*, whereas one that exhibits a vapor pressure is *volatile*.

A solution consisting of a *volatile* liquid solvent and a *nonvolatile* solute forms spontaneously because of the increase in entropy that accompanies their mixing. In effect, the solvent molecules are stabilized in their liquid state by this process and thus have a lower tendency to escape into the vapor state. Therefore, when a *nonvolatile* solute is present, the vapor pressure of the solvent is lower than the vapor pressure of the pure solvent, as illustrated in Figure 13.18.

Ideally, the vapor pressure of a *volatile* solvent above a solution containing a *nonvolatile* solute is proportional to the solvent's concentration in the solution. This relationship is expressed quantitatively by **Raoult's law**, which states that the partial pressure exerted by solvent vapor above the solution,  $P_{\text{solution}}$ , equals the product of the mole fraction of the solvent,  $X_{\text{solvent}}$ , times the vapor pressure of the pure solvent,  $P_{\text{solvent}}^{\circ}$ :

$$P_{\text{solution}} = X_{\text{solvent}} P_{\text{solvent}}^{\circ} \quad [13.10]$$

For example, the vapor pressure of pure water at 20 °C is  $P_{\text{H}_2\text{O}}^{\circ} = 17.5$  torr. Imagine holding the temperature constant while adding glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) to the water so that the mole fractions in the resulting solution are  $X_{\text{H}_2\text{O}} = 0.800$  and  $X_{\text{C}_6\text{H}_{12}\text{O}_6} = 0.200$ .

► **Figure 13.18** Vapor–pressure lowering. The presence of nonvolatile solute particles in a liquid solvent results in a reduction of the vapor pressure above the liquid.

According to Equation 13.10, the vapor pressure of the water above this solution is 80.0% of that of pure water:

$$P_{\text{solution}} = (0.800)(17.5 \text{ torr}) = 14.0 \text{ torr}$$

The presence of the *nonvolatile* solute lowers the vapor pressure of the *volatile* solvent by  $17.5 \text{ torr} - 14.0 \text{ torr} = 3.5 \text{ torr}$ .

The vapor-pressure lowering,  $\Delta P$ , is directly proportional to the mole fraction of the solute,  $X_{\text{solute}}$ :

$$\Delta P = X_{\text{solute}} P_{\text{solvent}}^{\circ} \quad [13.11]$$

Thus, for the example of the solution of glucose in water, we have

$$\Delta P = X_{\text{C}_6\text{H}_{12}\text{O}_6} P_{\text{H}_2\text{O}}^{\circ} = (0.200)(17.5 \text{ torr}) = 3.50 \text{ torr}$$

The vapor-pressure lowering caused by adding a *nonvolatile* solute depends on the total concentration of solute particles, regardless of whether they are molecules or ions. Remember that vapor-pressure lowering is a colligative property, so its value for any solution depends on the concentration of solute particles and not on their kind or identity.

### Give It Some Thought

Does adding 1 mol of NaCl to 1 kg of water lower the vapor pressure of water to the same extent, a lesser extent, or a greater extent than adding 1 mol of  $\text{C}_6\text{H}_{12}\text{O}_6$  to 1 kg of water?

## Sample Exercise 13.7

### Calculation of Vapor Pressure of a Solution

Glycerin ( $\text{C}_3\text{H}_8\text{O}_3$ ) is a nonvolatile nonelectrolyte with a density of  $1.26 \text{ g/mL}$  at  $25^\circ\text{C}$ . Calculate the vapor pressure at  $25^\circ\text{C}$  of a solution made by adding  $50.0 \text{ mL}$  of glycerin to  $500.0 \text{ mL}$  of water. The vapor pressure of pure water at  $25^\circ\text{C}$  is  $23.8 \text{ torr}$  (Appendix B), and its density is  $1.00 \text{ g/mL}$ .

### SOLUTION

**Analyze** Our goal is to calculate the vapor pressure of a solution, given the volume of solute and solvent and the density of the solute.

**Plan** We can use Raoult's law (Equation 13.10) to calculate the vapor pressure of a solution. The mole fraction of the solvent in the solution,  $X_{\text{solvent}}$ , is the ratio of the number of moles of solvent ( $\text{H}_2\text{O}$ ) to total moles of solution (moles  $\text{C}_3\text{H}_8\text{O}_3$  + moles  $\text{H}_2\text{O}$ ).

### Solve

To calculate the mole fraction of water in the solution, we must determine the number of moles of  $\text{C}_3\text{H}_8\text{O}_3$  and  $\text{H}_2\text{O}$ :

$$\text{Moles } \text{C}_3\text{H}_8\text{O}_3 = (50.0 \text{ mL } \text{C}_3\text{H}_8\text{O}_3) \left( \frac{1.26 \text{ g } \text{C}_3\text{H}_8\text{O}_3}{1 \text{ mL } \text{C}_3\text{H}_8\text{O}_3} \right) \left( \frac{1 \text{ mol } \text{C}_3\text{H}_8\text{O}_3}{92.1 \text{ g } \text{C}_3\text{H}_8\text{O}_3} \right) = 0.684 \text{ mol}$$

$$\text{Moles } \text{H}_2\text{O} = (500.0 \text{ mL } \text{H}_2\text{O}) \left( \frac{1.00 \text{ g } \text{H}_2\text{O}}{1 \text{ mL } \text{H}_2\text{O}} \right) \left( \frac{1 \text{ mol } \text{H}_2\text{O}}{18.0 \text{ g } \text{H}_2\text{O}} \right) = 27.8 \text{ mol}$$

$$X_{\text{H}_2\text{O}} = \frac{\text{mol } \text{H}_2\text{O}}{\text{mol } \text{H}_2\text{O} + \text{mol } \text{C}_3\text{H}_8\text{O}_3} = \frac{27.8}{27.8 + 0.684} = 0.976$$

We now use Raoult's law to calculate the vapor pressure of water for the solution:

$$P_{\text{H}_2\text{O}} = X_{\text{H}_2\text{O}} P_{\text{H}_2\text{O}}^{\circ} = (0.976)(23.8 \text{ torr}) = 23.2 \text{ torr}$$

**Comment** The vapor pressure of the solution has been lowered by  $23.8 \text{ torr} - 23.2 \text{ torr} = 0.6 \text{ torr}$  relative to that of pure water. The vapor-pressure lowering can be calculated directly using Equation 13.11 together with the mole fraction of the solute,  $\text{C}_3\text{H}_8\text{O}_3$ :  $\Delta P = X_{\text{C}_3\text{H}_8\text{O}_3} P_{\text{H}_2\text{O}}^{\circ} = (0.024)(23.8 \text{ torr}) = 0.57 \text{ torr}$ . Notice that the use of Equation 13.11 gives one more significant figure than the number obtained by subtracting the vapor pressure of the solution from that of the pure solvent.

### Practice Exercise 1

The vapor pressure of benzene,  $\text{C}_6\text{H}_6$ , is  $100.0 \text{ torr}$  at  $26.1^\circ\text{C}$ . Assuming Raoult's law is obeyed, how many moles of a

nonvolatile solute must be added to  $100.0 \text{ mL}$  of benzene to decrease its vapor pressure by  $10.0\%$  at  $26.1^\circ\text{C}$ ? The density of benzene is  $0.8765 \text{ g/cm}^3$ .

(a) 0.011237 (b) 0.11237 (c) 0.1248 (d) 0.1282 (e) 8.765

### Practice Exercise 2

The vapor pressure of pure water at  $110^\circ\text{C}$  is  $1070 \text{ torr}$ . A solution of ethylene glycol and water has a vapor pressure of  $1.00 \text{ atm}$  at  $110^\circ\text{C}$ . Assuming that Raoult's law is obeyed, what is the mole fraction of ethylene glycol in the solution?

## A CLOSER LOOK Ideal Solutions with Two or More Volatile Components

Solutions sometimes have two or more volatile components. Gasoline, for example, is a solution of several volatile liquids. To gain some understanding of such mixtures, consider an ideal solution of two volatile liquids, A and B. (For our purposes here, it does not matter which we call the solute and which the solvent.) The partial pressures above the solution are given by Raoult's law:

$$P_A = X_A P_A^\circ \quad \text{and} \quad P_B = X_B P_B^\circ$$

and the total vapor pressure above the solution is

$$P_{\text{total}} = P_A + P_B = X_A P_A^\circ + X_B P_B^\circ$$

▲ **Figure 13.19** The volatile components of organic mixtures can be separated on an industrial scale in these distillation towers.

Consider a mixture of 1.0 mol of benzene ( $\text{C}_6\text{H}_6$ ) and 2.0 mol of toluene ( $\text{C}_7\text{H}_8$ ) ( $X_{\text{ben}} = 0.33$ ,  $X_{\text{tol}} = 0.67$ ). At  $20^\circ\text{C}$ , the vapor pressures of the pure substances are  $P_{\text{ben}}^\circ = 75 \text{ torr}$  and  $P_{\text{tol}}^\circ = 22 \text{ torr}$ . Thus, the partial pressures above the solution are

$$P_{\text{ben}} = (0.33)(75 \text{ torr}) = 25 \text{ torr}$$

$$P_{\text{tol}} = (0.67)(22 \text{ torr}) = 15 \text{ torr}$$

and the total vapor pressure above the liquid is

$$P_{\text{total}} = P_{\text{ben}} + P_{\text{tol}} = 25 \text{ torr} + 15 \text{ torr} = 40 \text{ torr}$$

Note that the vapor is richer in benzene, the more volatile component.

The mole fraction of benzene in the vapor is given by the ratio of its vapor pressure to the total pressure (Equations 10.14 and 10.15):

$$X_{\text{ben}} \text{ in vapor} = \frac{P_{\text{ben}}}{P_{\text{total}}} = \frac{25 \text{ torr}}{40 \text{ torr}} = 0.63$$

Although benzene constitutes only 33% of the molecules in the solution, it makes up 63% of the molecules in the vapor.

When an ideal liquid solution containing two volatile components is in equilibrium with its vapor, the more volatile component will be relatively richer in the vapor. This fact forms the basis of *distillation*, a technique used to separate (or partially separate) mixtures containing volatile components. [∞ \(Section 1.3\)](#) Distillation is a way of purifying liquids and is the procedure by which petrochemical plants achieve the separation of crude petroleum into gasoline, diesel fuel, lubricating oil, and other products (**Figure 13.19**). Distillation is also used routinely on a small scale in the laboratory.

**Related Exercises:** 13.67, 13.68

An ideal gas is defined as one that obeys the ideal-gas equation [∞ \(Section 10.4\)](#), and an **ideal solution** is defined as one that obeys Raoult's law. Whereas ideality for a gas arises from a complete lack of intermolecular interaction, ideality for a solution implies total uniformity of interaction. The molecules in an ideal solution all influence one another in the same way—in other words, solute–solute, solvent–solvent, and solute–solvent interactions are indistinguishable from one another. Real solutions best approximate ideal behavior when the solute concentration is low and solute and solvent have similar molecular sizes and take part in similar types of intermolecular attractions.

Many solutions do not obey Raoult's law exactly and so are not ideal. If, for instance, the solvent–solute interactions in a solution are weaker than either the solvent–solvent or solute–solute interactions, the vapor pressure tends to be greater than that predicted by Raoult's law. When the solute–solvent interactions in a solution are exceptionally strong, as might be the case when hydrogen bonding exists, the vapor pressure is lower than that predicted by Raoult's law. Although you should be aware that these departures from ideality occur, we will ignore them for the remainder of this chapter.

## Boiling-Point Elevation

In Sections 11.5 and 11.6, we examined the vapor pressures of pure substances and how to use them to construct phase diagrams. How does the phase diagram of a solution and, hence, its boiling and freezing points differ from that of the pure solvent? The addition of a nonvolatile solute lowers the vapor pressure of the solution. Thus, in **Figure 13.20** the vapor–pressure curve of the solution is shifted downward relative to the vapor–pressure curve of the pure solvent.

▲ **Figure 13.20** Phase diagram illustrating boiling-point elevation. The black lines show the pure solvent's phase equilibria curves, and the blue lines show the solution's phase equilibria curves.

Recall from Section 11.5 that the normal boiling point of a liquid is the temperature at which its vapor pressure equals 1 atm. Because the solution has a lower vapor pressure than the pure solvent, a higher temperature is required for the solution to achieve a vapor pressure of 1 atm. As a result, *the boiling point of the solution is higher than that of the pure solvent*. This effect is seen in Figure 13.20.

The increase in the boiling point of a solution, relative to the pure solvent, depends on the molality of the solute. But it is important to remember that boiling-point elevation is proportional to the *total* concentration of solute particles, regardless of whether the particles are molecules or ions. When NaCl dissolves in water, 2 mol of solute particles (1 mol of  $\text{Na}^+$  and 1 mol of  $\text{Cl}^-$ ) are formed for each mole of NaCl that dissolves. We take this into account by defining  $i$ , the **van't Hoff factor**, as the number of fragments that a solute breaks up into for a particular solvent. The change in boiling point for a solution compared to the pure solvent is:

$$\Delta T_b = T_b(\text{solution}) - T_b(\text{solvent}) = iK_b m \quad [13.12]$$

In this equation,  $T_b(\text{solution})$  is the boiling point of the solution,  $T_b(\text{solvent})$  is the boiling point of the pure solvent,  $m$  is the molality of the solute,  $K_b$  is the **molal boiling-point-elevation constant** for the solvent (which is a proportionality constant that is experimentally determined for each solvent), and  $i$  is the van't Hoff factor. For a nonelectrolyte, we can always assume  $i = 1$ ; for an electrolyte,  $i$  will depend on how the substance ionizes in that solvent. For instance,  $i = 2$  for NaCl in water, assuming complete dissociation of ions. As a result, we expect the boiling-point elevation of a 1 *m* aqueous solution of NaCl to be twice as large as the boiling-point elevation of a 1 *m* solution of a nonelectrolyte such as sucrose. Thus, to properly predict the effect of a particular solute on boiling-point elevation (or any other colligative property), it is important to know whether the solute is an electrolyte or a nonelectrolyte. ∞ (Sections 4.1 and 4.3)

## Freezing-Point Depression

The vapor–pressure curves for the liquid and solid phases meet at the triple point. ∞ (Section 11.6) In **Figure 13.21** we see that the triple-point temperature of the solution is lower than the triple-point temperature of pure liquid because the solution has a lower vapor pressure than the pure liquid.

► **Figure 13.21** Phase diagram illustrating freezing-point depression. The black lines show the pure solvent's phase equilibria curves, and the blue lines show the solution's phase equilibria curves.

The freezing point of a solution is the temperature at which the first crystals of pure solvent form in equilibrium with the solution. Recall from Section 11.6 that the line representing the solid–liquid equilibrium rises nearly vertically from the triple point. It is easy to see in Figure 13.21 that the triple-point temperature of the solution is lower than that of the pure liquid, but it is also true for all points along the solid–liquid equilibrium curve: *the freezing point of the solution is lower than that of the pure liquid*.

Like the boiling-point elevation, the change in freezing point  $\Delta T_f$  is directly proportional to solute molality, taking into account the van't Hoff factor  $i$ :

$$\Delta T_f = T_f(\text{solution}) - T_f(\text{solvent}) = -iK_f m \quad [13.13]$$

The proportionality constant  $K_f$  is the **molal freezing-point-depression constant**, analogous to  $K_b$  for boiling-point elevation. Note that because the solution freezes at a lower temperature than does the pure solvent, the value of  $\Delta T_f$  is *negative*.

Some typical values of  $K_b$  and  $K_f$  for several common solvents are given in Table 13.3. For water, the table shows  $K_b = 0.51^\circ\text{C}/m$ , which means that the boiling point of any aqueous solution that is 1  $m$  in nonvolatile solute particles is  $0.51^\circ\text{C}$  higher than the boiling point of pure water. Because solutions generally do not behave ideally, the constants listed in Table 13.3 serve well only for solutions that are rather dilute.

For water,  $K_f$  is  $1.86^\circ\text{C}/m$ . Therefore, any aqueous solution that is 1  $m$  in nonvolatile solute particles (such as 1  $m$   $\text{C}_6\text{H}_{12}\text{O}_6$  or 0.5  $m$   $\text{NaCl}$ ) freezes at the temperature that is  $1.86^\circ\text{C}$  lower than the freezing point of pure water.

The freezing-point depression caused by solutes has useful applications: it is why antifreeze works in car cooling systems and why calcium chloride ( $\text{CaCl}_2$ ) promotes the melting of ice on roads during winter.

### Give It Some Thought

A solute dissolved in water causes the boiling point to increase by  $0.51^\circ\text{C}$ . Does this necessarily mean that the concentration of the solute is 1.0  $m$  (Table 13.3)?

**TABLE 13.3** Molal Boiling-Point-Elevation and Freezing-Point-Depression Constants

| Solvent                                  | Normal Boiling Point ( $^\circ\text{C}$ ) | $K_b$ ( $^\circ\text{C}/m$ ) | Normal Freezing Point ( $^\circ\text{C}$ ) | $K_f$ ( $^\circ\text{C}/m$ ) |
|--|---|------------------------------|--|------------------------------|
| Water, $\text{H}_2\text{O}$              | 100.0                                     | 0.51                         | 0.0  | 1.86                         |
| Benzene, $\text{C}_6\text{H}_6$          | 80.1                                      | 2.53                         | 5.5  | 5.12                         |

## Sample Exercise 13.8

### Calculation of Boiling-Point Elevation and Freezing-Point Depression

Automotive antifreeze contains ethylene glycol,  $\text{CH}_2(\text{OH})\text{CH}_2(\text{OH})$ , a nonvolatile nonelectrolyte, in water. Calculate the boiling point and freezing point of a 25.0% by mass solution of ethylene glycol in water.

### SOLUTION

**Analyze** We are given that a solution contains 25.0% by mass of a nonvolatile, nonelectrolyte solute and asked to calculate the boiling and freezing points of the solution. To do this, we need to calculate the boiling-point elevation and freezing-point depression.

**Plan** To calculate the boiling-point elevation and the freezing-point depression using Equations 13.12 and 13.13, we must express the concentration of the solution as molality. Let's assume for convenience that we have 1000 g of solution. Because the solution is 25.0% by mass ethylene glycol, the masses of ethylene glycol and water in the solution are 250 and 750 g, respectively. Using these quantities, we can calculate the molality of the solution, which we use with the molal boiling-point-elevation and freezing-point-depression constants (Table 13.3) to calculate  $\Delta T_b$  and  $\Delta T_f$ . We add  $\Delta T_b$  to the boiling point and  $\Delta T_f$  to the freezing point of the solvent to obtain the boiling point and freezing point of the solution.

### Solve

The molality of the solution is calculated as follows:

$$\begin{aligned}\text{Molality} &= \frac{\text{moles } \text{C}_2\text{H}_6\text{O}_2}{\text{kilograms } \text{H}_2\text{O}} \\ &= \left( \frac{250 \text{ g } \text{C}_2\text{H}_6\text{O}_2}{750 \text{ g } \text{H}_2\text{O}} \right) \left( \frac{1 \text{ mol } \text{C}_2\text{H}_6\text{O}_2}{62.1 \text{ g } \text{C}_2\text{H}_6\text{O}_2} \right) \left( \frac{1000 \text{ g } \text{H}_2\text{O}}{1 \text{ kg } \text{H}_2\text{O}} \right) = 5.37 \text{ m}\end{aligned}$$

We can now use Equations 13.12 and 13.13 to calculate the changes in the boiling and freezing points:

$$\begin{aligned}\Delta T_b &= iK_b m = (1)(0.51^\circ\text{C}/\text{m})(5.37 \text{ m}) = 2.7^\circ\text{C} \\ \Delta T_f &= -iK_f m = -(1)(1.86^\circ\text{C}/\text{m})(5.37 \text{ m}) = -10.0^\circ\text{C}\end{aligned}$$

Hence, the boiling and freezing points of the solution are readily calculated:

$$\begin{aligned}\Delta T_b &= T_b(\text{solution}) - T_b(\text{solvent}) \\ 2.7^\circ\text{C} &= T_b(\text{solution}) - 100.0^\circ\text{C} \\ T_b(\text{solution}) &= 102.7^\circ\text{C} \\ \Delta T_f &= T_f(\text{solution}) - T_f(\text{solvent}) \\ -10.0^\circ\text{C} &= T_f(\text{solution}) - 0.0^\circ\text{C} \\ T_f(\text{solution}) &= -10.0^\circ\text{C}\end{aligned}$$

**Comment** Notice that the solution is a liquid over a larger temperature range than the pure solvent.

### Practice Exercise 1

Which aqueous solution will have the lowest freezing point?

- (a) 0.050 *m*  $\text{CaCl}_2$  (b) 0.15 *m*  $\text{NaCl}$  (c) 0.10 *m*  $\text{HCl}$   
(d) 0.050 *m*  $\text{CH}_3\text{COOH}$  (e) 0.20 *m*  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$

### Practice Exercise 2

Referring to Table 13.3, calculate the freezing point of a solution containing 0.600 kg of  $\text{CHCl}_3$  and 42.0 g of eucalyptol ( $\text{C}_{10}\text{H}_{18}\text{O}$ ), a fragrant substance found in the leaves of eucalyptus trees.

## Osmosis

Certain materials, including many membranes in biological systems and synthetic substances such as cellophane, are *semipermeable*. When in contact with a solution, these materials allow only ions or small molecules—water molecules, for instance—to pass through their network of tiny pores.

Consider a situation in which only solvent molecules are able to pass through a semipermeable membrane placed between two solutions of different concentrations. The rate at which the solvent molecules pass from the less concentrated solution (lower solute concentration but higher solvent concentration) to the more concentrated solution (higher solute concentration but lower solvent concentration) is greater than the rate in the opposite direction. Thus, there is a net movement of solvent molecules from the solution with a

## Go Figure

If the pure water in the left arm of the U-tube is replaced by a solution more concentrated than the one in the right arm, what will happen?

▲ **Figure 13.22** Osmosis is the process of a solvent moving from one compartment to another, across a semipermeable membrane, toward higher solute concentration. Osmotic pressure is generated at equilibrium due to the different heights of liquid on either side of the membrane and is equivalent to the pressure needed to equalize the fluid levels across the membrane.

lower solute concentration into the one with a higher solute concentration. In this process, called **osmosis**, the net movement of solvent is always toward the solution with the lower solvent (higher solute) concentration, as if the solutions were driven to attain equal concentrations.

**Figure 13.22** shows the osmosis that occurs between an aqueous solution and pure water, separated by a semipermeable membrane. The U-tube contains water on the left and an aqueous solution on the right. Initially, there is a net movement of water through the membrane from left to right, leading to unequal liquid levels in the two arms of the U-tube. Eventually, at equilibrium (middle panel of **Figure 13.22**), the pressure difference resulting from the unequal liquid heights becomes so large that the net flow of water ceases. This pressure, which stops osmosis, is the **osmotic pressure**,  $\Pi$ , of the solution. If an external pressure equal to the osmotic pressure is applied to the solution, the liquid levels in the two arms can be equalized, as shown in the right panel of **Figure 13.22**.

The osmotic pressure obeys a law similar in form to the ideal-gas law,  $\Pi V = i n R T$  where  $\Pi$  is the osmotic pressure,  $V$  is the volume of the solution,  $i$  is the van't Hoff factor,  $n$  is the number of moles of solute,  $R$  is the ideal-gas constant, and  $T$  is the absolute temperature. From this equation, we can write

$$\Pi = i \left( \frac{n}{V} \right) R T = i M R T \quad [13.14]$$

where  $M$  is the molarity of the solution. Because the osmotic pressure for any solution depends on the solution concentration, osmotic pressure is a colligative property.

If two solutions of identical osmotic pressure are separated by a semipermeable membrane, no osmosis will occur. The two solutions are *isotonic* with respect to each other. If one solution is of lower osmotic pressure, it is *hypotonic* with respect to the more concentrated solution. The more concentrated solution is *hypertonic* with respect to the dilute solution.

## Give It Some Thought

Of two KBr solutions, one 0.50  $m$  and the other 0.20  $m$ , which is hypotonic with respect to the other?

## Go Figure

If the fluid surrounding a patient's red blood cells is depleted in electrolytes, is crenation or hemolysis more likely to occur?

The arrows represent the net movement of water molecules.

Red blood cell in isotonic medium neither swells nor shrinks.

Crenation of red blood cell placed in hypertonic environment

Hemolysis of red blood cell placed in hypotonic environment

▲ **Figure 13.23 Osmosis through red blood cell walls.** If water moves out of the red blood cell, it shrivels (crenation); if water moves into the red blood cell, it will swell and may burst (hemolysis).

Osmosis plays an important role in living systems. The membranes of red blood cells, for example, are semipermeable. Placing a red blood cell in a solution that is *hypertonic* relative to the intracellular solution (the solution inside the cells) causes water to move out of the cell (**Figure 13.23**). This causes the cell to shrivel, a process called *crenation*. Placing the cell in a solution that is *hypotonic* relative to the intracellular fluid causes water to move into the cell, which may cause the cell to rupture, a process called *hemolysis*. People who need body fluids or nutrients replaced but cannot be fed orally are given solutions by intravenous (IV) infusion, which feeds nutrients directly into the veins. To prevent crenation or hemolysis of red blood cells, the IV solutions must be isotonic with the intracellular fluids of the blood cells.

## Sample Exercise 13.9

## Osmotic Pressure Calculations

The average osmotic pressure of blood is 7.7 atm at 25 °C. What molarity of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) will be isotonic with blood?

## SOLUTION

**Analyze** We are asked to calculate the concentration of glucose in water that would be isotonic with blood, given that the osmotic pressure of blood at 25 °C is 7.7 atm.

**Plan** Because we are given the osmotic pressure and temperature, we can solve for the concentration, using Equation 13.14. Because glucose is a nonelectrolyte,  $i = 1$ .

**Solve**

$$\Pi = iMRT$$

$$M = \frac{\Pi}{iRT} = \frac{(7.7 \text{ atm})}{(1) \left( 0.0821 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}} \right) (298 \text{ K})} = 0.31 \text{ M}$$

**Comment** In clinical situations, the concentrations of solutions are generally expressed as mass percentages. The mass percentage of a

0.31 M solution of glucose is 5.3%. The concentration of NaCl that is isotonic with blood is 0.16 M, because  $i = 2$  for NaCl in water (a 0.155 M solution of NaCl is 0.310 M in particles). A 0.16 M solution of NaCl is 0.9% mass in NaCl. This kind of solution is known as a physiological saline solution.

## ► Practice Exercise 1

Which of the following actions will raise the osmotic pressure of a solution? (a) decreasing the solute concentration (b) decreasing the temperature (c) adding more solvent (d) increasing the temperature (e) none of the above

## ► Practice Exercise 2

What is the osmotic pressure, in atm, of a 0.0020 M sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) solution at 20.0 °C?

There are many interesting biological examples of osmosis. A cucumber placed in concentrated brine loses water via osmosis and shrivels into a pickle. People who eat a lot of salty food retain water in tissue cells and intercellular space because of osmosis. The resultant swelling or puffiness is called *edema*. Water moves from soil into plant roots partly because of osmosis. Bacteria on salted meat or candied fruit lose water through osmosis, shrivel, and die—thus preserving the food.

### Give It Some Thought

Is the osmotic pressure of a 0.10 *M* solution of NaCl greater than, less than, or equal to that of a 0.10 *M* solution of KBr?

## Determination of Molar Mass from Colligative Properties

The colligative properties of solutions provide a useful means of determining the molar mass of solutes. Any of the four colligative properties can be used, as shown in Sample Exercises 13.10 and 13.11.

### Sample Exercise 13.10

#### Molar Mass from Freezing-Point Depression or Boiling-Point Elevation

A solution of an unknown nonvolatile nonelectrolyte was prepared by dissolving 0.250 g of the substance in 40.0 g of CCl<sub>4</sub>. The boiling point of the resulting solution was 0.357 °C higher than that of the pure solvent. Calculate the molar mass of the solute.

#### SOLUTION

**Analyze** Our goal is to calculate the molar mass of a solute based on knowledge of the boiling-point elevation of its solution in CCl<sub>4</sub>,  $\Delta T_b = 0.357\text{ }^\circ\text{C}$ , and the masses of solute and solvent. Table 13.3 gives  $K_b$  for the solvent (CCl<sub>4</sub>),  $K_b = 5.02\text{ }^\circ\text{C}/m$ .

**Plan** We can use Equation 13.12,  $\Delta T_b = iK_b m$ , to calculate the molality of the solution. Because the solute is a nonelectrolyte,  $i = 1$ . Then we can use molality and the quantity of solvent (40.0 g CCl<sub>4</sub>) to calculate the number of moles of solute. Finally, the molar mass of the solute equals the number of grams per mole, so we divide the number of grams of solute (0.250 g) by the number of moles we have just calculated.

#### Solve

From Equation 13.12, we have:

$$\text{Molality} = \frac{\Delta T_b}{iK_b} = \frac{0.357\text{ }^\circ\text{C}}{(1)5.02\text{ }^\circ\text{C}/m} = 0.0711\text{ }m$$

Thus, the solution contains 0.0711 mol of solute per kilogram of solvent. The solution was prepared using 40.0 g = 0.0400 kg of solvent (CCl<sub>4</sub>). The number of moles of solute in the solution is therefore:

$$(0.0400\text{ kg CCl}_4) \left( 0.0711 \frac{\text{mol solute}}{\text{kg CCl}_4} \right) = 2.84 \times 10^{-3}\text{ mol solute}$$

The molar mass of the solute is the number of grams per mole of the substance:

$$\text{Molar mass} = \frac{0.250\text{ g}}{2.84 \times 10^{-3}\text{ mol}} = 88.0\text{ g/mol}$$

#### Practice Exercise 1

A mysterious white powder could be powdered sugar (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>), cocaine (C<sub>17</sub>H<sub>21</sub>NO<sub>4</sub>), codeine (C<sub>18</sub>H<sub>21</sub>NO<sub>3</sub>), norfenefrine (C<sub>8</sub>H<sub>11</sub>NO<sub>2</sub>), or fructose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>).

When 80 mg of the powder is dissolved in 1.50 mL of ethanol ( $d = 0.789\text{ g/cm}^3$ , normal freezing point  $-114.6\text{ }^\circ\text{C}$ ,  $K_f = 1.99\text{ }^\circ\text{C}/m$ ), the freezing point is lowered to  $-115.5\text{ }^\circ\text{C}$ . What is the identity of the white powder?

(a) powdered sugar (b) cocaine (c) codeine (d) norfenefrine (e) fructose

#### Practice Exercise 2

Camphor (C<sub>10</sub>H<sub>16</sub>O) melts at 179.8 °C, and it has a particularly large freezing-point-depression constant,  $K_f = 40.0\text{ }^\circ\text{C}/m$ . When 0.186 g of an organic substance of unknown molar mass is dissolved in 22.01 g of liquid camphor, the freezing point of the mixture is found to be 176.7 °C. What is the molar mass of the solute?

### Sample Exercise 13.11

#### Molar Mass from Osmotic Pressure

The osmotic pressure of an aqueous solution of a certain protein was measured to determine the protein's molar mass. The solution contained 3.50 mg of protein dissolved in sufficient water to form 5.00 mL of solution. The osmotic pressure of the solution at 25 °C was found to be 1.54 torr. Treating the protein as a nonelectrolyte, calculate its molar mass.

#### SOLUTION

**Analyze** Our goal is to calculate the molar mass of a high-molecular-mass protein, based on the osmotic pressure and a knowledge of the mass of protein and solution volume. Since the protein will be considered as a nonelectrolyte,  $i = 1$ .

**Plan** The temperature ( $T = 25\text{ °C}$ ) and osmotic pressure ( $\Pi = 1.54\text{ torr}$ ) are given, and we know the value of  $R$  so we can

use Equation 13.14 to calculate the molarity of the solution,  $M$ . In doing so, we must convert temperature from °C to K and the osmotic pressure from torr to atm. We then use the molarity and the volume of the solution (5.00 mL) to determine the number of moles of solute. Finally, we obtain the molar mass by dividing the mass of the solute (3.50 mg) by the number of moles of solute.

#### Solve

Solving Equation 13.14 for molarity gives:

$$\text{Molarity} = \frac{\Pi}{iRT} = \frac{(1.54 \text{ torr})\left(\frac{1 \text{ atm}}{760 \text{ torr}}\right)}{(1)\left(0.0821 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}\right)(298 \text{ K})} = 8.28 \times 10^{-5} \frac{\text{mol}}{\text{L}}$$

Because the volume of the solution is  $5.00\text{ mL} = 5.00 \times 10^{-3}\text{ L}$ , the number of moles of protein must be:

$$\text{Moles} = (8.28 \times 10^{-5} \text{ mol/L})(5.00 \times 10^{-3} \text{ L}) = 4.14 \times 10^{-7} \text{ mol}$$

The molar mass is the number of grams per mole of the substance. Because we know the sample has a mass of  $3.50\text{ mg} = 3.50 \times 10^{-3}\text{ g}$ , we can calculate the molar mass by dividing the number of grams in the sample by the number of moles we just calculated:

$$\text{Molar mass} = \frac{\text{grams}}{\text{moles}} = \frac{3.50 \times 10^{-3} \text{ g}}{4.14 \times 10^{-7} \text{ mol}} = 8.45 \times 10^3 \text{ g/mol}$$

**Comment** Because small pressures can be measured easily and accurately, osmotic pressure measurements provide a useful way to determine the molar masses of large molecules.

#### Practice Exercise 1

Proteins frequently form complexes in which 2, 3, 4, or even more individual proteins (“monomers”) interact specifically with each other via hydrogen bonds or electrostatic interactions. The entire assembly of proteins can act as one unit in solution, and this assembly is called the “quaternary structure” of the protein. Suppose you discover a new

protein whose monomer molar mass is 25,000 g/mol. You measure an osmotic pressure of 0.0916 atm at 37 °C for 7.20 g of the protein in 10.00 mL of an aqueous solution. How many protein monomers form the quaternary protein structure in solution? Treat the protein as a nonelectrolyte.

(a) 1 (b) 2 (c) 3 (d) 4 (e) 8

#### Practice Exercise 2

A sample of 2.05 g of polystyrene of uniform polymer chain length was dissolved in enough toluene to form 0.100 L of solution. The osmotic pressure of this solution was found to be 1.21 kPa at 25 °C. Calculate the molar mass of the polystyrene.

## A CLOSER LOOK The van't Hoff Factor

The colligative properties of solutions depend on the *total* concentration of solute particles, regardless of whether the particles are ions or molecules. Thus, we expect a 0.100 *m* solution of NaCl to have a freezing-point depression of  $(2)(0.100\text{ m})(1.86\text{ °C/m}) = 0.372\text{ °C}$  because it is 0.100 *m* in  $\text{Na}^+(\text{aq})$  and 0.100 *m* in  $\text{Cl}^-(\text{aq})$ . The measured freezing-point depression is only 0.348 °C, however, and the situation is similar for other strong electrolytes. A 0.100 *m* solution of KCl, for example, freezes at  $-0.344\text{ °C}$ .

The difference between expected and observed colligative properties for strong electrolytes is due to electrostatic attractions between ions. As the ions move about in solution, ions of opposite charge collide and “stick together” for brief moments. While they are together, they behave as a single particle called an *ion pair* (Figure 13.24). The number of independent particles is thereby reduced, causing a

reduction in the freezing-point depression (as well as in boiling-point elevation, vapor-pressure reduction, and osmotic pressure).

We have been assuming that the van't Hoff factor,  $i$ , is equal to the number of ions per formula unit of the electrolyte. The true (measured) value of this factor, however, is given by the ratio of the measured value of a colligative property to the value calculated when the substance is assumed to be a nonelectrolyte. Using the freezing-point depression, for example, we have

$$i = \frac{\Delta T_f(\text{measured})}{\Delta T_f(\text{calculated for nonelectrolyte})} \quad [13.15]$$

The limiting value of  $i$  can be determined for a salt from the number of ions per formula unit. For NaCl, for example, the limiting van't Hoff factor is 2 because NaCl consists of one  $\text{Na}^+$  and one  $\text{Cl}^-$  per formula

*Continued*

▲ **Figure 13.24** Ion pairing and colligative properties. A solution of NaCl contains not only separated  $\text{Na}^+(\text{aq})$  and  $\text{Cl}^-(\text{aq})$  ions but ion pairs as well.

**TABLE 13.4** Measured and Expected van't Hoff Factors for Several Substances at 25 °C

| Compound                | Concentration  |                 |                  | Expected Value |
|-------------------------|----------------|-----------------|------------------|----------------|
|                         | 0.100 <i>m</i> | 0.0100 <i>m</i> | 0.00100 <i>m</i> |                |
| Sucrose                 | 1.00           | 1.00            | 1.00             | 1.00           |
| NaCl                    | 1.87           | 1.94            | 1.97             | 2.00           |
| $\text{K}_2\text{SO}_4$ | 2.32           | 2.70            | 2.84             | 3.00           |
| $\text{MgSO}_4$         | 1.21           | 1.53            | 1.82             | 2.00           |

unit; for  $\text{K}_2\text{SO}_4$  it is 3 because  $\text{K}_2\text{SO}_4$  consists of two  $\text{K}^+$  and one  $\text{SO}_4^{2-}$  per formula unit. In the absence of any information about the actual value of  $i$  for a solution, we will use the limiting value in calculations.

Two trends are evident in **Table 13.4**, which gives measured van't Hoff factors for several substances at different dilutions. First, dilution affects the value of  $i$  for electrolytes; the more dilute the solution, the more closely  $i$  approaches the expected value based on the number of ions in the formula unit. Thus, we conclude that the extent of ion pairing in electrolyte solutions decreases upon dilution. Second, the lower the charges on the ions, the less  $i$  departs from the expected value because the extent of ion pairing decreases as the ionic charges decrease. Both trends are consistent with simple electrostatics: The force of interaction between charged particles decreases as their separation increases and as their charges decrease.

## 13.6 | Colloids

Some substances appear to initially dissolve in a solvent, but over time, the substance separates from the pure solvent. For example, finely divided clay particles dispersed in water eventually settle out because of gravity. Gravity affects the clay particles because they are much larger than most molecules, consisting of thousands or even millions of atoms. In contrast, the dispersed particles in a true solution (ions in a salt solution or glucose molecules in a sugar solution) are small. Between these extremes lie dispersed particles that are larger than typical molecules but not so large that the components of the mixture separate under the influence of gravity. These intermediate types of dispersions are called either **colloidal dispersions** or simply **colloids**. Colloids form the dividing line between solutions and heterogeneous mixtures. Like solutions, colloids can be gases, liquids, or solids. Examples of each are listed in **Table 13.5**.

Particle size can be used to classify a mixture as colloid or solution. Colloid particles range in diameter from 5 to 1000 nm; solute particles are smaller than 5 nm in diameter. The nanomaterials we saw in Chapter 12 (Section 12.9), when dispersed in a liquid,

**TABLE 13.5** Types of Colloids

| Phase of Colloid | Dispersing (solvent-like) Substance | Dispersed (solute-like) Substance | Colloid Type   | Example                  |
|------------------|-------------------------------------|-----------------------------------|----------------|--------------------------|
| Gas              | Gas                                 | Gas                               | —              | None (all are solutions) |
| Gas              | Gas                                 | Liquid                            | Aerosol        | Fog                      |
| Gas              | Gas                                 | Solid                             | Aerosol        | Smoke                    |
| Liquid           | Liquid                              | Gas                               | Foam           | Whipped cream            |
| Liquid           | Liquid                              | Liquid                            | Emulsion       | Milk                     |
| Liquid           | Liquid                              | Solid                             | Sol            | Paint                    |
| Solid            | Solid                               | Gas                               | Solid foam     | Marshmallow              |
| Solid            | Solid                               | Liquid                            | Solid emulsion | Butter                   |
| Solid            | Solid                               | Solid                             | Solid sol      | Ruby glass               |

◀ **Figure 13.25** Tyndall effect in the laboratory. The glass on the right contains a colloidal dispersion; that on the left contains a solution.

are colloids. A colloid particle may even consist of a single giant molecule. The hemoglobin molecule, for example, which carries oxygen in your blood, has molecular dimensions of  $6.5 \times 5.5 \times 5.0$  nm and a molar mass of 64,500 g/mol.

Although colloid particles may be so small that the dispersion appears uniform even under a microscope, they are large enough to scatter light. Consequently, most colloids appear cloudy or opaque unless they are very dilute. (For example, homogenized milk is a colloid of fat and protein molecules dispersed in water.) Furthermore, because they scatter light, a light beam can be seen as it passes through a colloidal dispersion (Figure 13.25). This scattering of light by colloidal particles, known as the **Tyndall effect**, makes it possible to see the light beam of an automobile on a dusty dirt road, or the sunlight streaming through trees or clouds. Not all wavelengths are scattered to the same extent. Colors at the blue end of the visible spectrum are scattered more than those at the red end by the molecules and small dust particles in the atmosphere. As a result, our sky appears blue. At sunset, light from the sun travels through more of the atmosphere; blue light is scattered even more, allowing the reds and yellows to pass through and be seen.

## Hydrophilic and Hydrophobic Colloids

The most important colloids are those in which the dispersing medium is water. These colloids may be **hydrophilic** (“water loving”) or **hydrophobic** (“water fearing”). Hydrophilic colloids are most like the solutions that we have previously examined. In the human body, the extremely large protein molecules such as enzymes and antibodies are kept in suspension by interaction with surrounding water molecules. A hydrophilic molecule folds in such a way that its hydrophobic groups are away from the water molecules, on the inside of the folded molecule, while its hydrophilic, polar groups are on the surface, interacting with the water molecules. The hydrophilic groups generally contain oxygen or nitrogen and often carry a charge (Figure 13.26).

### Give It Some Thought

Some proteins reside in the hydrophobic lipid bilayer of the cell membrane. Would hydrophilic groups of these proteins still be facing the lipid “solvent”?

Hydrophobic colloids can be dispersed in water only if they are stabilized in some way. Otherwise, their natural lack of affinity for water causes them to separate from the water. One method of stabilization involves adsorbing ions on the surface of the hydrophobic particles (Figure 13.27). (**Adsorption** means to adhere to a surface. It differs from **absorption**, which means to pass into the interior, as when a sponge absorbs water.) The adsorbed ions can interact with water, thereby stabilizing the colloid. At the same

### Go Figure

What is the chemical composition of the groups that carry a negative charge?

Hydrophilic polar and charged groups on a molecule's surface help the molecule remain dispersed in water and other polar solvents.

▲ **Figure 13.26** Hydrophilic colloidal particle. Examples of the hydrophilic groups that help to keep a giant molecule (macromolecule) suspended in water.

▲ **Figure 13.27** Hydrophobic colloids stabilized in water by adsorbed anions.

time, the electrostatic repulsion between adsorbed ions on neighboring colloid particles keeps the particles from sticking together rather than dispersing in the water.

Hydrophobic colloids can also be stabilized by hydrophilic groups on their surfaces. Oil drops are hydrophobic, for example, and they do not remain suspended in water. Instead, they aggregate, forming an oil slick on the water surface. Sodium stearate (**Figure 13.28**), or any similar substance having one end that is hydrophilic (either polar or charged) and one end that is hydrophobic (nonpolar), will stabilize a suspension of oil in water. Stabilization results from the interaction of the hydrophobic ends of the stearate ions with the oil drops and the hydrophilic ends with the water.

Colloid stabilization has an interesting application in the human digestive system. When fats in our diet reach the small intestine, a hormone causes the gallbladder to excrete a fluid called bile. Among the components of bile are compounds that have chemical structures similar to sodium stearate; that is, they have a hydrophilic (polar) end and a hydrophobic (nonpolar) end. These compounds emulsify the fats in the intestine and thus permit digestion and absorption of fat-soluble vitamins through the intestinal wall. The term *emulsify* means "to form an emulsion," a suspension of one liquid in another, with milk being one example (Table 13.5). A substance that aids in the formation of an emulsion is called an emulsifying agent. If you read the labels on foods and other materials, you will find that a variety of chemicals are used as emulsifying agents. These chemicals typically have a hydrophilic end and a hydrophobic end.

### Go Figure

Which kind of intermolecular force attracts the stearate ion to the oil drop?

▲ **Figure 13.28** Stabilization of an emulsion of oil in water by stearate ions.

## CHEMISTRY AND LIFE Sickle-Cell Anemia

Our blood contains the complex protein hemoglobin, which carries oxygen from the lungs to other parts of the body. In the genetic disease sickle-cell anemia, hemoglobin molecules are abnormal and have a lower solubility in water, especially in their unoxygenated form. Consequently, as much as 85% of the hemoglobin in red blood cells crystallizes out of solution.

The cause of the insolubility is a structural change in one part of an amino acid. Normal hemoglobin molecules contain an amino acid that has a  $\text{—CH}_2\text{CH}_2\text{COOH}$  group:

Normal

Normal

The polarity of the  $\text{—COOH}$  group contributes to the solubility of the hemoglobin molecule in water. In the hemoglobin molecules of sickle-cell anemia patients, the  $\text{—CH}_2\text{CH}_2\text{COOH}$  chain is absent and in its place is the nonpolar (hydrophobic)  $\text{—CH(CH}_3)_2$  group:

Abnormal

Abnormal

This change leads to the aggregation of the defective form of hemoglobin into particles too large to remain suspended in biological fluids. It also causes the cells to distort into the sickle shape shown in Figure 13.29. The sickled cells tend to clog capillaries, causing severe pain, weakness, and the gradual deterioration of vital organs. The disease is hereditary, and if both parents carry the defective genes, it is likely that their children will possess only abnormal hemoglobin.

You might wonder how it is that a life-threatening disease such as sickle-cell anemia has persisted in humans through evolutionary time. The answer in part is that people with the gene are far less susceptible to malaria. Thus, in tropical climates rife with malaria, those with sickle-cell genes have lower incidence of this debilitating disease.

▲ **Figure 13.29** A scanning electron micrograph of normal (round) and sickle (crescent-shaped) red blood cells. Normal red blood cells are about  $6 \times 10^{-3}$  mm in diameter.

## Colloidal Motion in Liquids

We learned in Chapter 10 that gas molecules move at some average speed that depends inversely on their molar mass, in a straight line, until they collide with something. The *mean free path* is the average distance molecules travel between collisions. ∞ (Section 10.8) Recall also that the kinetic-molecular theory of gases assumes that gas molecules are in continuous, random motion. ∞ (Section 10.7)

Colloidal particles in a solution undergo random motion as a result of collisions with solvent molecules. Because the colloidal particles are massive in comparison with solvent molecules, their movements from any one collision are very tiny. However, there are many such collisions, and they cause a random motion of the entire colloidal particle, called **Brownian motion**. In 1905, Einstein developed an equation for the average square of the displacement of a colloidal particle, a historically very important development. As you might expect, the larger the colloidal particle, the shorter its mean free path in a given liquid (Table 13.6). Today, the understanding of Brownian motion is applied to diverse problems in everything from cheese-making to medical imaging.

**TABLE 13.6** Calculated Mean Free Path, after One Hour, for Uncharged Colloidal Spheres in Water at 20 °C

| Radius of sphere, nm | Mean Free Path, mm |
|----------------------|--------------------|
| 1                    | 1.23               |
| 10                   | 0.390              |
| 100                  | 0.123              |
| 1000                 | 0.039              |

## Sample Integrative Exercise

### Putting Concepts Together

A 0.100-L solution is made by dissolving 0.441 g of  $\text{CaCl}_2(\text{s})$  in water. (a) Calculate the osmotic pressure of this solution at  $27^\circ\text{C}$ , assuming that it is completely dissociated into its component ions. (b) The measured osmotic pressure of this solution is 2.56 atm at  $27^\circ\text{C}$ . Explain why it is less than the value calculated in (a), and calculate the van't Hoff factor,  $i$ , for the solute in this solution. (c) The enthalpy of solution for  $\text{CaCl}_2$  is  $\Delta H = -81.3 \text{ kJ/mol}$ . If the final temperature of the solution is  $27^\circ\text{C}$ , what was its initial temperature? (Assume that the density of the solution is  $1.00 \text{ g/mL}$ , that its specific heat is  $4.18 \text{ J/g}\cdot\text{K}$ , and that the solution loses no heat to its surroundings.)

### SOLUTION

- (a) The osmotic pressure is given by Equation 13.14,  $\Pi = iMRT$ . We know the temperature,  $T = 27^\circ\text{C} = 300 \text{ K}$ , and the gas constant,  $R = 0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K}$ . We can calculate the molarity of the solution from the mass of  $\text{CaCl}_2$  and the volume of the solution:

$$\begin{aligned}\text{Molarity} &= \left( \frac{0.441 \text{ g CaCl}_2}{0.100 \text{ L}} \right) \left( \frac{1 \text{ mol CaCl}_2}{110 \text{ g CaCl}_2} \right) \\ &= 0.0397 \text{ mol CaCl}_2/\text{L}\end{aligned}$$

Soluble ionic compounds are strong electrolytes.  (Sections 4.1 and 4.3) Thus,  $\text{CaCl}_2$  consists of metal cations ( $\text{Ca}^{2+}$ ) and nonmetal anions ( $\text{Cl}^-$ ). When completely dissociated, each  $\text{CaCl}_2$  unit forms three ions (one  $\text{Ca}^{2+}$  and two  $\text{Cl}^-$ ). Hence, the calculated osmotic pressure is:

$$\begin{aligned}\Pi &= iMRT = (3)(0.0397 \text{ mol/L})(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(300 \text{ K}) \\ &= 2.93 \text{ atm}\end{aligned}$$

- (b) The actual values of colligative properties of electrolytes are less than those calculated because the electrostatic interactions between ions limit their independent movements. In this case, the van't Hoff factor, which measures the extent to which electrolytes actually dissociate into ions, is given by:

Thus, the solution behaves as if the  $\text{CaCl}_2$  has dissociated into 2.62 particles instead of the ideal 3.

$$\begin{aligned}i &= \frac{\Pi(\text{measured})}{\Pi(\text{calculated for nonelectrolyte})} \\ &= \frac{2.56 \text{ atm}}{(0.0397 \text{ mol/L})(0.0821 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(300 \text{ K})} = 2.62\end{aligned}$$

- (c) If the solution is  $0.0397 \text{ M}$  in  $\text{CaCl}_2$  and has a total volume of  $0.100 \text{ L}$ , the number of moles of solute is:

Hence, the quantity of heat generated in forming the solution is:

The solution absorbs this heat, causing its temperature to increase. The relationship between temperature change and heat is given by Equation 5.22:

$$\begin{aligned}(0.100 \text{ L})(0.0397 \text{ mol/L}) &= 0.00397 \text{ mol} \\ (0.00397 \text{ mol})(-81.3 \text{ kJ/mol}) &= -0.323 \text{ kJ}\end{aligned}$$

$$q = (\text{specific heat})(\text{grams})(\Delta T)$$

The heat absorbed by the solution is  $q = +0.323 \text{ kJ} = 323 \text{ J}$ . The mass of the  $0.100 \text{ L}$  of solution is  $(100 \text{ mL})(1.00 \text{ g/mL}) = 100 \text{ g}$  (to three significant figures). Thus, the temperature change is:

$$\begin{aligned}\Delta T &= \frac{q}{(\text{specific heat of solution})(\text{grams of solution})} \\ &= \frac{323 \text{ J}}{(4.18 \text{ J/g}\cdot\text{K})(100 \text{ g})} = 0.773 \text{ K}\end{aligned}$$

A kelvin has the same size as a degree Celsius.

 (Section 1.4) Because the solution temperature increases by  $0.773^\circ\text{C}$ , the initial temperature was:

$$27.0^\circ\text{C} - 0.773^\circ\text{C} = 26.2^\circ\text{C}$$

## Chapter Summary and Key Terms

**THE SOLUTION PROCESS (SECTION 13.1)** Solutions form when one substance disperses uniformly throughout another. The attractive interaction of solvent molecules with solute is called **solvation**. When the solvent is water, the interaction is called **hydration**. The dissolution of ionic substances in water is promoted by hydration of the separated

ions by the polar water molecules. The overall enthalpy change upon solution formation may be either positive or negative. Solution formation is favored both by a positive entropy change, corresponding to an increased dispersal of the components of the solution, and by a negative enthalpy change, indicating an exothermic process.

**SATURATED SOLUTIONS AND SOLUBILITY (SECTION 13.2)** The equilibrium between a saturated solution and undissolved solute is dynamic; the process of solution and the reverse process, **crystallization**, occur simultaneously. In a solution in equilibrium with undissolved solute, the two processes occur at equal rates, giving a **saturated** solution. If there is less solute present than is needed to saturate the solution, the solution is **unsaturated**. When solute concentration is greater than the equilibrium concentration value, the solution is **supersaturated**. This is an unstable condition, and separation of some solute from the solution will occur if the process is initiated with a solute seed crystal. The amount of solute needed to form a saturated solution at any particular temperature is the **solubility** of that solute at that temperature.

**FACTORS AFFECTING SOLUBILITY (SECTION 13.3)** The solubility of one substance in another depends on the tendency of systems to become more random, by becoming more dispersed in space, and on the relative intermolecular solute–solute and solvent–solvent energies compared with solute–solvent interactions. Polar and ionic solutes tend to dissolve in polar solvents, and nonpolar solutes tend to dissolve in nonpolar solvents (“like dissolves like”). Liquids that mix in all proportions are **miscible**; those that do not dissolve significantly in one another are **immiscible**. Hydrogen-bonding interactions between solute and solvent often play an important role in determining solubility; for example, ethanol and water, whose molecules form hydrogen bonds with each other, are miscible. The solubilities of gases in a liquid are generally proportional to the pressure of the gas over the solution, as expressed by **Henry’s law**:  $S_g = kP_g$ . The solubilities of most solid solutes in water increase as the temperature of the solution increases. In contrast, the solubilities of gases in water generally decrease with increasing temperature.

**EXPRESSING SOLUTION CONCENTRATIONS (SECTION 13.4)** Concentrations of solutions can be expressed quantitatively by several different measures, including **mass percentage** [(mass solute/mass solution)  $\times$  100] **parts per million (ppm)**, **parts per billion (ppb)**, and mole fraction. Molarity,  $M$ , is defined as moles of solute per liter of solution; **molality**,  $m$ , is defined as moles of solute per kilogram of solvent. Molarity can be converted to these other concentration units if the density of the solution is known.

**COLLIGATIVE PROPERTIES (SECTION 13.5)** A physical property of a solution that depends on the concentration of solute particles present, regardless of the nature of the solute, is a **colligative property**. Colligative properties include vapor–pressure lowering, freezing-point

lowering, boiling-point elevation, and osmotic pressure. **Raoult’s law** expresses the lowering of vapor pressure. An **ideal solution** obeys Raoult’s law. Differences in solvent–solute as compared with solvent–solvent and solute–solute intermolecular forces cause many solutions to depart from ideal behavior.

A solution containing a nonvolatile solute possesses a higher boiling point than the pure solvent. The **molal boiling-point-elevation constant**,  $K_b$ , represents the increase in boiling point for a 1  $m$  solution of solute particles as compared with the pure solvent. Similarly, the **molal freezing-point-depression constant**,  $K_f$ , measures the lowering of the freezing point of a solution for a 1  $m$  solution of solute particles. The temperature changes are given by the equations  $\Delta T_b = iK_b m$  and  $\Delta T_f = -iK_f m$  where  $i$  is the **van’t Hoff factor**, which represents how many particles the solute breaks up into in the solvent. When NaCl dissolves in water, two moles of solute particles are formed for each mole of dissolved salt. The boiling point or freezing point is thus elevated or depressed, respectively, approximately twice as much as that of a nonelectrolyte solution of the same concentration. Similar considerations apply to other strong electrolytes.

**Osmosis** is the movement of solvent molecules through a semipermeable membrane from a less concentrated to a more concentrated solution. This net movement of solvent generates an **osmotic pressure**,  $\Pi$ , which can be measured in units of gas pressure, such as atm. The osmotic pressure of a solution is proportional to the solution molarity:  $\Pi = iMRT$ . Osmosis is a very important process in living systems, in which cell walls act as semipermeable membranes, permitting the passage of water but restricting the passage of ionic and macromolecular components.

**COLLOIDS (SECTION 13.6)** Particles that are large on the molecular scale but still small enough to remain suspended indefinitely in a solvent system form **colloids**, or **colloidal dispersions**. Colloids, which are intermediate between solutions and heterogeneous mixtures, have many practical applications. One useful physical property of colloids, the scattering of visible light, is referred to as the **Tyndall effect**. Aqueous colloids are classified as **hydrophilic** or **hydrophobic**. Hydrophilic colloids are common in living organisms, in which large molecular aggregates (enzymes, antibodies) remain suspended because they have many polar, or charged, atomic groups on their surfaces that interact with water. Hydrophobic colloids, such as small droplets of oil, may remain in suspension through adsorption of charged particles on their surfaces.

Colloids undergo **Brownian motion** in liquids, analogous to the random three-dimensional motion of gas molecules.

## Learning Outcomes After studying this chapter, you should be able to:

- Describe how enthalpy and entropy changes affect solution formation. (Section 13.1) *Related Exercises: 13.1, 13.21, 13.22*
- Describe the relationship between intermolecular forces and solubility, including use of the “like dissolves like” rule. (Sections 13.1 and 13.3) *Related Exercises: 13.15, 13.16*
- Describe the role of equilibrium in the solution process and its relationship to the solubility of a solute. (Section 13.2) *Related Exercises: 13.23, 13.24*
- Describe the effect of temperature on the solubility of solids and gases in liquids. (Section 13.3) *Related Exercises: 13.35, 13.36*
- Describe the relationship between the partial pressure of a gas and its solubility. (Section 13.3) *Related Exercises: 13.37, 13.38*
- Calculate the concentration of a solution in terms of molarity, molality, mole fraction, percent composition, and parts per million and be able to interconvert between them. (Section 13.4) *Related Exercises: 13.47, 13.48*
- Describe what a colligative property is and explain the van’t Hoff factor. (Section 13.5) *Related Exercises: 13.61, 13.62, 13.69, 13.70*
- Calculate the vapor pressure of a solvent over a solution. (Section 13.5) *Related Exercises: 13.63, 13.66*
- Calculate the boiling-point elevation and freezing-point depression of a solution. (Section 13.5) *Related Exercises: 13.73, 13.74*
- Calculate the osmotic pressure of a solution. (Section 13.5) *Related Exercises: 13.77, 13.78*
- Use colligative properties of solutions to calculate molar masses of solutes. (Section 13.5) *Related Exercises: 13.79, 13.81*
- Explain the difference between a solution and a colloid. (Section 13.6) *Related Exercises: 13.85, 13.86*
- Explain how hydrophilic and hydrophobic colloids can be stabilized in water. (Section 13.6) *Related Exercises: 13.87, 13.90*

## Key Equations

- $S_g = kP_g$
  - Mass % of component =  $\frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 100$
  - ppm of component =  $\frac{\text{mass of component in soln}}{\text{total mass of soln}} \times 10^6$
  - Mole fraction of component =  $\frac{\text{moles of component}}{\text{total moles of all components}}$
  - Molarity =  $\frac{\text{moles of solute}}{\text{liters of soln}}$
  - Molality =  $\frac{\text{moles of solute}}{\text{kilograms of solvent}}$
  - $P_{\text{solution}} = X_{\text{solvent}} P_{\text{solvent}}^\circ$
  - $\Delta T_b = iK_b m$
  - $\Delta T_f = -iK_f m$
  - $\Pi = i\left(\frac{n}{V}\right)RT = iMRT$
- [13.4] Henry's law, which relates gas solubility to partial pressure
  - [13.5] Concentration in terms of mass percent
  - [13.6] Concentration in terms of parts per million (ppm)
  - [13.7] Concentration in terms of mole fraction
  - [13.8] Concentration in terms of molarity
  - [13.9] Concentration in terms of molality
  - [13.10] Raoult's law, calculating vapor pressure of solvent above a solution
  - [13.12] The boiling-point elevation of a solution
  - [13.13] The freezing-point depression of a solution
  - [13.14] The osmotic pressure of a solution

## Exercises

### Visualizing Concepts

**13.1** Rank the contents of the following containers in order of increasing entropy: [Section 13.1]

**13.2** This figure shows the interaction of a cation with surrounding water molecules.

- (a) Which atom of water is associated with the cation? Explain.
- (b) Which of the following explanations accounts for the fact that the ion-solvent interaction is greater for  $\text{Li}^+$  than for  $\text{K}^+$ ?
  - a.  $\text{Li}^+$  is of lower mass than  $\text{K}^+$ .
  - b. The ionization energy of Li is higher than that for K.
  - c.  $\text{Li}^+$  has a smaller ionic radius than  $\text{K}^+$ .
  - d. Li has a lower density than K.
  - e. Li reacts with water more slowly than K. [Section 13.1]

**13.3** Consider two ionic solids, both composed of singly charged ions, that have different lattice energies. (a) Will the solids have the same solubility in water? (b) If not, which solid will be more soluble in water, the one with the larger lattice energy or the one with the smaller lattice energy? Assume that solute-solvent interactions are the same for both solids. [Section 13.1]

**13.4** Which *two* statements about gas mixtures are true? [Section 13.1]

- (a) Gases always mix with other gases because the gas particles are too far apart to feel significant intermolecular attractions or repulsions.
- (b) Just like water and oil don't mix in the liquid phase, two gases can be immiscible and not mix in the gas phase.
- (c) If you cool a gaseous mixture, you will liquefy all the gases at the same temperature.
- (d) Gases mix in all proportions in part because the entropy of the system increases upon doing so.

**13.5** Which of the following is the best representation of a saturated solution? Explain your reasoning. [Section 13.2]

**13.6** If you compare the solubilities of the noble gases in water, you find that solubility increases from smallest atomic weight to largest,  $\text{Ar} < \text{Kr} < \text{Xe}$ . Which of the following statements is the best explanation? [Section 13.3]

- (a) The heavier the gas, the more it sinks to the bottom of the water and leaves room for more gas molecules at the top of the water.
- (b) The heavier the gas, the more dispersion forces it has, and therefore the more attractive interactions it has with water molecules.
- (c) The heavier the gas, the more likely it is to hydrogen-bond with water.
- (d) The heavier the gas, the more likely it is to make a saturated solution in water.

**13.7** The structures of vitamins E and B<sub>6</sub> are shown below. Predict which is more water soluble and which is more fat soluble. [Section 13.3]

Vitamin B<sub>6</sub>

Vitamin E

**13.8** You take a sample of water that is at room temperature and in contact with air and put it under a vacuum. Right away, you see bubbles leave the water, but after a little while, the bubbles stop. As you keep applying the vacuum, more bubbles appear. A friend tells you that the first bubbles were water vapor, and the low pressure had reduced the boiling point of water, causing the water to boil. Another friend tells you that the first bubbles were gas molecules from the air (oxygen, nitrogen, and so forth) that were dissolved in the water. Which friend is mostly likely to be correct? What, then, is responsible for the second batch of bubbles? [Section 13.4]

**13.9** The figure shows two identical volumetric flasks containing the same solution at two temperatures.

- (a) Does the molarity of the solution change with the change in temperature?
- (b) Does the molality of the solution change with the change in temperature? [Section 13.4]

**13.10** This portion of a phase diagram shows the vapor-pressure curves of a volatile solvent and of a solution of that solvent containing a nonvolatile solute. (a) Which line represents the solution? (b) What are the normal boiling points of the solvent and the solution? [Section 13.5]

**13.11** Suppose you had a balloon made of some highly flexible semipermeable membrane. The balloon is filled completely with a 0.2 M solution of some solute and is submerged in a 0.1 M solution of the same solute:

Initially, the volume of solution in the balloon is 0.25 L. Assuming the volume outside the semipermeable membrane is large, as the illustration shows, what would you expect for the solution volume inside the balloon once the system has come to equilibrium through osmosis? [Section 13.5]

- 13.12** Which diagram best represents a liquid–liquid emulsion such as milk? The colored balls represent different liquid molecules. [Section 13.6]

### The Solution Process (Section 13.1)

- 13.13** Indicate whether each statement is true or false:
- (a) A solute will dissolve in a solvent if solute–solute interactions are stronger than solute–solvent interactions.
  - (b) In making a solution, the enthalpy of mixing is always a positive number.
  - (c) An increase in entropy favors mixing.
- 13.14** Indicate whether each statement is true or false: (a) NaCl dissolves in water but not in benzene ( $C_6H_6$ ) because benzene is denser than water. (b) NaCl dissolves in water but not in benzene because water has a large dipole moment and benzene has zero dipole moment. (c) NaCl dissolves in water but not in benzene because the water–ion interactions are stronger than benzene–ion interactions.
- 13.15** Indicate the type of solute–solvent interaction (Section 11.2) that should be most important in each of the following solutions: (a)  $CCl_4$  in benzene ( $C_6H_6$ ), (b) methanol ( $CH_3OH$ ) in water, (c) KBr in water, (d) HCl in acetonitrile ( $CH_3CN$ ).
- 13.16** Indicate the principal type of solute–solvent interaction in each of the following solutions and rank the solutions from weakest to strongest solute–solvent interaction: (a) KCl in water, (b)  $CH_2Cl_2$  in benzene ( $C_6H_6$ ), (c) methanol ( $CH_3OH$ ) in water.
- 13.17** An ionic compound has a very negative  $\Delta H_{soln}$  in water. (a) Would you expect it to be very soluble or nearly insoluble in water? (b) Which term would you expect to be the largest negative number:  $\Delta H_{solvent}$ ,  $\Delta H_{solute}$ , or  $\Delta H_{mix}$ ?

- 13.18** When ammonium chloride dissolves in water, the solution becomes colder. (a) Is the solution process exothermic or endothermic? (b) Why does the solution form?

- 13.19** (a) In Equation 13.1, which of the enthalpy terms for dissolving an ionic solid would correspond to the lattice energy? (b) Which energy term in this equation is always exothermic?

- 13.20** For the dissolution of LiCl in water,  $\Delta H_{soln} = -37$  kJ/mol. Which term would you expect to be the largest negative number:  $\Delta H_{solvent}$ ,  $\Delta H_{solute}$ , or  $\Delta H_{mix}$ ?

- 13.21** Two nonpolar organic liquids, hexane ( $C_6H_{14}$ ) and heptane ( $C_7H_{16}$ ), are mixed. (a) Do you expect  $\Delta H_{soln}$  to be a large positive number, a large negative number, or close to zero? Explain. (b) Hexane and heptane are miscible with each other in all proportions. In making a solution of them, is the entropy of the system increased, decreased, or close to zero, compared to the separate pure liquids?

- 13.22** KBr is relatively soluble in water, yet its enthalpy of solution is +19.8 kJ/mol. Which of the following statements provides the best explanation for this behavior?

- (a) Potassium salts are always soluble in water.
- (b) The entropy of mixing must be unfavorable.
- (c) The enthalpy of mixing must be small compared to the enthalpies for breaking up water–water interactions and K–Br ionic interactions.
- (d) KBr has a high molar mass compared to other salts like NaCl.

### Saturated Solutions; Factors Affecting Solubility (Sections 13.2 and 13.3)

- 13.23** The solubility of  $Cr(NO_3)_3 \cdot 9H_2O$  in water is 208 g per 100 g of water at 15 °C. A solution of  $Cr(NO_3)_3 \cdot 9H_2O$  in water at 35 °C is formed by dissolving 324 g in 100 g of water. When this solution is slowly cooled to 15 °C, no precipitate forms. (a) Is the solution that has cooled down to 15 °C unsaturated, saturated, or supersaturated? (b) You take a metal spatula and scratch the side of the glass vessel that contains this cooled solution, and crystals start to appear. What has just happened? (c) At equilibrium, what mass of crystals do you expect to form?

- 13.24** The solubility of  $MnSO_4 \cdot H_2O$  in water at 20 °C is 70 g per 100 mL of water. (a) Is a 1.22 M solution of  $MnSO_4 \cdot H_2O$  in water at 20 °C saturated, supersaturated, or unsaturated? (b) Given a solution of  $MnSO_4 \cdot H_2O$  of unknown concentration, what experiment could you perform to determine whether the new solution is saturated, supersaturated, or unsaturated?

- 13.25** By referring to Figure 13.15, determine whether the addition of 40.0 g of each of the following ionic solids to 100 g of water at 40 °C will lead to a saturated solution: (a)  $NaNO_3$ , (b) KCl, (c)  $K_2Cr_2O_7$ , (d)  $Pb(NO_3)_2$ .

- 13.26** By referring to Figure 13.15, determine the mass of each of the following salts required to form a saturated solution in 250 g of water at 30 °C: (a)  $KClO_3$ , (b)  $Pb(NO_3)_2$ , (c)  $Ce_2(SO_4)_3$ .

- 13.27** Consider water and glycerol,  $CH_2(OH)CH(OH)CH_2OH$ . (a) Would you expect them to be miscible in all proportions? (b) List the intermolecular attractions that occur between a water molecule and a glycerol molecule.

- 13.28** Oil and water are immiscible. Which is the most likely reason? (a) Oil molecules are denser than water. (b) Oil molecules are composed mostly of carbon and hydrogen. (c) Oil molecules have higher molar masses than water.

- (d) Oil molecules have higher vapor pressures than water.  
 (e) Oil molecules have higher boiling points than water.

- 13.29** Common laboratory solvents include acetone ( $\text{CH}_3\text{COCH}_3$ ), methanol ( $\text{CH}_3\text{OH}$ ), toluene ( $\text{C}_6\text{H}_5\text{CH}_3$ ), and water. Which of these is the best solvent for nonpolar solutes?
- 13.30** Would you expect alanine (an amino acid) to be more soluble in water or in hexane?

Alanine

- 13.31** (a) Would you expect stearic acid,  $\text{CH}_3(\text{CH}_2)_{16}\text{COOH}$ , to be more soluble in water or in carbon tetrachloride?  
 (b) Which would you expect to be more soluble in water, cyclohexane or dioxane?

- 13.32** Ibuprofen, widely used as a pain reliever, has a limited solubility in water, less than 1 mg/mL. Which part of the molecule's structure (gray, white, red) contributes to its water solubility? Which part of the molecule (gray, white, red) contributes to its water insolubility?

Ibuprofen

- 13.33** Which of the following in each pair is likely to be more soluble in hexane,  $\text{C}_6\text{H}_{14}$ : (a)  $\text{CCl}_4$  or  $\text{CaCl}_2$ , (b) benzene ( $\text{C}_6\text{H}_6$ ) or glycerol,  $\text{CH}_2(\text{OH})\text{CH}(\text{OH})\text{CH}_2\text{OH}$ , (c) octanoic acid,  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{COOH}$ , or acetic acid,  $\text{CH}_3\text{COOH}$ ? Explain your answer in each case.
- 13.34** Which of the following in each pair is likely to be more soluble in water: (a) cyclohexane ( $\text{C}_6\text{H}_{12}$ ) or glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), (b) propionic acid ( $\text{CH}_3\text{CH}_2\text{COOH}$ ) or sodium propionate ( $\text{CH}_3\text{CH}_2\text{COONa}$ ), (c)  $\text{HCl}$  or ethyl chloride ( $\text{CH}_3\text{CH}_2\text{Cl}$ )? Explain in each case.
- 13.35** Indicate whether each statement is true or false:
- (a) The higher the temperature, the more soluble most gases are in water.

- (b) The higher the temperature, the more soluble most ionic solids are in water.  
 (c) As you cool a saturated solution from high temperature to low temperature, solids start to crystallize out of solution if you achieve a supersaturated solution.  
 (d) If you take a saturated solution and raise its temperature, you can (usually) add more solute and make the solution even more concentrated.

- 13.36** Indicate whether each statement is true or false:

- (a) If you compare the solubility of a gas in water at two different temperatures, you find the gas is more soluble at the lower temperature.  
 (b) The solubility of most ionic solids in water decreases as the temperature of the solution increases.  
 (c) The solubility of most gases in water decreases as the temperature increases because water is breaking its hydrogen bonding to the gas molecules as the temperature is raised.  
 (d) Some ionic solids become less soluble in water as the temperature is raised.

- 13.37** The Henry's law constant for helium gas in water at  $30^\circ\text{C}$  is  $3.7 \times 10^{-4} \text{ M/atm}$  and the constant for  $\text{N}_2$  at  $30^\circ\text{C}$  is  $6.0 \times 10^{-4} \text{ M/atm}$ . If the two gases are each present at 1.5 atm pressure, calculate the solubility of each gas.

- 13.38** The partial pressure of  $\text{O}_2$  in air at sea level is 0.21 atm. Using the data in Table 13.1, together with Henry's law, calculate the molar concentration of  $\text{O}_2$  in the surface water of a mountain lake saturated with air at  $20^\circ\text{C}$  and an atmospheric pressure of 650 torr.

### Concentrations of Solutions (Section 13.4)

- 13.39** (a) Calculate the mass percentage of  $\text{Na}_2\text{SO}_4$  in a solution containing 10.6 g of  $\text{Na}_2\text{SO}_4$  in 483 g of water. (b) An ore contains 2.86 g of silver per ton of ore. What is the concentration of silver in ppm?
- 13.40** (a) What is the mass percentage of iodine in a solution containing 0.035 mol  $\text{I}_2$  in 125 g of  $\text{CCl}_4$ ? (b) Seawater contains 0.0079 g of  $\text{Sr}^{2+}$  per kilogram of water. What is the concentration of  $\text{Sr}^{2+}$  in ppm?
- 13.41** A solution is made containing 14.6 g of  $\text{CH}_3\text{OH}$  in 184 g of  $\text{H}_2\text{O}$ . Calculate (a) the mole fraction of  $\text{CH}_3\text{OH}$ , (b) the mass percent of  $\text{CH}_3\text{OH}$ , (c) the molality of  $\text{CH}_3\text{OH}$ .
- 13.42** A solution is made containing 20.8 g of phenol ( $\text{C}_6\text{H}_5\text{OH}$ ) in 425 g of ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ). Calculate (a) the mole fraction of phenol, (b) the mass percent of phenol, (c) the molality of phenol.
- 13.43** Calculate the molarity of the following aqueous solutions: (a) 0.540 g of  $\text{Mg}(\text{NO}_3)_2$  in 250.0 mL of solution, (b) 22.4 g of  $\text{LiClO}_4 \cdot 3 \text{H}_2\text{O}$  in 125 mL of solution, (c) 25.0 mL of 3.50 M  $\text{HNO}_3$  diluted to 0.250 L.
- 13.44** What is the molarity of each of the following solutions: (a) 15.0 g of  $\text{Al}_2(\text{SO}_4)_3$  in 0.250 mL solution, (b) 5.25 g of  $\text{Mn}(\text{NO}_3)_2 \cdot 2 \text{H}_2\text{O}$  in 175 mL of solution, (c) 35.0 mL of 9.00 M  $\text{H}_2\text{SO}_4$  diluted to 0.500 L?
- 13.45** Calculate the molality of each of the following solutions: (a) 8.66 g of benzene ( $\text{C}_6\text{H}_6$ ) dissolved in 23.6 g of carbon tetrachloride ( $\text{CCl}_4$ ), (b) 4.80 g of  $\text{NaCl}$  dissolved in 0.350 L of water.
- 13.46** (a) What is the molality of a solution formed by dissolving 1.12 mol of  $\text{KCl}$  in 16.0 mol of water? (b) How many grams of sulfur ( $\text{S}_8$ ) must be dissolved in 100.0 g of naphthalene ( $\text{C}_{10}\text{H}_8$ ) to make a 0.12 m solution?

Caffeine

- 13.47** A sulfuric acid solution containing 571.6 g of  $\text{H}_2\text{SO}_4$  per liter of solution has a density of  $1.329 \text{ g/cm}^3$ . Calculate (a) the mass percentage, (b) the mole fraction, (c) the molality, (d) the molarity of  $\text{H}_2\text{SO}_4$  in this solution.
- 13.48** Ascorbic acid (vitamin C,  $\text{C}_6\text{H}_8\text{O}_6$ ) is a water-soluble vitamin. A solution containing 80.5 g of ascorbic acid dissolved in 210 g of water has a density of  $1.22 \text{ g/mL}$  at  $55^\circ\text{C}$ . Calculate (a) the mass percentage, (b) the mole fraction, (c) the molality, (d) the molarity of ascorbic acid in this solution.
- 13.49** The density of acetonitrile ( $\text{CH}_3\text{CN}$ ) is  $0.786 \text{ g/mL}$  and the density of methanol ( $\text{CH}_3\text{OH}$ ) is  $0.791 \text{ g/mL}$ . A solution is made by dissolving 22.5 mL of  $\text{CH}_3\text{OH}$  in 98.7 mL of  $\text{CH}_3\text{CN}$ . (a) What is the mole fraction of methanol in the solution? (b) What is the molality of the solution? (c) Assuming that the volumes are additive, what is the molarity of  $\text{CH}_3\text{OH}$  in the solution?
- 13.50** The density of toluene ( $\text{C}_7\text{H}_8$ ) is  $0.867 \text{ g/mL}$ , and the density of thiophene ( $\text{C}_4\text{H}_4\text{S}$ ) is  $1.065 \text{ g/mL}$ . A solution is made by dissolving 8.10 g of thiophene in 250.0 mL of toluene. (a) Calculate the mole fraction of thiophene in the solution. (b) Calculate the molality of thiophene in the solution. (c) Assuming that the volumes of the solute and solvent are additive, what is the molarity of thiophene in the solution?
- 13.51** Calculate the number of moles of solute present in each of the following aqueous solutions: (a) 600 mL of  $0.250 \text{ M SrBr}_2$ , (b) 86.4 g of  $0.180 \text{ m KCl}$ , (c) 124.0 g of a solution that is 6.45% glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) by mass.
- 13.52** Calculate the number of moles of solute present in each of the following solutions: (a) 255 mL of  $1.50 \text{ M HNO}_3(\text{aq})$ , (b) 50.0 mg of an aqueous solution that is  $1.50 \text{ m NaCl}$ , (c) 75.0 g of an aqueous solution that is 1.50% sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) by mass.
- 13.53** Describe how you would prepare each of the following aqueous solutions, starting with solid KBr: (a) 0.75 L of  $1.5 \times 10^{-2} \text{ M KBr}$ , (b) 125 g of  $0.180 \text{ m KBr}$ , (c) 1.85 L of a solution that is 12.0% KBr by mass (the density of the solution is  $1.10 \text{ g/mL}$ ), (d) a  $0.150 \text{ M}$  solution of KBr that contains just enough KBr to precipitate 16.0 g of AgBr from a solution containing 0.480 mol of  $\text{AgNO}_3$ .
- 13.54** Describe how you would prepare each of the following aqueous solutions: (a) 1.50 L of  $0.110 \text{ M (NH}_4)_2\text{SO}_4$  solution, starting with solid  $(\text{NH}_4)_2\text{SO}_4$ ; (b) 225 g of a solution that is 0.65  $\text{m}$  in  $\text{Na}_2\text{CO}_3$ , starting with the solid solute; (c) 1.20 L of a solution that is 15.0%  $\text{Pb(NO}_3)_2$  by mass (the density of the solution is  $1.16 \text{ g/mL}$ ), starting with solid solute; (d) a  $0.50 \text{ M}$  solution of HCl that would just neutralize 5.5 g of  $\text{Ba(OH)}_2$  starting with  $6.0 \text{ M HCl}$ .
- 13.55** Commercial aqueous nitric acid has a density of  $1.42 \text{ g/mL}$  and is 16  $\text{M}$ . Calculate the percent  $\text{HNO}_3$  by mass in the solution.
- 13.56** Commercial concentrated aqueous ammonia is 28%  $\text{NH}_3$  by mass and has a density of  $0.90 \text{ g/mL}$ . What is the molarity of this solution?
- 13.57** Brass is a substitutional alloy consisting of a solution of copper and zinc. A particular sample of red brass consisting of 80.0 % Cu and 20.0 % Zn by mass has a density of  $8750 \text{ kg/m}^3$ . (a) What is the molality of Zn in the solid solution? (b) What is the molarity of Zn in the solution?
- 13.58** Caffeine ( $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ ) is a stimulant found in coffee and tea. If a solution of caffeine in the solvent chloroform ( $\text{CHCl}_3$ ) has a concentration of  $0.0500 \text{ m}$ , calculate (a) the percentage of caffeine by mass, (b) the mole fraction of caffeine in the solution.

- 13.59** During a person's typical breathing cycle, the  $\text{CO}_2$  concentration in the expired air rises to a peak of 4.6% by volume. (a) Calculate the partial pressure of the  $\text{CO}_2$  in the expired air at its peak, assuming 1 atm pressure and a body temperature of  $37^\circ\text{C}$ . (b) What is the molarity of the  $\text{CO}_2$  in the expired air at its peak, assuming a body temperature of  $37^\circ\text{C}$ ?
- 13.60** Breathing air that contains 4.0 % by volume  $\text{CO}_2$  over time causes rapid breathing, throbbing headache, and nausea, among other symptoms. What is the concentration of  $\text{CO}_2$  in such air in terms of (a) mol percentage, (b) molarity, assuming 1 atm pressure and a body temperature of  $37^\circ\text{C}$ ?

### Colligative Properties (Section 13.5)

- 13.61** You make a solution of a nonvolatile solute with a liquid solvent. Indicate whether each of the following statements is true or false. (a) The freezing point of the solution is higher than that of the pure solvent. (b) The freezing point of the solution is lower than that of the pure solvent. (c) The boiling point of the solution is higher than that of the pure solvent. (d) The boiling point of the solution is lower than that of the pure solvent.
- 13.62** You make a solution of a nonvolatile solute with a liquid solvent. Indicate if each of the following statements is true or false. (a) The freezing point of the solution is unchanged by addition of the solvent. (b) The solid that forms as the solution freezes is nearly pure solute. (c) The freezing point of the solution is independent of the concentration of the solute. (d) The boiling point of the solution increases in proportion to the concentration of the solute. (e) At any temperature, the vapor pressure of the solvent over the solution is lower than what it would be for the pure solvent.
- 13.63** Consider two solutions, one formed by adding 10 g of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) to 1 L of water and the other formed by adding 10 g of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) to 1 L of water. Calculate the vapor pressure for each solution at  $20^\circ\text{C}$ ; the vapor pressure of pure water at this temperature is 17.5 torr.
- 13.64** The vapor pressure of pure water at  $60^\circ\text{C}$  is 149 torr. The vapor pressure of water over a solution at  $60^\circ\text{C}$  containing equal numbers of moles of water and ethylene glycol (a nonvolatile solute) is 67 torr. Is the solution ideal according to Raoult's law?
- 13.65** (a) Calculate the vapor pressure of water above a solution prepared by adding 22.5 g of lactose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) to 200.0 g of water at 338 K. (Vapor-pressure data for water are given in Appendix B.) (b) Calculate the mass of propylene glycol ( $\text{C}_3\text{H}_8\text{O}_2$ ) that must be added to 0.340 kg of water to reduce the vapor pressure by 2.88 torr at  $40^\circ\text{C}$ .
- 13.66** (a) Calculate the vapor pressure of water above a solution prepared by dissolving 28.5 g of glycerin ( $\text{C}_3\text{H}_8\text{O}_3$ )

in 125 g of water at 343 K. (The vapor pressure of water is given in Appendix B.) **(b)** Calculate the mass of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) that must be added to 1.00 kg of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) to reduce its vapor pressure by 10.0 torr at 35 °C. The vapor pressure of pure ethanol at 35 °C is  $1.00 \times 10^2$  torr.

**[13.67]** At 63.5 °C, the vapor pressure of  $\text{H}_2\text{O}$  is 175 torr, and that of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) is 400 torr. A solution is made by mixing equal masses of  $\text{H}_2\text{O}$  and  $\text{C}_2\text{H}_5\text{OH}$ . **(a)** What is the mole fraction of ethanol in the solution? **(b)** Assuming ideal-solution behavior, what is the vapor pressure of the solution at 63.5 °C? **(c)** What is the mole fraction of ethanol in the vapor above the solution?

**[13.68]** At 20 °C, the vapor pressure of benzene ( $\text{C}_6\text{H}_6$ ) is 75 torr, and that of toluene ( $\text{C}_7\text{H}_8$ ) is 22 torr. Assume that benzene and toluene form an ideal solution. **(a)** What is the composition in mole fraction of a solution that has a vapor pressure of 35 torr at 20 °C? **(b)** What is the mole fraction of benzene in the vapor above the solution described in part (a)?

**13.69** **(a)** Does a 0.10 *m* aqueous solution of NaCl have a higher boiling point, a lower boiling point, or the same boiling point as a 0.10 *m* aqueous solution of  $\text{C}_6\text{H}_{12}\text{O}_6$ ? **(b)** The experimental boiling point of the NaCl solution is lower than that calculated assuming that NaCl is completely dissociated in solution. Why is this the case?

**13.70** Arrange the following aqueous solutions, each 10% by mass in solute, in order of increasing boiling point: glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), sodium nitrate ( $\text{NaNO}_3$ ).

**13.71** List the following aqueous solutions in order of increasing boiling point: 0.120 *m* glucose, 0.050 *m* LiBr, 0.050 *m*  $\text{Zn}(\text{NO}_3)_2$ .

**13.72** List the following aqueous solutions in order of decreasing freezing point: 0.040 *m* glycerin ( $\text{C}_3\text{H}_8\text{O}_3$ ), 0.020 *m* KBr, 0.030 *m* phenol ( $\text{C}_6\text{H}_5\text{OH}$ ).

**13.73** Using data from Table 13.3, calculate the freezing and boiling points of each of the following solutions: **(a)** 0.22 *m* glycerol ( $\text{C}_3\text{H}_8\text{O}_3$ ) in ethanol, **(b)** 0.240 mol of naphthalene ( $\text{C}_{10}\text{H}_8$ ) in 2.45 mol of chloroform, **(c)** 1.50 g NaCl in 0.250 kg of water, **(d)** 2.04 g KBr and 4.82 g glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 188 g of water.

**13.74** Using data from Table 13.3, calculate the freezing and boiling points of each of the following solutions: **(a)** 0.25 *m* glucose in ethanol; **(b)** 20.0 g of decane,  $\text{C}_{10}\text{H}_{22}$ , in 50.0 g  $\text{CHCl}_3$ ; **(c)** 3.50 g NaOH in 175 g of water, **(d)** 0.45 mol ethylene glycol and 0.15 mol KBr in 150 g  $\text{H}_2\text{O}$ .

**13.75** How many grams of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) must be added to 1.00 kg of water to produce a solution that freezes at  $-5.00^\circ\text{C}$ ?

**13.76** What is the freezing point of an aqueous solution that boils at  $105.0^\circ\text{C}$ ?

**13.77** What is the osmotic pressure formed by dissolving 44.2 mg of aspirin ( $\text{C}_9\text{H}_8\text{O}_4$ ) in 0.358 L of water at 25 °C?

**13.78** Seawater contains 34 g of salts for every liter of solution. Assuming that the solute consists entirely of NaCl (in fact, over 90% of the salt is indeed NaCl), calculate the osmotic pressure of seawater at 20 °C.

**13.79** Adrenaline is the hormone that triggers the release of extra glucose molecules in times of stress or emergency. A solution of 0.64 g of adrenaline in 36.0 g of  $\text{CCl}_4$  elevates the boiling point by  $0.49^\circ\text{C}$ . Calculate the approximate molar mass of adrenaline from this data.

Adrenaline

**13.80** Lauryl alcohol is obtained from coconut oil and is used to make detergents. A solution of 5.00 g of lauryl alcohol in 0.100 kg of benzene freezes at  $4.1^\circ\text{C}$ . What is the molar mass of lauryl alcohol from this data?

**13.81** Lysozyme is an enzyme that breaks bacterial cell walls. A solution containing 0.150 g of this enzyme in 210 mL of solution has an osmotic pressure of 0.953 torr at 25 °C. What is the molar mass of lysozyme?

**13.82** A dilute aqueous solution of an organic compound soluble in water is formed by dissolving 2.35 g of the compound in water to form 0.250 L of solution. The resulting solution has an osmotic pressure of 0.605 atm at 25 °C. Assuming that the organic compound is a nonelectrolyte, what is its molar mass?

**13.83** The osmotic pressure of a 0.010 *M* aqueous solution of  $\text{CaCl}_2$  is found to be 0.674 atm at 25 °C. Calculate the van't Hoff factor, *i*, for the solution.

**[13.84]** Based on the data given in Table 13.4, which solution would give the larger freezing-point lowering, a 0.030 *m* solution of NaCl or a 0.020 *m* solution of  $\text{K}_2\text{SO}_4$ ?

## Colloids (Section 13.6)

**13.85** **(a)** Do colloids made only of gases exist? Why or why not? **(b)** In the 1850s, Michael Faraday prepared ruby-red colloids of gold nanoparticles in water that are still stable today. These brightly colored colloids look like solutions. What experiment(s) could you do to determine whether a given colored preparation is a solution or colloid?

**13.86** Choose the best answer: A colloidal dispersion of one liquid in another is called **(a)** a gel, **(b)** an emulsion, **(c)** a foam, **(d)** an aerosol.

**13.87** An “emulsifying agent” is a compound that helps stabilize a hydrophobic colloid in a hydrophilic solvent (or a hydrophilic colloid in a hydrophobic solvent). Which of the following choices is the best emulsifying agent? **(a)**  $\text{CH}_3\text{COOH}$ , **(b)**  $\text{CH}_3\text{CH}_2\text{CH}_2\text{COOH}$ , **(c)**  $\text{CH}_3(\text{CH}_2)_{11}\text{COOH}$ , **(d)**  $\text{CH}_3(\text{CH}_2)_{11}\text{COONa}$ .

**13.88** Aerosols are important components of the atmosphere. Does the presence of aerosols in the atmosphere increase or decrease the amount of sunlight that arrives at the Earth's surface, compared to an “aerosol-free” atmosphere? Explain your reasoning.

**[13.89]** Proteins can be precipitated out of aqueous solution by the addition of an electrolyte; this process is called “salting out” the protein. **(a)** Do you think that all proteins would be precipitated out to the same extent by the same concentration of the same electrolyte? **(b)** If a protein has been salted out, are the protein-protein interactions stronger or weaker than they were before the electrolyte was added?

(c) A friend of yours who is taking a biochemistry class says that salting out works because the waters of hydration that surround the protein prefer to surround the electrolyte as the electrolyte is added; therefore, the protein's hydration shell is stripped away, leading to protein precipitation. Another friend of yours in the same biochemistry class says that salting out works because the incoming ions adsorb tightly to the protein, making ion pairs on the protein surface, which end up giving the protein a zero net charge in water and therefore leading to precipitation. Discuss these two hypotheses. What kind of measurements would you need to make to distinguish between these two hypotheses?

- 13.90** Soaps consist of compounds such as sodium stearate,  $\text{CH}_3(\text{CH}_2)_{16}\text{COO}^-\text{Na}^+$ , that have both hydrophobic and

hydrophilic parts. Consider the hydrocarbon part of sodium stearate to be the “tail” and the charged part to be the “head.”

- Which part of sodium stearate, head or tail, is more likely to be solvated by water?
- Grease is a complex mixture of (mostly) hydrophobic compounds. Which part of sodium stearate, head or tail, is most likely to bind to grease?
- If you have large deposits of grease that you want to wash away with water, you can see that adding sodium stearate will help you produce an emulsion. What intermolecular interactions are responsible for this?

## Additional Exercises

- 13.91** The “free-base” form of cocaine ( $\text{C}_{17}\text{H}_{21}\text{NO}_4$ ) and its protonated hydrochloride form ( $\text{C}_{17}\text{H}_{22}\text{ClNO}_4$ ) are shown below; the free-base form can be converted to the hydrochloride form with one equivalent of HCl. For clarity, not all the carbon and hydrogen atoms are shown; each vertex represents a carbon atom with the appropriate number of hydrogen atoms so that each carbon makes four bonds to other atoms.

- One of these forms of cocaine is relatively water-soluble: which form, the free base or the hydrochloride?
- One of these forms of cocaine is relatively insoluble in water: which form, the free base or the hydrochloride?

- 13.92** A supersaturated solution of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) is made by dissolving sucrose in hot water and slowly letting the solution cool to room temperature. After a long time, the excess sucrose crystallizes out of the solution. Indicate whether each of the following statements is true or false:

- After the excess sucrose has crystallized out, the remaining solution is saturated.
- After the excess sucrose has crystallized out, the system is now unstable and is not in equilibrium.
- After the excess sucrose has crystallized out, the rate of sucrose molecules leaving the surface of the crystals to be hydrated by water is equal to the rate of sucrose molecules in water attaching to the surface of the crystals.

- 13.93** Most fish need at least 4 ppm dissolved  $\text{O}_2$  in water for survival. (a) What is this concentration in mol/L? (b) What partial pressure of  $\text{O}_2$  above water is needed to obtain 4 ppm  $\text{O}_2$  in water at  $10^\circ\text{C}$ ? (The Henry's law constant for  $\text{O}_2$  at this temperature is  $1.71 \times 10^{-3}$  mol/L-atm.)

- 13.94** The presence of the radioactive gas radon (Rn) in well water presents a possible health hazard in parts of the United States. (a) Assuming that the solubility of radon in water with 1 atm pressure of the gas over the water at  $30^\circ\text{C}$  is  $7.27 \times 10^{-3}$  M, what is the Henry's law constant for radon

in water at this temperature? (b) A sample consisting of various gases contains  $3.5 \times 10^{-6}$  mole fraction of radon. This gas at a total pressure of 32 atm is shaken with water at  $30^\circ\text{C}$ . Calculate the molar concentration of radon in the water.

- 13.95** Glucose makes up about 0.10% by mass of human blood. Calculate this concentration in (a) ppm, (b) molality. (c) What further information would you need to determine the molarity of the solution?

- 13.96** The concentration of gold in seawater has been reported to be between 5 ppt (parts per trillion) and 50 ppt. Assuming that seawater contains 13 ppt of gold, calculate the number of grams of gold contained in  $1.0 \times 10^3$  gal of seawater.

- 13.97** The maximum allowable concentration of lead in drinking water is 9.0 ppb. (a) Calculate the molarity of lead in a 9.0-ppb solution. (b) How many grams of lead are in a swimming pool containing 9.0 ppb lead in  $60 \text{ m}^3$  of water?

- 13.98** Acetonitrile ( $\text{CH}_3\text{CN}$ ) is a polar organic solvent that dissolves a wide range of solutes, including many salts. The density of a 1.80 M LiBr solution in acetonitrile is  $0.826 \text{ g/cm}^3$ . Calculate the concentration of the solution in (a) molality, (b) mole fraction of LiBr, (c) mass percentage of  $\text{CH}_3\text{CN}$ .

- 13.99** A “canned heat” product used to warm buffet dishes consists of a homogeneous mixture of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) and paraffin, which has an average formula of  $\text{C}_{24}\text{H}_{50}$ . What mass of  $\text{C}_2\text{H}_5\text{OH}$  should be added to 620 kg of the paraffin to produce 8 torr of ethanol vapor pressure at  $35^\circ\text{C}$ ? The vapor pressure of pure ethanol at  $35^\circ\text{C}$  is 100 torr.
- 13.100** A solution contains 0.115 mol  $\text{H}_2\text{O}$  and an unknown number of moles of sodium chloride. The vapor pressure of the solution at  $30^\circ\text{C}$  is 25.7 torr. The vapor pressure of pure water at this temperature is 31.8 torr. Calculate the number of grams of sodium chloride in the solution. (*Hint:* Remember that sodium chloride is a strong electrolyte.)
- 13.101** Two beakers are placed in a sealed box at  $25^\circ\text{C}$ . One beaker contains 30.0 mL of a 0.050 M aqueous solution of a non-volatile nonelectrolyte. The other beaker contains 30.0 mL of a 0.035 M aqueous solution of  $\text{NaCl}$ . The water vapor from the two solutions reaches equilibrium. **(a)** In which beaker does the solution level rise, and in which one does it fall? **(b)** What are the volumes in the two beakers when equilibrium is attained, assuming ideal behavior?
- 13.102** The normal boiling point of ethanol,  $\text{CH}_3\text{CH}_2\text{OH}$ , is  $78.4^\circ\text{C}$ . When 9.15 g of a soluble nonelectrolyte is dissolved in 100.0 g of ethanol at that temperature, the vapor pressure of the solution is  $7.40 \times 10^2$  torr. What is the molar mass of the solute?
- 13.103** Calculate the freezing point of a 0.100 m aqueous solution of  $\text{K}_2\text{SO}_4$ , **(a)** ignoring interionic attractions, and **(b)** taking interionic attractions into consideration by using the van't Hoff factor (Table 13.4).
- 13.104** Carbon disulfide ( $\text{CS}_2$ ) boils at  $46.30^\circ\text{C}$  and has a density of 1.261 g/mL. **(a)** When 0.250 mol of a nondissociating solute is dissolved in 400.0 mL of  $\text{CS}_2$ , the solution boils at  $47.46^\circ\text{C}$ . What is the molal boiling-point-elevation constant for  $\text{CS}_2$ ? **(b)** When 5.39 g of a nondissociating unknown is dissolved in 50.0 mL of  $\text{CS}_2$ , the solution boils at  $47.08^\circ\text{C}$ . What is the molar mass of the unknown?
- [13.105]** A lithium salt used in lubricating grease has the formula  $\text{LiC}_n\text{H}_{2n+1}\text{O}_2$ . The salt is soluble in water to the extent of 0.036 g per 100 g of water at  $25^\circ\text{C}$ . The osmotic pressure of this solution is found to be 57.1 torr. Assuming that molality and molarity in such a dilute solution are the same and that the lithium salt is completely dissociated in the solution, determine an appropriate value of  $n$  in the formula for the salt.

## Integrative Exercises

- 13.106** Fluorocarbons (compounds that contain both carbon and fluorine) were, until recently, used as refrigerants. The compounds listed in the following table are all gases at  $25^\circ\text{C}$ , and their solubilities in water at  $25^\circ\text{C}$  and 1 atm fluorocarbon pressure are given as mass percentages. **(a)** For each fluorocarbon, calculate the molality of a saturated solution. **(b)** Which molecular property best predicts the solubility of these gases in water: molar mass, dipole moment, or ability to hydrogen-bond to water? **(c)** Infants born with severe respiratory problems are sometimes given *liquid ventilation*: They breathe a liquid that can dissolve more oxygen than air can hold. One of these liquids is a fluorinated compound,  $\text{CF}_3(\text{CF}_2)_7\text{Br}$ . The solubility of oxygen in this liquid is 66 mL  $\text{O}_2$  per 100 mL liquid. In contrast, air is 21% oxygen by volume. Calculate the moles of  $\text{O}_2$  present in an infant's lungs (volume: 15 mL) if the infant takes a full breath of air compared to taking a full “breath” of a saturated solution of  $\text{O}_2$  in the fluorinated liquid. Assume a pressure of 1 atm in the lungs.

| Fluorocarbon             | Solubility (mass %) |
|--------------------------|---------------------|
| $\text{CF}_4$            | 0.0015              |
| $\text{CClF}_3$          | 0.009               |
| $\text{CCl}_2\text{F}_2$ | 0.028               |
| $\text{CHClF}_2$         | 0.30                |

- [13.107]** At ordinary body temperature ( $37^\circ\text{C}$ ), the solubility of  $\text{N}_2$  in water at ordinary atmospheric pressure (1.0 atm) is 0.015 g/L. Air is approximately 78 mol %  $\text{N}_2$ . **(a)** Calculate the number of moles of  $\text{N}_2$  dissolved per liter of blood, assuming blood is a simple aqueous solution. **(b)** At a depth of 100 ft in water, the external pressure is 4.0 atm. What is the solubility of  $\text{N}_2$  from air in blood at this pressure? **(c)** If a scuba diver suddenly surfaces from this depth, how many milliliters of  $\text{N}_2$  gas, in the form of tiny bubbles, are released into the bloodstream from each liter of blood?

- [13.108]** Consider the following values for enthalpy of vaporization (kJ/mol) of several organic substances:

- (a)** Account for the variations in heats of vaporization for these substances, considering their relative intermolecular forces. **(b)** How would you expect the solubilities of these substances to vary in hexane as solvent? In ethanol? Use intermolecular forces, including hydrogen-bonding interactions where applicable, to explain your responses.

**[13.109]** A series of anions is shown below:

(i)

(ii)

(iii)

(iv)

(v)

The anion on the far right is called “BARF” by chemists, as its common abbreviation sounds similar to this word.

- What is the central atom and the number of electron-pair domains around the central atom in each of these anions?
- What is the electron-domain geometry around the central B in BARF?
- Which, if any, of these anions has an expanded octet around its central atom?
- Tetrabutylammonium,  $(\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2)_4\text{N}^+$  is a bulky cation. Which anion, when paired with the tetrabutylammonium cation, would lead to a salt that will be most soluble in nonpolar solvents?

**13.110** (a) A sample of hydrogen gas is generated in a closed container by reacting 2.050 g of zinc metal with 15.0 mL of 1.00 M sulfuric acid. Write the balanced equation for the reaction, and calculate the number of moles of hydrogen formed, assuming that the reaction is complete. (b) The volume over the solution in the container is 122 mL. Calculate the partial pressure of the hydrogen gas in this volume at 25 °C, ignoring any solubility of the gas in the solution. (c) The Henry’s law constant for hydrogen in water at 25 °C is  $7.8 \times 10^{-4}$  mol/L·atm. Estimate the number of moles of hydrogen gas that remain dissolved in the solution. What fraction of the gas molecules in the system is dissolved in the solution? Was it reasonable to ignore any dissolved hydrogen in part (b)?

**13.111** The following table presents the solubilities of several gases in water at 25 °C under a total pressure of gas and water vapor of 1 atm. (a) What volume of  $\text{CH}_4(\text{g})$  under standard conditions of temperature and pressure is contained in 4.0 L of a saturated solution at 25 °C? (b) The solubilities (in water) of the hydrocarbons are as follows: methane < ethane < ethylene. Is this because ethylene is the most polar molecule? (c) What intermolecular interactions can these hydrocarbons have with water? (d) Draw the Lewis dot structures for the three hydrocarbons. Which of these hydrocarbons possess  $\pi$  bonds? Based on their solubilities, would you say  $\pi$  bonds are more or less polarizable than  $\sigma$  bonds? (e) Explain why NO is more soluble in water than either  $\text{N}_2$  or  $\text{O}_2$ . (f)  $\text{H}_2\text{S}$  is more water-soluble than almost all the other gases in table. What intermolecular forces is  $\text{H}_2\text{S}$  likely to have with water? (g)  $\text{SO}_2$  is by far the most water-soluble gas in table. What intermolecular forces is  $\text{SO}_2$  likely to have with water?

| Gas                               | Solubility (mM) |
|-----------------------------------|-----------------|
| $\text{CH}_4$ (methane)           | 1.3             |
| $\text{C}_2\text{H}_6$ (ethane)   | 1.8             |
| $\text{C}_2\text{H}_4$ (ethylene) | 4.7             |
| $\text{N}_2$                      | 0.6             |
| $\text{O}_2$                      | 1.2             |
| NO                                | 1.9             |
| $\text{H}_2\text{S}$              | 99              |
| $\text{SO}_2$                     | 1476            |

**13.112** A small cube of lithium (density = 0.535 g/cm<sup>3</sup>) measuring 1.0 mm on each edge is added to 0.500 L of water. The following reaction occurs:

What is the freezing point of the resulting solution, assuming that the reaction goes to completion?

**[13.113]** At 35 °C the vapor pressure of acetone,  $(\text{CH}_3)_2\text{CO}$ , is 360 torr, and that of chloroform,  $\text{CHCl}_3$ , is 300 torr. Acetone and chloroform can form very weak hydrogen bonds between one another; the chlorines on the carbon give the carbon a sufficient partial positive charge to enable this behavior:

A solution composed of an equal number of moles of acetone and chloroform has a vapor pressure of 250 torr at 35 °C. (a) What would be the vapor pressure of the solution if it exhibited ideal behavior? (b) Based on the behavior of the solution, predict whether the mixing of acetone and chloroform is an exothermic ( $\Delta H_{\text{soln}} < 0$ ) or endothermic ( $\Delta H_{\text{soln}} > 0$ ) process.

**13.114** Compounds like sodium stearate, called “surfactants” in general, can form structures known as micelles in water, once the solution concentration reaches the value known as the critical micelle concentration (cmc). Micelles contain dozens to hundreds of molecules. The cmc depends on the substance, the solvent, and the temperature.

At and above the cmc, the properties of the solution vary drastically.

(a) The turbidity (the amount of light scattering) of solutions increases dramatically at the cmc. Suggest an explanation. (b) The ionic conductivity of the solution dramatically changes at the cmc. Suggest an explanation. (c) Chemists have developed fluorescent dyes that glow brightly only when the dye molecules are in a hydrophobic environment. Predict how the intensity of such fluorescence would relate to the concentration of sodium stearate as the sodium stearate concentration approaches and then increases past the cmc.

## Design an Experiment

Based on Figure 13.18, you might think that the reason volatile solvent molecules in a solution are less likely to escape to the gas phase, compared to the pure solvent, is because the solute molecules are physically blocking the solvent molecules from leaving

at the surface. This is a common misconception. Design an experiment to test the hypothesis that solute blocking of solvent vaporization is not the reason that solutions have lower vapor pressures than pure solvents.

14

# CHEMICAL KINETICS

## Chemical reactions take time

to occur. Some reactions, such as the rusting of iron, occur relatively slowly, requiring days, months, or years to complete. Others, such as the decomposition of sodium azide, the reaction used to inflate automobile air bags, occur so quickly they are difficult to measure. As chemists, we need to be concerned about the *speed* of chemical reactions as well as the products of those reactions.

The speed at which a chemical reaction occurs is called the **reaction rate**. One mechanism for controlling reaction rate is to adjust the temperature. Reaction rates slow down as the temperature decreases and speed up when the temperature increases. The chemical reactions that govern the metabolism of food, the transport of essential nutrients, and many other important physiological processes in the human body must proceed with the appropriate speeds. To do so, it's essential that our internal body temperature remain relatively constant regardless of the outside temperature. However, not all mammals operate within these strict confines. The body temperatures of animals that hibernate during the cold winter months often drop considerably in order to slow their metabolisms and conserve energy. The most extreme case is the arctic ground squirrel, an animal that hibernates for 7 to 8 months every year. Scientists have measured body temperatures as low as  $-3^{\circ}\text{C}$  in hibernating arctic ground squirrels! At these low temperatures, reaction rates are slowed by several orders of magnitude, which allow the squirrels to hibernate over such long periods.

◀ **ARCTIC GROUND SQUIRRELS** can hibernate for more than half the year by allowing their bodies to fall to temperatures near the freezing point of water. Every 2 to 3 weeks they shiver involuntarily to raise the temperature back to  $36^{\circ}\text{C}$  in order to minimize brain damage caused by the low-temperature hibernation.

## WHAT'S AHEAD

- 14.1** ▶ **Factors That Affect Reaction Rates** Describe the relationships between reaction rates and the factors that affect those rates: concentration, physical states of reactants, temperature, and presence of catalysts.
- 14.2** ▶ **Reaction Rates** Learn the difference between average and instantaneous reaction rates, and use reaction stoichiometry to determine the relative rates of reactant disappearance and product appearance.
- 14.3** ▶ **Concentration and Rate Laws** Learn how to determine *rate laws*, expressions that quantitatively express reaction rates in terms of reactant concentrations and experimentally determined *rate constants*.
- 14.4** ▶ **The Change of Concentration with Time** Learn that rate equations can be written to express how concentrations change with time and look at several classifications of rate equations: *zero-order*, *first-order*, and *second-order* reactions.
- 14.5** ▶ **Temperature and Rate** Explore the effect of temperature on rate. In order to occur, most reactions require a minimum input of energy called the *activation energy*.
- 14.6** ▶ **Reaction Mechanisms** Understand how rate laws are derived from *reaction mechanisms*, the step-by-step molecular pathways leading from reactants to products.
- 14.7** ▶ **Catalysis** Examine the role of catalysts, substances that increase the rates of reactions but do not appear in the overall reaction equation, and consider biological catalysts called *enzymes*.

The part of chemistry that deals with the reaction rates is known as **chemical kinetics**. It plays an important role in processes as diverse as the production of chemicals on an industrial scale and the decay of radioactive isotopes used in medicine.

Chemical kinetics is also useful in providing information about how reactions occur—the order in which chemical bonds are broken and formed during the course of a reaction. To understand how reactions happen, we must examine the reaction rates and the factors that influence them. Experimental information on the rate of a given reaction provides important evidence that helps us formulate a *reaction mechanism*, which is a step-by-step, molecular-level view of the pathway from reactants to products.

Our goal in this chapter is to understand how to determine reaction rates and to consider the factors that control these rates. What factors determine how rapidly food spoils, for instance? What determines the rate at which steel rusts? How can we remove hazardous pollutants in automobile exhaust before the exhaust leaves the tailpipe? Although we will not address these specific questions, we will see that the rates of all chemical reactions are subject to the same principles.

### Go Figure

If a heated steel nail were placed in pure  $O_2$ , would you expect it to burn as readily as the steel wool does?

Steel wool heated in air (about 20%  $O_2$ ) glows red-hot but oxidizes to  $Fe_2O_3$  slowly.

Red-hot steel wool in 100%  $O_2$  burns vigorously, forming  $Fe_2O_3$  quickly.

▲ **Figure 14.1** Effect of concentration on reaction rate. The difference in behavior is due to the different concentrations of  $O_2$  in the two environments.

## 14.1 | Factors That Affect Reaction Rates

Four factors affect the rate at which any particular reaction occurs:

1. **Physical state of the reactants.** Reactants must come together to react. The more readily reactant molecules collide with one another, the more rapidly they react. Reactions may broadly be classified as *homogeneous*, involving either all gases or all liquids, or as *heterogeneous*, in which reactants are in different phases. Under heterogeneous conditions, a reaction is limited by the area of contact of the reactants. Thus, heterogeneous reactions that involve solids tend to proceed more rapidly if the surface area of the solid is increased. For example, a medicine in the form of a fine powder dissolves in the stomach and enters the blood more quickly than the same medicine in the form of a tablet.
2. **Reactant concentrations.** Most chemical reactions proceed more quickly if the concentration of one or more reactants is increased. For example, steel wool burns only slowly in air, which contains 20%  $O_2$ , but bursts into flame in pure oxygen (Figure 14.1). As reactant concentration increases, the frequency with which the reactant molecules collide increases, leading to increased rates.
3. **Reaction temperature.** Reaction rates generally increase as temperature is increased. The bacterial reactions that spoil milk, for instance, proceed more rapidly at room temperature than at the lower temperature of a refrigerator. Increasing temperature increases the kinetic energies of molecules. ∞ (Section 10.7) As molecules move more rapidly, they collide more frequently and with higher energy, leading to increased reaction rates.
4. **The presence of a catalyst.** Catalysts are agents that increase reaction rates without themselves being used up. They affect the kinds of collisions (and therefore alter the mechanism) that lead to reaction. Catalysts play many crucial roles in living organisms.

On a molecular level, reaction rates depend on the frequency of collisions between molecules. *The greater the frequency of collisions, the higher the reaction rate.* For a collision to lead to a reaction, however, it must occur with sufficient energy to break bonds and with suitable orientation for new bonds to form in the proper locations. We will consider these factors as we proceed through this chapter.

### Give It Some Thought

In a reaction involving reactants in the gas state, how does increasing the partial pressures of the gases affect the reaction rate?

## 14.2 | Reaction Rates

The *speed* of an event is defined as the *change* that occurs in a given *time* interval, which means that whenever we talk about speed, we necessarily bring in the notion of time. For example, the speed of a car is expressed as the change in the car's position over a certain time interval. In the United States, the speed of cars is usually measured in units of miles per hour—that is, the quantity that is changing (position measured in miles) divided by a time interval (measured in hours).

Similarly, the speed of a chemical reaction—its reaction rate—is the change in the concentration of reactants or products per unit of time. The units for reaction rate are usually molarity per second ( $M/s$ )—that is, the change in concentration measured in molarity divided by a time interval measured in seconds.

Let's consider the hypothetical reaction  $A \longrightarrow B$ , depicted in [Figure 14.2](#). Each red sphere represents 0.01 mol of A, each blue sphere represents 0.01 mol of B, and the container has a volume of 1.00 L. At the beginning of the reaction, there is 1.00 mol A, so the concentration is  $1.00 \text{ mol/L} = 1.00 M$ . After 20 s, the concentration of A has fallen to  $0.54 M$  and the concentration of B has risen to  $0.46 M$ . The sum of the concentrations is still  $1.00 M$  because 1 mol of B is produced for each mole of A that reacts. After 40 s, the concentration of A is  $0.30 M$  and that of B is  $0.70 M$ .

The rate of this reaction can be expressed either as the rate of disappearance of reactant A or as the rate of appearance of product B. The *average* rate of appearance of B over a particular time interval is given by the change in concentration of B divided by the change in time:

$$\begin{aligned} \text{Average rate of appearance of B} &= \frac{\text{change in concentration of B}}{\text{change in time}} \\ &= \frac{[B] \text{ at } t_2 - [B] \text{ at } t_1}{t_2 - t_1} = \frac{\Delta[B]}{\Delta t} \end{aligned} \quad [14.1]$$

We use brackets around a chemical formula, as in  $[B]$ , to indicate molarity. The Greek letter delta,  $\Delta$ , is read “change in” and is always equal to a final value minus an initial value. [∞ \(Equation 5.3, Section 5.2\)](#) The average rate of appearance of B over the 20 s interval from the beginning of the reaction ( $t_1 = 0 \text{ s}$  to  $t_2 = 20 \text{ s}$ ) is

$$\text{Average rate} = \frac{0.46 M - 0.00 M}{20 \text{ s} - 0 \text{ s}} = 2.3 \times 10^{-2} M/s$$

We could equally well express the reaction rate in terms of the reactant, A. In this case, we would be describing the rate of disappearance of A, which we express as

$$\begin{aligned}\text{Average rate of disappearance of A} &= -\frac{\text{change in concentration of A}}{\text{change in time}} \\ &= -\frac{\Delta[A]}{\Delta t}\end{aligned}\quad [14.2]$$

Notice the minus sign in this equation, which we use to indicate that the concentration of A decreases.

*By convention, rates are always expressed as positive quantities.*

Because [A] decreases,  $\Delta[A]$  is a negative number. The minus sign we put in the equation converts the negative  $\Delta[A]$  to a positive rate of disappearance.

Because one molecule of A is consumed for every molecule of B that forms, the average rate of disappearance of A equals the average rate of appearance of B:

$$\text{Average rate} = -\frac{\Delta[A]}{\Delta t} = -\frac{0.54\text{ M} - 1.00\text{ M}}{20\text{ s} - 0\text{ s}} = 2.3 \times 10^{-2}\text{ M/s}$$

### Sample Exercise 14.1

#### Calculating an Average Rate of Reaction

From the data in Figure 14.2, calculate the average rate at which A disappears over the time interval from 20 s to 40 s.

#### SOLUTION

**Analyze** We are given the concentration of A at 20 s (0.54 M) and at 40 s (0.30 M) and asked to calculate the average rate of reaction over this time interval.

**Plan** The average rate is given by the change in concentration,  $\Delta[A]$ , divided by the change in time,  $\Delta t$ . Because A is a reactant, a minus sign is used in the calculation to make the rate a positive quantity.

**Solve**

$$\begin{aligned}\text{Average rate} &= -\frac{\Delta[A]}{\Delta t} = -\frac{0.30\text{ M} - 0.54\text{ M}}{40\text{ s} - 20\text{ s}} \\ &= 1.2 \times 10^{-2}\text{ M/s}\end{aligned}$$

#### Practice Exercise 1

If the experiment in Figure 14.2 is run for 60 s, 0.16 mol A remain. Which of the following statements is or are true?

- (i) After 60 s there are 0.84 mol B in the flask.
- (ii) The decrease in the number of moles of A from  $t_1 = 0\text{ s}$  to  $t_2 = 20\text{ s}$  is greater than that from  $t_1 = 40\text{ s}$  to  $t_2 = 60\text{ s}$ .
- (iii) The average rate for the reaction from  $t_1 = 40\text{ s}$  to  $t_2 = 60\text{ s}$  is  $7.0 \times 10^{-3}\text{ M/s}$ .
- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

#### Practice Exercise 2

Use the data in Figure 14.2 to calculate the average rate of appearance of B over the time interval from 0 s to 40 s.

## Change of Rate with Time

Now let's consider the reaction between butyl chloride ( $\text{C}_4\text{H}_9\text{Cl}$ ) and water to form butyl alcohol ( $\text{C}_4\text{H}_9\text{OH}$ ) and hydrochloric acid:

Suppose we prepare a 0.1000-M aqueous solution of  $\text{C}_4\text{H}_9\text{Cl}$  and then measure the concentration of  $\text{C}_4\text{H}_9\text{Cl}$  at various times after time zero (which is the instant at which the reactants are mixed, thereby initiating the reaction). We can use the resulting data, shown in the first two columns of Table 14.1, to calculate the average rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$  over various time intervals; these rates are given in the third column. Notice that the average rate decreases over each 50-s interval for the first several measurements and continues to decrease over even larger intervals through the remaining measurements. *It is typical for rates to decrease as a reaction*

**TABLE 14.1** Rate Data for Reaction of  $\text{C}_4\text{H}_9\text{Cl}$  with Water

| Time, $t$ (s) | $[\text{C}_4\text{H}_9\text{Cl}]$ (M) | Average Rate (M/s)     |
|---------------|---------------------------------------|------------------------|
| 0.0           | 0.1000                                | $1.9 \times 10^{-4}$   |
| 50.0          | 0.0905                                | $1.7 \times 10^{-4}$   |
| 100.0         | 0.0820                                | $1.6 \times 10^{-4}$   |
| 150.0         | 0.0741                                | $1.4 \times 10^{-4}$   |
| 200.0         | 0.0671                                | $1.22 \times 10^{-4}$  |
| 300.0         | 0.0549                                | $1.01 \times 10^{-4}$  |
| 400.0         | 0.0448                                | $0.80 \times 10^{-4}$  |
| 500.0         | 0.0368                                | $0.560 \times 10^{-4}$ |
| 800.0         | 0.0200                                |                        |
| 10,000        | 0                                     |                        |

proceeds because the concentration of reactants decreases. The change in rate as the reaction proceeds is also seen in a graph of  $[\text{C}_4\text{H}_9\text{Cl}]$  versus time (Figure 14.3). Notice how the steepness of the curve decreases with time, indicating a decreasing reaction rate.

### Instantaneous Rate

Graphs such as Figure 14.3 that show how the concentration of a reactant or product changes with time allow us to evaluate the **instantaneous rate** of a reaction, which is the rate at a particular instant during the reaction. The instantaneous rate is determined from the slope of the curve at a particular point in time. We have drawn two tangent lines in Figure 14.3, a dashed line running through the point at  $t = 0$  s and a solid line running through the point at  $t = 600$  s. The slopes of these tangent lines give the instantaneous rates at these two time points.\* To determine the instantaneous rate at 600 s, for example, we construct horizontal and vertical lines to form the blue right triangle in Figure 14.3. The slope of the tangent line is the ratio of the height of the vertical side to the length of the horizontal side:

$$\begin{aligned}\text{Instantaneous rate} &= -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = -\frac{(0.017 - 0.042) \text{ M}}{(800 - 400) \text{ s}} \\ &= 6.3 \times 10^{-5} \text{ M/s}\end{aligned}$$

In discussions that follow, the term *rate* means instantaneous rate unless indicated otherwise. The instantaneous rate at  $t = 0$  is called the *initial rate* of the reaction. To understand the difference between average and instantaneous rates, imagine you have just driven 98 mi in 2.0 h. Your average speed for the trip is 49 mi/hr, but your instantaneous speed at any moment during the trip is the speedometer reading at that moment.

\*You may wish to review graphical determination of slopes in Appendix A. If you are familiar with calculus, you may recognize that the average rate approaches the instantaneous rate as the time interval approaches zero. This limit, in the notation of calculus, is the negative of the derivative of the curve at time  $t$ ,  $-d[\text{C}_4\text{H}_9\text{Cl}]/dt$ .

### Go Figure

Does the instantaneous rate increase, decrease, or remain the same as the reaction proceeds?

▲ **Figure 14.3** Concentration of butyl chloride ( $\text{C}_4\text{H}_9\text{Cl}$ ) as a function of time.

**Sample Exercise 14.2****Calculating an Instantaneous Rate of Reaction**

Using Figure 14.3, calculate the instantaneous rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$  at  $t = 0$  s (the initial rate).

**SOLUTION**

**Analyze** We are asked to determine an instantaneous rate from a graph of reactant concentration versus time.

**Plan** To obtain the instantaneous rate at  $t = 0$  s, we must determine the slope of the curve at  $t = 0$ . The tangent is drawn on the graph as the hypotenuse of the tan triangle. The slope of this straight line equals the change in the vertical axis divided by the corresponding change in the horizontal axis (which, in the case of this example, is the change in molarity over change in time).

**Solve** The tangent line falls from  $[\text{C}_4\text{H}_9\text{Cl}] = 0.100\text{ M}$  to  $0.060\text{ M}$  in the time change from  $0\text{ s}$  to  $210\text{ s}$ . Thus, the initial rate is

$$\begin{aligned}\text{Rate} &= -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = -\frac{(0.060 - 0.100)\text{ M}}{(210 - 0)\text{ s}} \\ &= 1.9 \times 10^{-4}\text{ M/s}\end{aligned}$$

**Practice Exercise 1**

Which of the following could be the instantaneous rate of the reaction in Figure 14.3 at  $t = 1000\text{ s}$ ?

- (a)  $1.2 \times 10^{-4}\text{ M/s}$
- (b)  $8.8 \times 10^{-5}\text{ M/s}$
- (c)  $6.3 \times 10^{-5}\text{ M/s}$
- (d)  $2.7 \times 10^{-5}\text{ M/s}$
- (e) More than one of these.

**Practice Exercise 2**

Using Figure 14.3, determine the instantaneous rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$  at  $t = 300\text{ s}$ .

**Give It Some Thought**

In Figure 14.3, order the following three rates from fastest to slowest: (i) The average rate of the reaction between  $0\text{ s}$  and  $600\text{ s}$ , (ii) the instantaneous rate at  $t = 0\text{ s}$ , and (iii) the instantaneous rate at  $t = 600\text{ s}$ . You should not have to do any calculations.

**Reaction Rates and Stoichiometry**

During our discussion of the hypothetical reaction  $\text{A} \longrightarrow \text{B}$ , we saw that the stoichiometry requires that the rate of disappearance of A equal the rate of appearance of B. Likewise, the stoichiometry of Equation 14.3 indicates that 1 mol of  $\text{C}_4\text{H}_9\text{OH}$  is produced for each mole of  $\text{C}_4\text{H}_9\text{Cl}$  consumed. Therefore, the rate of appearance of  $\text{C}_4\text{H}_9\text{OH}$  equals the rate of disappearance of  $\text{C}_4\text{H}_9\text{Cl}$ :

$$\text{Rate} = -\frac{\Delta[\text{C}_4\text{H}_9\text{Cl}]}{\Delta t} = \frac{\Delta[\text{C}_4\text{H}_9\text{OH}]}{\Delta t}$$

What happens when the stoichiometric relationships are not one-to-one? For example, consider the reaction  $2\text{HI(g)} \longrightarrow \text{H}_2\text{(g)} + \text{I}_2\text{(g)}$ . We can measure either the rate of disappearance of HI or the rate of appearance of either  $\text{H}_2$  or  $\text{I}_2$ . Because 2 mol of HI disappears for each mole of  $\text{H}_2$  or  $\text{I}_2$  that forms, the rate of disappearance of HI is *twice* the rate of appearance of either  $\text{H}_2$  or  $\text{I}_2$ . How do we decide which number to use for the rate of the reaction? Depending on whether we monitor HI,  $\text{I}_2$ , or  $\text{H}_2$ , the rates can differ by a factor of 2. To fix this problem, we need to take into account the reaction stoichiometry. To arrive at a number for the reaction rate that does not depend on which component we measured, we must divide the rate of disappearance of HI by 2 (its coefficient in the balanced chemical equation):

$$\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{HI}]}{\Delta t} = \frac{\Delta[\text{H}_2]}{\Delta t} = \frac{\Delta[\text{I}_2]}{\Delta t}$$

In general, for the reaction

the rate is given by

$$\text{Rate} = -\frac{1}{a} \frac{\Delta[\text{A}]}{\Delta t} = -\frac{1}{b} \frac{\Delta[\text{B}]}{\Delta t} = \frac{1}{c} \frac{\Delta[\text{C}]}{\Delta t} = \frac{1}{d} \frac{\Delta[\text{D}]}{\Delta t} \quad [14.4]$$

When we speak of the rate of a reaction without specifying a particular reactant or product, we utilize the definition in Equation 14.4.\*

### Sample Exercise 14.3

#### Relating Rates at Which Products Appear and Reactants Disappear

- (a) How is the rate at which ozone disappears related to the rate at which oxygen appears in the reaction  $2 \text{O}_3(g) \longrightarrow 3 \text{O}_2(g)$ ?
- (b) If the rate at which  $\text{O}_2$  appears,  $\Delta[\text{O}_2]/\Delta t$ , is  $6.0 \times 10^{-5} \text{ M/s}$  at a particular instant, at what rate is  $\text{O}_3$  disappearing at this same time,  $-\Delta[\text{O}_3]/\Delta t$ ?

#### SOLUTION

**Analyze** We are given a balanced chemical equation and asked to relate the rate of appearance of the product to the rate of disappearance of the reactant.

**Plan** We can use the coefficients in the chemical equation as shown in Equation 14.4 to express the relative rates of reactions.

#### Solve

- (a) Using the coefficients in the balanced equation and the relationship given by Equation 14.4, we have:

$$\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{O}_3]}{\Delta t} = \frac{1}{3} \frac{\Delta[\text{O}_2]}{\Delta t}$$

- (b) Solving the equation from part (a) for the rate at which  $\text{O}_3$  disappears,  $-\Delta[\text{O}_3]/\Delta t$ , we have:

$$-\frac{\Delta[\text{O}_3]}{\Delta t} = \frac{2}{3} \frac{\Delta[\text{O}_2]}{\Delta t} = \frac{2}{3} (6.0 \times 10^{-5} \text{ M/s}) = 4.0 \times 10^{-5} \text{ M/s}$$

**Check** We can apply a stoichiometric factor to convert the  $\text{O}_2$  formation rate to the  $\text{O}_3$  disappearance rate:

$$-\frac{\Delta[\text{O}_3]}{\Delta t} = \left( 6.0 \times 10^{-5} \frac{\text{mol O}_2/\text{L}}{\text{s}} \right) \left( \frac{2 \text{ mol O}_3}{3 \text{ mol O}_2} \right) = 4.0 \times 10^{-5} \frac{\text{mol O}_3/\text{L}}{\text{s}} = 4.0 \times 10^{-5} \text{ M/s}$$

#### Practice Exercise 1

At a certain time in a reaction, substance A is disappearing at a rate of  $4.0 \times 10^{-2} \text{ M/s}$ , substance B is appearing at a rate of  $2.0 \times 10^{-2} \text{ M/s}$ , and substance C is appearing at a rate of  $6.0 \times 10^{-2} \text{ M/s}$ . Which of the following could be the stoichiometry for the reaction being studied?

- (a)  $2 \text{A} + \text{B} \longrightarrow 3 \text{C}$     (b)  $\text{A} \longrightarrow 2 \text{B} + 3 \text{C}$

- (c)  $2 \text{A} \longrightarrow \text{B} + 3 \text{C}$     (d)  $4 \text{A} \longrightarrow 2 \text{B} + 3 \text{C}$   
 (e)  $\text{A} + 2 \text{B} \longrightarrow 3 \text{C}$

#### Practice Exercise 2

If the rate of decomposition of  $\text{N}_2\text{O}_5$  in the reaction  $2 \text{N}_2\text{O}_5(g) \longrightarrow 4 \text{NO}_2(g) + \text{O}_2(g)$  at a particular instant is  $4.2 \times 10^{-7} \text{ M/s}$ , what is the rate of appearance of (a)  $\text{NO}_2$  and (b)  $\text{O}_2$  at that instant?

## 14.3 | Concentration and Rate Laws

One way of studying the effect of concentration on reaction rate is to determine the way in which the initial rate of a reaction depends on the initial concentrations. For example, we might study the rate of the reaction

by measuring the concentration of  $\text{NH}_4^+$  or  $\text{NO}_2^-$  as a function of time or by measuring the volume of  $\text{N}_2$  collected as a function of time. Because the stoichiometric coefficients on  $\text{NH}_4^+$ ,  $\text{NO}_2^-$ , and  $\text{N}_2$  are the same, all of these rates are the same.

Table 14.2 shows that changing the initial concentration of either reactant changes the initial reaction rate. If we double  $[\text{NH}_4^+]$  while holding  $[\text{NO}_2^-]$  constant, the rate doubles (compare experiments 1 and 2). If we increase  $[\text{NH}_4^+]$  by a factor of 4 but

\*Equation 14.4 does not hold true if substances other than C and D are formed in significant amounts. For example, sometimes intermediate substances build in concentration before forming the final products. In that case, the relationship between the rate of disappearance of reactants and the rate of appearance of products is not given by Equation 14.4. All reactions whose rates we consider in this chapter obey Equation 14.4.

**TABLE 14.2** Rate Data for the Reaction of Ammonium and Nitrite Ions in Water at 25 °C

| Experiment Number | Initial $\text{NH}_4^+$ Concentration (M) | Initial $\text{NO}_2^-$ Concentration (M) | Observed Initial Rate (M/s) |
|-------------------|---|---|-----------------------------|
| 1                 | 0.0100                                    | 0.200                                     | $5.4 \times 10^{-7}$        |
| 2                 | 0.0200                                    | 0.200                                     | $10.8 \times 10^{-7}$       |
| 3                 | 0.0400                                    | 0.200                                     | $21.5 \times 10^{-7}$       |
| 4                 | 0.200                                     | 0.0202                                    | $10.8 \times 10^{-7}$       |
| 5                 | 0.200                                     | 0.0404                                    | $21.6 \times 10^{-7}$       |
| 6                 | 0.200                                     | 0.0808                                    | $43.3 \times 10^{-7}$       |

### A CLOSER LOOK Using Spectroscopic Methods to Measure Reaction Rates: Beer's Law

A variety of techniques can be used to monitor reactant and product concentration during a reaction, including spectroscopic methods, which rely on the ability of substances to absorb (or emit) light. Spectroscopic kinetic studies are often performed with the reaction mixture in the sample compartment of a *spectrometer*, an instrument that measures the amount of light transmitted or absorbed by a sample at different wavelengths. For kinetic studies, the spectrometer is set to measure the light absorbed at a wavelength characteristic of one of the reactants or products. In the decomposition of  $\text{HI(g)}$  into  $\text{H}_2\text{(g)}$

and  $\text{I}_2\text{(g)}$ , for example, both  $\text{HI}$  and  $\text{H}_2$  are colorless, whereas  $\text{I}_2$  is violet. During the reaction, the violet color of the reaction mixture gets more intense as  $\text{I}_2$  forms. Thus, visible light of appropriate wavelength can be used to monitor the reaction (Figure 14.4).

Figure 14.5 shows the components of a spectrometer. The spectrometer measures the amount of light absorbed by the sample by comparing the intensity of the light emitted from the light source with the intensity of the light transmitted through the sample, for various wavelengths. As the concentration of  $\text{I}_2$  increases and its color becomes more intense, the amount of light absorbed by the reaction mixture increases, as Figure 14.4 shows, causing less light to reach the detector.

How can we relate the amount of light detected by the spectrometer to the concentration of a species? A relationship called *Beer's law* gives us a direct route to the information we seek. Beer's law connects the amount of light absorbed to the concentration of the absorbing substance:

$$A = \epsilon bc \quad [14.5]$$

In this equation,  $A$  is the measured absorbance,  $\epsilon$  is the extinction coefficient (a characteristic of the substance being monitored at a given wavelength of light),  $b$  is the path length through which the light passes, and  $c$  is the molar concentration of the absorbing substance. Thus, the concentration is directly proportional to absorbance. Many chemical and pharmaceutical companies routinely use Beer's law to calculate the concentration of purified solutions of the compounds that they make. In the laboratory portion of your course, you may very well perform one or more experiments in which you use Beer's law to relate absorption of light to concentration.

**Related Exercises:** 14.101, 14.102, Design an Experiment

▲ Figure 14.4 Visible spectra of  $\text{I}_2$  at different concentrations.

▲ Figure 14.5 Components of a spectrometer.

leave  $[\text{NO}_2^-]$  unchanged (experiments 1 and 3), the rate changes by a factor of 4, and so forth. These results indicate that the initial reaction rate is proportional to  $[\text{NH}_4^+]$ . When  $[\text{NO}_2^-]$  is similarly varied while  $[\text{NH}_4^+]$  is held constant, the rate is affected in the same manner. Thus, the rate is also directly proportional to the concentration of  $[\text{NO}_2^-]$ .

We express the way in which the rate depends on the reactant concentrations by the equation

$$\text{Rate} = k[\text{NH}_4^+][\text{NO}_2^-] \quad [14.6]$$

An equation such as Equation 14.6, which shows how the rate depends on reactant concentrations, is called a **rate law**. For the general reaction

the rate law generally has the form

$$\text{Rate} = k[\text{A}]^m[\text{B}]^n \quad [14.7]$$

Notice that only the concentrations of the reactants generally appear in the rate law. The constant  $k$  is called the **rate constant**. The magnitude of  $k$  changes with temperature and therefore determines how temperature affects rate, as we will see in Section 14.5. The exponents  $m$  and  $n$  are typically small whole numbers, whose values are not necessarily equal to the coefficients  $a$  and  $b$  from the balanced equation. As we will learn shortly, if we know  $m$  and  $n$  for a reaction, we can gain great insight into the individual steps that occur during the reaction.

### Give It Some Thought

Does the rate constant depend on the concentrations of the reactants?

Once we know the rate law for a reaction and the reaction rate for a set of reactant concentrations, we can calculate the value of  $k$ . For example, using the values for experiment 1 in Table 14.2, we can substitute into Equation 14.6:

$$\begin{aligned} 5.4 \times 10^{-7} \text{ M/s} &= k(0.0100 \text{ M})(0.200 \text{ M}) \\ k &= \frac{5.4 \times 10^{-7} \text{ M/s}}{(0.0100 \text{ M})(0.200 \text{ M})} = 2.7 \times 10^{-4} \text{ M}^{-1}\text{s}^{-1} \end{aligned}$$

You should verify that this same value of  $k$  is obtained using any of the other experimental results in Table 14.2.

Once we have both the rate law and the  $k$  value for a reaction, we can calculate the reaction rate for any set of concentrations. For example, using Equation 14.7 with  $k = 2.7 \times 10^{-4} \text{ M}^{-1}\text{s}^{-1}$ ,  $m = 1$ , and  $n = 1$ , we can calculate the rate for  $[\text{NH}_4^+] = 0.100 \text{ M}$  and  $[\text{NO}_2^-] = 0.100 \text{ M}$ :

$$\text{Rate} = (2.7 \times 10^{-4} \text{ M}^{-1}\text{s}^{-1})(0.100 \text{ M})(0.100 \text{ M}) = 2.7 \times 10^{-6} \text{ M/s}$$

### Give It Some Thought

Does the rate constant have the same units as the rate?

## Reaction Orders: The Exponents in the Rate Law

The rate law for most reactions has the form

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots \quad [14.8]$$

The exponents  $m$  and  $n$  are called **reaction orders**. For example, consider again the rate law for the reaction of  $\text{NH}_4^+$  with  $\text{NO}_2^-$ :

$$\text{Rate} = k[\text{NH}_4^+][\text{NO}_2^-]$$

Because the exponent of  $[\text{NH}_4^+]$  is 1, the rate is *first order* in  $\text{NH}_4^+$ . The rate is also first order in  $\text{NO}_2^-$ . (The exponent 1 is not shown in rate laws.) The **overall reaction order** is the sum of the orders with respect to each reactant represented in the rate law. Thus, for the reaction between  $\text{NH}_4^+$  and  $\text{NO}_2^-$  the rate law has an overall reaction order of  $1 + 1 = 2$ , and the reaction is *second order overall*.

The exponents in a rate law indicate how the rate is affected by each reactant concentration. Because the rate at which  $\text{NH}_4^+$  reacts with  $\text{NO}_2^-$  depends on  $[\text{NH}_4^+]$  raised to the first power, the rate doubles when  $[\text{NH}_4^+]$  doubles, triples when  $[\text{NH}_4^+]$  triples, and so forth. Doubling or tripling  $[\text{NO}_2^-]$  likewise doubles or triples the rate. If a rate law is second order with respect to a reactant,  $[\text{A}]^2$ , then doubling the concentration of that substance causes the reaction rate to quadruple because  $[2]^2 = 4$ , whereas tripling the concentration causes the rate to increase ninefold:  $[3]^2 = 9$ .

The following are some additional examples of experimentally determined rate laws:

Although the exponents in a rate law are sometimes the same as the coefficients in the balanced equation, this is not necessarily the case, as Equations 14.9 and 14.11 show.

*For any reaction, the rate law must be determined experimentally.*

In most rate laws, reaction orders are 0, 1, or 2. However, we also occasionally encounter rate laws in which the reaction order is fractional (as is the case with Equation 14.11) or even negative.

### Give It Some Thought

The experimentally determined rate law for the reaction

$$\text{is Rate} = k[\text{NO}]^2[\text{H}_2].$$

If the concentration of  $\text{H}_2$  is doubled, will the reaction rate quadruple, double, or remain the same?

## Sample Exercise 14.4

### Relating a Rate Law to the Effect of Concentration on Rate

Consider a reaction  $\text{A} + \text{B} \longrightarrow \text{C}$  for which  $\text{rate} = k[\text{A}][\text{B}]^2$ . Each of the following boxes represents a reaction mixture in which A is shown as red spheres and B as purple ones. Rank these mixtures in order of increasing rate of reaction.

(1)

(2)

(3)

### SOLUTION

**Analyze** We are given three boxes containing different numbers of spheres representing mixtures containing different reactant concentrations. We are asked to use the given rate law and the compositions of the boxes to rank the mixtures in order of increasing reaction rates.

**Plan** Because all three boxes have the same volume, we can put the number of spheres of each kind into the rate law and calculate the rate for each box.

**Solve** Box 1 contains 5 red spheres and 5 purple spheres, giving the following rate:

$$\text{Box 1: Rate} = k(5)(5)^2 = 125k$$

Box 2 contains 7 red spheres and 3 purple spheres:

$$\text{Box 2: Rate} = k(7)(3)^2 = 63k$$

Box 3 contains 3 red spheres and 7 purple spheres:

$$\text{Box 3: Rate} = k(3)(7)^2 = 147k$$

The slowest rate is  $63k$  (Box 2), and the highest is  $147k$  (Box 3). Thus, the rates vary in the order  $2 < 1 < 3$ .

**Check** Each box contains 10 spheres. The rate law indicates that in this case [B] has a greater influence on rate than [A] because B has a larger reaction order. Hence, the mixture with the highest concentration of B (most purple spheres) should react fastest. This analysis confirms the order  $2 < 1 < 3$ .

### Practice Exercise 1

Suppose the rate law for the reaction in this Sample Exercise were  $\text{rate} = k[\text{A}]^2[\text{B}]$ . What would be the ordering of the rates for the three mixtures shown above, from slowest to fastest?

- (a)  $1 < 2 < 3$
- (b)  $1 < 3 < 2$
- (c)  $3 < 2 < 1$
- (d)  $2 < 1 < 3$
- (e)  $3 < 1 < 2$

### Practice Exercise 2

Assuming that  $\text{rate} = k[\text{A}][\text{B}]$ , rank the mixtures represented in this Sample Exercise in order of increasing rate.

## Magnitudes and Units of Rate Constants

If chemists want to compare reactions to evaluate which ones are relatively fast and which ones are relatively slow, the quantity of interest is the rate constant. A good general rule is that a large value of  $k$  ( $\sim 10^9$  or higher) means a fast reaction and a small value of  $k$  (10 or lower) means a slow reaction.

The units of the rate constant depend on the overall reaction order of the rate law. In a reaction that is second order overall, for example, the units of the rate constant must satisfy the equation:

$$\text{Units of rate} = (\text{units of rate constant})(\text{units of concentration})^2$$

Hence, in our usual units of molarity for concentration and seconds for time, we have

$$\text{Units of rate constant} = \frac{\text{units of rate}}{(\text{units of concentration})^2} = \frac{M/s}{M^2} = M^{-1}s^{-1}$$

## Sample Exercise 14.5

### Determining Reaction Orders and Units for Rate Constants

- (a) What are the overall reaction orders for the reactions described in Equations 14.9 and 14.11?
- (b) What are the units of the rate constant for the rate law in Equation 14.9?

### SOLUTION

**Analyze** We are given two rate laws and asked to express (a) the overall reaction order for each and (b) the units for the rate constant for the first reaction.

**Plan** The overall reaction order is the sum of the exponents in the rate law. The units for the rate constant,  $k$ , are found by using the normal units for rate ( $M/s$ ) and concentration ( $M$ ) in the rate law and applying algebra to solve for  $k$ .

### Solve

- (a) The rate of the reaction in Equation 14.9 is first order in  $\text{N}_2\text{O}_5$  and first order overall. The reaction in Equation 14.11 is first order in  $\text{CHCl}_3$  and one-half order in  $\text{Cl}_2$ . The overall reaction order is three halves.
- (b) For the rate law for Equation 14.9, we have

$$\text{Units of rate} = (\text{units of rate constant})(\text{units of concentration})$$

so

$$\text{Units of rate constant} = \frac{\text{units of rate}}{\text{units of concentration}} = \frac{M/s}{M} = s^{-1}$$

Note that if the reaction order changes, the units of the rate constant change.

### Practice Exercise 1

Which of the following are the units of the rate constant for Equation 14.11?

- (a)  $M^{-1/2}s^{-1}$  (b)  $M^{-1/2}s^{-1/2}$  (c)  $M^{1/2}s^{-1}$  (d)  $M^{-3/2}s^{-1}$  (e)  $M^{-3/2}s^{-1/2}$

### Practice Exercise 2

(a) What is the reaction order of the reactant  $\text{H}_2$  in Equation 14.10? (b) What are the units of the rate constant for Equation 14.10?

## Using Initial Rates to Determine Rate Laws

We have seen that the rate law for most reactions has the general form

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots$$

Thus, the task of determining the rate law becomes one of determining the reaction orders,  $m$  and  $n$ . In most reactions, the reaction orders are 0, 1, or 2. As noted earlier in this section, we can use the response of the reaction rate to a change in initial concentration to determine the reaction order.

In working with rate laws, it is important to realize that the *rate* of a reaction depends on concentration but the *rate constant* does not. As we will see later in this chapter, the rate constants (and hence the reaction rate) are affected by temperature and by the presence of a catalyst.

## Sample Exercise 14.6

## Determining a Rate Law from Initial Rate Data

The initial rate of a reaction  $A + B \longrightarrow C$  was measured for three different starting concentrations of A and B, and the results are as follows:

| Experiment Number | [A](M) | [B](M) | Initial Rate (M/s)    |
|-------------------|--------|--------|-----------------------|
| 1                 | 0.100  | 0.100  | $4.0 \times 10^{-5}$  |
| 2                 | 0.100  | 0.200  | $4.0 \times 10^{-5}$  |
| 3                 | 0.200  | 0.100  | $16.0 \times 10^{-5}$ |

Using these data, determine (a) the rate law for the reaction, (b) the rate constant, (c) the rate of the reaction when  $[A] = 0.050M$  and  $[B] = 0.100M$ .

## SOLUTION

**Analyze** We are given a table of data that relates concentrations of reactants with initial rates of reaction and asked to determine (a) the rate law, (b) the rate constant, and (c) the rate of reaction for a set of concentrations not listed in the table.

**Plan** (a) We assume that the rate law has the following form:  $\text{Rate} = k[A]^m[B]^n$ . We will use the given data to deduce the reaction orders  $m$  and  $n$  by determining how changes in the concentration change the rate. (b) Once we know  $m$  and  $n$ , we can use the rate law and one of the sets of data to determine the rate constant  $k$ . (c) Upon determining both the rate constant and the reaction orders, we can use the rate law with the given concentrations to calculate rate.

## Solve

- (a) If we compare experiments 1 and 2, we see that  $[A]$  is held constant and  $[B]$  is doubled. Thus, this pair of experiments shows how  $[B]$  affects the rate, allowing us to deduce the order of the rate law with respect to B.

Inserting values of rate and concentration from the experiments gives:

The only way this equation can be true is if  $n = 0$ . Therefore, the rate law is zero order in B, which means that the rate is independent of  $[B]$ .

In experiments 1 and 3,  $[B]$  is held constant, so these data allow us to determine the order of the rate law with respect to  $[A]$ .

Inserting values of rate and concentration from the experiments gives:

Because the rate increases by a factor of four when  $[A]$  is doubled, we can conclude that  $m = 2$  and the rate law is second order in B.

Combining these results, we arrive at the rate law:

$$\frac{\text{Rate 1}}{\text{Rate 2}} = \frac{k[A_1]^m[B_1]^n}{k[A_2]^m[B_2]^n}$$

$$\frac{4.0 \times 10^{-5} \text{ M/s}}{4.0 \times 10^{-5} \text{ M/s}} = \frac{k[0.100 \text{ M}]^m[0.100 \text{ M}]^n}{k[0.100 \text{ M}]^m[0.200 \text{ M}]^n}$$

$$1 = (1/2)^n$$

$$\frac{\text{Rate 1}}{\text{Rate 3}} = \frac{k[A_1]^m[B_1]^n}{k[A_3]^m[B_3]^n}$$

$$\frac{16.0 \times 10^{-5} \text{ M/s}}{4.0 \times 10^{-5} \text{ M/s}} = \frac{k[0.200 \text{ M}]^m[0.100 \text{ M}]^n}{k[0.100 \text{ M}]^m[0.100 \text{ M}]^n}$$

$$4 = (2)^m$$

$$\text{Rate} = k[A]^2[B]^0 = k[A]^2$$

(b) Using the rate law and the data from experiment 1, we have:

$$k = \frac{\text{rate}}{[\text{A}]^2} = \frac{4.0 \times 10^{-5} \text{ M/s}}{(0.100 \text{ M})^2} = 4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$$

(c) Using the rate law from part (a) and the rate constant from part (b), we have:

$$\begin{aligned}\text{Rate} &= k[\text{A}]^2 \\ &= (4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1})(0.050 \text{ M})^2 \\ &= 1.0 \times 10^{-5} \text{ M/s}\end{aligned}$$

Because [B] is not part of the rate law, it is irrelevant to the rate if there is at least some B present to react with A.

**Check** A good way to check our rate law is to use the concentrations in experiment 2 or 3 and see if we can correctly calculate the rate. Using data from experiment 3, we have

$$\begin{aligned}\text{Rate} &= k[\text{A}]^2 = (4.0 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1})(0.200 \text{ M})^2 \\ &= 1.6 \times 10^{-4} \text{ M/s}\end{aligned}$$

Thus, the rate law correctly reproduces the data, giving both the correct number and the correct units for the rate.

### Practice Exercise 1

Consider the reaction examined above in the Sample Exercise,  $\text{A} + \text{B} \rightarrow \text{C}$ . If the concentration of B is doubled, the rate of disappearance of B \_\_\_\_\_, whereas if the concentration of A is doubled, the rate of disappearance of B \_\_\_\_\_.

- (a) does not change; does not change
- (b) increases by a factor of two; increases by a factor of two
- (c) increases by a factor of four; increases by a factor of two
- (d) does not change; increases by a factor of four
- (e) increases by a factor of four; does not change

### Practice Exercise 2

The following data were measured for the reaction of nitric oxide with hydrogen:

| Experiment Number | [NO](M) | [H <sub>2</sub> ](M) | Initial Rate (M/s)    |
|-------------------|---------|----------------------|-----------------------|
| 1                 | 0.10    | 0.10                 | $1.23 \times 10^{-3}$ |
| 2                 | 0.10    | 0.20                 | $2.46 \times 10^{-3}$ |
| 3                 | 0.20    | 0.10                 | $4.92 \times 10^{-3}$ |

- (a) Determine the rate law for this reaction.
- (b) Calculate the rate constant.
- (c) Calculate the rate when  $[\text{NO}] = 0.050 \text{ M}$  and  $[\text{H}_2] = 0.150 \text{ M}$ .

## 14.4 | The Change of Concentration with Time

The rate laws we have examined so far enable us to calculate the rate of a reaction from the rate constant and reactant concentrations. In this section, we will show that rate laws can also be converted into equations that show the relationship between concentrations of reactants or products and time. The mathematics required to accomplish this conversion involves calculus. We do not expect you to be able to perform the calculus operations, but you should be able to use the resulting equations. We will apply this conversion to three of the simplest rate laws: those that are first order overall, those that are second order overall, and those that are zero order overall.

### First-Order Reactions

A **first-order reaction** is one whose rate depends on the concentration of a single reactant raised to the first power. If a reaction of the type  $\text{A} \longrightarrow \text{products}$  is first order, the rate law is:

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]$$

This form of a rate law, which expresses how rate depends on concentration, is called the *differential rate law*. Using the operation from calculus called integration, we see that this relationship can be transformed into an equation known as the *integrated rate law* for a first-order reaction that relates the initial concentration of A,  $[\text{A}]_0$ , to its concentration at any other time  $t$ ,  $[\text{A}]_t$ :

$$\ln[\text{A}]_t - \ln[\text{A}]_0 = -kt \quad \text{or} \quad \ln \frac{[\text{A}]_t}{[\text{A}]_0} = -kt \quad [14.12]$$

The function “ln” in Equation 14.12 is the natural logarithm (Appendix A.2). Equation 14.12 can also be rearranged to

$$\ln[\text{A}]_t = -kt + \ln[\text{A}]_0 \quad [14.13]$$

Equations 14.12 and 14.13 can be used with any concentration units as long as the units are the same for both  $[A]_t$  and  $[A]_0$ . When dealing with gases, we can use pressure as a concentration in Equations 14.12 and 14.13. This substitution follows from the fact that the ideal gas law (see Section 10.4) dictates that at constant temperature the pressure is directly proportional to the concentration ( $n/V$ ).

For a first-order reaction, Equation 14.12 or 14.13 can be used in several ways. Given any three of the following quantities, we can solve for the fourth:  $k$ ,  $t$ ,  $[A]_0$ , and  $[A]_t$ . Thus, you can use these equations to determine (1) the concentration of a reactant remaining at any time after the reaction has started, (2) the time interval required for a given fraction of a sample to react, or (3) the time interval required for a reactant concentration to fall to a certain level.

## Sample Exercise 14.7

### Using the Integrated First-Order Rate Law

The decomposition of a certain insecticide in water at 12 °C follows first-order kinetics with a rate constant of  $1.45 \text{ yr}^{-1}$ . A quantity of this insecticide is washed into a lake on June 1, leading to a concentration of  $5.0 \times 10^{-7} \text{ g/cm}^3$ . Assume that the temperature of the lake is constant (so that there are no effects of temperature variation on the rate). (a) What is the concentration of the insecticide on June 1 of the following year? (b) How long will it take for the insecticide concentration to decrease to  $3.0 \times 10^{-7} \text{ g/cm}^3$ ?

### SOLUTION

**Analyze** We are given the rate constant for a reaction that obeys first-order kinetics, as well as information about concentrations and times, and asked to calculate how much reactant (insecticide) remains after 1 yr. We must also determine the time interval needed to reach a particular insecticide concentration.

**Plan** In part (a) we are given the rate constant, a period of time, and the initial concentration of the reactant, so we can use Equation 14.13 to determine the concentration of the reactant after 1 year has passed. In part (b) we are given the initial and final concentrations and the rate constant. In this case we can use Equation 14.13 to calculate the time that must pass to reach the desired concentration.

### Solve

(a) Substituting the known quantities into Equation 14.13, we have:  $\ln[\text{insecticide}]_{t=1 \text{ yr}} = -(1.45 \text{ yr}^{-1})(1.00 \text{ yr}) + \ln(5.0 \times 10^{-7})$

We use the  $\ln$  function on a calculator to evaluate the second term on the right [that is,  $\ln(5.0 \times 10^{-7})$ ], giving:

$$\ln[\text{insecticide}]_{t=1 \text{ yr}} = -1.45 + (-14.51) = -15.96$$

To obtain  $[\text{insecticide}]_{t=1 \text{ yr}}$ , we use the inverse natural logarithm, or  $e^x$ , function on the calculator:

$$[\text{insecticide}]_{t=1 \text{ yr}} = e^{-15.96} = 1.2 \times 10^{-7} \text{ g/cm}^3$$

Note that the concentration units for  $[A]_t$  and  $[A]_0$  must be the same.

(b) Again substituting into Equation 14.13, with  $[\text{insecticide}]_t = 3.0 \times 10^{-7} \text{ g/cm}^3$ , gives:

$$\ln(3.0 \times 10^{-7}) = -(1.45 \text{ yr}^{-1})(t) + \ln(5.0 \times 10^{-7})$$

Solving for  $t$  gives:

$$\begin{aligned} t &= -[\ln(3.0 \times 10^{-7}) - \ln(5.0 \times 10^{-7})]/1.45 \text{ yr}^{-1} \\ &= -(-15.02 + 14.51)/1.45 \text{ yr}^{-1} = 0.35 \text{ yr} \end{aligned}$$

**Check** In part (a) the concentration remaining after 1.00 yr (that is,  $1.2 \times 10^{-7} \text{ g/cm}^3$ ) is less than the original concentration ( $5.0 \times 10^{-7} \text{ g/cm}^3$ ), as it should be. In (b) the given concentration ( $3.0 \times 10^{-7} \text{ g/cm}^3$ ) is greater than that remaining after 1.00 yr, indicating that the time must be less than a year. Thus,  $t = 0.35 \text{ yr}$  is a reasonable answer.

### Practice Exercise 1

At 25 °C, the decomposition of dinitrogen pentoxide,  $\text{N}_2\text{O}_5(\text{g})$ , into  $\text{NO}_2(\text{g})$  and  $\text{O}_2(\text{g})$  follows first-order kinetics with  $k = 3.4 \times 10^{-5} \text{ s}^{-1}$ . A sample of  $\text{N}_2\text{O}_5$  with an initial

pressure of 760 torr decomposes at 25 °C until its partial pressure is 650 torr. How much time (in seconds) has elapsed?

(a)  $5.3 \times 10^{-6}$  (b) 2000 (c) 4600 (d) 34,000 (e) 190,000

### Practice Exercise 2

The decomposition of dimethyl ether,  $(\text{CH}_3)_2\text{O}$ , at 510 °C is a first-order process with a rate constant of  $6.8 \times 10^{-4} \text{ s}^{-1}$ :

If the initial pressure of  $(\text{CH}_3)_2\text{O}$  is 135 torr, what is its pressure after 1420 s?

Equation 14.13 can be used to verify whether a reaction is first order and to determine its rate constant. This equation has the form of the general equation for a straight line,  $y = mx + b$ , in which  $m$  is the slope and  $b$  is the  $y$ -intercept of the line (Appendix A.4):

$$\ln [A]_t = -kt + \ln [A]_0$$

$$\begin{array}{ccccc} \updownarrow & & \updownarrow & & \updownarrow \\ y & = & mx & + & b \end{array}$$

For a first-order reaction, therefore, a graph of  $\ln[A]_t$  versus time gives a straight line with a slope of  $-k$  and a  $y$ -intercept of  $\ln[A]_0$ . A reaction that is not first order will not yield a straight line.

As an example, consider the conversion of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) to its isomer acetonitrile ( $\text{CH}_3\text{CN}$ ) (Figure 14.6). Because experiments show that the reaction is first order, we can write the rate equation:

$$\ln[\text{CH}_3\text{NC}]_t = -kt + \ln[\text{CH}_3\text{NC}]_0$$

We run the reaction at a temperature at which methyl isonitrile is a gas ( $199^\circ\text{C}$ ), and Figure 14.7(a) shows how the pressure of this gas varies with time. Figure 14.7(b) shows that a plot of the natural logarithm of the pressure versus time is a straight line. The slope of this line is  $-5.1 \times 10^{-5} \text{ s}^{-1}$ . (You should verify this for yourself, remembering that your result may vary slightly from ours because of inaccuracies associated with reading the graph.) Because the slope of the line equals  $-k$ , the rate constant for this reaction equals  $5.1 \times 10^{-5} \text{ s}^{-1}$ .

Methyl isonitrile

Acetonitrile

▲ Figure 14.6 The first-order reaction of  $\text{CH}_3\text{NC}$  conversion into  $\text{CH}_3\text{CN}$ .

## Second-Order Reactions

A **second-order reaction** is one for which the rate depends either on a reactant concentration raised to the second power or on the concentrations of two reactants each raised to the first power. For simplicity, let's consider reactions of the type  $\text{A} \longrightarrow \text{products}$  or  $\text{A} + \text{B} \longrightarrow \text{products}$  that are second order in just one reactant, A:

$$\text{Rate} = -\frac{\Delta[\text{A}]}{\Delta t} = k[\text{A}]^2$$

With the use of calculus, this differential rate law can be used to derive the integrated rate law for second-order reactions:

$$\frac{1}{[\text{A}]_t} = kt + \frac{1}{[\text{A}]_0} \quad [14.14]$$

### Go Figure

What can you conclude given that the plot of  $\ln P$  versus  $t$  is linear?

(a)

(b)

▲ Figure 14.7 Kinetic data for conversion of methyl isonitrile into acetonitrile.

This equation, like Equation 14.13, has four variables,  $k$ ,  $t$ ,  $[A]_0$ , and  $[A]_t$ , and any one of these can be calculated knowing the other three. Equation 14.14 also has the form of a straight line ( $y = mx + b$ ). If the reaction is second order, a plot of  $1/[A]_t$  versus  $t$  yields a straight line with slope  $k$  and  $y$ -intercept  $1/[A]_0$ . One way to distinguish between first- and second-order rate laws is to graph both  $\ln[A]_t$  and  $1/[A]_t$  against  $t$ . If the  $\ln[A]_t$  plot is linear, the reaction is first order; if the  $1/[A]_t$  plot is linear, the reaction is second order.

### Sample Exercise 14.8

#### Determining Reaction Order from the Integrated Rate Law

The following data were obtained for the gas-phase decomposition of nitrogen dioxide at 300 °C,  $\text{NO}_2(g) \longrightarrow \text{NO}(g) + \frac{1}{2}\text{O}_2(g)$ . Is the reaction first or second order in  $\text{NO}_2$ ?

| Time (s) | $[\text{NO}_2](M)$ |
|----------|--------------------|
| 0.0      | 0.01000            |
| 50.0     | 0.00787            |
| 100.0    | 0.00649            |
| 200.0    | 0.00481            |
| 300.0    | 0.00380            |

#### SOLUTION

**Analyze** We are given the concentrations of a reactant at various times during a reaction and asked to determine whether the reaction is first or second order.

**Plan** We can plot  $\ln[\text{NO}_2]$  and  $1/[\text{NO}_2]$  against time. If one plot or the other is linear, we will know the reaction is either first or second order.

#### Solve

To graph  $\ln[\text{NO}_2]$  and  $1/[\text{NO}_2]$  against time, we first make the following calculations from the data given:

| Time (s) | $[\text{NO}_2](M)$ | $\ln[\text{NO}_2]$ | $1/[\text{NO}_2] (1/M)$ |
|----------|--------------------|--------------------|-------------------------|
| 0.0      | 0.01000            | -4.605             | 100                     |
| 50.0     | 0.00787            | -4.845             | 127                     |
| 100.0    | 0.00649            | -5.037             | 154                     |
| 200.0    | 0.00481            | -5.337             | 208                     |
| 300.0    | 0.00380            | -5.573             | 263                     |

As Figure 14.8 shows, only the plot of  $1/[\text{NO}_2]$  versus time is linear. Thus, the reaction obeys a second-order rate law:  $\text{Rate} = k[\text{NO}_2]^2$ . From the slope of this straight-line graph, we determine that  $k = 0.543 M^{-1} s^{-1}$  for the disappearance of  $\text{NO}_2$ .

▲ Figure 14.8 Kinetic data for decomposition of  $\text{NO}_2$ .

#### Practice Exercise 1

For a certain reaction  $A \longrightarrow \text{products}$ , a plot of  $\ln[A]$  versus time produces a straight line with a slope of  $-3.0 \times 10^{-2} s^{-1}$ . Which of the following statements is or are true?

- (i) The reaction follows first-order kinetics.
  - (ii) The rate constant for the reaction is  $3.0 \times 10^{-2} s^{-1}$ .
  - (iii) The initial concentration of  $[A]$  was 1.0 M.
- (a) Only one of the statements is true.  
 (b) Statements (i) and (ii) are true.

- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

#### Practice Exercise 2

The decomposition of  $\text{NO}_2$  discussed in the Sample Exercise is second order in  $\text{NO}_2$  with  $k = 0.543 M^{-1} s^{-1}$ . If the initial concentration of  $\text{NO}_2$  in a closed vessel is 0.0500 M, what is the concentration of this reactant after 0.500 h?

## Zero-Order Reactions

We have seen that in a first-order reaction the concentration of a reactant A decreases nonlinearly, as shown by the red curve in Figure 14.9. As [A] declines, the *rate* at which it disappears declines in proportion. A **zero-order reaction** is one in which the rate of disappearance of A is *independent* of [A]. The rate law for a zero-order reaction is

$$\text{Rate} = \frac{-\Delta[A]}{\Delta t} = k \quad [14.15]$$

The integrated rate law for a zero-order reaction is

$$[A]_t = -kt + [A]_0 \quad [14.16]$$

where  $[A]_t$  is the concentration of A at time  $t$  and  $[A]_0$  is the initial concentration. This is the equation for a straight line with vertical intercept  $[A]_0$  and slope  $-kt$ , as shown in the blue curve in Figure 14.9.

The most common type of zero-order reaction occurs when a gas undergoes decomposition on the surface of a solid. If the surface is completely covered by decomposing molecules, the rate of reaction is constant because the number of reacting surface molecules is constant, so long as there is some gas-phase substance left.

## Half-Life

The **half-life** of a reaction,  $t_{1/2}$ , is the time required for the concentration of a reactant to reach half its initial value,  $[A]_{t_{1/2}} = \frac{1}{2}[A]_0$ . Half-life is a convenient way to describe how fast a reaction occurs, especially if it is a first-order process. A fast reaction has a short half-life.

We can determine the half-life of a first-order reaction by substituting  $[A]_{t_{1/2}} = \frac{1}{2}[A]_0$  for  $[A]_t$  and  $t_{1/2}$  for  $t$  in Equation 14.12:

$$\begin{aligned} \ln \frac{\frac{1}{2}[A]_0}{[A]_0} &= -kt_{1/2} \\ \ln \frac{1}{2} &= -kt_{1/2} \\ t_{1/2} &= -\frac{\ln \frac{1}{2}}{k} = \frac{0.693}{k} \end{aligned} \quad [14.17]$$

From Equation 14.17, we see that  $t_{1/2}$  for a first-order rate law does not depend on the initial concentration of any reactant. Consequently, the half-life remains constant throughout the reaction. If, for example, the initial concentration of a reactant is 0.120 M it will be  $\frac{1}{2}(0.120 \text{ M}) = 0.060 \text{ M}$  after one half-life. After one more half-life passes, the concentration will drop to 0.030 M, and so on. Equation 14.17 also indicates that, for a first-order reaction, we can calculate  $t_{1/2}$  if we know  $k$  and calculate  $k$  if we know  $t_{1/2}$ .

The change in concentration over time for the first-order rearrangement of gaseous methyl isonitrile at 199 °C is graphed in Figure 14.10. Because the concentration of this gas is directly proportional to its pressure during the reaction, we have chosen to plot pressure rather than concentration in this graph. The first half-life occurs at 13,600 s (3.78 h). At a time 13,600 s later, the methyl isonitrile pressure (and therefore, concentration) has decreased to half of one-half, or one-fourth, of the initial value.

*In a first-order reaction, the concentration of the reactant decreases by one-half in each of a series of regularly spaced time intervals, each interval equal to  $t_{1/2}$ .*

### Give It Some Thought

If a solution containing 10.0 g of a substance reacts by first-order kinetics, how many grams remain after three half-lives?

### Go Figure

At which times during the reaction would you have trouble distinguishing a zero-order reaction from a first-order reaction?

▲ Figure 14.9 Comparison of first-order and zero-order reactions for the disappearance of reactant A with time.

▲ Figure 14.10 Kinetic data for the rearrangement of methyl isonitrile to acetonitrile at 199 °C, showing the half-life of the reaction.

## CHEMISTRY PUT TO WORK Methyl Bromide in the Atmosphere

The compounds known as chlorofluorocarbons (CFCs) are well-known agents responsible for the destruction of Earth's protective ozone layer. Another simple molecule that has the potential to destroy the stratospheric ozone layer is methyl bromide,  $\text{CH}_3\text{Br}$  (Figure 14.11). Because this substance has a wide range of uses, including antifungal treatment of plant seeds, it has been produced in large quantities in the past (about 150 million pounds per year worldwide in 1997, at the height of its production). In the stratosphere, the C—Br bond is

broken through absorption of short-wavelength radiation. The resultant Br atoms then catalyze decomposition of  $\text{O}_3$ .

Methyl bromide is removed from the lower atmosphere by a variety of mechanisms, including a slow reaction with ocean water:

To determine the potential importance of  $\text{CH}_3\text{Br}$  in destruction of the ozone layer, it is important to know how rapidly the reaction in Equation 14.18 and all other reactions remove  $\text{CH}_3\text{Br}$  from the lower atmosphere before it can diffuse into the stratosphere.

The average lifetime of  $\text{CH}_3\text{Br}$  in Earth's lower atmosphere is difficult to measure because the conditions that exist in the atmosphere are too complex to be simulated in the laboratory. Instead, scientists analyzed nearly 4000 atmospheric samples collected above the Pacific Ocean for the presence of several trace organic substances, including methyl bromide. From these measurements, it was possible to estimate the *atmospheric residence time* for  $\text{CH}_3\text{Br}$ .

The atmospheric residence time is related to the half-life for  $\text{CH}_3\text{Br}$  in the lower atmosphere, assuming  $\text{CH}_3\text{Br}$  decomposes by a first-order process. From the experimental data, the half-life for methyl bromide in the lower atmosphere is estimated to be  $0.8 \pm 0.1$  yr. That is, a collection of  $\text{CH}_3\text{Br}$  molecules present at any given time will, on average, be 50% decomposed after 0.8 yr, 75% decomposed after 1.6 yr, and so on. A half-life of 0.8 yr, while comparatively short, is still sufficiently long so that  $\text{CH}_3\text{Br}$  contributes significantly to the destruction of the ozone layer.

In 1997 an international agreement was reached to phase out use of methyl bromide in developed countries by 2005. Although exemptions for critical agricultural use have been granted, global consumption in 2013 was only 3% of the levels seen in the early 1990s.

▲ Figure 14.11 Distribution and fate of methyl bromide in Earth's atmosphere.

## Sample Exercise 14.9

## Determining the Half-Life of a First-Order Reaction

The reaction of  $\text{C}_4\text{H}_9\text{Cl}$  with water is a first-order reaction. (a) Use Figure 14.3 to estimate the half-life for this reaction. (b) Use the half-life from (a) to calculate the rate constant.

## SOLUTION

**Analyze** We are asked to estimate the half-life of a reaction from a graph of concentration versus time and then to use the half-life to calculate the rate constant for the reaction.

## Plan

- (a) To estimate a half-life, we can select a concentration and then determine the time required for the concentration to decrease to half of that value.  
 (b) Equation 14.17 is used to calculate the rate constant from the half-life.

## Solve

- (a) From the graph, we see that the initial value of  $[\text{C}_4\text{H}_9\text{Cl}]$  is  $0.100\text{ M}$ . The half-life for this first-order reaction is the time required for  $[\text{C}_4\text{H}_9\text{Cl}]$  to decrease to  $0.050\text{ M}$ , which we can read off the graph. This point occurs at approximately 340 s.  
 (b) Solving Equation 14.17 for  $k$ , we have

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{340\text{ s}} = 2.0 \times 10^{-3}\text{ s}^{-1}$$

**Check** At the end of the second half-life, which should occur at 680 s, the concentration should have decreased by yet another factor of 2, to  $0.025\text{ M}$ . Inspection of the graph shows that this is indeed the case.

## Practice Exercise 1

We noted in an earlier Practice Exercise that at  $25^\circ\text{C}$  the decomposition of  $\text{N}_2\text{O}_5(g)$  into  $\text{NO}_2(g)$  and  $\text{O}_2(g)$  follows first-order kinetics with  $k = 3.4 \times 10^{-5}\text{ s}^{-1}$ . How long will it take for a sample originally containing  $2.0\text{ atm}$  of  $\text{N}_2\text{O}_5$  to reach a partial pressure of 380 torr?

- (a) 5.7 h (b) 8.2 h (c) 11 h (d) 16 h (e) 32 h

## Practice Exercise 2

- (a) Using Equation 14.17, calculate  $t_{1/2}$  for the decomposition of the insecticide described in Sample Exercise 14.7.  
 (b) How long does it take for the concentration of the insecticide to reach one-quarter of the initial value?

The half-life for second-order and other reactions depends on reactant concentrations and therefore changes as the reaction progresses. We obtained Equation 14.17 for the half-life for a first-order reaction by substituting  $[A]_{t_{1/2}} = \frac{1}{2}[A]_0$  for  $[A]_t$  and  $t_{1/2}$  for  $t$  in Equation 14.12. We find the half-life of a second-order reaction by making the same substitutions into Equation 14.14:

$$\begin{aligned}\frac{1}{\frac{1}{2}[A]_0} &= kt_{1/2} + \frac{1}{[A]_0} \\ \frac{2}{[A]_0} - \frac{1}{[A]_0} &= kt_{1/2} \\ t_{1/2} &= \frac{1}{k[A]_0}\end{aligned}\quad [14.19]$$

In this case, the half-life depends on the initial concentration of reactant—the lower the initial concentration, the longer the half-life.

### Give It Some Thought

Does the half-life of a zero-order reaction depend on the initial concentration of the reactant?

## 14.5 | Temperature and Rate

The rates of most chemical reactions increase as the temperature rises. For example, dough rises faster at room temperature than when refrigerated, and plants grow more rapidly in warm weather than in cold. We can see the effect of temperature on reaction rate by observing a chemiluminescence reaction (one that produces light), such as that in Cyalume® light sticks (Figure 14.12).

How is this experimentally observed temperature effect reflected in the rate law? The faster rate at higher temperature is due to an increase in the rate constant with increasing temperature. For example, let's reconsider the first-order reaction we saw in Figure 14.6 namely,  $\text{CH}_3\text{NC} \longrightarrow \text{CH}_3\text{CN}$ . Figure 14.13 shows the rate constant for this reaction as a function of temperature. The rate constant and, hence, the rate of the reaction increase rapidly with temperature, approximately doubling for each 10 °C rise.

### The Collision Model

Reaction rates are affected both by reactant concentrations and by temperature. The **collision model**, based on the kinetic-molecular theory (Section 10.7), accounts for both of these effects at the molecular level. The central idea of the collision model is that molecules must collide to react. The greater the number of collisions per second, the greater the reaction rate. As reactant concentration increases, therefore, the number of collisions increases, leading to an increase in reaction rate. According to the kinetic-molecular theory of gases, increasing the temperature increases molecular speeds. As molecules move faster, they collide more forcefully (with more energy) and more frequently, both of which increase the reaction rate.

For a reaction to occur, though, more is required than simply a collision—it must be the right kind of collision. For most reactions, in fact, only a tiny fraction of collisions leads to a reaction. For example, in a mixture of  $\text{H}_2$  and  $\text{I}_2$  at ordinary temperatures and pressures, each molecule undergoes about  $10^{10}$  collisions per second. If every collision

Hot water

Cold water

▲ **Figure 14.12** Temperature affects the rate of the chemiluminescence reaction in light sticks: The chemiluminescent reaction occurs more rapidly in hot water, and more light is produced.

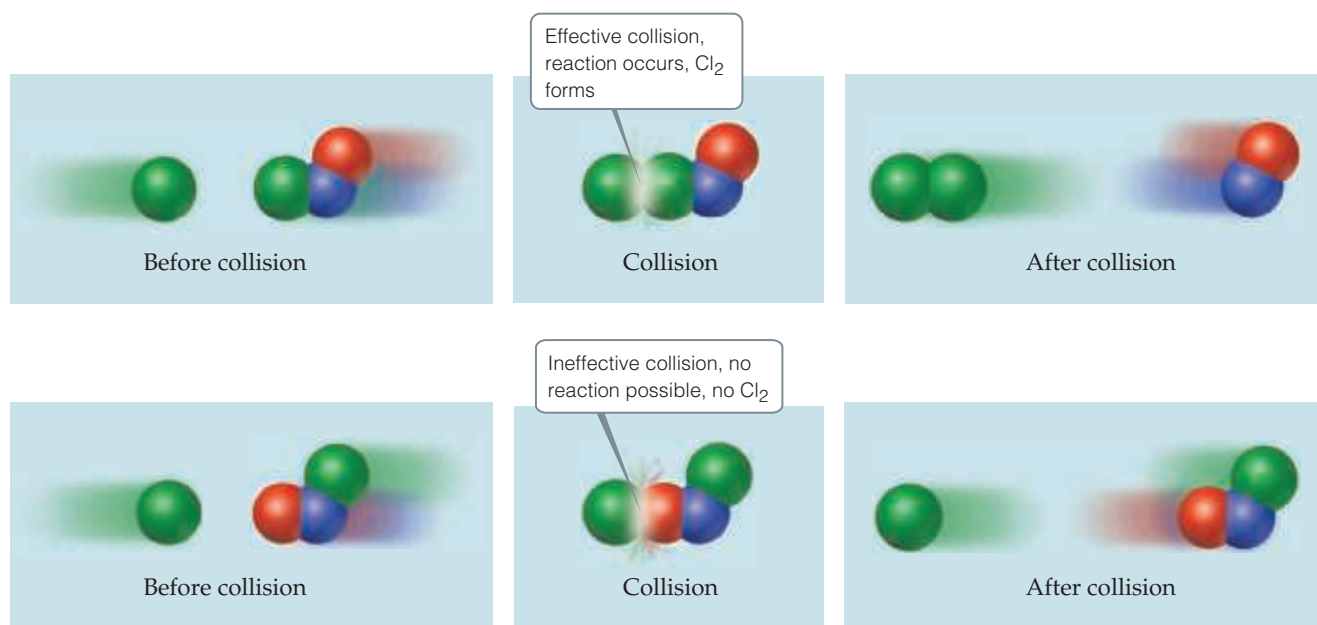

### Go Figure

Would you expect this curve to eventually go back down to lower values? Why or why not?

▲ **Figure 14.13** Temperature dependence of the rate constant for methyl isonitrile conversion to acetonitrile. The four points indicated are used in Sample Exercise 14.11.

▲ **Figure 14.14** Molecular collisions may or may not lead to a chemical reaction between Cl and NOCl.

between H<sub>2</sub> and I<sub>2</sub> resulted in the formation of HI, the reaction would be over in much less than a second. Instead, at room temperature the reaction proceeds very slowly because only about one in every 10<sup>13</sup> collisions produces a reaction. What keeps the reaction from occurring more rapidly?

### The Orientation Factor

In most reactions, collisions between molecules result in a chemical reaction only if the molecules are oriented in a certain way when they collide. The relative orientations of the molecules during collision determine whether the atoms are suitably positioned to form new bonds. For example, consider the reaction

which takes place if the collision brings Cl atoms together to form Cl<sub>2</sub>, as shown in the top panel of **Figure 14.14**. In contrast, in the collision shown in the lower panel, the two Cl atoms are not colliding directly with one another, and no products are formed.

### Activation Energy

Molecular orientation is not the only factor influencing whether a molecular collision will produce a reaction. In 1888 the Swedish chemist Svante Arrhenius suggested that molecules must possess a certain minimum amount of energy to react. According to the collision model, this energy comes from the kinetic energies of the colliding molecules. Upon collision, the kinetic energy of the molecules can be used to stretch, bend, and ultimately break bonds, leading to chemical reactions. That is, the kinetic energy is used to change the potential energy of the molecule. If molecules are moving too slowly—in other words, with too little kinetic energy—they merely bounce off one another without changing. The minimum energy required to initiate a chemical reaction is called the **activation energy**,  $E_a$ , and its value varies from reaction to reaction.

The situation during reactions is analogous to that shown in **Figure 14.15**. The golfer hits the ball to make it move over the hill in the direction of the cup. The hill is a *barrier* between ball and cup. To reach the cup, the player must impart enough kinetic energy with the putter to move the ball to the top of the barrier. If he does not impart enough energy, the ball will roll partway up the hill and then back down toward him. In the same way, molecules require a certain minimum energy to break existing bonds during a

## Go Figure

Which of the following determines how hard the golfer must strike the ball: the difference in elevation between the ball and the hole or between the ball and the top of the barrier?

▲ Figure 14.15 Energy is needed to overcome a barrier between initial and final states.

chemical reaction. We can think of this minimum energy as an *energy barrier*. In the rearrangement of methyl isonitrile to acetonitrile, for example, we might imagine the reaction passing through an intermediate state in which the  $\text{N}\equiv\text{C}$  portion of the methyl isonitrile molecule is sideways:

Figure 14.16 shows that energy must be supplied to stretch the bond between the  $\text{H}_3\text{C}$  group and the  $\text{N}\equiv\text{C}$  group to allow the  $\text{N}\equiv\text{C}$  group to rotate. After the  $\text{N}\equiv\text{C}$  group has twisted sufficiently, the  $\text{C}-\text{C}$  bond begins to form, and the energy of the molecule drops. Thus, the barrier to formation of acetonitrile represents the energy necessary to force the molecule through the relatively unstable intermediate state, analogous to forcing the ball in Figure 14.15 over the hill. The difference between the energy of the starting molecule and the highest energy along the reaction pathway is the activation energy,  $E_a$ . The molecule having the arrangement of atoms shown at the top of the barrier is called either the **activated complex** or the **transition state**.

The conversion of  $\text{H}_3\text{C}-\text{N}\equiv\text{C}$  to  $\text{H}_3\text{C}-\text{C}\equiv\text{N}$  is exothermic. Figure 14.16 therefore shows the product as having a lower energy than the reactant. The energy change for the reaction,  $\Delta E$ , has no effect on reaction rate, however.

*The rate constant depends on the magnitude of  $E_a$ ; generally, the lower the value of  $E_a$  is, the larger the rate constant and the faster the reaction.*

Notice that the reverse reaction is endothermic. The activation energy for the reverse reaction is equal to the energy that must be overcome if approaching the barrier from the right:  $\Delta E + E_a$ . Thus, to reach the activated complex for the reverse reaction requires more energy than for the forward reaction—for this reaction, there is a larger barrier to overcome going from right to left than from left to right.

## Give It Some Thought

Suppose you could measure the rate constants for both the forward and reverse reactions of the process in Figure 14.16. In which direction would the rate constant be larger?

## Go Figure

How does the energy needed to overcome the energy barrier compare with the overall change in energy for this reaction?

▲ Figure 14.16 Energy profile for conversion of methyl isonitrile ( $\text{H}_3\text{CNC}$ ) to its isomer acetonitrile ( $\text{H}_3\text{CCN}$ ).

## Go Figure

What would the curve look like for a temperature higher than that for the red curve in the figure?

▲ **Figure 14.17** The effect of temperature on the distribution of kinetic energies of molecules in a sample.

Any particular methyl isonitrile molecule acquires sufficient energy to overcome the energy barrier through collisions with other molecules. Recall from the kinetic-molecular theory of gases that, at any instant, gas molecules are distributed in energy over a wide range. ∞ (Section 10.7) **Figure 14.17** shows the distribution of kinetic energies for two temperatures, comparing them with the minimum energy needed for reaction,  $E_a$ . At the higher temperature a much greater fraction of the molecules have kinetic energy greater than  $E_a$ , which leads to a greater rate of reaction.

## Give It Some Thought

Suppose we have two reactions,  $A \longrightarrow B$  and  $B \longrightarrow C$ . You can isolate B, and it is stable. Is B the transition state for the reaction  $A \longrightarrow C$ ?

For a collection of molecules in the gas phase, the fraction of molecules that have kinetic energy equal to or greater than  $E_a$  is given by the expression

$$f = e^{-E_a/RT} \quad [14.20]$$

In this equation,  $R$  is the gas constant (8.314 J/mol-K) and  $T$  is the absolute temperature. To get an idea of the magnitude of  $f$ , let's suppose that  $E_a$  is 100 kJ/mol, a value typical of many reactions, and that  $T$  is 300 K. The calculated value of  $f$  is  $3.9 \times 10^{-18}$ , an extremely small number! At 320 K,  $f = 4.7 \times 10^{-17}$ . Thus, only a 20° increase in temperature produces a more than tenfold increase in the fraction of molecules possessing at least 100 kJ/mol of energy.

## The Arrhenius Equation

Arrhenius noted that for most reactions the increase in rate with increasing temperature is nonlinear (Figure 14.13). He found that most reaction-rate data obeyed an equation based on (a) the fraction of molecules possessing energy  $E_a$  or greater, (b) the number of collisions per second, and (c) the fraction of collisions that have the appropriate orientation. These three factors are incorporated into the **Arrhenius equation**:

$$k = Ae^{-E_a/RT} \quad [14.21]$$

In this equation,  $k$  is the rate constant,  $E_a$  is the activation energy,  $R$  is the gas constant (8.314 J/mol-K), and  $T$  is the absolute temperature. The **frequency factor**,  $A$ , is constant, or nearly so, as temperature is varied. This factor is related to the frequency of collisions and the probability that the collisions are favorably oriented for reaction.\* As the magnitude of  $E_a$  increases,  $k$  decreases because the fraction of molecules that possess the required energy is smaller. Thus, at fixed values of  $T$  and  $A$ , *the rate constant decreases as  $E_a$  increases*.

\*Because collision frequency increases with temperature,  $A$  also has some temperature dependence, but this dependence is much smaller than the exponential term. Therefore,  $A$  is considered to be approximately constant.

## Sample Exercise 14.10

### Activation Energies and Speeds of Reaction

Consider a series of reactions having these energy profiles:

Rank the forward rate constants from smallest to largest assuming all three reactions have nearly the same value for the frequency factor  $A$ .

### SOLUTION

The lower the activation energy, the larger the rate constant and the faster the reaction. The value of  $\Delta E$  does not affect the value of the rate constant. Hence, the order of the rate constants is  $2 < 3 < 1$ .

#### Practice Exercise 1

Which of the following changes *always* leads to an increase in the rate constant for a reaction:

- (i) Decreasing the temperature
- (ii) Decreasing the activation energy
- (iii) Making the value of  $\Delta E$  more negative

- (a) Only one—(i), or (ii), or (iii)—increases the reaction rate.
- (b) (i) and (ii)
- (c) (i) and (iii)
- (d) (ii) and (iii)
- (e) All three—(i), (ii), and (iii)—increase the reaction rate.

#### Practice Exercise 2

Rank the rate constants of the reverse reactions from slowest to fastest.

## Determining the Activation Energy

We can calculate the activation energy for a reaction by manipulating the Arrhenius equation. Taking the natural log of both sides of Equation 14.21, we obtain

$$\ln k = \ln A e^{-E_a/RT}$$

$$\ln k = \ln e^{-E_a/RT} + \ln A$$

$$\ln k = -\frac{E_a}{RT} + \ln A$$

$$\begin{array}{c} \updownarrow \\ y \end{array} = \begin{array}{c} \updownarrow \\ mx \end{array} + \begin{array}{c} \updownarrow \\ b \end{array}$$

[14.22]

which has the form of the equation for a straight line. A graph of  $\ln k$  versus  $1/T$  is a line with a slope equal to  $-E_a/R$  and a  $y$ -intercept equal to  $\ln A$ . Thus, the activation energy can be determined by measuring  $k$  at a series of temperatures, graphing  $\ln k$  versus  $1/T$ , and calculating  $E_a$  from the slope of the resultant line.

We can also use Equation 14.22 to evaluate  $E_a$  in a nongraphical way if we know the rate constant of a reaction at two or more temperatures. For example, suppose that at two different temperatures  $T_1$  and  $T_2$  a reaction has rate constants  $k_1$  and  $k_2$ . For each condition, we have

$$\ln k_1 = -\frac{E_a}{RT_1} + \ln A \quad \text{and} \quad \ln k_2 = -\frac{E_a}{RT_2} + \ln A$$

Subtracting  $\ln k_2$  from  $\ln k_1$  gives

$$\ln k_1 - \ln k_2 = \left(-\frac{E_a}{RT_1} + \ln A\right) - \left(-\frac{E_a}{RT_2} + \ln A\right)$$

Assuming temperature-dependent changes in the frequency factor  $A$  are negligible, we can simplify to obtain

$$\ln \frac{k_1}{k_2} = \frac{E_a}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \quad [14.23]$$

Equation 14.23 provides a convenient way to calculate a rate constant  $k_1$  at some temperature  $T_1$  when we know the activation energy and the rate constant  $k_2$  at some other temperature  $T_2$ .

## Sample Exercise 14.11

### Determining the Activation Energy

The table at right shows the rate constants for the rearrangement of methyl isonitrile at various temperatures (these are the data points in Figure 14.13):

- (a) From these data, calculate the activation energy for the reaction.  
(b) What is the value of the rate constant at 430.0 K?

| Temperature (°C) | $k$ (s <sup>-1</sup> ) |
|------------------|------------------------|
| 189.7            | $2.52 \times 10^{-5}$  |
| 198.9            | $5.25 \times 10^{-5}$  |
| 230.3            | $6.30 \times 10^{-4}$  |
| 251.2            | $3.16 \times 10^{-3}$  |

### SOLUTION

**Analyze** We are given rate constants,  $k$ , measured at several temperatures and asked to determine the activation energy,  $E_a$ , and the rate constant,  $k$ , at a particular temperature.

**Plan** We can obtain  $E_a$  from the slope of a graph of  $\ln k$  versus  $1/T$ . Once we know  $E_a$ , we can use Equation 14.23 together with the given rate data to calculate the rate constant at 430.0 K.

### Solve

- (a) We must first convert the temperatures from degrees Celsius to kelvins. We then take the inverse of each temperature,  $1/T$ , and the natural log of each rate constant,  $\ln k$ . This gives us the table shown below:

| $T$ (K) | $1/T$ (K <sup>-1</sup> ) | $\ln k$ |
|---------|--------------------------|---------|
| 462.9   | $2.160 \times 10^{-3}$   | -10.589 |
| 472.1   | $2.118 \times 10^{-3}$   | -9.855  |
| 503.5   | $1.986 \times 10^{-3}$   | -7.370  |
| 524.4   | $1.907 \times 10^{-3}$   | -5.757  |

A graph of  $\ln k$  versus  $1/T$  is a straight line (Figure 14.18).

▲ Figure 14.18 Graphical determination of activation energy  $E_a$ .

The slope of the line is obtained by choosing any two well-separated points and using the coordinates of each:

$$\text{Slope} = \frac{\Delta y}{\Delta x} = \frac{-6.6 - (-10.4)}{0.00195 - 0.00215} = -1.9 \times 10^4$$

Because logarithms have no units, the numerator in this equation is dimensionless. The denominator has the units of  $1/T$ , namely, K<sup>-1</sup>. Thus, the overall units for the slope are K. The slope equals  $-E_a/R$ . We use the value for the gas constant  $R$  in units of J/mol·K (Table 10.2). We thus obtain

$$\begin{aligned} \text{Slope} &= -\frac{E_a}{R} \\ E_a &= -(\text{slope})(R) = -(-1.9 \times 10^4 \text{ K}) \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) \left( \frac{1 \text{ kJ}}{1000 \text{ J}} \right) \\ &= 1.6 \times 10^2 \text{ kJ/mol} = 160 \text{ kJ/mol} \end{aligned}$$

We report the activation energy to only two significant figures because we are limited by the precision with which we can read the graph in Figure 14.18.

- (b) To determine the rate constant,  $k_1$ , at  $T_1 = 430.0$  K, we can use Equation 14.23 with  $E_a = 160$  kJ/mol and one of the rate constants and temperatures from the given data, such as  $k_2 = 2.52 \times 10^{-5} \text{ s}^{-1}$  and  $T_2 = 462.9$  K:

$$\begin{aligned} \ln \left( \frac{k_1}{2.52 \times 10^{-5} \text{ s}^{-1}} \right) &= \\ \left( \frac{160 \text{ kJ/mol}}{8.314 \text{ J/mol}\cdot\text{K}} \right) \left( \frac{1}{462.9 \text{ K}} - \frac{1}{430.0 \text{ K}} \right) \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) &= -3.18 \end{aligned}$$

Thus,

$$\begin{aligned} \frac{k_1}{2.52 \times 10^{-5} \text{ s}^{-1}} &= e^{-3.18} = 4.15 \times 10^{-2} \\ k_1 &= (4.15 \times 10^{-2})(2.52 \times 10^{-5} \text{ s}^{-1}) = 1.0 \times 10^{-6} \text{ s}^{-1} \end{aligned}$$

Note that the units of  $k_1$  are the same as those of  $k_2$  and the rate constant at 430.0 K is smaller than it is at 462.9 K, as it should be.

### Practice Exercise 1

Using the data in Sample Exercise 14.11, which of the following is the rate constant for the rearrangement of methyl isonitrile at 320 °C?

- (a)  $8.1 \times 10^{-15} \text{ s}^{-1}$  (b)  $2.2 \times 10^{-13} \text{ s}^{-1}$  (c)  $2.7 \times 10^{-9} \text{ s}^{-1}$   
(d)  $2.3 \times 10^{-1} \text{ s}^{-1}$  (e)  $9.2 \times 10^3 \text{ s}^{-1}$

### Practice Exercise 2

To one significant figure, what is the value for the frequency factor  $A$  for the data presented in Sample Exercise 14.11.

## 14.6 | Reaction Mechanisms

A balanced equation for a chemical reaction indicates the substances present at the start of the reaction and those present at the end of the reaction. It provides no information, however, about the detailed steps that occur at the molecular level as the reactants are turned into products. The steps by which a reaction occurs is called the **reaction mechanism**. At the most sophisticated level, a reaction mechanism describes the order in which bonds are broken and formed and the changes in relative positions of the atoms in the course of the reaction.

### Elementary Reactions

We have seen that reactions take place because of collisions between reacting molecules. For example, the collisions between molecules of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) can provide the energy to allow the  $\text{CH}_3\text{NC}$  to rearrange to acetonitrile:

Similarly, the reaction of NO and  $\text{O}_3$  to form  $\text{NO}_2$  and  $\text{O}_2$  appears to occur as a result of a single collision involving suitably oriented and sufficiently energetic NO and  $\text{O}_3$  molecules:

Both reactions occur in a single event or step and are called **elementary reactions**.

The number of molecules that participate as reactants in an elementary reaction defines the **molecularity** of the reaction. If a single molecule is involved, the reaction is **unimolecular**. The rearrangement of methyl isonitrile is a unimolecular process. Elementary reactions involving the collision of two reactant molecules are **bimolecular**. The reaction between NO and  $\text{O}_3$  is bimolecular. Elementary reactions involving the simultaneous collision of three molecules are **termolecular**. Termolecular reactions are far less probable than unimolecular or bimolecular processes and are extremely rare. The chance that four or more molecules will collide simultaneously with any regularity is even more remote; consequently, such collisions are never proposed as part of a reaction mechanism. Thus, nearly all reaction mechanisms contain only unimolecular and bimolecular elementary reactions.

### Give It Some Thought

What is the molecularity of the elementary reaction?

### Multistep Mechanisms

The net change represented by a balanced chemical equation often occurs by a *multistep mechanism* consisting of a sequence of elementary reactions. For example, below  $225^\circ\text{C}$ , the reaction

appears to proceed in two elementary reactions (or two *elementary steps*), each of which is bimolecular. First, two  $\text{NO}_2$  molecules collide, and an oxygen atom is transferred from one to the other. The resultant  $\text{NO}_3$  then collides with a CO molecule and transfers an oxygen atom to it:

### Go Figure

For this profile, which elementary reaction rate is faster, intermediates converting to products or intermediates converting back to reactants?

▲ Figure 14.19 The energy profile of a reaction, showing transition states and an intermediate.

Thus, we say that the reaction occurs by a two-step mechanism.

*The chemical equations for the elementary reactions in a multistep mechanism must always add to give the chemical equation of the overall process.*

In the present example, the sum of the two elementary reactions is

Simplifying this equation by eliminating substances that appear on both sides gives Equation 14.25, the net equation for the process.

Because  $\text{NO}_3$  is neither a reactant nor a product of the reaction—it is formed in one elementary reaction and consumed in the next—it is called an **intermediate**. Multistep mechanisms involve one or more intermediates. Intermediates are not the same as transition states, as shown in Figure 14.19. Intermediates can be stable and can therefore sometimes be identified and even isolated. Transition states, on the other hand, are always inherently unstable and as such can never be isolated. Nevertheless, the use of advanced “ultrafast” techniques sometimes allows us to characterize them.

## Sample Exercise 14.12

### Determining Molecularity and Identifying Intermediates

It has been proposed that the conversion of ozone into  $\text{O}_2$  proceeds by a two-step mechanism:

- Describe the molecularity of each elementary reaction in this mechanism.
- Write the equation for the overall reaction.
- Identify the intermediate(s).

### SOLUTION

**Analyze** We are given a two-step mechanism and asked for (a) the molecularities of each of the two elementary reactions, (b) the equation for the overall process, and (c) the intermediate.

**Plan** The molecularity of each elementary reaction depends on the number of reactant molecules in the equation for that reaction. The overall equation is the sum of the equations for the elementary reactions. The intermediate is a substance formed in one step of the mechanism and used in another and therefore not part of the equation for the overall reaction.

#### Solve

- The first elementary reaction involves a single reactant and is consequently unimolecular. The second reaction, which involves two reactant molecules, is bimolecular.
- Adding the two elementary reactions gives

Because  $\text{O}(g)$  appears in equal amounts on both sides of the equation, it can be eliminated to give the net equation for the chemical process:

- The intermediate is  $\text{O}(g)$ . It is neither an original reactant nor a final product but is formed in the first step of the mechanism and consumed in the second.

### Practice Exercise 1

Consider the following two-step reaction mechanism:

Which of the following statements about this mechanism is or are true?

- Both of the steps in this mechanism are bimolecular.
  - The overall reaction is  $\text{A}(g) + \text{B}(g) + \text{C}(g) \longrightarrow \text{Y}(g) + \text{Z}(g)$ .
  - The substance  $\text{X}(g)$  is an intermediate in this mechanism.
- Only one of the statements is true.
  - Statements (i) and (ii) are true.
  - Statements (i) and (iii) are true.
  - Statements (ii) and (iii) are true.
  - All three statements are true.

### Practice Exercise 2

For the reaction

the proposed mechanism is

- Is the proposed mechanism consistent with the equation for the overall reaction? (b) What is the molecularity of each step of the mechanism? (c) Identify the intermediate(s).

## Rate Laws for Elementary Reactions

In Section 14.3, we stressed that rate laws must be determined experimentally; they cannot be predicted from the coefficients of balanced chemical equations. We are now in a position to understand why this is so. Every reaction is made up of a series of one or more elementary steps, and the rate laws and relative speeds of these steps dictate the overall rate law for the reaction. Indeed, the rate law for a reaction can be determined from its mechanism, as we will see shortly, and compared with the experimental rate law. Thus, our next challenge in kinetics is to arrive at reaction mechanisms that lead to rate laws consistent with those observed experimentally. We start by examining the rate laws of elementary reactions.

Elementary reactions are significant in a very important way: *If a reaction is elementary, its rate law is based directly on its molecularity.* For example, consider the unimolecular reaction

As the number of A molecules increases, the number that reacts in a given time interval increases proportionally. Thus, the rate of a unimolecular process is first order:

$$\text{Rate} = k[A]$$

For bimolecular elementary steps, the rate law is second order, as in the reaction

The second-order rate law follows directly from collision theory. If we double the concentration of A, the number of collisions between the molecules of A and B doubles; likewise, if we double [B], the number of collisions between A and B doubles. Therefore, the rate law is first order in both [A] and [B] and second order overall.

The rate laws for all feasible elementary reactions are given in Table 14.3. Notice how each rate law follows directly from the molecularity of the reaction. It is important to remember, however, that we cannot tell by merely looking at a balanced, overall chemical equation whether the reaction involves one or several elementary steps.

**TABLE 14.3 Elementary Reactions and Their Rate Laws**

| Molecularity | Elementary Reaction                         | Rate Law                   |
|--------------|---|----------------------------|
| Unimolecular | $A \longrightarrow \text{products}$         | $\text{Rate} = k[A]$       |
| Bimolecular  | $A + A \longrightarrow \text{products}$     | $\text{Rate} = k[A]^2$     |
| Bimolecular  | $A + B \longrightarrow \text{products}$     | $\text{Rate} = k[A][B]$    |
| Termolecular | $A + A + A \longrightarrow \text{products}$ | $\text{Rate} = k[A]^3$     |
| Termolecular | $A + A + B \longrightarrow \text{products}$ | $\text{Rate} = k[A]^2[B]$  |
| Termolecular | $A + B + C \longrightarrow \text{products}$ | $\text{Rate} = k[A][B][C]$ |

### Sample Exercise 14.13

#### Predicting the Rate Law for an Elementary Reaction

If the following reaction occurs in a single elementary reaction, predict its rate law:

#### SOLUTION

**Analyze** We are given the equation and asked for its rate law, assuming that it is an elementary process.

**Plan** Because we are assuming that the reaction occurs as a single elementary reaction, we are able to write the rate law using the coefficients for the reactants in the equation as the reaction orders.

**Solve** The reaction is bimolecular, involving one molecule of  $\text{H}_2$  and one molecule of  $\text{Br}_2$ . Thus, the rate law is first order in each reactant and second order overall:

$$\text{Rate} = k[\text{H}_2][\text{Br}_2]$$

**Comment** Experimental studies of this reaction show that the reaction actually has a very different rate law:

$$\text{Rate} = k[\text{H}_2][\text{Br}_2]^{1/2}$$

*Continued*

Because the experimental rate law differs from the one obtained by assuming a single elementary reaction, we can conclude that the mechanism cannot occur by a single elementary step. It must, therefore, involve two or more elementary steps.

### Practice Exercise 1

Consider the following reaction:  $2A + B \longrightarrow X + 2Y$ . You are told that the first step in the mechanism of this reaction has the following rate law:  $\text{Rate} = k[A][B]$ . Which of the following could be the first step in the reaction mechanism (note that substance Z is an intermediate)?

- (a)  $A + A \longrightarrow Y + Z$
- (b)  $A \longrightarrow X + Z$
- (c)  $A + A + B \longrightarrow X + Y + Y$
- (d)  $B \longrightarrow X + Y$
- (e)  $A + B \longrightarrow X + Z$

### Practice Exercise 2

Consider the following reaction:  $2\text{NO}(g) + \text{Br}_2(g) \longrightarrow 2\text{NOBr}(g)$ .  
 (a) Write the rate law for the reaction, assuming it involves a single elementary reaction. (b) Is a single-step mechanism likely for this reaction?

## The Rate-Determining Step for a Multistep Mechanism

As with the reaction in Sample Exercise 14.13, most reactions occur by mechanisms that involve two or more elementary reactions. Each step of the mechanism has its own rate constant and activation energy. Often one step is much slower than the others, and the overall rate of a reaction cannot exceed the rate of the slowest elementary step. Because the slow step limits the overall reaction rate, it is called the **rate-determining step** (or *rate-limiting step*).

To understand the concept of the rate-determining step for a reaction, consider a toll road with two toll plazas (Figure 14.20). Cars enter the toll road at point 1 and pass through toll plaza A. They then pass an intermediate point 2 before passing through toll plaza B and arriving at point 3. We can envision this trip along the toll road as occurring in two elementary steps:

### Go Figure

In scenario (a), would increasing the rate at which cars pass through Toll plaza B increase the rate at which cars go from point 1 to point 3?

(a) Cars slowed at toll plaza A, rate-determining step is passage through A

(b) Cars slowed at toll plaza B, rate-determining step is passage through B

▲ Figure 14.20 Rate-determining steps in traffic flow on a toll road.

Now suppose that one or more gates at toll plaza A are malfunctioning, so that traffic backs up behind the gates, as depicted in Figure 14.20(a). The rate at which cars can get to point 3 is limited by the rate at which they can get through the traffic jam at plaza A. Thus, step 1 is the rate-determining step of the journey along the toll road. If, however, all gates at A are functioning but one or more at B are not, traffic flows quickly through A but gets backed up at B, as depicted in Figure 14.20(b). In this case, step 2 is the rate-determining step.

In the same way, *the slowest step in a multistep reaction determines the overall rate*. By analogy to Figure 14.20(a), the rate of a fast step following the rate-determining step does not speed up the overall rate. If the slow step is not the first one, as is the case in Figure 14.20(b), the faster preceding steps produce intermediate products that accumulate before being consumed in the slow step. In either case, *the rate-determining step governs the rate law for the overall reaction*.

## Mechanisms with a Slow Initial Step

We can most easily see the relationship between the slow step in a mechanism and the rate law for the overall reaction by considering an example in which the first step in a multistep mechanism is the rate-determining step. Consider the reaction of  $\text{NO}_2$  and CO to produce NO and  $\text{CO}_2$  (Equation 14.25). Below  $225^\circ\text{C}$ , it is found experimentally that the rate law for this reaction is second order in  $\text{NO}_2$  and zero order in CO:  $\text{Rate} = k[\text{NO}_2]^2$ . Can we propose a reaction mechanism consistent with this rate law? Consider the two-step mechanism:\*

Step 2 is much faster than step 1; that is,  $k_2 \gg k_1$ , telling us that the intermediate  $\text{NO}_3(\text{g})$  is slowly produced in step 1 and immediately consumed in step 2.

Because step 1 is slow and step 2 is fast, step 1 is the rate-determining step. Thus, the rate of the overall reaction depends on the rate of step 1, and the rate law of the overall reaction equals the rate law of step 1. Step 1 is a bimolecular process that has the rate law

$$\text{Rate} = k_1[\text{NO}_2]^2$$

Thus, the rate law predicted by this mechanism agrees with the one observed experimentally. The reactant CO is absent from the rate law because it reacts in a step that follows the rate-determining step.

A scientist would not, at this point, say that we have “proved” that this mechanism is correct. All we can say is that the rate law predicted by the mechanism is *consistent with experiment*. We can often envision a different sequence of steps that leads to the same rate law. If, however, the predicted rate law of the proposed mechanism disagrees with experiment, we know for certain that the mechanism cannot be correct.

## Sample Exercise 14.14

### Determining the Rate Law for a Multistep Mechanism

The decomposition of nitrous oxide,  $\text{N}_2\text{O}$ , is believed to occur by a two-step mechanism:

(a) Write the equation for the overall reaction. (b) Write the rate law for the overall reaction.

*Continued*

\*Note the rate constants  $k_1$  and  $k_2$  written above the reaction arrows. The subscript on each rate constant identifies the elementary step involved. Thus,  $k_1$  is the rate constant for step 1, and  $k_2$  is the rate constant for step 2. A negative subscript refers to the rate constant for the reverse of an elementary step. For example,  $k_{-1}$  is the rate constant for the reverse of the first step.

**SOLUTION**

**Analyze** Given a multistep mechanism with the relative speeds of the steps, we are asked to write the overall reaction and the rate law for that overall reaction.

**Plan** (a) Find the overall reaction by adding the elementary steps and eliminating the intermediates. (b) The rate law for the overall reaction will be that of the slow, rate-determining step.

**Solve**

(a) Adding the two elementary reactions gives

Omitting the intermediate,  $\text{O}(g)$ , which occurs on both sides of the equation, gives the overall reaction:

(b) The rate law for the overall reaction is just the rate law for the slow, rate-determining elementary reaction. Because that slow step is a unimolecular elementary reaction, the rate law is first order:

$$\text{Rate} = k[\text{N}_2\text{O}]$$

**► Practice Exercise 1**

An alternative two-step reaction mechanism has been proposed for the reaction  $\text{NO}_2(g) + \text{CO}(g) \longrightarrow \text{NO}(g) + \text{CO}_2(g)$ , which was discussed on page 597:

Step 1:

Step 2:

Which experiment would allow you to distinguish between the two proposed mechanisms?

(a) Run trials with different initial concentrations of  $\text{NO}_2(g)$  and measure the initial reaction rates. (b) Run trials with different initial concentrations of  $\text{CO}(g)$  and measure the initial reaction rates. (c) Conduct experiments to identify the reaction intermediate(s). (d) It is not possible to distinguish between the two proposed reaction mechanisms.

**► Practice Exercise 2**

Ozone reacts with nitrogen dioxide to produce dinitrogen pentoxide and oxygen:

The reaction is believed to occur in two steps:

The experimental rate law is  $\text{rate} = k[\text{O}_3][\text{NO}_2]$ . What can you say about the relative rates of the two steps of the mechanism?

**Mechanisms with a Fast Initial Step**

It is possible, but not particularly straightforward, to derive the rate law for a mechanism in which an intermediate is a reactant in the rate-determining step. This situation arises in multistep mechanisms when the first step is fast and therefore *not* the rate-determining step. Let's consider one example: the gas-phase reaction of nitric oxide ( $\text{NO}$ ) with bromine ( $\text{Br}_2$ ):

The experimentally determined rate law for this reaction is second order in  $\text{NO}$  and first order in  $\text{Br}_2$ :

$$\text{Rate} = k[\text{NO}]^2[\text{Br}_2] \quad [14.27]$$

We seek a reaction mechanism that is consistent with this rate law. One possibility is that the reaction occurs in a single termolecular step:

As noted in Practice Exercise 2 of Exercise 14.13, this does not seem likely because termolecular processes are so rare.

**Give It Some Thought**

Why are termolecular elementary steps rare in gas-phase reactions?

Let's consider an alternative mechanism that does not involve a termolecular step:

In this mechanism, step 1 involves two processes: a forward reaction and its reverse.

Because step 2 is the rate-determining step, the rate law for that step governs the rate of the overall reaction:

$$\text{Rate} = k_2[\text{NOBr}_2][\text{NO}] \quad [14.30]$$

Note that  $\text{NOBr}_2$  is an intermediate generated in the forward reaction of step 1. Intermediates are usually unstable and have a low, unknown concentration. Thus, the rate law of Equation 14.30 depends on the unknown concentration of an intermediate, which isn't desirable. We want instead to express the rate law for a reaction in terms of the reactants, or the products if necessary, of the reaction.

With the aid of some assumptions, we can express the concentration of the intermediate  $\text{NOBr}_2$  in terms of the concentrations of the starting reactants  $\text{NO}$  and  $\text{Br}_2$ . We first assume that  $\text{NOBr}_2$  is unstable and does not accumulate to any significant extent in the reaction mixture. Once formed,  $\text{NOBr}_2$  can be consumed either by reacting with  $\text{NO}$  to form  $\text{NOBr}$  or by falling back apart into  $\text{NO}$  and  $\text{Br}_2$ . The first of these possibilities is step 2 of our alternative mechanism, a slow process. The second is the reverse of step 1, a unimolecular process:

Because step 2 is slow, we assume that most of the  $\text{NOBr}_2$  falls apart according to this reaction. Thus, we have both the forward and reverse reactions of step 1 occurring much faster than step 2. Because they occur rapidly relative to step 2, the forward and reverse reactions of step 1 establish an equilibrium. As in any other dynamic equilibrium, the rate of the forward reaction equals that of the reverse reaction:

$$\begin{array}{ccc} k[\text{NO}][\text{Br}_2] & = & k_{-1}[\text{NOBr}_2] \\ \text{Rate of forward reaction} & & \text{Rate of reverse reaction} \end{array}$$

Solving for  $[\text{NOBr}_2]$ , we have

$$[\text{NOBr}_2] = \frac{k_1}{k_{-1}} [\text{NO}][\text{Br}_2]$$

Substituting this relationship into Equation 14.30, we have

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}} [\text{NO}][\text{Br}_2][\text{NO}] = k[\text{NO}]^2[\text{Br}_2]$$

where the experimental rate constant  $k$  equals  $k_2k_1/k_{-1}$ . This expression is consistent with the experimental rate law (Equation 14.27). Thus, our alternative mechanism (Equation 14.29), which involves two steps but only unimolecular and bimolecular processes, is far more probable than the single-step termolecular mechanism of Equation 14.28.

*In general, whenever a fast step precedes a slow one, we can solve for the concentration of an intermediate by assuming that an equilibrium is established in the fast step.*

### Sample Exercise 14.15

#### Deriving the Rate Law for a Mechanism with a Fast Initial Step

Show that the following mechanism for Equation 14.26 also produces a rate law consistent with the experimentally observed one:

#### SOLUTION

**Analyze** We are given a mechanism with a fast initial step and asked to write the rate law for the overall reaction.

**Plan** The rate law of the slow elementary step in a mechanism determines the rate law for the overall reaction. Thus, we first write

the rate law based on the molecularity of the slow step. In this case, the slow step involves the intermediate  $\text{N}_2\text{O}_2$  as a reactant. Experimental rate laws, however, do not contain the concentrations of intermediates; instead they are expressed in terms of the concentrations of reactants, and in some cases products. Thus, we must relate the concentration of  $\text{N}_2\text{O}_2$  to the concentration

*Continued*

of NO by assuming that an equilibrium is established in the first step.

**Solve** The second step is rate determining, so the overall rate is

$$\text{Rate} = k_2[\text{N}_2\text{O}_2][\text{Br}_2]$$

We solve for the concentration of the intermediate  $\text{N}_2\text{O}_2$  by assuming that an equilibrium is established in step 1; thus, the rates of the forward and reverse reactions in step 1 are equal:

$$k_1[\text{NO}]^2 = k_{-1}[\text{N}_2\text{O}_2]$$

Solving for the concentration of the intermediate,  $\text{N}_2\text{O}_2$ , gives

$$[\text{N}_2\text{O}_2] = \frac{k_1}{k_{-1}}[\text{NO}]^2$$

Substituting this expression into the rate expression gives

$$\text{Rate} = k_2 \frac{k_1}{k_{-1}} [\text{NO}]^2 [\text{Br}_2] = k [\text{NO}]^2 [\text{Br}_2]$$

Thus, this mechanism also yields a rate law consistent with the experimental one. Remember: There may be more than one mechanism that leads to an observed experimental rate law!

### Practice Exercise 1

Consider the following hypothetical reaction:  
 $2\text{P} + \text{Q} \longrightarrow 2\text{R} + \text{S}$ . The following mechanism is proposed for this reaction:

Substances T and U are unstable intermediates. What rate law is predicted by this mechanism?

- (a)  $\text{Rate} = k[\text{P}]^2$  (b)  $\text{Rate} = k[\text{P}][\text{Q}]$  (c)  $\text{Rate} = k[\text{P}]^2[\text{Q}]$   
 (d)  $\text{Rate} = k[\text{P}][\text{Q}]^2$  (e)  $\text{Rate} = k[\text{U}]$

### Practice Exercise 2

The first step of a mechanism involving the reaction of bromine is

What is the expression relating the concentration of  $\text{Br}(\text{g})$  to that of  $\text{Br}_2(\text{g})$ ?

So far we have considered only three reaction mechanisms: one for a reaction that occurs in a single elementary step and two for simple multistep reactions where there is one rate-determining step. There are other more complex mechanisms, however. If you take a biochemistry class, for example, you will learn about cases in which the concentration of an intermediate cannot be neglected in deriving the rate law. Furthermore, some mechanisms require a large number of steps, sometimes 35 or more, to arrive at a rate law that agrees with experimental data!

## 14.7 | Catalysis

A **catalyst** is a substance that changes the speed of a chemical reaction without undergoing a permanent chemical change itself. Most reactions in the body, the atmosphere, and the oceans occur with the help of catalysts. Much industrial chemical research is devoted to the search for more effective catalysts for reactions of commercial importance. Extensive research efforts also are devoted to finding means of inhibiting or removing certain catalysts that promote undesirable reactions, such as those that corrode metals, age our bodies, and cause tooth decay.

### Homogeneous Catalysis

A catalyst that is present in the same phase as the reactants in a reaction mixture is called a **homogeneous catalyst**. Examples abound both in solution and in the gas phase. Consider, for example, the decomposition of aqueous hydrogen peroxide,  $\text{H}_2\text{O}_2(\text{aq})$ , into water and oxygen:

In the absence of a catalyst, this reaction occurs extremely slowly. Many substances are capable of catalyzing the reaction, however, including bromide ion, which reacts with hydrogen peroxide in acidic solution, forming aqueous bromine and water (Figure 14.21).

If this were the complete reaction, bromide ion would not be a catalyst because it undergoes chemical change during the reaction. However, hydrogen peroxide also reacts with the  $\text{Br}_2(\text{aq})$  generated in Equation 14.32:

## Go Figure

Which species is responsible for the brownish color in the middle cylinder:  $\text{H}_2\text{O}_2$ ,  $\text{Br}_2$ ,  $\text{Na}^+$ ,  $\text{Br}^-$ , or  $\text{O}_2$ ? Is the brown substance a catalyst or an intermediate?

▲ **Figure 14.21 Homogeneous catalysis.** Effect of catalyst on the speed of hydrogen peroxide decomposition to water and oxygen gas.

The sum of Equations 14.32 and 14.33 is just Equation 14.31, a result that you can check for yourself.

When the  $\text{H}_2\text{O}_2$  has been completely decomposed, we are left with a colorless solution of  $\text{Br}^-(\text{aq})$ , which means that this ion is indeed a catalyst of the reaction because it speeds up the reaction without itself undergoing any net change. In contrast,  $\text{Br}_2$  is an intermediate because it is first formed (Equation 14.32) and then consumed (Equation 14.33). The color change we see in Figure 14.22 illustrates that the presence of intermediates can in some cases be readily detected. Neither the catalyst nor the intermediate appears in the equation for the overall reaction. Notice, however, that *the catalyst is present at the start of the reaction, whereas the intermediate is formed during the course of the reaction.*

How does a catalyst work? If we think about the general form of rate laws (Equation 14.7,  $\text{rate} = k[\text{A}]^m[\text{B}]^n$ ), we conclude that the catalyst must affect the numerical value of  $k$ , the rate constant. On the basis of the Arrhenius equation (Equation 14.21,  $k = Ae^{-E_a/RT}$ ),  $k$  is determined by the activation energy ( $E_a$ ) and the frequency factor ( $A$ ). A catalyst may affect the rate of reaction by altering the value of either  $E_a$  or  $A$ . We can envision this happening in two ways: The catalyst could provide a new mechanism for the reaction that has an  $E_a$  value lower than the  $E_a$  value for the uncatalyzed reaction,

## Go Figure

How many steps are there in the catalyzed reaction?

▲ **Figure 14.22** Energy profiles for the uncatalyzed and bromide-catalyzed decomposition of  $\text{H}_2\text{O}_2$ .

or the catalyst could assist in the orientation of reactants and so increase  $A$ . The most dramatic catalytic effects come from lowering  $E_a$ . As a general rule, *a catalyst lowers the overall activation energy for a chemical reaction*.

A catalyst can lower the activation energy for a reaction by providing a different mechanism for the reaction. In the decomposition of hydrogen peroxide, for example, two successive reactions of  $\text{H}_2\text{O}_2$ , first with bromide and then with bromine, take place. Because these two reactions together serve as a catalytic pathway for hydrogen peroxide decomposition, *both* of them must have significantly lower activation energies than the uncatalyzed decomposition (Figure 14.22).

## Heterogeneous Catalysis

A **heterogeneous catalyst** is one that exists in a phase different from the phase of the reactant molecules, usually as a solid in contact with either gaseous reactants or reactants in a liquid solution. Many industrially important reactions are catalyzed by the surfaces of solids. For example, raw petroleum is transformed into smaller hydrocarbon molecules by using what are called “cracking” catalysts. Heterogeneous catalysts are often composed of metals or metal oxides.

The initial step in heterogeneous catalysis is usually **adsorption** of reactants. **Adsorption** refers to the binding of molecules to a surface, whereas **absorption** refers to the uptake of molecules into the interior of a substance. [↔ \(Section 13.6\)](#) Adsorption occurs because the atoms or ions at the surface of a solid are extremely reactive. Because the catalyzed reaction occurs on the surface, special methods are often used to prepare catalysts so that they have very large surface areas. Unlike their counterparts in the interior of the substance, surface atoms and ions have unused bonding capacity that can be used to bond molecules from the gas or solution phase to the surface of the solid.

The reaction of hydrogen gas with ethylene gas to form ethane gas provides an example of heterogeneous catalysis:

Even though this reaction is exothermic, it occurs very slowly in the absence of a catalyst. In the presence of a finely powdered metal, however, such as nickel, palladium, or platinum, the reaction occurs easily at room temperature via the

◀ **Figure 14.23 Heterogeneous catalysis.** Mechanism for reaction of ethylene with hydrogen on a catalytic surface.

mechanism diagrammed in **Figure 14.23**. Both ethylene and hydrogen are adsorbed on the metal surface. Upon adsorption, the  $\text{H}-\text{H}$  bond of  $\text{H}_2$  breaks, leaving two  $\text{H}$  atoms initially bonded to the metal surface but relatively free to move. When a hydrogen encounters an adsorbed ethylene molecule, it can form a  $\sigma$  bond to one of the carbon atoms, effectively destroying the  $\text{C}-\text{C}$   $\pi$  bond and leaving an *ethyl group* ( $\text{C}_2\text{H}_5$ ) bonded to the surface via a metal-to-carbon  $\sigma$  bond. This  $\sigma$  bond is relatively weak, so when the other carbon atom also encounters a hydrogen atom, a sixth  $\text{C}-\text{H}$   $\sigma$  bond is readily formed, and an ethane molecule ( $\text{C}_2\text{H}_6$ ) is released from the metal surface.

### Give It Some Thought

In general, which type of catalyst, homogeneous or heterogeneous, will be easier to recover from the reaction mixture?

## Enzymes

The human body is characterized by an extremely complex system of interrelated chemical reactions, all of which must occur at carefully controlled rates to maintain life. A large number of marvelously efficient biological catalysts known as **enzymes** are necessary for many of these reactions to occur at suitable rates. Most enzymes are large protein molecules with molecular weights ranging from about 10,000 to about 1 million amu. They are very selective in the reactions they catalyze, and some are absolutely specific, operating for only one substance in only one reaction. The decomposition of hydrogen peroxide, for example, is an important biological process. Because hydrogen peroxide is strongly oxidizing, it can be physiologically harmful. For this reason, the blood and liver of mammals contain an enzyme, *catalase*, that

## CHEMISTRY PUT TO WORK Catalytic Converters

Heterogeneous catalysis plays a major role in the fight against urban air pollution. Two components of automobile exhausts that help form photochemical smog are nitrogen oxides and unburned hydrocarbons. In addition, automobile exhaust may contain considerable quantities of carbon monoxide. Even with the most careful attention to engine design, it is impossible under normal driving conditions to reduce the quantity of these pollutants to an acceptable level in the exhaust gases. It is therefore necessary to remove them from the exhaust before they are vented to the air. This removal is accomplished in the *catalytic converter*.

The catalytic converter, which is part of an automobile's exhaust system, must perform two functions: (1) oxidation of CO and unburned hydrocarbons ( $C_xH_y$ ) to carbon dioxide and water, and (2) reduction of nitrogen oxides to nitrogen gas:

These two functions require different catalysts, so the development of a successful catalyst system is a difficult challenge. The catalysts must be effective over a wide range of operating temperatures. They must continue to be active despite the fact that various components of the exhaust can block the active sites of the catalyst. And the catalysts must be sufficiently rugged to withstand exhaust gas turbulence and the mechanical shocks of driving under various conditions for thousands of miles.

Catalysts that promote the combustion of CO and hydrocarbons are, in general, the transition-metal oxides and the noble metals. These materials are supported on a structure (Figure 14.24) that allows the best possible contact between the flowing exhaust gas and the catalyst surface. A honeycomb structure made from alumina ( $Al_2O_3$ ) and impregnated with the catalyst that is employed. Such catalysts operate by first adsorbing oxygen gas present in the exhaust gas. This adsorption weakens the O—O bond in  $O_2$ , so that oxygen atoms are available for reaction with adsorbed CO to form  $CO_2$ . Hydrocarbon oxidation probably proceeds somewhat similarly, with the hydrocarbons first being adsorbed followed by rupture of a C—H bond.

Transition-metal oxides and noble metals are also the most effective catalysts for reduction of NO to  $N_2$  and  $O_2$ . The catalysts that are most effective in one reaction, however, are usually much less effective in the other. It is therefore necessary to have two catalytic components.

Catalytic converters contain remarkably efficient heterogeneous catalysts. The automotive exhaust gases are in contact with the catalyst for only 100 to 400 ms, but in this very short time, 96% of the hydrocarbons and CO is converted to  $CO_2$  and  $H_2O$ , and the emission of nitrogen oxides is reduced by 76%.

Although the exact combination of catalysts used varies from one catalytic converter to another, precious metals are an essential component of any catalytic converter. Platinum is very good at catalyzing the oxidation reactions and has good resistance to impurities such as lead, sulfur, and phosphorus that can poison or disable the catalyst. Palladium is a slightly less expensive alternative to platinum, but it is more sensitive to poisoning from impurities in the exhaust stream. Rhodium is the metal of choice for reduction of nitrogen oxides and has reasonable activity for the oxidation reactions. Unfortunately, it is even rarer and more expensive than platinum. Catalytic converters currently account for approximately 35% of the world's use of platinum, 65% of palladium, and 95% of rhodium. Deposits of these metals tend to be concentrated in South Africa and Russia.

## Go Figure

Why is the reaction faster when the liver is ground up?

▲ Figure 14.25 Enzymes speed up reactions.

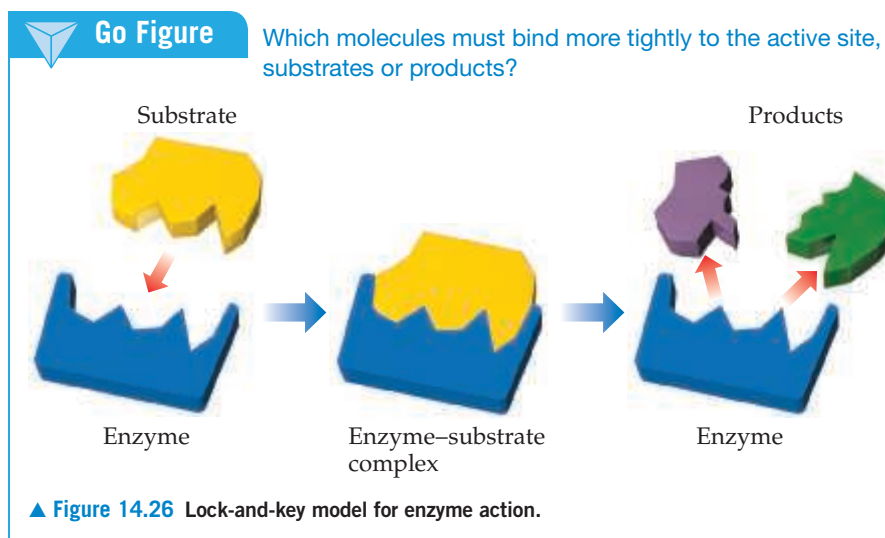

catalyzes the decomposition of hydrogen peroxide into water and oxygen (Equation 14.31). Figure 14.25 shows the dramatic acceleration of this chemical reaction by the catalase in beef liver.

The reaction any given enzyme catalyzes takes place at a specific location in the enzyme called the **active site**. The substances that react at this site are called **substrates**. The **lock-and-key model** provides a simple explanation for the specificity of an enzyme (Figure 14.26). The substrate is pictured as fitting neatly into the active site, much like a key fits into a lock.

Lysozyme is an enzyme that is important to the functioning of our immune system because it accelerates reactions that damage (or “lyse”) bacterial cell walls. Figure 14.27 shows a model of the enzyme lysozyme without and with a bound substrate molecule.

The combination of enzyme and substrate is called the *enzyme-substrate complex*. Although Figure 14.26 shows both the active site and its substrate as having a fixed shape, the active site is often fairly flexible and so may change shape as it binds the substrate. The binding between substrate and active site involves dipole-dipole attractions, hydrogen bonds, and dispersion forces.

∞ (Section 11.2)

As substrate molecules enter the active site, they are somehow activated so that they are capable of reacting rapidly. This activation process may occur, for example, by the withdrawal or donation of electron density from a particular bond or group of atoms in the enzyme's active site. In addition, the substrate may become distorted in the process of fitting into the active site and made more reactive. Once the reaction occurs, the products depart from the active site, allowing another substrate molecule to enter.

The activity of an enzyme is destroyed if some molecule other than the substrate specific to that enzyme binds to the active site and blocks entry of the substrate. Such substances are called *enzyme inhibitors*. Nerve poisons and certain toxic metal ions, such as lead and mercury, are believed to act in this way to inhibit enzyme activity. Some other poisons act by attaching elsewhere on the enzyme, thereby distorting the active site so that the substrate no longer fits.

Enzymes are enormously more efficient than nonbiochemical catalysts. The number of individual catalyzed reaction events occurring at a particular active site, called the *turnover number*, is generally in the range of  $10^3$  to  $10^7$  per second. Such large turnover numbers correspond to very low activation energies. Compared with a simple chemical catalyst, enzymes can increase the rate constant for a given reaction by a millionfold or more.

### Give It Some Thought

True or false: enzymes lower the energy of the transition state for a reaction.

▲ **Figure 14.27** Lysozyme was one of the first enzymes for which a structure-function relationship was described. This model shows how the substrate (yellow) “fits” into the active site of the enzyme.

## CHEMISTRY AND LIFE Nitrogen Fixation and Nitrogenase

Nitrogen is one of the most essential elements in living organisms, found in many compounds vital to life, including proteins, nucleic acids, vitamins, and hormones. Nitrogen is continually cycling through the biosphere in various forms, as shown in Figure 14.28. For example, certain microorganisms convert the nitrogen in animal waste and dead plants and animals into  $\text{N}_2(\text{g})$ , which then returns to the atmosphere. For the food chain to be sustained, there must be a means of converting atmospheric  $\text{N}_2(\text{g})$  into a form plants can use.

For this reason, if a chemist were asked to name the most important chemical reaction in the world, she might easily say *nitrogen fixation*, the process by which atmospheric  $\text{N}_2(\text{g})$  is converted into compounds suitable for plant use. Some fixed nitrogen results from the action of lightning on the atmosphere, and some is produced industrially using a process we will discuss in Chapter 15. About 60% of fixed nitrogen, however, is a consequence of the action of the remarkable and complex enzyme *nitrogenase*. This enzyme is *not* present in humans or other animals; rather, it is found in bacteria that live in the root nodules of certain plants, such as the legumes clover and alfalfa.

Nitrogenase converts  $\text{N}_2$  into  $\text{NH}_3$ , a process that, in the absence of a catalyst, has a very large activation energy. This process is a *reduction* reaction in which the oxidation state of N is reduced from 0 in  $\text{N}_2$  to  $-3$  in  $\text{NH}_3$ . The mechanism by which nitrogenase reduces  $\text{N}_2$  is not fully understood. Like many other enzymes, including catalase, the active site of nitrogenase contains transition-metal atoms; such enzymes are called *metalloenzymes*. Because transition metals can readily change oxidation state, metalloenzymes are especially useful for effecting transformations in which substrates are either oxidized or reduced.

It has been known for nearly 40 years that a portion of nitrogenase contains iron and molybdenum atoms. This portion, called the *FeMo-cofactor*, is thought to serve as the active site of the enzyme. The FeMo-cofactor of nitrogenase is a cluster of seven Fe atoms and one Mo atom, all linked by sulfur atoms (Figure 14.29).

It is one of the wonders of life that simple bacteria can contain beautifully complex and vitally important enzymes such as nitrogenase. Because of this enzyme, nitrogen is continually cycled between its comparatively inert role in the atmosphere and its critical role in living organisms. Without nitrogenase, life as we know it could not exist on Earth.

**Related Exercises:** 14.86, 14.115, 14.116

▲ Figure 14.28 Simplified picture of the nitrogen cycle.

► Figure 14.29 The FeMo-cofactor of nitrogenase. Nitrogenase is found in nodules in the roots of certain plants, such as the white clover roots shown at the left. The cofactor, which is thought to be the active site of the enzyme, contains seven Fe atoms and one Mo atom, linked by sulfur atoms. The molecules on the outside of the cofactor connect it to the rest of the protein.

## Sample Integrative Exercise

### Putting Concepts Together

Formic acid ( $\text{HCOOH}$ ) decomposes in the gas phase at elevated temperatures as follows:

The uncatalyzed decomposition reaction is determined to be first order. A graph of the partial pressure of  $\text{HCOOH}$  versus time for decomposition at 838 K is shown as the red curve in Figure 14.30. When a small amount of solid  $\text{ZnO}$  is added to the reaction chamber, the partial pressure of acid versus time varies as shown by the blue curve in Figure 14.30.

▲ Figure 14.30 Variation in pressure of  $\text{HCOOH}(g)$  as a function of time at 838 K.

- Estimate the half-life and first-order rate constant for formic acid decomposition.
- What can you conclude from the effect of added  $\text{ZnO}$  on the decomposition of formic acid?
- The progress of the reaction was followed by measuring the partial pressure of formic acid vapor at selected times. Suppose that, instead, we had plotted the concentration of formic acid in units of  $\text{mol/L}$ . What effect would this have had on the calculated value of  $k$ ?
- The pressure of formic acid vapor at the start of the reaction is  $3.00 \times 10^2$  torr. Assuming constant temperature and ideal-gas behavior, what is the pressure in the system at the end of the reaction? If the volume of the reaction chamber is  $436 \text{ cm}^3$ , how many moles of gas occupy the reaction chamber at the end of the reaction?
- The standard heat of formation of formic acid vapor is  $\Delta H_f^\circ = -378.6 \text{ kJ/mol}$ . Calculate  $\Delta H^\circ$  for the overall reaction. If the activation energy ( $E_a$ ) for the reaction is  $184 \text{ kJ/mol}$ , sketch an approximate energy profile for the reaction, and label  $E_a$ ,  $\Delta H^\circ$ , and the transition state.

### SOLUTION

- The initial pressure of  $\text{HCOOH}$  is  $3.00 \times 10^2$  torr. On the graph we move to the level at which the partial pressure of  $\text{HCOOH}$  is  $1.50 \times 10^2$  torr, half the initial value. This corresponds to a time of about  $6.60 \times 10^2 \text{ s}$ , which is therefore the half-life. The first-order rate constant is given by Equation 14.17:  
 $k = 0.693/t_{1/2} = 0.693/660 \text{ s} = 1.05 \times 10^{-3} \text{ s}^{-1}$ .
- The reaction proceeds much more rapidly in the presence of solid  $\text{ZnO}$ , so the surface of the oxide must be acting as a catalyst for the decomposition of the acid. This is an example of heterogeneous catalysis.
- If we had graphed the concentration of formic acid in units of moles per liter, we would still have determined that the half-life for decomposition is 660 s, and we would have computed the same value for  $k$ . Because the units for  $k$  are  $\text{s}^{-1}$ , the value for  $k$  is independent of the units used for concentration.
- According to the stoichiometry of the reaction, two moles of product are formed for each mole of reactant. When reaction is completed, therefore, the pressure will be 600 torr, just twice the initial pressure, assuming ideal-gas behavior. (Because we are working at quite high temperature and fairly low gas pressure, assuming ideal-gas behavior is reasonable.) The number of moles of gas present can be calculated using the ideal-gas equation (Section 10.4):

$$n = \frac{PV}{RT} = \frac{(600/760 \text{ atm})(0.436 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(838 \text{ K})} = 5.00 \times 10^{-3} \text{ mol}$$

- We first calculate the overall change in energy,  $\Delta H^\circ$  (Section 5.7 and Appendix C), as in

$$\begin{aligned} \Delta H^\circ &= \Delta H_f^\circ(\text{CO}_2(g)) + \Delta H_f^\circ(\text{H}_2(g)) - \Delta H_f^\circ(\text{HCOOH}(g)) \\ &= -393.5 \text{ kJ/mol} + 0 - (-378.6 \text{ kJ/mol}) \\ &= -14.9 \text{ kJ/mol} \end{aligned}$$

From this and the given value for  $E_a$ , we can draw an approximate energy profile for the reaction, in analogy to Figure 14.16.

## Chapter Summary and Key Terms

### INTRODUCTION TO KINETICS (INTRODUCTION AND SECTION 14.1)

**Chemical kinetics** is the area of chemistry in which **reaction rates** are studied. Factors that affect reaction rate are the physical state of the reactants; concentration; temperature; and the presence of catalysts.

**REACTION RATES (SECTION 14.2)** Reaction rates are usually expressed as changes in concentration per unit time: Typically, for reactions in solution, rates are given in units of molarity per second (M/s). For most reactions, a plot of molarity versus time shows that the rate slows down as the reaction proceeds. The **instantaneous rate** is the slope of a line drawn tangent to the concentration-versus-time curve at a specific time. Rates can be written in terms of the appearance of products or the disappearance of reactants; the stoichiometry of the reaction dictates the relationship between rates of appearance and disappearance.

**RATES AND CONCENTRATION (SECTION 14.3)** The quantitative relationship between rate and concentration is expressed by a **rate law**, which usually has the following form:

$$\text{Rate} = k[\text{reactant 1}]^m[\text{reactant 2}]^n \dots$$

The constant  $k$  in the rate law is called the **rate constant**; the exponents  $m$ ,  $n$ , and so forth are called **reaction orders** for the reactants. The sum of the reaction orders gives the **overall reaction order**. Reaction orders must be determined experimentally. The units of the rate constant depend on the overall reaction order. For a reaction in which the overall reaction order is 1,  $k$  has units of  $\text{s}^{-1}$ ; for one in which the overall reaction order is 2,  $k$  has units of  $\text{M}^{-1} \text{s}^{-1}$ .

Spectroscopy is one technique that can be used to monitor the course of a reaction. According to Beer's law, the absorption of electromagnetic radiation by a substance at a particular wavelength is directly proportional to its concentration.

**CONCENTRATION AND TIME (SECTION 14.4)** Rate laws can be used to determine the concentrations of reactants or products at any time during a reaction. In a **first-order reaction** the rate is proportional to the concentration of a single reactant raised to the first power:  $\text{Rate} = k[A]$ . In such cases the integrated form of the rate law is  $\ln[A]_t = -kt + \ln[A]_0$ , where  $[A]_t$  is the concentration of reactant A at time  $t$ ,  $k$  is the rate constant, and  $[A]_0$  is the initial concentration of A. Thus, for a first-order reaction, a graph of  $\ln[A]$  versus time yields a straight line of slope  $-k$ .

A **second-order reaction** is one for which the overall reaction order is 2. If a second-order rate law depends on the concentration of only one reactant, then  $\text{rate} = k[A]^2$ , and the time dependence of  $[A]$  is given by the integrated form of the rate law:  $1/[A]_t = 1/[A]_0 + kt$ . In this case, a graph of  $1/[A]_t$  versus time yields a straight line. A **zero-order reaction** is one for which the overall reaction order is 0.  $\text{Rate} = k$  if the reaction is zero order.

The **half-life** of a reaction,  $t_{1/2}$ , is the time required for the concentration of a reactant to drop to one-half of its original value. For a first-order reaction, the half-life depends only on the rate constant and not on the initial concentration:  $t_{1/2} = 0.693/k$ . The half-life of a second-order reaction depends on both the rate constant and the initial concentration of A:  $t_{1/2} = 1/(k[A]_0)$ .

**THE EFFECT OF TEMPERATURE ON RATES (SECTION 14.5)** The **collision model**, which assumes that reactions occur as a result of

collisions between molecules, helps explain why the magnitudes of rate constants increase with increasing temperature. The greater the kinetic energy of the colliding molecules, the greater is the energy of collision. The minimum energy required for a reaction to occur is called the **activation energy**,  $E_a$ . A collision with energy  $E_a$  or greater can cause the atoms of the colliding molecules to reach the **activated complex** (or **transition state**), which is the highest energy arrangement in the pathway from reactants to products. Even if a collision is energetic enough, it may not lead to reaction; the reactants must also be correctly oriented relative to one another in order for a collision to be effective.

Because the kinetic energy of molecules depends on temperature, the rate constant of a reaction is very dependent on temperature. The relationship between  $k$  and temperature is given by the **Arrhenius equation**:  $k = Ae^{-E_a/RT}$ . The term  $A$  is called the **frequency factor**; it relates to the number of collisions that are favorably oriented for reaction. The Arrhenius equation is often used in logarithmic form:  $\ln k = \ln A - E_a/RT$ . Thus, a graph of  $\ln k$  versus  $1/T$  yields a straight line with slope  $-E_a/R$ .

**REACTION MECHANISMS (SECTION 14.6)** A **reaction mechanism** details the individual steps that occur in the course of a reaction. Each of these steps, called **elementary reactions**, has a well-defined rate law that depends on the number of molecules (the **molecularity**) of the step. Elementary reactions are defined as either **unimolecular**, **bimolecular**, or **termolecular**, depending on whether one, two, or three reactant molecules are involved, respectively. Termolecular elementary reactions are very rare. Unimolecular, bimolecular, and termolecular reactions follow rate laws that are first order overall, second order overall, and third order overall, respectively.

Many reactions occur by a multistep mechanism, involving two or more elementary reactions, or steps. An **intermediate** is produced in one elementary step and is consumed in a later elementary step, therefore it does not appear in the overall equation for the reaction. When a mechanism has several elementary steps, the overall rate is limited by the slowest elementary step, called the **rate-determining step**. A fast elementary step that follows the rate-determining step will have no effect on the rate law of the reaction. A fast step that precedes the rate-determining step often creates an equilibrium that involves an intermediate. For a mechanism to be valid, the rate law predicted by the mechanism must be the same as that observed experimentally.

**CATALYSTS (SECTION 14.7)** A **catalyst** is a substance that increases the rate of a reaction without undergoing a net chemical change itself. It does so by providing a different mechanism for the reaction, one that has a lower activation energy. A **homogeneous catalyst** is one that is in the same phase as the reactants. A **heterogeneous catalyst** has a different phase from the reactants. Finely divided metals are often used as heterogeneous catalysts for solution- and gas-phase reactions. Reacting molecules can undergo binding, or **adsorption**, at the surface of the catalyst. The adsorption of a reactant at specific sites on the surface makes bond breaking easier, lowering the activation energy. Catalysis in living organisms is achieved by **enzymes**, large protein molecules that usually catalyze a very specific reaction. The specific reactant molecules involved in an enzymatic reaction are called **substrates**. The site of the enzyme where the catalysis occurs is called the **active site**. In the **lock-and-key model** for enzyme catalysis, substrate molecules bind very specifically to the active site of the enzyme, after which they can undergo reaction.

## Learning Outcomes After studying this chapter, you should be able to:

- List the factors that affect the rate of chemical reactions. (Section 14.1) *Related Exercises: 14.17, 14.18*
- Determine the rate of a reaction by measuring the concentration of a reactant or product as a function of time. (Section 14.2) *Related Exercises: 14.19–14.22*

- Relate the rate of formation of products and the rate of disappearance of reactants given the balanced chemical equation for the reaction. (Section 14.2)  
*Related Exercises: 14.23–14.26*
- Explain the form and meaning of a rate law, including the ideas of reaction order and rate constant. (Section 14.3)  
*Related Exercises: 14.27, 14.28, 14.30, 14.32*
- Determine the rate law and rate constant for a reaction from a series of experiments given the measured rates for various concentrations of reactants. (Section 14.3)  
*Related Exercises: 14.33–14.36*
- Apply the integrated form of a rate law to determine the concentration of a reactant at a given time. (Section 14.4)  
*Related Exercises: 14.42–14.44*

- Apply the relationship between the rate constant of a first-order reaction and its half-life. (Section 14.4)  
*Related Exercises: 14.41, 14.42, 14.99, 14.100*
- Determine the order of a reaction from a table of reactant concentration as a function of time. (Section 14.4)  
*Related Exercises: 14.47–14.50*
- Explain how the activation energy affects a rate and be able to use the Arrhenius equation. (Section 14.5)  
*Related Exercises: 14.59, 14.61, 14.62, 14.64*
- Predict a rate law for a reaction having a multistep mechanism given the individual steps in the mechanism. (Section 14.6)  
*Related Exercises: 14.71–14.74*
- Explain the principles underlying catalysis. (Section 14.7)  
*Related Exercises: 14.75–14.77, 14.79*

## Key Equations

$$\text{Rate} = -\frac{1}{a} \frac{\Delta[A]}{\Delta t} = -\frac{1}{b} \frac{\Delta[B]}{\Delta t} = \frac{1}{c} \frac{\Delta[C]}{\Delta t} = \frac{1}{d} \frac{\Delta[D]}{\Delta t} \quad [14.4]$$

$$\text{Rate} = k[A]^m[B]^n \quad [14.7]$$

$$\ln[A]_t - \ln[A]_0 = -kt \quad \text{or} \quad \ln \frac{[A]_t}{[A]_0} = -kt \quad [14.12]$$

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0} \quad [14.14]$$

$$[A]_t = -kt + [A]_0 \quad [14.16]$$

$$t_{1/2} = \frac{0.693}{k} \quad [14.17]$$

$$k = Ae^{-E_a/RT} \quad [14.21]$$

$$\ln k = -\frac{E_a}{RT} + \ln A \quad [14.22]$$

Definition of reaction rate in terms of the components of the balanced chemical equation  $aA + bB \longrightarrow cC + dD$

General form of a rate law for the reaction  $A + B \longrightarrow \text{products}$

The integrated form of a first-order rate law for the reaction  $A \longrightarrow \text{products}$

The integrated form of a second-order rate law for the reaction  $A \longrightarrow \text{products}$

The integrated form of a zero-order rate law for the reaction  $A \longrightarrow \text{products}$

Relating the half-life and rate constant for a first-order reaction

The Arrhenius equation, which expresses how the rate constant depends on temperature

Logarithmic form of the Arrhenius equation

## Exercises

### Visualizing Concepts

- 14.1** An automotive fuel injector dispenses a fine spray of gasoline into the automobile cylinder, as shown in the bottom drawing here. When an injector gets clogged, as shown in the top drawing, the spray is not as fine or even and the performance of the car declines. How is this observation related to chemical kinetics? [Section 14.1]

- 14.2** Consider the following graph of the concentration of a substance X over time. Is each of the following statements true or false? (a) X is a product of the reaction. (b) The rate of the reaction remains the same as time progresses. (c) The average rate between points 1 and 2 is greater than the average rate between points 1 and 3. (d) As time progresses, the curve will eventually turn downward toward the x-axis. [Section 14.2]

- 14.3** You study the rate of a reaction, measuring both the concentration of the reactant and the concentration of the product as a function of time, and obtain the following results:

- (a) Which chemical equation is consistent with these data:  
 (i)  $A \longrightarrow B$ , (ii)  $B \longrightarrow A$ , (iii)  $A \longrightarrow 2B$ ,  
 (iv)  $B \longrightarrow 2A$ ?
- (b) Write equivalent expressions for the rate of the reaction in terms of the appearance or disappearance of the two substances. [Section 14.2]
- 14.4** Suppose that for the reaction  $K + L \longrightarrow M$ , you monitor the production of M over time, and then plot the following graph from your data:

- (a) Is the reaction occurring at a constant rate from  $t = 0$  to  $t = 15$  min? (b) Is the reaction completed at  $t = 15$  min? (c) Suppose the reaction as plotted here were started with 0.20 mol K and 0.40 mol L. After 30 min, an additional 0.20 mol K are added to the reaction mixture. Which of the following correctly describes how the plot would look from  $t = 30$  min to  $t = 60$  min? (i) [M] would remain at the same constant value it has at  $t = 30$  min, (ii) [M] would increase with the same slope as  $t = 0$  to 15 min, until  $t = 45$  min at which point the plot becomes horizontal again, or (iii) [M] decreases and reaches 0 at  $t = 45$  min. [Section 14.2]
- 14.5** The following diagrams represent mixtures of NO(g) and O<sub>2</sub>(g). These two substances react as follows:

It has been determined experimentally that the rate is second order in NO and first order in O<sub>2</sub>. Based on this

fact, which of the following mixtures will have the fastest initial rate? [Section 14.3]

- 14.6** A friend studies a first-order reaction and obtains the following three graphs for experiments done at two different temperatures. (a) Which two graphs represent experiments done at the same temperature? What accounts for the difference in these two graphs? In what way are they the same? (b) Which two graphs represent experiments done with the same starting concentration but at different temperatures? Which graph probably represents the lower temperature? How do you know? [Section 14.4]

- 14.7** (a) Given the following diagrams at  $t = 0$  min and  $t = 30$  min, what is the half-life of the reaction if it follows first-order kinetics?

- (b) After four half-life periods for a first-order reaction, what fraction of reactant remains? [Section 14.4]
- 14.8** Which of the following linear plots do you expect for a reaction  $A \longrightarrow$  products if the kinetics are (a) zero order, (b) first order, or (c) second order? [Section 14.4]

**14.9** The following diagram shows a reaction profile. Label the components indicated by the boxes. [Section 14.5]

**14.10** The accompanying graph shows plots of  $\ln k$  versus  $1/T$  for two different reactions. The plots have been extrapolated to the  $y$ -intercepts. Which reaction (red or blue) has (a) the larger value for  $E_a$ , and (b) the larger value for the frequency factor,  $A$ ? [Section 14.5]

**14.11** The following graph shows two different reaction pathways for the same overall reaction at the same temperature. Is each of the following statements true or false? (a) The rate is faster for the red path than for the blue path. (b) For both paths, the rate of the reverse reaction is slower than the rate of the forward reaction. (c) The energy change  $\Delta E$  is the same for both paths. [Section 14.6]

**14.12** Consider the diagram that follows, which represents two steps in an overall reaction. The red spheres are oxygen, the blue ones nitrogen, and the green ones fluorine. (a) Write the chemical equation for each step in the reaction. (b) Write the equation for the overall reaction. (c) Identify the intermediate in the mechanism. (d) Write the rate law for the overall reaction if the first step is the slow, rate-determining step. [Section 14.6]

**14.13** Based on the following reaction profile, how many intermediates are formed in the reaction  $A \rightarrow C$ ? How many transition states are there? Which step,  $A \rightarrow B$  or  $B \rightarrow C$ , is the faster? For the reaction  $A \rightarrow C$ , is  $\Delta E$  positive, negative, or zero? [Section 14.6]

- 14.14** Draw a possible transition state for the bimolecular reaction depicted here. (The blue spheres are nitrogen atoms, and the red ones are oxygen atoms.) Use dashed lines to represent the bonds that are in the process of being broken or made in the transition state. [Section 14.6]

- 14.15** The following diagram represents an imaginary two-step mechanism. Let the red spheres represent element A, the green ones element B, and the blue ones element C. (a) Write the equation for the net reaction that is occurring. (b) Identify the intermediate. (c) Identify the catalyst. [Sections 14.6 and 14.7]

- 14.16** Draw a graph showing the reaction pathway for an overall exothermic reaction with two intermediates that are produced at different rates. On your graph indicate the reactants, products, intermediates, transition states, and activation energies. [Sections 14.6 and 14.7]

## Reaction Rates (Sections 14.1 and 14.2)

- 14.17** (a) What is meant by the term *reaction rate*? (b) Name three factors that can affect the rate of a chemical reaction. (c) Is the rate of disappearance of reactants always the same as the rate of appearance of products?

- 14.18** (a) What are the units usually used to express the rates of reactions occurring in solution? (b) As the temperature increases, does the reaction rate increase or decrease? (c) As a reaction proceeds, does the instantaneous reaction rate increase or decrease?

- 14.19** Consider the following hypothetical aqueous reaction:  $A(aq) \rightarrow B(aq)$ . A flask is charged with 0.065 mol of A in a total volume of 100.0 mL. The following data are collected:

| Time (min) | 0     | 10    | 20    | 30    | 40    |
|------------|-------|-------|-------|-------|-------|
| Moles of A | 0.065 | 0.051 | 0.042 | 0.036 | 0.031 |

(a) Calculate the number of moles of B at each time in the table, assuming that there are no molecules of B at time zero and that A cleanly converts to B with no intermediates. (b) Calculate the average rate of disappearance of A for each 10-min interval in units of M/s. (c) Between  $t = 10$  min and  $t = 30$  min, what is the average rate of appearance of B in units of M/s? Assume that the volume of the solution is constant.

- 14.20** A flask is charged with 0.100 mol of A and allowed to react to form B according to the hypothetical gas-phase reaction  $A(g) \rightarrow B(g)$ . The following data are collected:

| Time (s)   | 0     | 40    | 80    | 120   | 160   |
|------------|-------|-------|-------|-------|-------|
| Moles of A | 0.100 | 0.067 | 0.045 | 0.030 | 0.020 |

(a) Calculate the number of moles of B at each time in the table, assuming that A is cleanly converted to B with

no intermediates. (b) Calculate the average rate of disappearance of A for each 40 s interval in units of mol/s. (c) Which of the following would be needed to calculate the rate in units of concentration per time: (i) the pressure of the gas at each time, (ii) the volume of the reaction flask, (iii) the temperature, or (iv) the molecular weight of A?

- 14.21** The isomerization of methyl isonitrile ( $\text{CH}_3\text{NC}$ ) to acetonitrile ( $\text{CH}_3\text{CN}$ ) was studied in the gas phase at  $215^\circ\text{C}$ , and the following data were obtained:

| Time (s) | $[\text{CH}_3\text{NC}]$ (M) |
|----------|------------------------------|
| 0        | 0.0165                       |
| 2000     | 0.0110                       |
| 5000     | 0.00591                      |
| 8000     | 0.00314                      |
| 12,000   | 0.00137                      |
| 15,000   | 0.00074                      |

(a) Calculate the average rate of reaction, in M/s, for the time interval between each measurement. (b) Calculate the average rate of reaction over the entire time of the data from  $t = 0$  to  $t = 15,000$  s. (c) Which is greater, the average rate between  $t = 2000$  and  $t = 12,000$  s, or between  $t = 8000$  and  $t = 15,000$  s? (d) Graph  $[\text{CH}_3\text{NC}]$  versus time and determine the instantaneous rates in M/s at  $t = 5000$  s and  $t = 8000$  s.

- 14.22** The rate of disappearance of HCl was measured for the following reaction:

The following data were collected:

| Time (min) | $[\text{HCl}]$ (M) |
|------------|--------------------|
| 0.0        | 1.85               |
| 54.0       | 1.58               |
| 107.0      | 1.36               |
| 215.0      | 1.02               |
| 430.0      | 0.580              |

(a) Calculate the average rate of reaction, in M/s, for the time interval between each measurement. (b) Calculate the average rate of reaction for the entire time for the data from  $t = 0.0$  min to  $t = 430.0$  min. (c) Which is greater, the average rate between  $t = 54.0$  and  $t = 215.0$  min, or between  $t = 107.0$  and  $t = 430.0$  min? (d) Graph  $[\text{HCl}]$  versus time and determine the instantaneous rates in M/min and M/s at  $t = 75.0$  min and  $t = 250$  min.

- 14.23** For each of the following gas-phase reactions, indicate how the rate of disappearance of each reactant is related to the rate of appearance of each product:

- (a)  $\text{H}_2\text{O}_2(g) \longrightarrow \text{H}_2(g) + \text{O}_2(g)$   
 (b)  $2\text{N}_2\text{O}(g) \longrightarrow 2\text{N}_2(g) + \text{O}_2(g)$   
 (c)  $\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g)$   
 (d)  $\text{C}_2\text{H}_5\text{NH}_2(g) \longrightarrow \text{C}_2\text{H}_4(g) + \text{NH}_3(g)$

- 14.24** For each of the following gas-phase reactions, write the rate expression in terms of the appearance of each product and disappearance of each reactant:

- (a)  $2\text{H}_2\text{O}(g) \longrightarrow 2\text{H}_2(g) + \text{O}_2(g)$   
 (b)  $2\text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2\text{SO}_3(g)$   
 (c)  $2\text{NO}(g) + 2\text{H}_2(g) \longrightarrow \text{N}_2(g) + 2\text{H}_2\text{O}(g)$   
 (d)  $\text{N}_2(g) + 2\text{H}_2(g) \longrightarrow \text{N}_2\text{H}_4(g)$

- 14.25** (a) Consider the combustion of hydrogen,  $2\text{H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{H}_2\text{O}(\text{g})$ . If hydrogen is burning at the rate of  $0.48 \text{ mol/s}$ , what is the rate of consumption of oxygen? What is the rate of formation of water vapor? (b) The reaction  $2\text{NO}(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow 2\text{NOCl}(\text{g})$  is carried out in a closed vessel. If the partial pressure of NO is decreasing at the rate of  $56 \text{ torr/min}$ , what is the rate of change of the total pressure of the vessel?
- 14.26** (a) Consider the combustion of ethylene,  $\text{C}_2\text{H}_4(\text{g}) + 3\text{O}_2(\text{g}) \longrightarrow 2\text{CO}_2(\text{g}) + 2\text{H}_2\text{O}(\text{g})$ . If the concentration of  $\text{C}_2\text{H}_4$  is decreasing at the rate of  $0.036 \text{ M/s}$ , what are the rates of change in the concentrations of  $\text{CO}_2$  and  $\text{H}_2\text{O}$ ? (b) The rate of decrease in  $\text{N}_2\text{H}_4$  partial pressure in a closed reaction vessel from the reaction  $\text{N}_2\text{H}_4(\text{g}) + \text{H}_2(\text{g}) \longrightarrow 2\text{NH}_3(\text{g})$  is  $74 \text{ torr per hour}$ . What are the rates of change of  $\text{NH}_3$  partial pressure and total pressure in the vessel?

### Rate Laws (Section 14.3)

- 14.27** A reaction  $\text{A} + \text{B} \longrightarrow \text{C}$  obeys the following rate law:  $\text{Rate} = k[\text{B}]^2$ . (a) If  $[\text{A}]$  is doubled, how will the rate change? Will the rate constant change? (b) What are the reaction orders for A and B? What is the overall reaction order? (c) What are the units of the rate constant?
- 14.28** Consider a hypothetical reaction between A, B, and C that is first order in A, zero order in B, and second order in C. (a) Write the rate law for the reaction. (b) How does the rate change when  $[\text{A}]$  is doubled and the other reactant concentrations are held constant? (c) How does the rate change when  $[\text{B}]$  is tripled and the other reactant concentrations are held constant? (d) How does the rate change when  $[\text{C}]$  is tripled and the other reactant concentrations are held constant? (e) By what factor does the rate change when the concentrations of all three reactants are tripled? (f) By what factor does the rate change when the concentrations of all three reactants are cut in half?
- 14.29** The decomposition reaction of  $\text{N}_2\text{O}_5$  in carbon tetrachloride is  $2\text{N}_2\text{O}_5 \longrightarrow 4\text{NO}_2 + \text{O}_2$ . The rate law is first order in  $\text{N}_2\text{O}_5$ . At  $64^\circ\text{C}$  the rate constant is  $4.82 \times 10^{-3} \text{ s}^{-1}$ . (a) Write the rate law for the reaction. (b) What is the rate of reaction when  $[\text{N}_2\text{O}_5] = 0.0240 \text{ M}$ ? (c) What happens to the rate when the concentration of  $\text{N}_2\text{O}_5$  is doubled to  $0.0480 \text{ M}$ ? (d) What happens to the rate when the concentration of  $\text{N}_2\text{O}_5$  is halved to  $0.0120 \text{ M}$ ?

- 14.30** Consider the following reaction:

(a) The rate law for this reaction is first order in  $\text{H}_2$  and second order in NO. Write the rate law. (b) If the rate constant for this reaction at  $1000 \text{ K}$  is  $6.0 \times 10^4 \text{ M}^{-2}\text{s}^{-1}$ , what is the reaction rate when  $[\text{NO}] = 0.035 \text{ M}$  and  $[\text{H}_2] = 0.015 \text{ M}$ ? (c) What is the reaction rate at  $1000 \text{ K}$  when the concentration of NO is increased to  $0.10 \text{ M}$ , while the concentration of  $\text{H}_2$  is  $0.010 \text{ M}$ ? (d) What is the reaction rate at  $1000 \text{ K}$  if  $[\text{NO}]$  is decreased to  $0.010 \text{ M}$  and  $[\text{H}_2]$  is increased to  $0.030 \text{ M}$ ?

- 14.31** Consider the following reaction:

The rate law for this reaction is first order in  $\text{CH}_3\text{Br}$  and first order in  $\text{OH}^-$ . When  $[\text{CH}_3\text{Br}]$  is  $5.0 \times 10^{-3} \text{ M}$  and  $[\text{OH}^-]$  is  $0.050 \text{ M}$ , the reaction rate at  $298 \text{ K}$  is  $0.0432 \text{ M/s}$ . (a) What is the value of the rate constant? (b) What are the units of the rate constant? (c) What would happen

to the rate if the concentration of  $\text{OH}^-$  were tripled? (d) What would happen to the rate if the concentration of both reactants were tripled?

- 14.32** The reaction between ethyl bromide ( $\text{C}_2\text{H}_5\text{Br}$ ) and hydroxide ion in ethyl alcohol at  $330 \text{ K}$ ,  $\text{C}_2\text{H}_5\text{Br}(\text{alc}) + \text{OH}^-(\text{alc}) \longrightarrow \text{C}_2\text{H}_5\text{OH}(\text{l}) + \text{Br}^-(\text{alc})$ , is first order each in ethyl bromide and hydroxide ion. When  $[\text{C}_2\text{H}_5\text{Br}]$  is  $0.0477 \text{ M}$  and  $[\text{OH}^-]$  is  $0.100 \text{ M}$ , the rate of disappearance of ethyl bromide is  $1.7 \times 10^{-7} \text{ M/s}$ . (a) What is the value of the rate constant? (b) What are the units of the rate constant? (c) How would the rate of disappearance of ethyl bromide change if the solution were diluted by adding an equal volume of pure ethyl alcohol to the solution?

- 14.33** The iodide ion reacts with hypochlorite ion (the active ingredient in chlorine bleaches) in the following way:  $\text{OCl}^- + \text{I}^- \longrightarrow \text{OI}^- + \text{Cl}^-$ . This rapid reaction gives the following rate data:

| $[\text{OCl}^-] (\text{M})$ | $[\text{I}^-] (\text{M})$ | Initial Rate ( $\text{M/s}$ ) |
|-----------------------------|---------------------------|-------------------------------|
| $1.5 \times 10^{-3}$        | $1.5 \times 10^{-3}$      | $1.36 \times 10^{-4}$         |
| $3.0 \times 10^{-3}$        | $1.5 \times 10^{-3}$      | $2.72 \times 10^{-4}$         |
| $1.5 \times 10^{-3}$        | $3.0 \times 10^{-3}$      | $2.72 \times 10^{-4}$         |

(a) Write the rate law for this reaction. (b) Calculate the rate constant with proper units. (c) Calculate the rate when  $[\text{OCl}^-] = 2.0 \times 10^{-3} \text{ M}$  and  $[\text{I}^-] = 5.0 \times 10^{-4} \text{ M}$ .

- 14.34** The reaction  $2\text{ClO}_2(\text{aq}) + 2\text{OH}^-(\text{aq}) \longrightarrow \text{ClO}_3^-(\text{aq}) + \text{ClO}_2^-(\text{aq}) + \text{H}_2\text{O}(\text{l})$  was studied with the following results:

| Experiment | $[\text{ClO}_2] (\text{M})$ | $[\text{OH}^-] (\text{M})$ | Initial Rate ( $\text{M/s}$ ) |
|------------|-----------------------------|----------------------------|-------------------------------|
| 1          | 0.060                       | 0.030                      | 0.0248                        |
| 2          | 0.020                       | 0.030                      | 0.00276                       |
| 3          | 0.020                       | 0.090                      | 0.00828                       |

(a) Determine the rate law for the reaction. (b) Calculate the rate constant with proper units. (c) Calculate the rate when  $[\text{ClO}_2] = 0.100 \text{ M}$  and  $[\text{OH}^-] = 0.050 \text{ M}$ .

- 14.35** The following data were measured for the reaction  $\text{BF}_3(\text{g}) + \text{NH}_3(\text{g}) \longrightarrow \text{F}_3\text{BNH}_3(\text{g})$ :

| Experiment | $[\text{BF}_3] (\text{M})$ | $[\text{NH}_3] (\text{M})$ | Initial Rate ( $\text{M/s}$ ) |
|------------|----------------------------|----------------------------|-------------------------------|
| 1          | 0.250                      | 0.250                      | 0.2130                        |
| 2          | 0.250                      | 0.125                      | 0.1065                        |
| 3          | 0.200                      | 0.100                      | 0.0682                        |
| 4          | 0.350                      | 0.100                      | 0.1193                        |
| 5          | 0.175                      | 0.100                      | 0.0596                        |

(a) What is the rate law for the reaction? (b) What is the overall order of the reaction? (c) Calculate the rate constant with proper units? (d) What is the rate when  $[\text{BF}_3] = 0.100 \text{ M}$  and  $[\text{NH}_3] = 0.500 \text{ M}$ ?

- 14.36** The following data were collected for the rate of disappearance of NO in the reaction  $2\text{NO}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{NO}_2(\text{g})$ :

| Experiment | $[\text{NO}] (\text{M})$ | $[\text{O}_2] (\text{M})$ | Initial Rate ( $\text{M/s}$ ) |
|------------|--------------------------|---------------------------|-------------------------------|
| 1          | 0.0126                   | 0.0125                    | $1.41 \times 10^{-2}$         |
| 2          | 0.0252                   | 0.0125                    | $5.64 \times 10^{-2}$         |
| 3          | 0.0252                   | 0.0250                    | $1.13 \times 10^{-1}$         |

(a) What is the rate law for the reaction? (b) What are the units of the rate constant? (c) What is the average value of the rate constant calculated from the three data sets? (d) What is the rate of disappearance of NO when  $[\text{NO}] = 0.0750\text{ M}$  and  $[\text{O}_2] = 0.0100\text{ M}$ ? (e) What is the rate of disappearance of  $\text{O}_2$  at the concentrations given in part (d)?

**[14.37]** Consider the gas-phase reaction between nitric oxide and bromine at  $273^\circ\text{C}$ :  $2\text{NO}(\text{g}) + \text{Br}_2(\text{g}) \longrightarrow 2\text{NOBr}(\text{g})$ . The following data for the initial rate of appearance of NOBr were obtained:

| Experiment | $[\text{NO}] (\text{M})$ | $[\text{Br}_2] (\text{M})$ | Initial Rate ( $\text{M/s}$ ) |
|------------|--------------------------|----------------------------|-------------------------------|
| 1          | 0.10                     | 0.20                       | 24                            |
| 2          | 0.25                     | 0.20                       | 150                           |
| 3          | 0.10                     | 0.50                       | 60                            |
| 4          | 0.35                     | 0.50                       | 735                           |

(a) Determine the rate law. (b) Calculate the average value of the rate constant for the appearance of NOBr from the four data sets. (c) How is the rate of appearance of NOBr related to the rate of disappearance of  $\text{Br}_2$ ? (d) What is the rate of disappearance of  $\text{Br}_2$  when  $[\text{NO}] = 0.075\text{ M}$  and  $[\text{Br}_2] = 0.25\text{ M}$ ?

**[14.38]** Consider the reaction of peroxydisulfate ion ( $\text{S}_2\text{O}_8^{2-}$ ) with iodide ion ( $\text{I}^-$ ) in aqueous solution:

At a particular temperature, the initial rate of disappearance of  $\text{S}_2\text{O}_8^{2-}$  varies with reactant concentrations in the following manner:

| Experiment | $[\text{S}_2\text{O}_8^{2-}] (\text{M})$ | $[\text{I}^-] (\text{M})$ | Initial Rate ( $\text{M/s}$ ) |
|------------|--|---------------------------|-------------------------------|
| 1          | 0.018                                    | 0.036                     | $2.6 \times 10^{-6}$          |
| 2          | 0.027                                    | 0.036                     | $3.9 \times 10^{-6}$          |
| 3          | 0.036                                    | 0.054                     | $7.8 \times 10^{-6}$          |
| 4          | 0.050                                    | 0.072                     | $1.4 \times 10^{-5}$          |

(a) Determine the rate law for the reaction and state the units of the rate constant. (b) What is the average value of the rate constant for the disappearance of  $\text{S}_2\text{O}_8^{2-}$  based on the four sets of data? (c) How is the rate of disappearance of  $\text{S}_2\text{O}_8^{2-}$  related to the rate of disappearance of  $\text{I}^-$ ? (d) What is the rate of disappearance of  $\text{I}^-$  when  $[\text{S}_2\text{O}_8^{2-}] = 0.025\text{ M}$  and  $[\text{I}^-] = 0.050\text{ M}$ ?

## Change of Concentration with Time (Section 14.4)

**14.39** (a) For the generic reaction  $\text{A} \rightarrow \text{B}$  what quantity, when graphed versus time, will yield a straight line for a first-order reaction? (b) How can you calculate the rate constant for a first-order reaction from the graph you made in part (a)?

**14.40** (a) For a generic second-order reaction  $\text{A} \longrightarrow \text{B}$ , what quantity, when graphed versus time, will yield a straight line? (b) What is the slope of the straight line from part (a)? (c) Does the half-life of a second-order reaction increase, decrease, or remain the same as the reaction proceeds?

**14.41** (a) The gas-phase decomposition of  $\text{SO}_2\text{Cl}_2$ ,  $\text{SO}_2\text{Cl}_2(\text{g}) \longrightarrow \text{SO}_2(\text{g}) + \text{Cl}_2(\text{g})$ , is first order in  $\text{SO}_2\text{Cl}_2$ . At  $600\text{ K}$  the half-life for this process is  $2.3 \times 10^5\text{ s}$ . What is the rate constant at this temperature? (b) At  $320^\circ\text{C}$  the rate

constant is  $2.2 \times 10^{-5}\text{ s}^{-1}$ . What is the half-life at this temperature?

**14.42** Molecular iodine,  $\text{I}_2(\text{g})$ , dissociates into iodine atoms at  $625\text{ K}$  with a first-order rate constant of  $0.271\text{ s}^{-1}$ . (a) What is the half-life for this reaction? (b) If you start with  $0.050\text{ M I}_2$  at this temperature, how much will remain after  $5.12\text{ s}$  assuming that the iodine atoms do not recombine to form  $\text{I}_2$ ?

**14.43** As described in Exercise 14.41, the decomposition of sulfuryl chloride ( $\text{SO}_2\text{Cl}_2$ ) is a first-order process. The rate constant for the decomposition at  $660\text{ K}$  is  $4.5 \times 10^{-2}\text{ s}^{-1}$ . (a) If we begin with an initial  $\text{SO}_2\text{Cl}_2$  pressure of  $450\text{ torr}$ , what is the partial pressure of this substance after  $60\text{ s}$ ? (b) At what time will the partial pressure of  $\text{SO}_2\text{Cl}_2$  decline to one-tenth its initial value?

**14.44** The first-order rate constant for the decomposition of  $\text{N}_2\text{O}_5$ ,  $2\text{N}_2\text{O}_5(\text{g}) \longrightarrow 4\text{NO}_2(\text{g}) + \text{O}_2(\text{g})$ , at  $70^\circ\text{C}$  is  $6.82 \times 10^{-3}\text{ s}^{-1}$ . Suppose we start with  $0.0250\text{ mol}$  of  $\text{N}_2\text{O}_5(\text{g})$  in a volume of  $2.0\text{ L}$ . (a) How many moles of  $\text{N}_2\text{O}_5$  will remain after  $5.0\text{ min}$ ? (b) How many minutes will it take for the quantity of  $\text{N}_2\text{O}_5$  to drop to  $0.010\text{ mol}$ ? (c) What is the half-life of  $\text{N}_2\text{O}_5$  at  $70^\circ\text{C}$ ?

**14.45** The reaction  $\text{SO}_2\text{Cl}_2(\text{g}) \longrightarrow \text{SO}_2(\text{g}) + \text{Cl}_2(\text{g})$  is first order in  $\text{SO}_2\text{Cl}_2$ . Using the following kinetic data, determine the magnitude and units of the first-order rate constant:

| Time (s) | Pressure $\text{SO}_2\text{Cl}_2$ (atm) |
|----------|---|
| 0        | 1.000                                   |
| 2500     | 0.947                                   |
| 5000     | 0.895                                   |
| 7500     | 0.848                                   |
| 10,000   | 0.803                                   |

**14.46** From the following data for the first-order gas-phase isomerization of  $\text{CH}_3\text{NC}$  at  $215^\circ\text{C}$ , calculate the first-order rate constant and half-life for the reaction:

| Time (s) | Pressure $\text{CH}_3\text{NC}$ (torr) |
|----------|--|
| 0        | 502                                    |
| 2000     | 335                                    |
| 5000     | 180                                    |
| 8000     | 95.5                                   |
| 12,000   | 41.7                                   |
| 15,000   | 22.4                                   |

**14.47** Consider the data presented in Exercise 14.19. (a) By using appropriate graphs, determine whether the reaction is first order or second order. (b) What is the rate constant for the reaction? (c) What is the half-life for the reaction?

**14.48** Consider the data presented in Exercise 14.20. (a) Determine whether the reaction is first order or second order. (b) What is the rate constant? (c) What is the half-life?

**14.49** The gas-phase decomposition of  $\text{NO}_2$ ,  $2\text{NO}_2(\text{g}) \longrightarrow 2\text{NO}(\text{g}) + \text{O}_2(\text{g})$ , is studied at  $383^\circ\text{C}$ , giving the following data:

| Time (s) | $[\text{NO}_2] (\text{M})$ |
|----------|----------------------------|
| 0.0      | 0.100                      |
| 5.0      | 0.017                      |
| 10.0     | 0.0090                     |
| 15.0     | 0.0062                     |
| 20.0     | 0.0047                     |

(a) Is the reaction first order or second order with respect to the concentration of  $\text{NO}_2$ ? (b) What is the rate constant? (c) Predict the reaction rates at the beginning of the reaction for initial concentrations of 0.200 M, 0.100 M, and 0.050 M  $\text{NO}_2$ .

- 14.50** Sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), commonly known as table sugar, reacts in dilute acid solutions to form two simpler sugars, glucose and fructose, both of which have the formula  $\text{C}_6\text{H}_{12}\text{O}_6$ . At 23 °C and in 0.5 M HCl, the following data were obtained for the disappearance of sucrose:

| Time (min) | $[\text{C}_{12}\text{H}_{22}\text{O}_{11}] \text{ (M)}$ |
|------------|---|
| 0          | 0.316   |
| 39         | 0.274   |
| 80         | 0.238   |
| 140        | 0.190   |
| 210        | 0.146   |

(a) Is the reaction first order or second order with respect to  $[\text{C}_{12}\text{H}_{22}\text{O}_{11}]$ ? (b) What is the rate constant? (c) Using this rate constant, calculate the concentration of sucrose at 39, 80, 140, and 210 min if the initial sucrose concentration was 0.316 M and the reaction were zero order in sucrose.

## Temperature and Rate (Section 14.5)

- 14.51** (a) What factors determine whether a collision between two molecules will lead to a chemical reaction? (b) Does the rate constant for a reaction generally increase or decrease with an increase in reaction temperature? (c) Which factor is most sensitive to changes in temperature—the frequency of collisions, the orientation factor, or the fraction of molecules with energy greater than the activation energy?

- 14.52** (a) In which of the following reactions would you expect the orientation factor to be least important in leading to reaction:  $\text{NO} + \text{O} \longrightarrow \text{NO}_2$  or  $\text{H} + \text{Cl} \longrightarrow \text{HCl}$ ? (b) Does the orientation factor depend on temperature?

- 14.53** Calculate the fraction of atoms in a sample of argon gas at 400 K that has an energy of 10.0 kJ or greater.

- 14.54** (a) The activation energy for the isomerization of methyl isonitrile (Figure 14.6) is 160 kJ/mol. Calculate the fraction of methyl isonitrile molecules that has an energy equal to or greater than the activation energy at 500 K. (b) Calculate this fraction for a temperature of 520 K. What is the ratio of the fraction at 520 K to that at 500 K?

- 14.55** The gas-phase reaction  $\text{Cl(g)} + \text{HBr(g)} \longrightarrow \text{HCl(g)} + \text{Br(g)}$  has an overall energy change of  $-66 \text{ kJ}$ . The activation energy for the reaction is 7 kJ. (a) Sketch the energy profile for the reaction, and label  $E_a$  and  $\Delta E$ . (b) What is the activation energy for the reverse reaction?

- 14.56** For the elementary process  $\text{N}_2\text{O}_5(\text{g}) \longrightarrow \text{NO}_2(\text{g}) + \text{NO}_3(\text{g})$  the activation energy ( $E_a$ ) and overall  $\Delta E$  are 154 kJ/mol and 136 kJ/mol, respectively. (a) Sketch the energy profile for this reaction, and label  $E_a$  and  $\Delta E$ . (b) What is the activation energy for the reverse reaction?

- 14.57** Indicate whether each statement is true or false.

- (a) If you compare two reactions with similar collision factors, the one with the larger activation energy will be faster.  
 (b) A reaction that has a small rate constant must have a small frequency factor.  
 (c) Increasing the reaction temperature increases the fraction of successful collisions between reactants.

- 14.58** Indicate whether each statement is true or false.

- (a) If you measure the rate constant for a reaction at different temperatures, you can calculate the overall enthalpy change for the reaction.  
 (b) Exothermic reactions are faster than endothermic reactions.  
 (c) If you double the temperature for a reaction, you cut the activation energy in half.

- 14.59** Based on their activation energies and energy changes and assuming that all collision factors are the same, rank the following reactions from slowest to fastest.

- (a)  $E_a = 45 \text{ kJ/mol}$ ;  $\Delta E = -25 \text{ kJ/mol}$   
 (b)  $E_a = 35 \text{ kJ/mol}$ ;  $\Delta E = -10 \text{ kJ/mol}$   
 (c)  $E_a = 55 \text{ kJ/mol}$ ;  $\Delta E = 10 \text{ kJ/mol}$

- 14.60** Which of the reactions in Exercise 14.59 will be fastest in the reverse direction? Which will be slowest?

- 14.61** (a) A certain first-order reaction has a rate constant of  $2.75 \times 10^{-2} \text{ s}^{-1}$  at 20 °C. What is the value of  $k$  at 60 °C if  $E_a = 75.5 \text{ kJ/mol}$ ? (b) Another first-order reaction also has a rate constant of  $2.75 \times 10^{-2} \text{ s}^{-1}$  at 20 °C. What is the value of  $k$  at 60 °C if  $E_a = 125 \text{ kJ/mol}$ ? (c) What assumptions do you need to make in order to calculate answers for parts (a) and (b)?

- 14.62** Understanding the high-temperature behavior of nitrogen oxides is essential for controlling pollution generated in automobile engines. The decomposition of nitric oxide ( $\text{NO}$ ) to  $\text{N}_2$  and  $\text{O}_2$  is second order with a rate constant of  $0.0796 \text{ M}^{-1}\text{s}^{-1}$  at 737 °C and  $0.0815 \text{ M}^{-1}\text{s}^{-1}$  at 947 °C. Calculate the activation energy for the reaction.

- 14.63** The rate of the reaction

was measured at several temperatures, and the following data were collected:

| Temperature (°C) | $k \text{ (M}^{-1} \text{ s}^{-1})$ |
|------------------|-------------------------------------|
| 15               | 0.0521                              |
| 25               | 0.101                               |
| 35               | 0.184                               |
| 45               | 0.332                               |

Calculate the value of  $E_a$  by constructing an appropriate graph.

- 14.64** The temperature dependence of the rate constant for a reaction is tabulated as follows:

| Temperature (K) | $k \text{ (M}^{-1} \text{ s}^{-1})$ |
|-----------------|-------------------------------------|
| 600             | 0.028                               |
| 650             | 0.22                                |
| 700             | 1.3                                 |
| 750             | 6.0                                 |
| 800             | 23                                  |

Calculate  $E_a$  and  $A$ .

## Reaction Mechanisms (Section 14.6)

- 14.65** (a) What is meant by the term *elementary reaction*? (b) What is the difference between a *unimolecular* and a *bimolecular* elementary reaction? (c) What is a

reaction mechanism? (d) What is meant by the term *rate-determining step*?

- 14.66** (a) Can an intermediate appear as a reactant in the first step of a reaction mechanism? (b) On a reaction energy profile diagram, is an intermediate represented as a peak or a valley? (c) If a molecule like  $\text{Cl}_2$  falls apart in an elementary reaction, what is the molecularity of the reaction?

- 14.67** What is the molecularity of each of the following elementary reactions? Write the rate law for each.

- 14.68** What is the molecularity of each of the following elementary reactions? Write the rate law for each.

- 14.69** (a) Based on the following reaction profile, how many intermediates are formed in the reaction  $\text{A} \longrightarrow \text{D}$ ? (b) How many transition states are there? (c) Which step is the fastest? (d) For the reaction  $\text{A} \longrightarrow \text{D}$ , is  $\Delta E$  positive, negative, or zero?

- 14.70** Consider the following energy profile.

- (a) How many elementary reactions are in the reaction mechanism? (b) How many intermediates are formed in the reaction? (c) Which step is rate limiting? (d) For the overall reaction, is  $\Delta E$  positive, negative, or zero?

- 14.71** The following mechanism has been proposed for the gas-phase reaction of  $\text{H}_2$  with  $\text{ICl}$ :

- (a) Write the balanced equation for the overall reaction. (b) Identify any intermediates in the mechanism. (c) If

the first step is slow and the second one is fast, which rate law do you expect to be observed for the overall reaction?

- 14.72** The decomposition of hydrogen peroxide is catalyzed by iodide ion. The catalyzed reaction is thought to proceed by a two-step mechanism:

- (a) Write the chemical equation for the overall process. (b) Identify the intermediate, if any, in the mechanism. (c) Assuming that the first step of the mechanism is rate determining, predict the rate law for the overall process.

- [14.73]** The reaction  $2 \text{NO}(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow 2 \text{NOCl}(\text{g})$  was performed and the following data were obtained under conditions of constant  $[\text{Cl}_2]$ :

- (a) Is the following mechanism consistent with the data?

- (b) Does the linear plot guarantee that the overall rate law is second order?

- 14.74** You have studied the gas-phase oxidation of  $\text{HBr}$  by  $\text{O}_2$ :

You find the reaction to be first order with respect to  $\text{HBr}$  and first order with respect to  $\text{O}_2$ . You propose the following mechanism:

- (a) Confirm that the elementary reactions add to give the overall reaction. (b) Based on the experimentally determined rate law, which step is rate determining? (c) What are the intermediates in this mechanism? (d) If you are unable to detect  $\text{HOBr}$  or  $\text{HOOBr}$  among the products, does this disprove your mechanism?

## Catalysis (Section 14.7)

- 14.75** (a) What is a catalyst? (b) What is the difference between a homogeneous and a heterogeneous catalyst? (c) Do catalysts affect the overall enthalpy change for a reaction, the activation energy, or both?

- 14.76** (a) Most commercial heterogeneous catalysts are extremely finely divided solid materials. Why is particle size important? (b) What role does adsorption play in the action of a heterogeneous catalyst?

- 14.77** In Figure 14.21, we saw that  $\text{Br}^-(\text{aq})$  catalyzes the decomposition of  $\text{H}_2\text{O}_2(\text{aq})$  into  $\text{H}_2\text{O}(\text{l})$  and  $\text{O}_2(\text{g})$ . Suppose that some  $\text{KBr}(\text{s})$  is added to an aqueous solution of hydrogen

peroxide. Make a sketch of  $[\text{Br}^-(aq)]$  versus time from the addition of the solid to the end of the reaction.

- 14.78** In solution, chemical species as simple as  $\text{H}^+$  and  $\text{OH}^-$  can serve as catalysts for reactions. Imagine you could measure the  $[\text{H}^+]$  of a solution containing an acid-catalyzed reaction as it occurs. Assume the reactants and products themselves are neither acids nor bases. Sketch the  $[\text{H}^+]$  concentration profile you would measure as a function of time for the reaction, assuming  $t = 0$  is when you add a drop of acid to the reaction.

- 14.79** The oxidation of  $\text{SO}_2$  to  $\text{SO}_3$  is accelerated by  $\text{NO}_2$ . The reaction proceeds according to:

(a) Show that, with appropriate coefficients, the two reactions can be summed to give the overall oxidation of  $\text{SO}_2$  by  $\text{O}_2$  to give  $\text{SO}_3$ . (b) Do we consider  $\text{NO}_2$  a catalyst or an intermediate in this reaction? (c) Would you classify  $\text{NO}$  as a catalyst or as an intermediate? (d) Is this an example of homogeneous catalysis or heterogeneous catalysis?

- 14.80** The addition of  $\text{NO}$  accelerates the decomposition of  $\text{N}_2\text{O}$ , possibly by the following mechanism:

(a) What is the chemical equation for the overall reaction? Show how the two steps can be added to give the overall equation. (b) Is  $\text{NO}$  serving as a catalyst or an intermediate in this reaction? (c) If experiments show that during the decomposition of  $\text{N}_2\text{O}$ ,  $\text{NO}_2$  does not accumulate in measurable quantities, does this rule out the proposed mechanism?

- 14.81** Many metallic catalysts, particularly the precious-metal ones, are often deposited as very thin films on a substance of high surface area per unit mass, such as alumina ( $\text{Al}_2\text{O}_3$ ) or silica ( $\text{SiO}_2$ ). (a) Why is this an effective way of utilizing the catalyst material compared to having powdered metals? (b) How does the surface area affect the rate of reaction?
- 14.82** (a) If you were going to build a system to check the effectiveness of automobile catalytic converters on cars, what substances would you want to look for in the car exhaust? (b) Automobile catalytic converters have to work at high temperatures, as hot exhaust gases stream through them. In what ways could this be an advantage? In what ways a disadvantage? (c) Why is the rate of flow of exhaust gases over a catalytic converter important?

- 14.83** When  $\text{D}_2$  reacts with ethylene ( $\text{C}_2\text{H}_4$ ) in the presence of a finely divided catalyst, ethane with two deuteriums,  $\text{CH}_2\text{D}-\text{CH}_2\text{D}$ , is formed. (Deuterium, D, is an isotope of hydrogen of mass 2.) Very little ethane forms in which two deuteriums are bound to one carbon (for example,  $\text{CH}_3-\text{CHD}_2$ ). Use the sequence of steps involved in the reaction (Figure 14.23) to explain why this is so.

- 14.84** Heterogeneous catalysts that perform hydrogenation reactions, as illustrated in Figure 14.23, are subject to “poisoning,” which shuts down their catalytic ability. Compounds of sulfur are often poisons. Suggest a mechanism by which such compounds might act as poisons.

- [14.85]** The enzyme carbonic anhydrase catalyzes the reaction  $\text{CO}_2(g) + \text{H}_2\text{O}(l) \longrightarrow \text{HCO}_3^-(aq) + \text{H}^+(aq)$ . In water, without the enzyme, the reaction proceeds with a rate constant of  $0.039\text{ s}^{-1}$  at  $25^\circ\text{C}$ . In the presence of the enzyme in water, the reaction proceeds with a rate constant of  $1.0 \times 10^6\text{ s}^{-1}$  at  $25^\circ\text{C}$ . Assuming the collision factor is the same for both situations, calculate the difference in activation energies for the uncatalyzed versus enzyme-catalyzed reaction.

- [14.86]** The enzyme urease catalyzes the reaction of urea,  $(\text{NH}_2\text{CONH}_2)$ , with water to produce carbon dioxide and ammonia. In water, without the enzyme, the reaction proceeds with a first-order rate constant of  $4.15 \times 10^{-5}\text{ s}^{-1}$  at  $100^\circ\text{C}$ . In the presence of the enzyme in water, the reaction proceeds with a rate constant of  $3.4 \times 10^4\text{ s}^{-1}$  at  $21^\circ\text{C}$ . (a) Write out the balanced equation for the reaction catalyzed by urease. (b) If the rate of the catalyzed reaction were the same at  $100^\circ\text{C}$  as it is at  $21^\circ\text{C}$ , what would be the difference in the activation energy between the catalyzed and uncatalyzed reactions? (c) In actuality, what would you expect for the rate of the catalyzed reaction at  $100^\circ\text{C}$  as compared to that at  $21^\circ\text{C}$ ? (d) On the basis of parts (c) and (d), what can you conclude about the difference in activation energies for the catalyzed and uncatalyzed reactions?

- [14.87]** The activation energy of an uncatalyzed reaction is  $95\text{ kJ/mol}$ . The addition of a catalyst lowers the activation energy to  $55\text{ kJ/mol}$ . Assuming that the collision factor remains the same, by what factor will the catalyst increase the rate of the reaction at (a)  $25^\circ\text{C}$ , (b)  $125^\circ\text{C}$ ?

- [14.88]** Suppose that a certain biologically important reaction is quite slow at physiological temperature ( $37^\circ\text{C}$ ) in the absence of a catalyst. Assuming that the collision factor remains the same, by how much must an enzyme lower the activation energy of the reaction to achieve a  $1 \times 10^5$ -fold increase in the reaction rate?

## Additional Exercises

- 14.89** Consider the reaction  $\text{A} + \text{B} \longrightarrow \text{C} + \text{D}$ . Is each of the following statements true or false? (a) The rate law for the reaction must be  $\text{Rate} = k[\text{A}][\text{B}]$ . (b) If the reaction is an elementary reaction, the rate law is second order. (c) If the reaction is an elementary reaction, the rate law of the reverse reaction is first order. (d) The activation energy for the reverse reaction must be greater than that for the forward reaction.
- 14.90** Hydrogen sulfide ( $\text{H}_2\text{S}$ ) is a common and troublesome pollutant in industrial wastewaters. One way to remove  $\text{H}_2\text{S}$  is to treat the water with chlorine, in which case the following reaction occurs:

The rate of this reaction is first order in each reactant. The rate constant for the disappearance of  $\text{H}_2\text{S}$  at  $28^\circ\text{C}$  is  $3.5 \times 10^{-2}\text{ M}^{-1}\text{ s}^{-1}$ . If at a given time the concentration of  $\text{H}_2\text{S}$  is  $2.0 \times 10^{-4}\text{ M}$  and that of  $\text{Cl}_2$  is  $0.025\text{ M}$ , what is the rate of formation of  $\text{Cl}^-$ ?

- 14.91** The reaction  $2\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{NO}_2(g)$  is second order in  $\text{NO}$  and first order in  $\text{O}_2$ . When  $[\text{NO}] = 0.040\text{ M}$ , and  $[\text{O}_2] = 0.035\text{ M}$ , the observed rate of disappearance of  $\text{NO}$  is  $9.3 \times 10^{-5}\text{ M/s}$ . (a) What is the rate of disappearance of  $\text{O}_2$  at this moment? (b) What is the value of the rate constant? (c) What are the units of the rate constant? (d) What would happen to the rate if the concentration of  $\text{NO}$  were increased by a factor of 1.8?

- 14.92** You perform a series of experiments for the reaction  $A \longrightarrow B + C$  and find that the rate law has the form  $\text{rate} = k[A]^x$ . Determine the value of  $x$  in each of the following cases: **(a)** There is no rate change when  $[A]_0$  is tripled. **(b)** The rate increases by a factor of 9 when  $[A]_0$  is tripled. **(c)** When  $[A]_0$  is doubled, the rate increases by a factor of 8.

- 14.93** Consider the following reaction between mercury(II) chloride and oxalate ion:

The initial rate of this reaction was determined for several concentrations of  $\text{HgCl}_2$  and  $\text{C}_2\text{O}_4^{2-}$ , and the following rate data were obtained for the rate of disappearance of  $\text{C}_2\text{O}_4^{2-}$ :

| Experiment | $[\text{HgCl}_2] (M)$ | $[\text{C}_2\text{O}_4^{2-}] (M)$ | Rate (M/s)           |
|------------|-----------------------|-----------------------------------|----------------------|
| 1          | 0.164                 | 0.15                              | $3.2 \times 10^{-5}$ |
| 2          | 0.164                 | 0.45                              | $2.9 \times 10^{-4}$ |
| 3          | 0.082                 | 0.45                              | $1.4 \times 10^{-4}$ |
| 4          | 0.246                 | 0.15                              | $4.8 \times 10^{-5}$ |

**(a)** What is the rate law for this reaction? **(b)** What is the value of the rate constant with proper units? **(c)** What is the reaction rate when the initial concentration of  $\text{HgCl}_2$  is 0.100 M and that of  $\text{C}_2\text{O}_4^{2-}$  is 0.25 M if the temperature is the same as that used to obtain the data shown?

- 14.94** The following kinetic data are collected for the initial rates of a reaction  $2X + Z \longrightarrow \text{products}$ :

| Experiment | $[X]_0 (M)$ | $[Z]_0 (M)$ | Rate (M/s)        |
|------------|-------------|-------------|-------------------|
| 1          | 0.25        | 0.25        | $4.0 \times 10^1$ |
| 2          | 0.50        | 0.50        | $3.2 \times 10^2$ |
| 3          | 0.50        | 0.75        | $7.2 \times 10^2$ |

**(a)** What is the rate law for this reaction? **(b)** What is the value of the rate constant with proper units? **(c)** What is the reaction rate when the initial concentration of X is 0.75 M and that of Z is 1.25 M?

- 14.95** The reaction  $2\text{NO}_2 \longrightarrow 2\text{NO} + \text{O}_2$  has the rate constant  $k = 0.63 \text{ M}^{-1}\text{s}^{-1}$ . **(a)** Based on the units for  $k$ , is the reaction first or second order in  $\text{NO}_2$ ? **(b)** If the initial concentration of  $\text{NO}_2$  is 0.100 M, how long would it take for the concentration to decrease to 0.025 M?

- 14.96** Consider two reactions. Reaction (1) has a constant half-life, whereas reaction (2) has a half-life that gets longer as the reaction proceeds. What can you conclude about the rate laws of these reactions from these observations?

- [14.97]** A first-order reaction  $A \longrightarrow B$  has the rate constant  $k = 3.2 \times 10^{-3} \text{ s}^{-1}$ . If the initial concentration of A is  $2.5 \times 10^{-2} \text{ M}$ , what is the rate of the reaction at  $t = 660 \text{ s}$ ?

- 14.98** **(a)** The reaction  $\text{H}_2\text{O}_2(aq) \longrightarrow \text{H}_2\text{O}(l) + \frac{1}{2}\text{O}_2(g)$  is first order. At 300 K the rate constant equals  $7.0 \times 10^{-4} \text{ s}^{-1}$ . Calculate the half-life at this temperature. **(b)** If the activation energy for this reaction is 75 kJ/mol, at what temperature would the reaction rate be doubled?

- 14.99** Americium-241 is used in smoke detectors. It has a first-order rate constant for radioactive decay of  $k = 1.6 \times 10^{-3} \text{ yr}^{-1}$ . By contrast, iodine-125, which is used to test for thyroid functioning, has a rate constant for radioactive decay of  $k = 0.011 \text{ day}^{-1}$ . **(a)** What are the half-lives of these two isotopes? **(b)** Which one decays at a faster rate? **(c)** How much of a 1.00-mg sample of each isotope remains after three half-lives? **(d)** How much of a 1.00-mg sample of each isotope remains after 4 days?

- 14.100** Urea ( $\text{NH}_2\text{CONH}_2$ ) is the end product in protein metabolism in animals. The decomposition of urea in 0.1 M HCl occurs according to the reaction

The reaction is first order in urea and first order overall. When  $[\text{NH}_2\text{CONH}_2] = 0.200 \text{ M}$ , the rate at 61.05 °C is  $8.56 \times 10^{-5} \text{ M/s}$ . **(a)** What is the rate constant,  $k$ ? **(b)** What is the concentration of urea in this solution after  $4.00 \times 10^3 \text{ s}$  if the starting concentration is 0.500 M? **(c)** What is the half-life for this reaction at 61.05 °C?

- [14.101]** The rate of a first-order reaction is followed by spectroscopy, monitoring the absorbance of a colored reactant at 520 nm. The reaction occurs in a 1.00-cm sample cell, and the only colored species in the reaction has an extinction coefficient of  $5.60 \times 10^3 \text{ M}^{-1}\text{cm}^{-1}$  at 520 nm. **(a)** Calculate the initial concentration of the colored reactant if the absorbance is 0.605 at the beginning of the reaction. **(b)** The absorbance falls to 0.250 at 30.0 min. Calculate the rate constant in units of  $\text{s}^{-1}$ . **(c)** Calculate the half-life of the reaction. **(d)** How long does it take for the absorbance to fall to 0.100?

- [14.102]** A colored dye compound decomposes to give a colorless product. The original dye absorbs at 608 nm and has an extinction coefficient of  $4.7 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$  at that wavelength. You perform the decomposition reaction in a 1-cm cuvette in a spectrometer and obtain the following data:

| Time (min) | Absorbance at 608 nm |
|------------|----------------------|
| 0          | 1.254                |
| 30         | 0.941                |
| 60         | 0.752                |
| 90         | 0.672                |
| 120        | 0.545                |

From these data, determine the rate law for the reaction "dye  $\longrightarrow$  product" and determine the rate constant.

- 14.103** Cyclopentadiene ( $\text{C}_5\text{H}_6$ ) reacts with itself to form dicyclopentadiene ( $\text{C}_{10}\text{H}_{12}$ ). A 0.0400 M solution of  $\text{C}_5\text{H}_6$  was monitored as a function of time as the reaction  $2\text{C}_5\text{H}_6 \longrightarrow \text{C}_{10}\text{H}_{12}$  proceeded. The following data were collected:

| Time (s) | $[\text{C}_5\text{H}_6] (M)$ |
|----------|------------------------------|
| 0.0      | 0.0400                       |
| 50.0     | 0.0300                       |
| 100.0    | 0.0240                       |
| 150.0    | 0.0200                       |
| 200.0    | 0.0174                       |

Plot  $[\text{C}_5\text{H}_6]$  versus time,  $\ln[\text{C}_5\text{H}_6]$  versus time, and  $1/[\text{C}_5\text{H}_6]$  versus time. **(a)** What is the order of the reaction? **(b)** What is the value of the rate constant?

- 14.104** The first-order rate constant for reaction of a particular organic compound with water varies with temperature as follows:

| Temperature (K) | Rate Constant ( $\text{s}^{-1}$ ) |
|-----------------|-----------------------------------|
| 300             | $3.2 \times 10^{-11}$             |
| 320             | $1.0 \times 10^{-9}$              |
| 340             | $3.0 \times 10^{-8}$              |
| 355             | $2.4 \times 10^{-7}$              |

From these data, calculate the activation energy in units of kJ/mol.

**14.105** At 28 °C, raw milk sours in 4.0 h but takes 48 h to sour in a refrigerator at 5 °C. Estimate the activation energy in kJ/mol for the reaction that leads to the souring of milk.

**[14.106]** The following is a quote from an article in the August 18, 1998, issue of *The New York Times* about the breakdown of cellulose and starch: “A drop of 18 degrees Fahrenheit [from 77 °F to 59 °F] lowers the reaction rate six times; a 36-degree drop [from 77 °F to 41 °F] produces a fortyfold decrease in the rate.” **(a)** Calculate activation energies for the breakdown process based on the two estimates of the effect of temperature on rate. Are the values consistent? **(b)** Assuming the value of  $E_a$  calculated from the 36° drop and that the rate of breakdown is first order with a half-life at 25 °C of 2.7 yr, calculate the half-life for breakdown at a temperature of –15 °C.

**14.107** The following mechanism has been proposed for the reaction of NO with H<sub>2</sub> to form N<sub>2</sub>O and H<sub>2</sub>O:

**(a)** Show that the elementary reactions of the proposed mechanism add to provide a balanced equation for the reaction. **(b)** Write a rate law for each elementary reaction in the mechanism. **(c)** Identify any intermediates in the mechanism. **(d)** The observed rate law is  $\text{rate} = k[\text{NO}]^2[\text{H}_2]$ . If the proposed mechanism is correct, what can we conclude about the relative speeds of the first and second reactions?

**14.108** Ozone in the upper atmosphere can be destroyed by the following two-step mechanism:

**(a)** What is the overall equation for this process? **(b)** What is the catalyst in the reaction? **(c)** What is the intermediate in the reaction?

**14.109** The gas-phase decomposition of ozone is thought to occur by the following two-step mechanism.

**(a)** Write the balanced equation for the overall reaction. **(b)** Derive the rate law that is consistent with this mechanism. (*Hint:* The product appears in the rate law.) **(c)** Is O a catalyst or an intermediate? **(d)** If instead the reaction occurred in a single step, would the rate law change? If so, what would it be?

**[14.110]** The following mechanism has been proposed for the gas-phase reaction of chloroform (CHCl<sub>3</sub>) and chlorine:

**(a)** What is the overall reaction? **(b)** What are the intermediates in the mechanism? **(c)** What is the molecularity of each of the elementary reactions? **(d)** What is the rate-determining step? **(e)** What is the rate law predicted by this mechanism? (*Hint:* The overall reaction order is not an integer.)

**[14.111]** Consider the hypothetical reaction  $2\text{A} + \text{B} \longrightarrow 2\text{C} + \text{D}$ . The following two-step mechanism is proposed for the reaction:

X is an unstable intermediate. **(a)** What is the predicted rate law expression if Step 1 is rate determining? **(b)** What

is the predicted rate law expression if Step 2 is rate determining? **(c)** Your result for part (b) might be considered surprising for which of the following reasons: **(i)** The concentration of a product is in the rate law. **(ii)** There is a negative reaction order in the rate law. **(iii)** Both reasons (i) and (ii). **(iv)** Neither reasons (i) nor (ii).

**[14.112]** In a hydrocarbon solution, the gold compound (CH<sub>3</sub>)<sub>3</sub>AuPH<sub>3</sub> decomposes into ethane (C<sub>2</sub>H<sub>6</sub>) and a different gold compound, (CH<sub>3</sub>)AuPH<sub>3</sub>. The following mechanism has been proposed for the decomposition of (CH<sub>3</sub>)<sub>3</sub>AuPH<sub>3</sub>:

**(a)** What is the overall reaction? **(b)** What are the intermediates in the mechanism? **(c)** What is the molecularity of each of the elementary steps? **(d)** What is the rate-determining step? **(e)** What is the rate law predicted by this mechanism? **(f)** What would be the effect on the reaction rate of adding PH<sub>3</sub> to the solution of (CH<sub>3</sub>)<sub>3</sub>AuPH<sub>3</sub>?

**[14.113]** Platinum nanoparticles of diameter ~2 nm are important catalysts in carbon monoxide oxidation to carbon dioxide. Platinum crystallizes in a face-centered cubic arrangement with an edge length of 3.924 Å. **(a)** Estimate how many platinum atoms would fit into a 2.0-nm sphere; the volume of a sphere is  $(4/3)\pi r^3$ . Recall that 1 Å = 1 × 10<sup>–10</sup> m and 1 nm = 1 × 10<sup>–9</sup> m. **(b)** Estimate how many platinum atoms are on the surface of a 2.0-nm Pt sphere, using the surface area of a sphere ( $4\pi r^2$ ) and assuming that the “footprint” of one Pt atom can be estimated from its atomic diameter of 2.8 Å. **(c)** Using your results from (a) and (b), calculate the percentage of Pt atoms that are on the surface of a 2.0-nm nanoparticle. **(d)** Repeat these calculations for a 5.0-nm platinum nanoparticle. **(e)** Which size of nanoparticle would you expect to be more catalytically active and why?

**14.114** One of the many remarkable enzymes in the human body is carbonic anhydrase, which catalyzes the interconversion of carbon dioxide and water with bicarbonate ion and protons. If it were not for this enzyme, the body could not rid itself rapidly enough of the CO<sub>2</sub> accumulated by cell metabolism. The enzyme catalyzes the dehydration (release to air) of up to 10<sup>7</sup> CO<sub>2</sub> molecules per second. Which components of this description correspond to the terms *enzyme*, *substrate*, and *turnover number*?

**14.115** Suppose that, in the absence of a catalyst, a certain biochemical reaction occurs  $x$  times per second at normal body temperature (37 °C). In order to be physiologically useful, the reaction needs to occur 5000 times faster than when it is uncatalyzed. By how many kJ/mol must an enzyme lower the activation energy of the reaction to make it useful?

**14.116** Enzymes are often described as following the two-step mechanism:

where E = enzyme, S = substrate,

ES = enzyme–substrate complex, and P = product.

**(a)** If an enzyme follows this mechanism, what rate law is expected for the reaction? **(b)** Molecules that can bind to the active site of an enzyme but are not converted into product are called *enzyme inhibitors*. Write an additional elementary step to add into the preceding mechanism to account for the reaction of E with I, an inhibitor.

## Integrative Exercises

**[14.117]** Dinitrogen pentoxide ( $\text{N}_2\text{O}_5$ ) decomposes in chloroform as a solvent to yield  $\text{NO}_2$  and  $\text{O}_2$ . The decomposition is first order with a rate constant at  $45^\circ\text{C}$  of  $1.0 \times 10^{-5} \text{ s}^{-1}$ . Calculate the partial pressure of  $\text{O}_2$  produced from 1.00 L of  $0.600 \text{ M N}_2\text{O}_5$  solution at  $45^\circ\text{C}$  over a period of 20.0 h if the gas is collected in a 10.0-L container. (Assume that the products do not dissolve in chloroform.)

**[14.118]** The reaction between ethyl iodide and hydroxide ion in ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) solution,  $\text{C}_2\text{H}_5\text{I}(\text{alc}) + \text{OH}^-(\text{alc}) \longrightarrow \text{C}_2\text{H}_5\text{OH}(\text{l}) + \text{I}^-(\text{alc})$ , has an activation energy of  $86.8 \text{ kJ/mol}$  and a frequency factor of  $2.10 \times 10^{11} \text{ M}^{-1} \text{ s}^{-1}$ . (a) Predict the rate constant for the reaction at  $35^\circ\text{C}$ . (b) A solution of KOH in ethanol is made up by dissolving 0.335 g KOH in ethanol to form 250.0 mL of solution. Similarly, 1.453 g of  $\text{C}_2\text{H}_5\text{I}$  is dissolved in ethanol to form 250.0 mL of solution. Equal volumes of the two solutions are mixed. Assuming the reaction is first order in each reactant, what is the initial rate at  $35^\circ\text{C}$ ? (c) Which reagent in the reaction is limiting, assuming the reaction proceeds to completion? (d) Assuming the frequency factor and activation energy do not change as a function of temperature, calculate the rate constant for the reaction at  $50^\circ\text{C}$ .

**[14.119]** You obtain kinetic data for a reaction at a set of different temperatures. You plot  $\ln k$  versus  $1/T$  and obtain the following graph:

Suggest a molecular-level interpretation of these unusual data.

**14.120** The gas-phase reaction of NO with  $\text{F}_2$  to form NOF and F has an activation energy of  $E_a = 6.3 \text{ kJ/mol}$  and a frequency factor of  $A = 6.0 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ . The reaction is believed to be bimolecular:

(a) Calculate the rate constant at  $100^\circ\text{C}$ . (b) Draw the Lewis structures for the NO and the NOF molecules, given that the chemical formula for NOF is misleading because the nitrogen atom is actually the central atom in the molecule. (c) Predict the shape for the NOF molecule. (d) Draw a possible transition state for the formation of NOF, using dashed lines to indicate the weak bonds that are beginning to form. (e) Suggest a reason for the low activation energy for the reaction.

**14.121** The mechanism for the oxidation of HBr by  $\text{O}_2$  to form  $2 \text{ H}_2\text{O}$  and  $\text{Br}_2$  is shown in Exercise 14.74. (a) Calculate the overall standard enthalpy change for the reaction process. (b) HBr does not react with  $\text{O}_2$  at a measurable rate at room temperature under ordinary conditions. What can you infer from this about the magnitude of the activation energy for the rate-determining step? (c) Draw a plausible Lewis structure for the intermediate  $\text{HOBr}$ . To

what familiar compound of hydrogen and oxygen does it appear similar?

**[14.122]** The rates of many atmospheric reactions are accelerated by the absorption of light by one of the reactants. For example, consider the reaction between methane and chlorine to produce methyl chloride and hydrogen chloride:

This reaction is very slow in the absence of light. However,  $\text{Cl}_2(\text{g})$  can absorb light to form Cl atoms:

Once the Cl atoms are generated, they can catalyze the reaction of  $\text{CH}_4$  and  $\text{Cl}_2$ , according to the following proposed mechanism:

The enthalpy changes and activation energies for these two reactions are tabulated as follows:

| Reaction | $\Delta H^\circ$ (kJ/mol) | $E_a$ (kJ/mol) |
|----------|---------------------------|----------------|
| 3        | +4                        | 17             |
| 4        | -109                      | 4              |

(a) By using the bond enthalpy for  $\text{Cl}_2$  (Table 8.4), determine the longest wavelength of light that is energetic enough to cause reaction 2 to occur. In which portion of the electromagnetic spectrum is this light found? (b) By using the data tabulated here, sketch a quantitative energy profile for the catalyzed reaction represented by reactions 3 and 4. (c) By using bond enthalpies, estimate where the reactants,  $\text{CH}_4(\text{g}) + \text{Cl}_2(\text{g})$ , should be placed on your diagram in part (b). Use this result to estimate the value of  $E_a$  for the reaction  $\text{CH}_4(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow \text{CH}_3(\text{g}) + \text{HCl}(\text{g}) + \text{Cl}(\text{g})$ . (d) The species  $\text{Cl}(\text{g})$  and  $\text{CH}_3(\text{g})$  in reactions 3 and 4 are radicals, that is, atoms or molecules with unpaired electrons. Draw a Lewis structure of  $\text{CH}_3$ , and verify that it is a radical. (e) The sequence of reactions 3 and 4 comprises a radical chain mechanism. Why do you think this is called a “chain reaction”? Propose a reaction that will terminate the chain reaction.

**[14.123]** Many primary amines,  $\text{RNH}_2$ , where R is a carbon-containing fragment such as  $\text{CH}_3$ ,  $\text{CH}_3\text{CH}_2$ , and so on, undergo reactions where the transition state is tetrahedral. (a) Draw a hybrid orbital picture to visualize the bonding at the nitrogen in a primary amine (just use a C atom for “R”). (b) What kind of reactant with a primary amine can produce a tetrahedral intermediate?

**[14.124]** The  $\text{NO}_x$  waste stream from automobile exhaust includes species such as NO and  $\text{NO}_2$ . Catalysts that convert these species to  $\text{N}_2$  are desirable to reduce air pollution. (a) Draw the Lewis dot and VSEPR structures of NO,  $\text{NO}_2$ , and  $\text{N}_2$ . (b) Using a resource such as Table 8.3, look up the energies of the bonds in these molecules. In what region of the electromagnetic spectrum are these energies? (c) Design a spectroscopic experiment to monitor the conversion of  $\text{NO}_x$  into  $\text{N}_2$ , describing what wavelengths of light need to be monitored as a function of time.

**[14.125]** As shown in Figure 14.23, the first step in the heterogeneous hydrogenation of ethylene is adsorption of the ethylene molecule on a metal surface. One proposed

explanation for the “sticking” of ethylene to a metal surface is the interaction of the electrons in the C—C  $\pi$  bond with vacant orbitals on the metal surface. **(a)** If this notion is correct, would ethane be expected to adsorb to a

metal surface, and, if so, how strongly would ethane bind compared to ethylene? **(b)** Based on its Lewis structure, would you expect ammonia to adsorb to a metal surface using a similar explanation as for ethylene?

## Design an Experiment

Let's explore the chemical kinetics of our favorite hypothetical reaction:  $aA + bB \longrightarrow cC + dD$ . We shall assume that all the substances are soluble in water and that we carry out the reaction in aqueous solution. Substances A and C both absorb visible light, and the absorption maxima are 510 nm for A and for 640 nm for C. Substances B and D are colorless. You are provided with pure samples of all four substances and you know their chemical formulas. You are also provided appropriate instrumentation to obtain visible absorption spectra (see the Closer Look box on using spectroscopic methods in Section 14.3). Let's design an experiment to ascertain the kinetics of our reaction. **(a)** What experiments could

you design to determine the rate law and the rate constant for the reaction at room temperature? Would you need to know the values of the stoichiometric constants  $a$  and  $c$  in order to find the rate law? **(b)** Design an experiment to determine the activation energy for the reaction. What challenges might you face in actually carrying out this experiment? **(c)** You now want to test whether a particular water-soluble substance Q is a homogeneous catalyst for the reaction. What experiments can you carry out to test this notion? **(d)** If Q does indeed catalyze the reaction, what follow-up experiments might you undertake to learn more about the reaction profile for the reaction?

15

# CHEMICAL EQUILIBRIUM

To be in equilibrium is to be in a state of balance. A tug of war in which the two sides pull with equal force so that the rope does not move is an example of a *static* equilibrium, one in which an object is at rest. Equilibria can also be *dynamic*, whereby a forward process and the reverse process take place at the same rate so that no net change occurs.

Imagine you are at sea in a small sailboat that springs a leak. As the boat slowly fills with water, you look for a way to get the water out of the boat before it sinks. Just as things are starting to look bleak, you find a plastic water bottle and start bailing water out of the boat. After much effort, you are able to lower the water level down to a few centimeters, at which point your rate of bailing slows down because you can no longer completely fill the bottle by submersing it. Eventually, the rate at which water enters the boat through the leak becomes equal to the rate at which you can displace the water by bailing it out. At that point, a state of dynamic equilibrium is reached, where the rates of the forward process (water coming into the boat) and the reverse process (water leaving the boat) are equal to each other and the level of water in the boat remains constant.

A somewhat analogous situation occurs when heavy rains fall in coastal cities that are partially below sea level, like New Orleans ([Figure 15.1](#)). The saucer-shaped elevation profile of New Orleans means that water cannot naturally drain away from the lower parts of the city.

◀ **A LEAKY BOAT.** A state of dynamic equilibrium, where the water level reaches a constant level, is eventually attained by bailing water from a small boat that has sprung a leak.

## WHAT'S AHEAD

- 15.1** ▶ **The Concept of Equilibrium** Examine reversible reactions and the concept of equilibrium.
- 15.2** ▶ **The Equilibrium Constant** Define the *equilibrium constant* based on rates of forward and reverse reactions, and learn how to write *equilibrium-constant expressions* for homogeneous reactions.
- 15.3** ▶ **Understanding and Working with Equilibrium Constants** Learn how to interpret the magnitude of an equilibrium constant and how its value depends on the way the corresponding chemical equation is expressed.
- 15.4** ▶ **Heterogeneous Equilibria** Write equilibrium-constant expressions for heterogeneous reactions.
- 15.5** ▶ **Calculating Equilibrium Constants** Calculate equilibrium constants from the equilibrium concentrations of reactants and products.
- 15.6** ▶ **Applications of Equilibrium Constants** Use equilibrium constants to predict equilibrium concentrations of reactants and products and to determine the direction in which a reaction mixture must proceed to achieve equilibrium.
- 15.7** ▶ **Le Châtelier's Principle** Use *Le Chatelier's principle* to make qualitative predictions of how a system at equilibrium will respond to changes in concentration, volume, pressure, and temperature.

A complex system of pumps is used to remove the rainwater, protecting residents and properties from flooding. In 2005 when Hurricane Katrina struck New Orleans, the storm surge and failures in the levee system upset this equilibrium with disastrous consequences for the city.

Over the past few chapters we've encountered several examples of dynamic equilibrium involving physical changes of matter, including vapor pressure  $\infty$  (Section 11.5), the formation of saturated solutions  $\infty$  (Section 13.2), and Henry's law  $\infty$  (Section 13.3). Consider vapor pressure as an illustrative example. In a closed container, the pressure of a vapor above a liquid stops changing when the rate at which molecules escaping from the liquid into the gas phase equals the rate at which molecules from the gas phase are captured by and reenter the liquid.

Just like evaporation and condensation, or dissolution and crystallization, chemical reactions can run in the forward and reverse directions. If the reverse reaction is sufficiently slow, we can neglect it altogether, as we have done in reactions we've encountered up to this point, but there are many important examples where we must consider the rates of both forward and reverse reactions.

**Chemical equilibrium** occurs when the forward and reverse reactions proceed at equal rates.

When a reaction is at equilibrium, the rate at which the products form from the reactants equals the rate at which the reactants form from the products. As a result, concentrations cease to change, and the reaction appears to stop before it reaches completion.

▲ **Figure 15.1** An elevation map of New Orleans. The areas colored yellow, red, and orange near the Mississippi River have elevations that are 10 or more feet above sea level, while those colored blue are below sea level.

In this and the next two chapters, we will explore chemical equilibrium in detail. Later, in Chapter 19, we will learn how to relate chemical equilibria to thermodynamics. Here, we learn how to express the equilibrium state of a reaction in quantitative terms and study the factors that determine the relative concentrations of reactants and products in equilibrium mixtures.

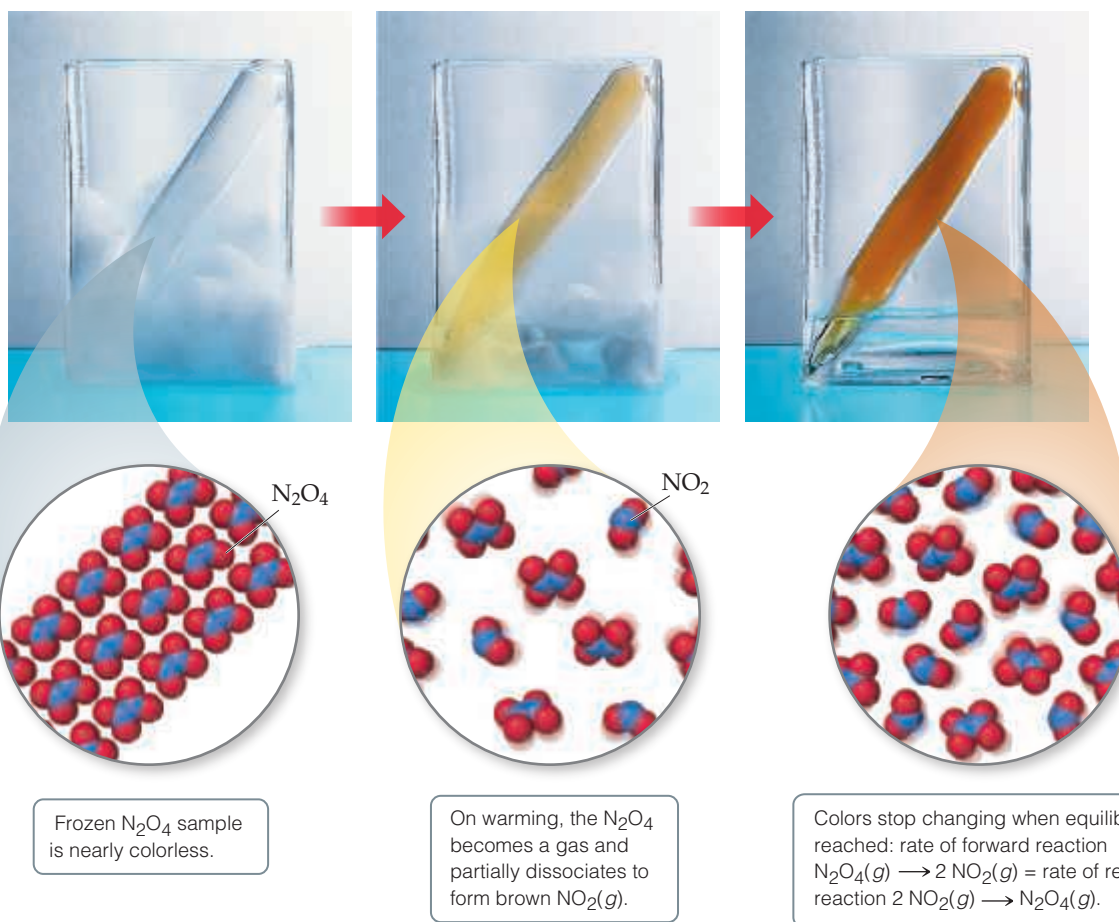

## 15.1 | The Concept of Equilibrium

Let's examine a simple chemical reaction to see how it reaches an *equilibrium state*—a mixture of reactants and products whose concentrations no longer change with time. We begin with  $\text{N}_2\text{O}_4$ , a colorless substance that dissociates to form brown  $\text{NO}_2$ . **Figure 15.2** shows a sample of frozen  $\text{N}_2\text{O}_4$  inside a sealed tube. The solid  $\text{N}_2\text{O}_4$  becomes a gas as it is warmed above its boiling point ( $21.2^\circ\text{C}$ ), and the gas turns darker as the colorless  $\text{N}_2\text{O}_4$  gas dissociates into brown  $\text{NO}_2$  gas. Eventually, even though there is still  $\text{N}_2\text{O}_4$  in the tube, the color stops getting darker because the system reaches equilibrium. We are left with an *equilibrium mixture* of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  in which the concentrations of the gases no longer change as time passes. Because the reaction is in a closed system, no gases escape, and the equilibrium mixture can be maintained.

### Go Figure

If you were to let the tube on the right sit overnight and then take another picture, would the brown color look darker, lighter, or the same?

**Figure 15.2** The equilibrium between  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ .

The equilibrium mixture results because the reaction is *reversible*:  $\text{N}_2\text{O}_4$  can form  $\text{NO}_2$ , and  $\text{NO}_2$  can form  $\text{N}_2\text{O}_4$ . Dynamic equilibrium is represented by writing the equation for the reaction with two half arrows pointing in opposite directions  $\rightleftharpoons$  (Section 4.1):

We can analyze this equilibrium using our knowledge of kinetics. Let's call the decomposition of  $\text{N}_2\text{O}_4$  the forward reaction and the formation of  $\text{N}_2\text{O}_4$  the reverse reaction. In this case, both the forward reaction and the reverse reaction are *elementary reactions*. As we learned in Section 14.6, the rate laws for elementary reactions can be written from their chemical equations:

At equilibrium, the rate at which  $\text{NO}_2$  forms in the forward reaction equals the rate at which  $\text{N}_2\text{O}_4$  forms in the reverse reaction:

$$\underset{\text{Forward reaction}}{k_f[\text{N}_2\text{O}_4]} = \underset{\text{Reverse reaction}}{k_r[\text{NO}_2]^2} \quad [15.4]$$

Rearranging this equation gives

$$\frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{k_f}{k_r} = \text{a constant} \quad [15.5]$$

From Equation 15.5, we see that the quotient of two rate constants is another constant, which as we will learn is called the equilibrium constant. We also see that, at equilibrium, the ratio of the concentration terms equals this same constant. It makes no difference whether we start with  $\text{N}_2\text{O}_4$  or with  $\text{NO}_2$ , or even with some mixture of the two. At equilibrium, at a given temperature, the ratio equals a specific value. Thus, there is an important constraint on the proportions of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  at equilibrium.

### Give It Some Thought

Which of the following variables are equal when the  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$  reaction reaches equilibrium: (a)  $k_f$  and  $k_r$ , (b) the forward and reverse reaction rates, (c) the concentrations of  $[\text{N}_2\text{O}_4]$  and  $[\text{NO}_2]$ ?

Once equilibrium is established, the concentrations of  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  no longer change, as shown in Figure 15.3(a). However, the fact that the composition of the

### Go Figure

Why does the rate of the forward reaction slow down as the reaction proceeds?

(a)

(b)

▲ **Figure 15.3** Achieving chemical equilibrium in the  $\text{N}_2\text{O}_4(\text{g}) \longrightarrow 2 \text{NO}_2(\text{g})$  reaction. Equilibrium occurs when the rate of the forward reaction equals the rate of the reverse reaction.

equilibrium mixture remains constant with time does not mean that  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  stop reacting. On the contrary, the equilibrium is *dynamic*—which means some  $\text{N}_2\text{O}_4$  is always converting to  $\text{NO}_2$  and some  $\text{NO}_2$  is always converting to  $\text{N}_2\text{O}_4$ . At equilibrium, however, the two processes occur at the same rate, as shown in Figure 15.3(b).

We learn several important lessons about equilibrium from this example:

- At equilibrium, the concentrations of reactants and products no longer change with time.
- For equilibrium to occur, neither reactants nor products can escape from the system.
- At equilibrium, a particular ratio of concentration terms equals a constant.

## 15.2 | The Equilibrium Constant

A reaction in which reactants convert to products and products convert to reactants in the same reaction vessel naturally leads to an equilibrium, regardless of how complicated the reaction is and regardless of the nature of the kinetic processes for the forward and reverse reactions. Consider the synthesis of ammonia from nitrogen and hydrogen:

This reaction is the basis for the **Haber process**, which is critical for the production of fertilizers and therefore critical to the world's food supply. In the Haber process,  $\text{N}_2$  and  $\text{H}_2$  react at high pressure and temperature in the presence of a catalyst to form ammonia. In a closed system, however, the reaction does not lead to complete consumption of the  $\text{N}_2$  and  $\text{H}_2$ . Rather, at some point the reaction appears to stop, with all three components of the reaction mixture present at the same time.

How the concentrations of  $\text{H}_2$ ,  $\text{N}_2$ , and  $\text{NH}_3$  vary with time is shown in Figure 15.4. Notice that an equilibrium mixture is obtained regardless of whether we begin with  $\text{N}_2$  and  $\text{H}_2$  or with  $\text{NH}_3$ . *The equilibrium condition is reached from either direction.*

### Give It Some Thought

True or False: You can determine if equilibrium has been reached by monitoring the concentration of a single reactant.

An expression similar to Equation 15.5 governs the concentrations of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  at equilibrium. If we were to systematically change the relative amounts of the three gases in the starting mixture and then analyze each equilibrium mixture, we could determine the relationship among the equilibrium concentrations.

### Go Figure

Is the rate of disappearance of  $\text{H}_2$  related to the rate of disappearance of  $\text{N}_2$ ? If so, how they are related?

▲ **Figure 15.4** The same equilibrium is reached whether we start with only reactants ( $\text{N}_2$  and  $\text{H}_2$ ) or with only product ( $\text{NH}_3$ ).

Chemists carried out studies of this kind on other chemical systems in the nineteenth century before Haber's work. In 1864, Cato Maximilian Guldberg (1836–1902) and Peter Waage (1833–1900) postulated their **law of mass action**, which expresses, for any reaction, the relationship between the concentrations of the reactants and products present at equilibrium. Suppose we have the general equilibrium equation

where A, B, D, and E are the chemical species involved and  $a$ ,  $b$ ,  $d$ , and  $e$  are their coefficients in the balanced chemical equation. According to the law of mass action, the equilibrium condition is described by the expression

$$K_c = \frac{[D]^d[E]^e}{[A]^a[B]^b} \quad \begin{array}{l} \longleftarrow \text{products} \\ \longleftarrow \text{reactants} \end{array} \quad [15.8]$$

We call this relationship the **equilibrium-constant expression** (or merely the *equilibrium expression*) for the reaction. The constant  $K_c$ , the **equilibrium constant**, is the numerical value obtained when we substitute molar equilibrium concentrations into the equilibrium-constant expression. The subscript  $c$  on the  $K$  indicates that concentrations expressed in molarity are used to evaluate the constant.

The numerator of the equilibrium-constant expression is the product of the concentrations of all substances on the product side of the equilibrium equation, each raised to a power equal to its coefficient in the balanced equation. The denominator is similarly derived from the reactant side of the equilibrium equation. Thus,

## CHEMISTRY PUT TO WORK The Haber Process

The quantity of food required to feed the ever-increasing human population far exceeds that provided by nitrogen-fixing plants.  (Section 14.7, “Nitrogen Fixation and Nitrogenase”) Therefore, human agriculture requires substantial amounts of ammonia-based fertilizers for croplands. Of all the chemical reactions that humans have learned to control for their own purposes, the synthesis of ammonia from hydrogen and atmospheric nitrogen is one of the most important.

In 1912, the German chemist Fritz Haber (1868–1934) developed the Haber process (Equation 15.6). The process is sometimes also called the *Haber–Bosch process* to honor Karl Bosch, the engineer who developed the industrial process on a large scale (Figure 15.5). The engineering needed to implement the Haber process requires the use of temperatures (approximately 500 °C) and pressures (200 to 600 atm) that were difficult to achieve at that time.

The Haber process provides a historically interesting example of the complex impact of chemistry on our lives. At the start of World War I, in 1914, Germany depended on nitrate deposits in Chile for the nitrogen-containing compounds needed to manufacture explosives. During the war, the Allied naval blockade of South America cut off this supply. However, by using the Haber reaction to fix nitrogen from air, Germany was able to continue to produce explosives. Experts have estimated that World War I would have ended perhaps a year earlier had it not been for the Haber process.

From these unhappy beginnings as a major factor in international warfare, the Haber process has become the world's principal source of fixed nitrogen. The same process that prolonged World War I has enabled the manufacture of fertilizers that have increased crop yields, thereby saving millions of people from starvation. About 40 billion pounds of ammonia are manufactured annually in the United States, mostly by the Haber process. The ammonia can be applied directly to the soil, or it can be converted into ammonium salts that are also used as fertilizers.

Haber was a patriotic German who gave enthusiastic support to his nation's war effort. He served as chief of Germany's Chemical Warfare Service during World War I and developed the use of chlorine as a poison-gas weapon. Consequently, the decision to award him the Nobel Prize in Chemistry in 1918 was the subject of considerable controversy and criticism. The ultimate irony, however, came in 1933 when Haber was expelled from Germany because he was Jewish.

**Related Exercises:** 15.44, 15.75, 15.78

 **Figure 15.5** A high-pressure steel reactor used in the Haber process is on display at Karlsruhe Institute of Technology in Germany where the Haber process was developed.

for the Haber process,  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ , the equilibrium-constant expression is

$$K_c = \frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3} \quad [15.9]$$

Once we know the balanced chemical equation for a reaction that reaches equilibrium, we can write the equilibrium-constant expression even if we do not know the reaction mechanism.

*The equilibrium-constant expression depends only on the stoichiometry of the reaction, not on its mechanism.*

In this way equilibrium-constant expressions are different from rate laws.

The value of the equilibrium constant at any given temperature does not depend on the initial amounts of reactants and products. It also does not matter whether other substances are present, as long as they do not react with a reactant or a product. The value of  $K_c$  depends only on the particular reaction and on the temperature.

### Sample Exercise 15.1

#### Writing Equilibrium-Constant Expressions

Write the equilibrium expression for  $K_c$  for the following reactions:

- (a)  $2 \text{O}_3(\text{g}) \rightleftharpoons 3 \text{O}_2(\text{g})$   
 (b)  $2 \text{NO}(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{NOCl}(\text{g})$   
 (c)  $\text{Ag}^+(\text{aq}) + 2 \text{NH}_3(\text{aq}) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(\text{aq})$

#### SOLUTION

**Analyze** We are given three equations and are asked to write an equilibrium-constant expression for each.

**Plan** Using the law of mass action, we write each expression as a quotient having the product concentration terms in the numerator and the reactant concentration terms in the denominator. Each concentration term is raised to the power of its coefficient in the balanced chemical equation.

**Solve**

$$\text{(a)} K_c = \frac{[\text{O}_2]^3}{[\text{O}_3]^2} \quad \text{(b)} K_c = \frac{[\text{NOCl}]^2}{[\text{NO}]^2[\text{Cl}_2]} \quad \text{(c)} K_c = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2}$$

#### Practice Exercise 1

For the reaction  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2 \text{SO}_3(\text{g})$ , which of the following is the correct equilibrium-constant expression?

- (a)  $K_c = \frac{[\text{SO}_2]^2[\text{O}_2]}{[\text{SO}_3]^2}$       (b)  $K_c = \frac{2[\text{SO}_2][\text{O}_2]}{2[\text{SO}_3]}$   
 (c)  $K_c = \frac{[\text{SO}_3]^2}{[\text{SO}_2]^2[\text{O}_2]}$       (d)  $K_c = \frac{2[\text{SO}_3]}{2[\text{SO}_2][\text{O}_2]}$

#### Practice Exercise 2

Write the equilibrium-constant expression  $K_c$  for

- (a)  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ ,  
 (b)  $\text{Cd}^{2+}(\text{aq}) + 4 \text{Br}^-(\text{aq}) \rightleftharpoons \text{CdBr}_4^{2-}(\text{aq})$ .

### Evaluating $K_c$

We can illustrate how the law of mass action was discovered empirically and demonstrate that the equilibrium constant is independent of starting concentrations by examining a series of experiments involving dinitrogen tetroxide and nitrogen dioxide:

We start with several sealed tubes containing different concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ . The tubes are kept at  $100^\circ\text{C}$  until equilibrium is reached. We then analyze the mixtures and determine the equilibrium concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ , which are shown in Table 15.1.

To evaluate  $K_c$ , we insert the equilibrium concentrations into the equilibrium-constant expression. For example, using Experiment 1 data,  $[\text{NO}_2] = 0.0172 \text{ M}$  and  $[\text{N}_2\text{O}_4] = 0.00140 \text{ M}$ , we find

$$K_c = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{[0.0172]^2}{0.00140} = 0.211$$

**TABLE 15.1** Initial and Equilibrium Concentrations of  $\text{N}_2\text{O}_4(g)$  and  $\text{NO}_2(g)$  at  $100^\circ\text{C}$ 

| Experiment | Initial $[\text{N}_2\text{O}_4] (M)$ | Initial $[\text{NO}_2] (M)$ | Equilibrium $[\text{N}_2\text{O}_4] (M)$ | Equilibrium $[\text{NO}_2] (M)$ | $K_c$ |
|------------|--------------------------------------|-----------------------------|--|---------------------------------|-------|
| 1          | 0.0                                  | 0.0200                      | 0.00140                                  | 0.0172                          | 0.211 |
| 2          | 0.0                                  | 0.0300                      | 0.00280                                  | 0.0243                          | 0.211 |
| 3          | 0.0                                  | 0.0400                      | 0.00452                                  | 0.0310                          | 0.213 |
| 4          | 0.0200                               | 0.0                         | 0.00452                                  | 0.0310                          | 0.213 |

**Go Figure**

In which experiment, 3 or 4, does the concentration of  $\text{N}_2\text{O}_4$  decrease to reach equilibrium?

**▲ Figure 15.6** The same equilibrium mixture is produced regardless of the initial  $\text{NO}_2$  concentration. The concentration of  $\text{NO}_2$  either increases or decreases until equilibrium is reached.

Proceeding in the same way, the values of  $K_c$  for the other samples are calculated. Note from Table 15.1 that the value for  $K_c$  is constant (within the limits of experimental error), even though the initial concentrations vary, as do the final concentrations. Furthermore, Experiment 4 shows that equilibrium can be achieved beginning with  $\text{N}_2\text{O}_4$  rather than with  $\text{NO}_2$ . That is, equilibrium can be approached from either direction. **Figure 15.6** shows how Experiments 3 and 4 result in the same equilibrium mixture even though the two experiments start with very different  $\text{NO}_2$  concentrations.

Notice that no units are given for  $K_c$  either in Table 15.1 or in the calculation we just did using Experiment 1 data. It is common practice to write equilibrium constants without units for reasons that we address later in this section.

**Give It Some Thought**

Does the value of  $K_c$  in Equation 15.10 depend on the starting concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$ ?

**Equilibrium Constants in Terms of Pressure,  $K_p$** 

When the reactants and products in a chemical reaction are gases, we can formulate the equilibrium-constant expression in terms of partial pressures. When partial pressures in atmospheres are used in the expression, we denote the equilibrium constant  $K_p$  (where the subscript  $p$  stands for pressure). For the general reaction in Equation 15.7, we have

$$K_p = \frac{(P_D)^d (P_E)^e}{(P_A)^a (P_B)^b} \quad [15.11]$$

where  $P_A$  is the partial pressure of A in atmospheres,  $P_B$  is the partial pressure of B in atmospheres, and so forth. For example, for our  $\text{N}_2\text{O}_4/\text{NO}_2$  reaction, we have

$$K_p = \frac{(P_{\text{NO}_2})^2}{P_{\text{N}_2\text{O}_4}}$$

For a given reaction, the numerical value of  $K_c$  is generally different from the numerical value of  $K_p$ . We must therefore take care to indicate, via subscript  $c$  or  $p$ , which constant we are using. It is possible, however, to calculate one from the other using the ideal-gas equation  $\infty$  (Section 10.4):

$$PV = nRT, \text{ so } P = \frac{n}{V}RT \quad [15.12]$$

The usual units for  $n/V$  are mol/L, which equals molarity,  $M$ . For substance A in our generic reaction, we therefore see that

$$P_A = \frac{n_A}{V}RT = [A]RT \quad [15.13]$$

When we substitute Equation 15.13 and like expressions for the other gaseous components of the reaction into Equation 15.11, we obtain a general expression relating  $K_p$  and  $K_c$ :

$$K_p = \frac{([D]RT)^d([E]RT)^e}{([A]RT)^a([B]RT)^b} = \left( \frac{[D]^d[E]^e}{[A]^a[B]^b} \right) \frac{(RT)^{d+e}}{(RT)^{a+b}} \quad [15.14]$$

Notice that the term in brackets is equal to  $K_c$ , so we can simplify the expression:

$$K_p = K_c(RT)^{(d+e)-(a+b)} = K_c(RT)^{\Delta n} \quad [15.15]$$

The quantity  $\Delta n$  is the change in the number of moles of gas in the balanced chemical equation. It equals the sum of the coefficients of the gaseous products minus the sum of the coefficients of the gaseous reactants:

$$\Delta n = (\text{moles of gaseous product}) - (\text{moles of gaseous reactant}) \quad [15.16]$$

For example, in the  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2\text{NO}_2(\text{g})$  reaction, there are 2 mol of product  $\text{NO}_2$  and 1 mol of reactant  $\text{N}_2\text{O}_4$ . Therefore,  $\Delta n = 2 - 1 = 1$ , and  $K_p = K_c(RT)$ , for this reaction. In our derivation gas pressures are expressed as atmospheres and concentrations in moles per liter, thus the appropriate form of the gas constant is  $R = 0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K}$ .

### Give It Some Thought

Is it possible to have a reaction where  $K_c = K_p$ ? If so, under what conditions would this relationship hold?

## Sample Exercise 15.2

### Converting between $K_c$ and $K_p$

For the Haber process,

$K_c = 9.60$  at  $300^\circ\text{C}$ . Calculate  $K_p$  for this reaction at this temperature.

### SOLUTION

**Analyze** We are given  $K_c$  for a reaction and asked to calculate  $K_p$ .

**Plan** The relationship between  $K_c$  and  $K_p$  is given by Equation 15.15. To apply that equation, we must determine  $\Delta n$  by comparing the number of moles of product with the number of moles of reactants (Equation 15.16).

**Solve** With 2 mol of gaseous products ( $2\text{NH}_3$ ) and 4 mol of gaseous reactants ( $1\text{N}_2 + 3\text{H}_2$ ),  $\Delta n = 2 - 4 = -2$ . (Remember that  $\Delta$  functions are always based on *products minus reactants*.) The temperature is  $273 + 300 = 573 \text{ K}$ . The value for the ideal-gas constant,  $R$ , is  $0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K}$ . Using  $K_c = 9.60$ , we therefore have

$$\begin{aligned} K_p &= K_c(RT)^{\Delta n} = (9.60)(0.08206 \times 573)^{-2} \\ &= \frac{(9.60)}{(0.08206 \times 573)^2} = 4.34 \times 10^{-3} \end{aligned}$$

### Practice Exercise 1

For which of the following reactions is the ratio  $K_p/K_c$  largest at  $300 \text{ K}$ ?

- (a)  $\text{N}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2\text{NO}(\text{g})$
- (b)  $\text{CaCO}_3(\text{s}) \rightleftharpoons \text{CaO}(\text{s}) + \text{CO}_2(\text{g})$
- (c)  $\text{Ni}(\text{CO})_4(\text{g}) \rightleftharpoons \text{Ni}(\text{s}) + 4\text{CO}(\text{g})$
- (d)  $\text{C}(\text{s}) + 2\text{H}_2(\text{g}) \rightleftharpoons \text{CH}_4(\text{g})$

### Practice Exercise 2

For the equilibrium  $2\text{SO}_3(\text{g}) \rightleftharpoons 2\text{SO}_2(\text{g}) + \text{O}_2(\text{g})$ ,  $K_c$  is  $4.08 \times 10^{-3}$  at  $1000 \text{ K}$ . Calculate the value for  $K_p$ .

## Equilibrium Constants and Units

You may wonder why equilibrium constants are reported without units. The equilibrium constant is related to the kinetics of a reaction as well as to the thermodynamics. (We explore this latter connection in Chapter 19.) Equilibrium constants derived from

thermodynamic measurements are defined in terms of *activities* rather than concentrations or partial pressures.

The activity of any substance in an *ideal* mixture is the ratio of the concentration or pressure of the substance either to a reference concentration (1 M) or to a reference pressure (1 atm). For example, if the concentration of a substance in an equilibrium mixture is 0.010 M, its activity is  $0.010\text{ M}/1\text{ M} = 0.010$ . The units of such ratios always cancel and, consequently, activities have no units. Furthermore, the numerical value of the activity equals the concentration. For pure solids and pure liquids, the situation is even simpler because the activities then merely equal 1 (again with no units).

In real systems, activities are also ratios that have no units. Even though these activities may not be exactly numerically equal to concentrations, we will assume those differences are small enough that we can neglect them. All we need to know at this point is that activities have no units. As a result, the *thermodynamic equilibrium constants* derived from them also have no units. It is therefore common practice to write all types of equilibrium constants without units, a practice that we adhere to in this text. In more advanced chemistry courses, you may make more rigorous distinctions between concentrations and activities.

### Give It Some Thought

If the concentration of  $\text{N}_2\text{O}_4$  in an equilibrium mixture is 0.00140 M, what is its activity? (Assume the solution is ideal.)

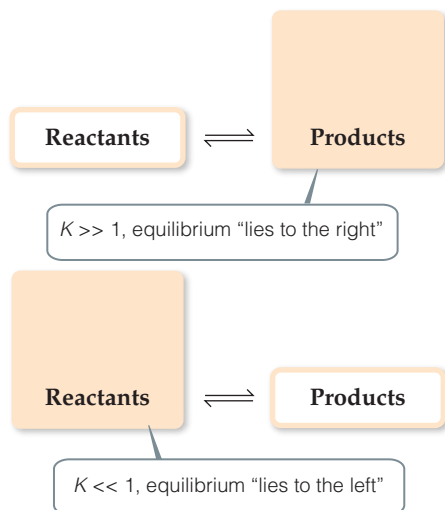

## 15.3 | Understanding and Working with Equilibrium Constants

Before doing calculations with equilibrium constants, it is valuable to understand what the magnitude of an equilibrium constant can tell us about the relative concentrations of reactants and products in an equilibrium mixture. It is also useful to consider how the magnitude of any equilibrium constant depends on how the chemical equation is expressed.

### Go Figure

What would this figure look like for a reaction in which  $K \approx 1$ ?

▲ **Figure 15.7** Relationship between magnitude of  $K$  and composition of an equilibrium mixture.

### The Magnitude of Equilibrium Constants

The magnitude of the equilibrium constant for a reaction gives us important information about the composition of the equilibrium mixture. For example, consider the experimental data for the reaction of carbon monoxide gas and chlorine gas at  $100^\circ\text{C}$  to form phosgene ( $\text{COCl}_2$ ), a toxic gas used in the manufacture of certain polymers and insecticides:

For the equilibrium constant to be so large, the numerator of the equilibrium-constant expression must be approximately a billion ( $10^9$ ) times larger than the denominator. Thus, the equilibrium concentration of  $\text{COCl}_2$  must be much greater than that of  $\text{CO}$  or  $\text{Cl}_2$ , and in fact, this is just what we find experimentally. We say that this equilibrium *lies to the right* (that is, toward the product side). Likewise, a very small equilibrium constant indicates that the equilibrium mixture contains mostly reactants. We then say that the equilibrium *lies to the left*. In general,

If  $K \gg 1$  (large  $K$ ): Equilibrium lies to right, products predominate

If  $K \ll 1$  (small  $K$ ): Equilibrium lies to left, reactants predominate

These situations are summarized in **Figure 15.7**. Remember, it is forward and reverse reaction rates, not reactant and product concentrations, that are equal at equilibrium.

## Sample Exercise 15.3

## Interpreting the Magnitude of an Equilibrium Constant

The following diagrams represent three systems at equilibrium, all in the same-size containers. (a) Without doing any calculations, rank the systems in order of increasing  $K_c$ . (b) If the volume of the containers is 1.0 L and each sphere represents 0.10 mol, calculate  $K_c$  for each system.

## SOLUTION

**Analyze** We are asked to judge the relative magnitudes of three equilibrium constants and then to calculate them.

**Plan** (a) The more product present at equilibrium, relative to reactant, the larger the equilibrium constant. (b) The equilibrium constant is given by Equation 15.8.

## Solve

- (a) Each box contains 10 spheres. The amount of product in each varies as follows: (i) 6, (ii) 1, (iii) 8. Therefore, the equilibrium constant varies in the order (ii) < (i) < (iii), from smallest (most reactants) to largest (most products).
- (b) In (i), we have 0.60 mol/L product and 0.40 mol/L reactant, giving  $K_c = 0.60/0.40 = 1.5$ . (You will get the same result by merely dividing the number of spheres of each kind: 6 spheres/4 spheres = 1.5.) In (ii), we have 0.10 mol/L product and 0.90 mol/L reactant, giving  $K_c = 0.10/0.90 = 0.11$  (or 1 sphere/9 spheres = 0.11). In (iii), we have 0.80 mol/L product and 0.20 mol/L reactant, giving  $K_c = 0.80/0.20 = 4.0$  (or 8 spheres/2 spheres = 4.0). These calculations verify the order in (a).

**Comment** Imagine a drawing that represents a reaction with a very small or very large value of  $K_c$ . For example, what would the drawing look like if  $K_c = 1 \times 10^{-5}$ ? In that case, there would need to be

100,000 reactant molecules for only 1 product molecule. But then, that would be impractical to draw.

## Practice Exercise 1

The equilibrium constant for the reaction  $\text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g)$  at  $2^\circ\text{C}$  is  $K_c = 2.0$ . If each yellow sphere represents 1 mol of  $\text{N}_2\text{O}_4$  and each brown sphere 1 mol of  $\text{NO}_2$  which of the following 1.0 L containers represents the equilibrium mixture at  $2^\circ\text{C}$ ?

## Practice Exercise 2

For the reaction  $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2\text{HI}(g)$ ,  $K_p = 794$  at  $298\text{ K}$  and  $K_p = 55$  at  $700\text{ K}$ . Is the formation of HI favored more at the higher or lower temperature?

## The Direction of the Chemical Equation and K

We have seen that we can represent the  $\text{N}_2\text{O}_4/\text{NO}_2$  equilibrium as

We could equally well consider this equilibrium in terms of the reverse reaction:

The equilibrium expression is then

$$K_c = \frac{[\text{N}_2\text{O}_4]}{[\text{NO}_2]^2} = \frac{1}{0.212} = 4.72 \quad (\text{at } 100^\circ\text{C}) \quad [15.18]$$

Equation 15.18 is the reciprocal of the expression in Equation 15.17. *The equilibrium-constant expression for a reaction written in one direction is the reciprocal of the expression for the reaction written in the reverse direction.* Consequently, the numerical value of the equilibrium constant for the reaction written in one direction is the reciprocal of that for the reverse reaction. Both expressions are equally valid, but it is meaningless to say that the equilibrium constant for the equilibrium between  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  is “0.212” or “4.72” unless we indicate how the equilibrium reaction is written and specify the temperature. Therefore, whenever you are using an equilibrium constant, you should always write the associated balanced chemical equation.

**Give It Some Thought**

For the reaction  $\text{PCl}_5(g) \rightleftharpoons \text{PCl}_3(g) + \text{Cl}_2(g)$ , the equilibrium constant  $K_c = 1.1 \times 10^{-2}$  at 400 K. What is the equilibrium constant for the reaction  $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$  at 400 K?

## Relating Chemical Equation Stoichiometry and Equilibrium Constants

There are many ways to write a balanced chemical equation for a given reaction. For example, if we multiply Equation 15.1,  $\text{N}_2\text{O}_4(g) \rightleftharpoons 2\text{NO}_2(g)$  by 2, we have

This chemical equation is balanced and might be written this way in some contexts. Therefore, the equilibrium-constant expression for this equation is

$$K_c = \frac{[\text{NO}_2]^4}{[\text{N}_2\text{O}_4]^2}$$

which is the square of the equilibrium-constant expression given in Equation 15.10 for the reaction as written in Equation 15.1:  $[\text{NO}_2]^2/[\text{N}_2\text{O}_4]$ . Because the new equilibrium-constant expression equals the original expression squared, the new equilibrium constant  $K_c$  equals the original constant squared:  $0.212^2 = 0.0449$  (at 100 °C). Once again, it is important to remember that you must relate each equilibrium constant you work with to a *specific* balanced chemical equation. *The concentrations of the substances in the equilibrium mixture will be the same no matter how you write the chemical equation, but the value of  $K_c$  you calculate depends on how you write the reaction.*

**Give It Some Thought**

How does the magnitude of  $K_p$  for the reaction  $2\text{HI}(g) \rightleftharpoons \text{H}_2(g) + \text{I}_2(g)$  change if the equilibrium is written  $6\text{HI}(g) \rightleftharpoons 3\text{H}_2(g) + 3\text{I}_2(g)$ ?

It is also possible to calculate the equilibrium constant for a reaction if we know the equilibrium constants for other reactions that add up to give us the one we want, similar to the manner in which the reaction enthalpy of an unknown reaction can be determined from known reaction enthalpies using Hess's law.  (Section 5.6) For example, consider the following two reactions, their equilibrium-constant expressions, and their equilibrium constants at 100 °C:

$$1. \quad 2\text{NOBr}(g) \rightleftharpoons 2\text{NO}(g) + \text{Br}_2(g) \quad K_{c1} = \frac{[\text{NO}]^2[\text{Br}_2]}{[\text{NOBr}]^2} = 0.014$$

$$2. \quad \text{Br}_2(g) + \text{Cl}_2(g) \rightleftharpoons 2\text{BrCl}(g) \quad K_{c2} = \frac{[\text{BrCl}]^2}{[\text{Br}_2][\text{Cl}_2]} = 7.2$$

The net sum of these two equations is:

You can prove algebraically that the equilibrium-constant expression for the net reaction is the product of the expressions for individual reactions:

$$K_{c3} = \frac{[\text{NO}]^2[\text{BrCl}]^2}{[\text{NOBr}]^2[\text{Cl}_2]} = \frac{[\text{NO}]^2[\text{Br}_2]}{[\text{NOBr}]^2} \times \frac{[\text{BrCl}]^2}{[\text{Br}_2][\text{Cl}_2]}$$

Thus,

$$K_{c3} = (K_{c1})(K_{c2}) = (0.014)(7.2) = 0.10$$

To summarize:

1. The equilibrium constant of a reaction in the *reverse* direction is the *inverse* (or *reciprocal*) of the equilibrium constant of the reaction in the forward direction:

2. The equilibrium constant of a reaction that has been *multiplied* by a number is equal to the original equilibrium constant raised to a *power* equal to that number.

3. The equilibrium constant for a net reaction made up by adding *two or more reactions* is the *product* of the equilibrium constants for the individual reactions:

## Sample Exercise 15.4

### Combining Equilibrium Expressions

Given the reactions

determine the value of  $K_c$  for the reaction

### SOLUTION

**Analyze** We are given two equilibrium equations and the corresponding equilibrium constants and are asked to determine the equilibrium constant for a third equation, which is related to the first two.

**Plan** We cannot simply add the first two equations to get the third. Instead, we need to determine how to manipulate these equations to come up with equations that we can add to give us the desired equation.

### Solve

If we multiply the first equation by 2 and make the corresponding change to its equilibrium constant (raising to the power 2), we get

Reversing the second equation and again making the corresponding change to its equilibrium constant (taking the reciprocal) gives

Now, we have two equations that sum to give the net equation, and we can multiply the individual  $K_c$  values to get the desired equilibrium constant.

### Practice Exercise 1

Given the equilibrium constants for the following two reactions in aqueous solution at 25 °C,

what is the value of  $K_c$  for the reaction?

- (a)  $4.9 \times 10^{-13}$  (b)  $4.1 \times 10^5$  (c)  $8.2 \times 10^5$  (d)  $1.8 \times 10^2$   
(e)  $5.4 \times 10^{-3}$

### Practice Exercise 2

Given that, at 700 K,  $K_p = 54.0$  for the reaction  $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2\text{HI}(g)$  and  $K_p = 1.04 \times 10^{-4}$  for the reaction  $\text{N}_2(g) + 3\text{H}_2(g) \rightleftharpoons 2\text{NH}_3(g)$ , determine the value of  $K_p$  for the reaction  $2\text{NH}_3(g) + 3\text{I}_2(g) \rightleftharpoons 6\text{HI}(g) + \text{N}_2(g)$  at 700 K.

## 15.4 | Heterogeneous Equilibria

Many equilibria involve substances that are all in the same phase. Such equilibria are called **homogeneous equilibria**. The equilibrium between  $\text{N}_2\text{O}_4(g)$  and  $\text{NO}_2(g)$  shown in Figure 15.2 is one such example. In some cases, however, the substances in equilibrium are in different phases, giving rise to **heterogeneous equilibria**. An example occurs when solid lead(II) chloride dissolves in water to form a saturated solution:

This system consists of a solid in equilibrium with two aqueous species. If we want to write the equilibrium-constant expression for this process, we encounter a problem we have not encountered previously: How do we express the concentration of a solid? If we were to carry out experiments starting with varying amounts of products and reactants, we would find that the equilibrium-constant expression for the reaction of Equation 15.19 is

$$K_c = [\text{Pb}^{2+}][\text{Cl}^-]^2 \quad [15.20]$$

Thus, our problem of how to express the concentration of a solid is not relevant in the end because  $\text{PbCl}_2(s)$  does not show up in the equilibrium-constant expression. More generally, we can state that *whenever a pure solid or a pure liquid is involved in a heterogeneous equilibrium, its concentration is not included in the equilibrium-constant expression.*

The fact that pure solids and pure liquids are excluded from equilibrium-constant expressions can be explained in two ways. First, the concentration of a pure solid or liquid has a constant value. If the mass of a solid is doubled, its volume also doubles. Thus, its concentration, which relates to the ratio of mass to volume, stays the same. Because equilibrium-constant expressions include terms only for reactants and products whose concentrations can change during a chemical reaction, the concentrations of pure solids and pure liquids are omitted.

The omission can also be rationalized in a second way. Recall from Section 15.2 that what is substituted into a thermodynamic equilibrium expression is the activity of each substance, which is a ratio of the concentration to a reference value. For a pure substance, the reference value is the concentration of the pure substance, so that the activity of any pure solid or liquid is always 1.

### Give It Some Thought

Write the equilibrium-constant expression for the evaporation of water,  $\text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{O}(g)$ , in terms of partial pressures.

Decomposition of calcium carbonate is another example of a heterogeneous reaction:

Omitting the concentrations of the solids from the equilibrium-constant expression gives

$$K_c = [\text{CO}_2] \quad \text{and} \quad K_p = P_{\text{CO}_2}$$

These equations tell us that at a given temperature, an equilibrium among  $\text{CaCO}_3$ ,  $\text{CaO}$ , and  $\text{CO}_2$  always leads to the same  $\text{CO}_2$  partial pressure as long as all three components are present. As shown in Figure 15.8, we have the same  $\text{CO}_2$  pressure regardless of the relative amounts of  $\text{CaO}$  and  $\text{CaCO}_3$ .

## Go Figure

If some of the  $\text{CO}_2(g)$  were released from the bell jar on the left, the seal then restored and the system allowed to return to equilibrium, would the amount of  $\text{CaCO}_3(s)$  increase, decrease, or remain the same?

▲ **Figure 15.8** At a given temperature, the equilibrium pressure of  $\text{CO}_2$  in the bell jars is the same no matter how much of each solid is present.

## Sample Exercise 15.5

## Writing Equilibrium-Constant Expressions for Heterogeneous Reactions

Write the equilibrium-constant expression  $K_c$  for

- (a)  $\text{CO}_2(g) + \text{H}_2(g) \rightleftharpoons \text{CO}(g) + \text{H}_2\text{O}(l)$   
 (b)  $\text{SnO}_2(s) + 2 \text{CO}(g) \rightleftharpoons \text{Sn}(s) + 2 \text{CO}_2(g)$

## SOLUTION

**Analyze** We are given two chemical equations, both for heterogeneous equilibria, and asked to write the corresponding equilibrium-constant expressions.

**Plan** We use the law of mass action, remembering to omit any pure solids and pure liquids from the expressions.

## Solve

- (a) The equilibrium-constant expression is

$$K_c = \frac{[\text{CO}]}{[\text{CO}_2][\text{H}_2]}$$

Because  $\text{H}_2\text{O}$  appears in the reaction as a liquid, its concentration does not appear in the equilibrium-constant expression.

- (b) The equilibrium-constant expression is

$$K_c = \frac{[\text{CO}_2]^2}{[\text{CO}]^2}$$

Because  $\text{SnO}_2$  and  $\text{Sn}$  are pure solids, their concentrations do not appear in the equilibrium-constant expression.

## Practice Exercise 1

Consider the equilibrium that is established in a saturated solution of silver chloride,  $\text{Ag}^+(aq) + \text{Cl}^-(aq) \rightleftharpoons \text{AgCl}(s)$ . If solid  $\text{AgCl}$  is added to this solution, what will happen to the concentration of  $\text{Ag}^+$  and  $\text{Cl}^-$  ions in solution?

- (a)  $[\text{Ag}^+]$  and  $[\text{Cl}^-]$  will both increase (b)  $[\text{Ag}^+]$  and  $[\text{Cl}^-]$  will both decrease (c)  $[\text{Ag}^+]$  will increase and  $[\text{Cl}^-]$  will decrease (d)  $[\text{Ag}^+]$  will decrease and  $[\text{Cl}^-]$  will increase (e) neither  $[\text{Ag}^+]$  nor  $[\text{Cl}^-]$  will change

## Practice Exercise 2

Write the following equilibrium-constant expressions:

- (a)  $K_c$  for  $\text{Cr}(s) + 3 \text{Ag}^+(aq) \rightleftharpoons \text{Cr}^{3+}(aq) + 3 \text{Ag}(s)$ ,  
 (b)  $K_p$  for  $3 \text{Fe}(s) + 4 \text{H}_2\text{O}(g) \rightleftharpoons \text{Fe}_3\text{O}_4(s) + 4 \text{H}_2(g)$ .

## Sample Exercise 15.6

## Analyzing a Heterogeneous Equilibrium

Each of these mixtures was placed in a closed container and allowed to stand:

- (a)  $\text{CaCO}_3(s)$
- (b)  $\text{CaO}(s)$  and  $\text{CO}_2(g)$  at a pressure greater than the value of  $K_p$
- (c)  $\text{CaCO}_3(s)$  and  $\text{CO}_2(g)$  at a pressure greater than the value of  $K_p$
- (d)  $\text{CaCO}_3(s)$  and  $\text{CaO}(s)$

Determine whether or not each mixture can attain the equilibrium

## SOLUTION

**Analyze** We are asked which of several combinations of species can establish an equilibrium between calcium carbonate and its decomposition products, calcium oxide and carbon dioxide.

**Plan** For equilibrium to be achieved, it must be possible for both the forward process and the reverse process to occur. For the forward process to occur, some calcium carbonate must be present. For the reverse process to occur, both calcium oxide and carbon dioxide must be present. In both cases, either the necessary compounds may be present initially or they may be formed by reaction of the other species.

**Solve** Equilibrium can be reached in all cases except (c) as long as sufficient quantities of solids are present. **(a)**  $\text{CaCO}_3$  simply decomposes, forming  $\text{CaO}(s)$  and  $\text{CO}_2(g)$  until the equilibrium pressure of  $\text{CO}_2$  is attained. There must be enough  $\text{CaCO}_3$ , however, to allow the  $\text{CO}_2$  pressure to reach equilibrium. **(b)**  $\text{CO}_2$  continues to combine with  $\text{CaO}$  until the partial pressure of the  $\text{CO}_2$  decreases to the equilibrium value. **(c)** Because there is no  $\text{CaO}$  present, equilibrium cannot be attained; there is no way the  $\text{CO}_2$  pressure can decrease to its equilibrium value (which would require some  $\text{CO}_2$  to react with  $\text{CaO}$ ). **(d)** The situation is essentially the same as

in (a):  $\text{CaCO}_3$  decomposes until equilibrium is attained. The presence of  $\text{CaO}$  initially makes no difference.

## Practice Exercise 1

If 8.0 g of  $\text{NH}_4\text{HS}(s)$  is placed in a sealed vessel with a volume of 1.0 L and heated to  $200^\circ\text{C}$  the reaction  $\text{NH}_4\text{HS}(s) \rightleftharpoons \text{NH}_3(g) + \text{H}_2\text{S}(g)$  will occur. When the system comes to equilibrium, some  $\text{NH}_4\text{HS}(s)$  is still present. Which of the following changes will lead to a reduction in the amount of  $\text{NH}_4\text{HS}(s)$  that is present, assuming in all cases that equilibrium is re-established following the change? **(a)** Adding more  $\text{NH}_3(g)$  to the vessel **(b)** Adding more  $\text{H}_2\text{S}(g)$  to the vessel **(c)** Adding more  $\text{NH}_4\text{HS}(s)$  to the vessel **(d)** Increasing the volume of the vessel **(e)** Decreasing the volume of the vessel

## Practice Exercise 2

When added to  $\text{Fe}_3\text{O}_4(s)$  in a closed container, which one of the following substances— $\text{H}_2(g)$ ,  $\text{H}_2\text{O}(g)$ ,  $\text{O}_2(g)$ —allows equilibrium to be established in the reaction  $3\text{Fe}(s) + 4\text{H}_2\text{O}(g) \rightleftharpoons \text{Fe}_3\text{O}_4(s) + 4\text{H}_2(g)$ ?

When a solvent is a reactant or product in an equilibrium, its concentration is omitted from the equilibrium-constant expression, provided the concentrations of reactants and products are low, so that the solvent is essentially a pure substance. Applying this guideline to an equilibrium involving water as a solvent,

gives an equilibrium-constant expression that does not contain  $[\text{H}_2\text{O}]$ :

$$K_c = \frac{[\text{OH}^-][\text{HCO}_3^-]}{[\text{CO}_3^{2-}]} \quad [15.22]$$

## Give It Some Thought

Write the equilibrium-constant expression for the reaction

## 15.5 | Calculating Equilibrium Constants

If we can measure the equilibrium concentrations of all the reactants and products in a chemical reaction, as we did with the data in Table 15.1, calculating the value of the equilibrium constant is straightforward. We simply insert all the equilibrium concentrations into the equilibrium-constant expression for the reaction.

### Sample Exercise 15.7

#### Calculating $K$ When All Equilibrium Concentrations Are Known

After a mixture of hydrogen and nitrogen gases in a reaction vessel is allowed to attain equilibrium at 472 °C, it is found to contain 7.38 atm  $\text{H}_2$ , 2.46 atm  $\text{N}_2$ , and 0.166 atm  $\text{NH}_3$ . From these data, calculate the equilibrium constant  $K_p$  for the reaction

#### SOLUTION

**Analyze** We are given a balanced equation and equilibrium partial pressures and are asked to calculate the value of the equilibrium constant.

**Plan** Using the balanced equation, we write the equilibrium-constant expression. We then substitute the equilibrium partial pressures into the expression and solve for  $K_p$ .

**Solve**

$$K_p = \frac{(P_{\text{NH}_3})^2}{P_{\text{N}_2}(P_{\text{H}_2})^3} = \frac{(0.166)^2}{(2.46)(7.38)^3} = 2.79 \times 10^{-5}$$

#### Practice Exercise 1

A mixture of gaseous sulfur dioxide and oxygen are added to a reaction vessel and heated to 1000 K where they react

to form  $\text{SO}_3(g)$ . If the vessel contains 0.669 atm  $\text{SO}_2(g)$ , 0.395 atm  $\text{O}_2(g)$ , and 0.0851 atm  $\text{SO}_3(g)$  after the system has reached equilibrium, what is the equilibrium constant  $K_p$  for the reaction  $2 \text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2 \text{SO}_3(g)$ ?  
(a) 0.0410 (b) 0.322 (c) 24.4 (d) 3.36 (e) 3.11

#### Practice Exercise 2

An aqueous solution of acetic acid is found to have the following equilibrium concentrations at 25 °C:  $[\text{CH}_3\text{COOH}] = 1.65 \times 10^{-2} \text{ M}$ ;  $[\text{H}^+] = 5.44 \times 10^{-4} \text{ M}$ ; and  $[\text{CH}_3\text{COO}^-] = 5.44 \times 10^{-4} \text{ M}$ . Calculate the equilibrium constant  $K_c$  for the ionization of acetic acid at 25 °C. The reaction is

Often, we do not know the equilibrium concentrations of all species in an equilibrium mixture. If we know the initial concentrations and the equilibrium concentration of at least one species, however, we can generally use the stoichiometry of the reaction to deduce the equilibrium concentrations of the others. The following steps outline the procedure:

#### How to Determine Concentrations of Unknown Species in an Equilibrium Mixture

1. Tabulate all known initial and equilibrium concentrations of the species that appear in the equilibrium-constant expression.
2. For those species for which initial and equilibrium concentrations are known, calculate the change in concentration that occurs as the system reaches equilibrium.
3. Use the stoichiometry of the reaction (that is, the coefficients in the balanced chemical equation) to calculate the changes in concentration for all other species in the equilibrium-constant expression.
4. Use initial concentrations from step 1 and changes in concentration from step 3 to calculate any equilibrium concentrations not tabulated in step 1.
5. Determine the value of the equilibrium constant.

The best way to illustrate this procedure is by example, as we do in Sample Exercise 15.8.

### Sample Exercise 15.8

#### Calculating $K$ from Initial and Equilibrium Concentrations

A reaction vessel containing  $1.000 \times 10^{-3} \text{ M}$   $\text{H}_2$  gas and  $2.000 \times 10^{-3} \text{ M}$   $\text{I}_2$  gas is heated to 448 °C where the following reaction takes place

What is the value of the equilibrium constant  $K_c$  if once the system comes to equilibrium at 448 °C the concentration of HI is  $1.87 \times 10^{-3} \text{ M}$ ?

*Continued*

## SOLUTION

**Analyze** We are given the initial concentrations of  $\text{H}_2$  and  $\text{I}_2$  and the equilibrium concentration of  $\text{HI}$ . We are asked to calculate the equilibrium constant  $K_c$  for  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ .

**Plan** We construct a table to find equilibrium concentrations of all species and then use the equilibrium concentrations to calculate the equilibrium constant.

## Solve

- (1) We tabulate the initial and equilibrium concentrations of as many species as we can. We also provide space in our table for listing the changes in concentrations. As shown, it is convenient to use the chemical equation as the heading for the table.

|                               | $\text{H}_2(\text{g})$ | + | $\text{I}_2(\text{g})$ | $\rightleftharpoons$ | $2 \text{HI}(\text{g})$ |
|-------------------------------|------------------------|---|------------------------|----------------------|-------------------------|
| Initial concentration (M)     | $1.000 \times 10^{-3}$ |   | $2.000 \times 10^{-3}$ |                      | 0                       |
| Change in concentration (M)   |                        |   |                        |                      |                         |
| Equilibrium concentration (M) |                        |   |                        |                      | $1.87 \times 10^{-3}$   |

- (2) We calculate the change in  $\text{HI}$  concentration, which is the difference between the equilibrium and initial values:

$$\text{Change in } [\text{HI}] = 1.87 \times 10^{-3} \text{ M} - 0 = 1.87 \times 10^{-3} \text{ M}$$

- (3) We use the coefficients in the balanced equation to relate the change in  $[\text{HI}]$  to the changes in  $[\text{H}_2]$  and  $[\text{I}_2]$ :

$$\left(1.87 \times 10^{-3} \frac{\text{mol HI}}{\text{L}}\right) \left(\frac{1 \text{ mol H}_2}{2 \text{ mol HI}}\right) = 0.935 \times 10^{-3} \frac{\text{mol H}_2}{\text{L}}$$

$$\left(1.87 \times 10^{-3} \frac{\text{mol HI}}{\text{L}}\right) \left(\frac{1 \text{ mol I}_2}{2 \text{ mol HI}}\right) = 0.935 \times 10^{-3} \frac{\text{mol I}_2}{\text{L}}$$

- (4) We calculate the equilibrium concentrations of  $\text{H}_2$  and  $\text{I}_2$ , using initial concentrations and changes in concentration. The equilibrium concentration equals the initial concentration minus that consumed:

$$[\text{H}_2] = (1.000 \times 10^{-3} \text{ M}) - (0.935 \times 10^{-3} \text{ M}) = 0.065 \times 10^{-3} \text{ M}$$

$$[\text{I}_2] = (2.000 \times 10^{-3} \text{ M}) - (0.935 \times 10^{-3} \text{ M}) = 1.065 \times 10^{-3} \text{ M}$$

- (5) Our table now is complete (with equilibrium concentrations in blue for emphasis):

|                               | $\text{H}_2(\text{g})$  | + | $\text{I}_2(\text{g})$  | $\rightleftharpoons$ | $2 \text{HI}(\text{g})$ |
|-------------------------------|-------------------------|---|-------------------------|----------------------|-------------------------|
| Initial concentration (M)     | $1.000 \times 10^{-3}$  |   | $2.000 \times 10^{-3}$  |                      | 0                       |
| Change in concentration (M)   | $-0.935 \times 10^{-3}$ |   | $-0.935 \times 10^{-3}$ |                      | $+1.87 \times 10^{-3}$  |
| Equilibrium concentration (M) | $0.065 \times 10^{-3}$  |   | $1.065 \times 10^{-3}$  |                      | $1.87 \times 10^{-3}$   |

Notice that the entries for the changes are negative when a reactant is consumed and positive when a product is formed.

Finally, we use the equilibrium-constant expression to calculate the equilibrium constant:

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.87 \times 10^{-3})^2}{(0.065 \times 10^{-3})(1.065 \times 10^{-3})} = 51$$

**Comment** The same method can be applied to gaseous equilibrium problems to calculate  $K_p$ , in which case partial pressures are used as table entries in place of molar concentrations. Your instructor may refer to this kind of table as an ICE chart, where ICE stands for Initial – Change – Equilibrium.

### Practice Exercise 1

In Section 15.1, we discussed the equilibrium between  $\text{N}_2\text{O}_4(\text{g})$  and  $\text{NO}_2(\text{g})$ . Let's return to that equation in a quantitative example. When 9.2 g of frozen  $\text{N}_2\text{O}_4$  is added to a 0.50 L

reaction vessel that is heated to 400 K and allowed to come to equilibrium, the concentration of  $\text{N}_2\text{O}_4$  is determined to be 0.057 M. Given this information, what is the value of  $K_c$  for the reaction  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$  at 400 K? (a) 0.23 (b) 0.36 (c) 0.13 (d) 1.4 (e) 2.5

### Practice Exercise 2

The gaseous compound  $\text{BrCl}$  decomposes at high temperature in a sealed container:  $2 \text{BrCl}(\text{g}) \rightleftharpoons \text{Br}_2(\text{g}) + \text{Cl}_2(\text{g})$ . Initially, the vessel is charged at 500 K with  $\text{BrCl}(\text{g})$  at a partial pressure of 0.500 atm. At equilibrium, the  $\text{BrCl}(\text{g})$  partial pressure is 0.040 atm. Calculate the value of  $K_p$  at 500 K.

## 15.6 | Applications of Equilibrium Constants

We have seen that the magnitude of  $K$  indicates the extent to which a reaction proceeds.

- If  $K$  is very large, the equilibrium mixture contains mostly substances on the product side of the equation for the reaction.

- If  $K$  is very small (that is, much less than 1), the equilibrium mixture contains mostly substances on the reactant side of the equation.

The equilibrium constant also allows us to (1) predict the direction in which a reaction mixture achieves equilibrium and (2) calculate equilibrium concentrations of reactants and products.

## Predicting the Direction of Reaction

For the formation of  $\text{NH}_3$  from  $\text{N}_2$  and  $\text{H}_2$  (Equation 15.6),  $K_c = 0.105$  at  $472^\circ\text{C}$ . Suppose we place 2.00 mol of  $\text{H}_2$ , 1.00 mol of  $\text{N}_2$ , and 2.00 mol of  $\text{NH}_3$  in a 1.00-L container at  $472^\circ\text{C}$ . How will the mixture react to reach equilibrium? Will  $\text{N}_2$  and  $\text{H}_2$  react to form more  $\text{NH}_3$ , or will  $\text{NH}_3$  decompose to  $\text{N}_2$  and  $\text{H}_2$ ?

To answer this question, we substitute the starting concentrations of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  into the equilibrium-constant expression and compare its value to the equilibrium constant:

$$\frac{[\text{NH}_3]^2}{[\text{N}_2][\text{H}_2]^3} = \frac{(2.00)^2}{(1.00)(2.00)^3} = 0.500 \quad \text{whereas} \quad K_c = 0.105 \quad [15.23]$$

To reach equilibrium, the quotient  $[\text{NH}_3]^2/[\text{N}_2][\text{H}_2]^3$  must decrease from the starting value of 0.500 to the equilibrium value of 0.105. Because the system is closed, this change can happen only if  $[\text{NH}_3]$  decreases and  $[\text{N}_2]$  and  $[\text{H}_2]$  increase. Thus, the reaction proceeds toward equilibrium by forming  $\text{N}_2$  and  $\text{H}_2$  from  $\text{NH}_3$ ; that is, the reaction as written in Equation 15.6 proceeds from right to left.

This approach can be formalized by defining a quantity called the reaction quotient.

*The **reaction quotient**,  $Q$ , is a number obtained by substituting reactant and product concentrations or partial pressures at any point during a reaction into an equilibrium-constant expression.*

Therefore, for the general reaction

the reaction quotient in terms of molar concentrations is

$$Q_c = \frac{[\text{D}]^d[\text{E}]^e}{[\text{A}]^a[\text{B}]^b} \quad [15.24]$$

A related quantity  $Q_p$  can be written for any reaction that involves gases by using partial pressures instead of concentrations.

Although we use what looks like the equilibrium-constant expression to calculate the reaction quotient, the concentrations we use may or may not be the equilibrium concentrations. For example, when we substituted the starting concentrations into the equilibrium-constant expression of Equation 15.23, we obtained  $Q_c = 0.500$  whereas  $K_c = 0.105$ . The equilibrium constant has only one value at each temperature. The reaction quotient, however, varies as the reaction proceeds.

Of what use is  $Q$ ? One practical thing we can do with  $Q$  is tell whether our reaction really is at equilibrium, which is an especially valuable option when a reaction is very slow. We can take samples of our reaction mixture as the reaction proceeds, separate the components, and measure their concentrations. Then we insert these numbers into Equation 15.24 for our reaction. To determine whether we are at equilibrium, or in which direction the reaction proceeds to achieve equilibrium, we compare the values of  $Q_c$  and  $K_c$  or  $Q_p$  and  $K_p$ . There are three possible scenarios (Figure 15.9), which can be summarized as follows:

### How to Use $Q$ to Analyze Reaction Progress

- $Q < K$ : The concentration of products is too small and that of reactants too large. The reaction achieves equilibrium by forming more products; it proceeds from left to right.
- $Q = K$ : The reaction quotient equals the equilibrium constant only if the system is at equilibrium.
- $Q > K$ : The concentration of products is too large and that of reactants too small. The reaction achieves equilibrium by forming more reactants; it proceeds from right to left.

**Figure 15.9** Predicting the direction of a reaction by comparing  $Q$  and  $K$  at a given temperature.

## Sample Exercise 15.9

## Predicting the Direction of Approach to Equilibrium

At 448 °C, the equilibrium constant  $K_c$  for the reaction

is 50.5. Predict in which direction the reaction proceeds to reach equilibrium if we start with  $2.0 \times 10^{-2}$  mol of HI,  $1.0 \times 10^{-2}$  mol of  $\text{H}_2$ , and  $3.0 \times 10^{-2}$  mol of  $\text{I}_2$  in a 2.00-L container.

## SOLUTION

**Analyze** We are given a volume and initial molar amounts of the species in a reaction and asked to determine in which direction the reaction must proceed to achieve equilibrium.

**Plan** We can determine the starting concentration of each species in the reaction mixture. We can then substitute the starting concentrations into the equilibrium-constant expression to calculate the reaction quotient,  $Q_c$ . Comparing the magnitudes of the equilibrium constant, which is given, and the reaction quotient will tell us in which direction the reaction will proceed.

## Solve

The initial concentrations are

$$[\text{HI}] = 2.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 1.0 \times 10^{-2} \text{ M}$$

$$[\text{H}_2] = 1.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 5.0 \times 10^{-3} \text{ M}$$

$$[\text{I}_2] = 3.0 \times 10^{-2} \text{ mol}/2.00 \text{ L} = 1.5 \times 10^{-2} \text{ M}$$

The reaction quotient is therefore

$$Q_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.0 \times 10^{-2})^2}{(5.0 \times 10^{-3})(1.5 \times 10^{-2})} = 1.3$$

Because  $Q_c < K_c$ , the concentration of HI must increase and the concentrations of  $\text{H}_2$  and  $\text{I}_2$  must decrease to reach equilibrium; the reaction as written proceeds left to right to attain equilibrium.

## Practice Exercise 1

Which of the following statements accurately describes what would happen to the direction of the reaction described in the sample exercise above, if the size of the container were different from 2.00 L? **(a)** The reaction would proceed in the opposite direction (from right to left) if the container volume were reduced sufficiently. **(b)** The reaction would proceed in the opposite direction if the container volume were expanded sufficiently. **(c)** The direction of this reaction does not depend on the volume of the container.

## Practice Exercise 2

At 1000 K, the value of  $K_p$  for the reaction  $2 \text{SO}_3(\text{g}) \rightleftharpoons 2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g})$  is 0.338. Calculate the value for  $Q_p$ , and predict the direction in which the reaction proceeds toward equilibrium if the initial partial pressures are  $P_{\text{SO}_3} = 0.16 \text{ atm}$ ;  $P_{\text{SO}_2} = 0.41 \text{ atm}$ ;  $P_{\text{O}_2} = 2.5 \text{ atm}$ .

## Calculating Equilibrium Concentrations

Chemists frequently need to calculate the amounts of reactants and products present at equilibrium in a reaction for which they know the equilibrium constant. The approach in solving problems of this type is similar to the one we used for evaluating equilibrium constants: We tabulate initial concentrations or partial pressures, changes in those concentrations or pressures, and final equilibrium concentrations or partial pressures. Usually, we end up using the equilibrium-constant expression to derive an equation that must be solved for an unknown quantity, as demonstrated in Sample Exercise 15.10.

## Sample Exercise 15.10

## Calculating Equilibrium Concentrations

For the Haber process,  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ ,  $K_p = 1.45 \times 10^{-5}$ , at 500 °C. In an equilibrium mixture of the three gases at 500 °C, the partial pressure of  $\text{H}_2$  is 0.928 atm and that of  $\text{N}_2$  is 0.432 atm. What is the partial pressure of  $\text{NH}_3$  in this equilibrium mixture?

## SOLUTION

**Analyze** We are given an equilibrium constant,  $K_p$ , and the equilibrium partial pressures of two of the three substances in the equation ( $\text{N}_2$  and  $\text{H}_2$ ), and we are asked to calculate the equilibrium partial pressure for the third substance ( $\text{NH}_3$ ).

**Plan** We can set  $K_p$  equal to the equilibrium-constant expression and substitute in the partial pressures that we know. Then we can solve for the only unknown in the equation.

## Solve

We tabulate the equilibrium pressures:

Equilibrium pressure (atm)    0.432    0.928     $x$

Because we do not know the equilibrium pressure of  $\text{NH}_3$ , we represent it with  $x$ . At equilibrium, the pressures must satisfy the equilibrium-constant expression:

$$K_p = \frac{(P_{\text{NH}_3})^2}{P_{\text{N}_2}(P_{\text{H}_2})^3} = \frac{x^2}{(0.432)(0.928)^3} = 1.45 \times 10^{-5}$$

We now rearrange the equation to solve for  $x$ :

$$x^2 = (1.45 \times 10^{-5})(0.432)(0.928)^3 = 5.01 \times 10^{-6}$$

$$x = \sqrt{5.01 \times 10^{-6}} = 2.24 \times 10^{-3} \text{ atm} = R_{\text{NH}_3}$$

**Check** We can always check our answer by using it to recalculate the value of the equilibrium constant:

$$K_p = \frac{(2.24 \times 10^{-3})^2}{(0.432)(0.928)^3} = 1.45 \times 10^{-5}$$

### Practice Exercise 1

At 500 K, the reaction  $2 \text{NO}(g) + \text{Cl}_2(g) \rightleftharpoons 2 \text{NOCl}(g)$  has  $K_p = 51$ . In an equilibrium mixture at 500 K, the partial pressure of NO is 0.125 atm and  $\text{Cl}_2$  is 0.165 atm. What is the partial pressure of NOCl in the equilibrium mixture? (a) 0.13 atm (b) 0.36 atm (c) 1.0 atm (d)  $5.1 \times 10^{-5}$  atm (e) 0.125 atm

### Practice Exercise 2

At 500 K, the reaction  $\text{PCl}_5(g) \rightleftharpoons \text{PCl}_3(g) + \text{Cl}_2(g)$  has  $K_p = 0.497$ . In an equilibrium mixture at 500 K, the partial pressure of  $\text{PCl}_5$  is 0.860 atm and that of  $\text{PCl}_3$  is 0.350 atm. What is the partial pressure of  $\text{Cl}_2$  in the equilibrium mixture?

In many situations, we know the value of the equilibrium constant and the initial amounts of all species. We must then solve for the equilibrium amounts. Solving this type of problem usually entails treating the change in concentration as a variable. The stoichiometry of the reaction gives us the relationship between the changes in the amounts of all the reactants and products, as illustrated in Sample Exercise 15.11. The calculations frequently involve the quadratic formula, as you will see in this exercise.

## Sample Exercise 15.11

### Calculating Equilibrium Concentrations from Initial Concentrations

A 1.000-L flask is filled with 1.000 mol of  $\text{H}_2(g)$  and 2.000 mol of  $\text{I}_2(g)$  at 448 °C. The value of the equilibrium constant  $K_c$  for the reaction

at 448 °C is 50.5. What are the equilibrium concentrations of  $\text{H}_2$ ,  $\text{I}_2$ , and HI in moles per liter?

### SOLUTION

**Analyze** We are given the volume of a container, an equilibrium constant, and starting amounts of reactants in the container and are asked to calculate the equilibrium concentrations of all species.

**Plan** In this case, we are not given any of the equilibrium concentrations. We must develop some relationships that relate the initial concentrations to those at equilibrium. The procedure is similar in many regards to that outlined in Sample Exercise 15.8, where we calculated an equilibrium constant using initial concentrations.

#### Solve

- (1) We note the initial concentrations of  $\text{H}_2$  and  $\text{I}_2$ :

$$[\text{H}_2] = 1.000 \text{ M} \quad \text{and} \quad [\text{I}_2] = 2.000 \text{ M}$$

- (2) We construct a table in which we tabulate the initial concentrations:

|                               | $\text{H}_2(g)$ | $+$ | $\text{I}_2(g)$ | $\rightleftharpoons$ | $2 \text{HI}(g)$ |
|-------------------------------|-----------------|-----|-----------------|----------------------|------------------|
| Initial concentration (M)     | 1.000           |     | 2.000           |                      | 0                |
| Change in concentration (M)   |                 |     |                 |                      |                  |
| Equilibrium concentration (M) |                 |     |                 |                      |                  |

- (3) We use the stoichiometry of the reaction to determine the changes in concentration that occur as the reaction proceeds to equilibrium. The  $\text{H}_2$  and  $\text{I}_2$  concentrations will decrease as equilibrium is established and that of HI will increase. Let's represent the change in concentration of  $\text{H}_2$  by  $x$ . The balanced chemical equation tells us that for each  $x$  mol of  $\text{H}_2$  that reacts,  $x$  mol of  $\text{I}_2$  are consumed and  $2x$  mol of HI are produced:

|                               | $\text{H}_2(g)$ | $+$ | $\text{I}_2(g)$ | $\rightleftharpoons$ | $2 \text{HI}(g)$ |
|-------------------------------|-----------------|-----|-----------------|----------------------|------------------|
| Initial concentration (M)     | 1.000           |     | 2.000           |                      | 0                |
| Change in concentration (M)   | $-x$            |     | $-x$            |                      | $+2x$            |
| Equilibrium concentration (M) |                 |     |                 |                      |                  |

Continued

- (4) We use initial concentrations and changes in concentrations, as dictated by stoichiometry, to express the equilibrium concentrations. With all our entries, our table now looks like this:

|                               | $\text{H}_2(\text{g})$ | + | $\text{I}_2(\text{g})$ | $\rightleftharpoons$ | $2 \text{HI}(\text{g})$ |
|-------------------------------|------------------------|---|------------------------|----------------------|-------------------------|
| Initial concentration (M)     | 1.000                  |   | 2.000                  |                      | 0                       |
| Change in concentration (M)   | $-x$                   |   | $-x$                   |                      | $+2x$                   |
| Equilibrium concentration (M) | $1.000 - x$            |   | $2.000 - x$            |                      | $2x$                    |

- (5) We substitute the equilibrium concentrations into the equilibrium-constant expression and solve for  $x$ :

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(2x)^2}{(1.000 - x)(2.000 - x)} = 50.5$$

If you have an equation-solving calculator, you can solve this equation directly for  $x$ . If not, expand this expression to obtain a quadratic equation in  $x$ :

$$4x^2 = 50.5(x^2 - 3.000x + 2.000)$$

$$46.5x^2 - 151.5x + 101.0 = 0$$

Solving the quadratic equation (Appendix A.3) leads to two solutions for  $x$ :

$$x = \frac{-(-151.5) \pm \sqrt{(-151.5)^2 - 4(46.5)(101.0)}}{2(46.5)} = 2.323 \text{ or } 0.935$$

When we substitute  $x = 2.323$  into the expressions for the equilibrium concentrations, we find *negative* concentrations of  $\text{H}_2$  and  $\text{I}_2$ . Because a negative concentration is not chemically meaningful, we reject this solution. We then use  $x = 0.935$  to find the equilibrium concentrations:

$$[\text{H}_2] = 1.000 - x = 0.065 \text{ M}$$

$$[\text{I}_2] = 2.000 - x = 1.065 \text{ M}$$

$$[\text{HI}] = 2x = 1.87 \text{ M}$$

**Check** We can check our solution by putting these numbers into the equilibrium-constant expression to assure that we correctly calculate the equilibrium constant:

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} = \frac{(1.87)^2}{(0.065)(1.065)} = 51$$

**Comment** Whenever you use a quadratic equation to solve an equilibrium problem, one of the solutions to the equation will give you a value that leads to negative concentrations and thus is not chemically meaningful. Reject this solution to the quadratic equation.

#### ► Practice Exercise 1

For the equilibrium  $\text{Br}_2(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{BrCl}(\text{g})$ , the equilibrium constant  $K_p$  is 7.0 at 400 K. If a cylinder is charged

with  $\text{BrCl}(\text{g})$  at an initial pressure of 1.00 atm and the system is allowed to come to equilibrium what is the final (equilibrium) pressure of  $\text{BrCl}$ ? (a) 0.57 atm (b) 0.22 atm (c) 0.45 atm (d) 0.15 atm (e) 0.31 atm

#### ► Practice Exercise 2

For the equilibrium  $\text{PCl}_5(\text{g}) \rightleftharpoons \text{PCl}_3(\text{g}) + \text{Cl}_2(\text{g})$ , the equilibrium constant  $K_p$  is 0.497 at 500 K. A gas cylinder at 500 K is charged with  $\text{PCl}_5(\text{g})$  at an initial pressure of 1.66 atm. What are the equilibrium pressures of  $\text{PCl}_5$ ,  $\text{PCl}_3$ , and  $\text{Cl}_2$  at this temperature?

## 15.7 | Le Châtelier's Principle

Many of the products we use in everyday life are obtained from the chemical industry. Chemists and chemical engineers in industry spend a great deal of time and effort to maximize the yield of valuable products and minimize waste. For example, when Haber developed his process for making ammonia from  $\text{N}_2$  and  $\text{H}_2$ , he examined how reaction conditions might be varied to increase yield. Using the values of the equilibrium constant at various temperatures, he calculated the equilibrium amounts of  $\text{NH}_3$  formed under a variety of conditions. Some of Haber's results are shown in **Figure 15.10**.

Notice that the percent of  $\text{NH}_3$  present at equilibrium decreases with increasing temperature and increases with increasing pressure.

We can understand these effects in terms of a principle first put forward by Henri-Louis Le Châtelier\* (1850–1936), a French industrial chemist:

*If a system at equilibrium is disturbed by a change in temperature, pressure, or a component concentration, the system will shift its equilibrium position so as to counteract the effect of the disturbance.*

\* Pronounced "le-SHOT-lee-ay."

## Go Figure

At what combination of pressure and temperature should you run the reaction to maximize  $\text{NH}_3$  yield?

▲ **Figure 15.10** Effect of temperature and pressure on  $\text{NH}_3$  yield in the Haber process. Each mixture was produced by starting with a 3 : 1 molar mixture of  $\text{H}_2$  and  $\text{N}_2$ .

## Le Châtelier's Principle

If a system at equilibrium is disturbed by a change in **concentration**, **pressure**, or **temperature**, the system will shift its equilibrium position so as to counter the effect of the disturbance.

**Concentration:** adding or removing a reactant or product

If a substance is added to a system at equilibrium, the system reacts to consume some of the substance. If a substance is removed from a system, the system reacts to produce more of substance.

**Pressure:** changing the pressure by changing the volume

At constant temperature, reducing the volume of a gaseous equilibrium mixture causes the system to shift in the direction that reduces the number of moles of gas.

**Temperature:**

If the temperature of a system at equilibrium is increased, the system reacts as if we added a reactant to an endothermic reaction or a product to an exothermic reaction. The equilibrium shifts in the direction that consumes the "excess reagent," namely, heat.

In this section, we use Le Châtelier's principle to make qualitative predictions about how a system at equilibrium responds to various changes in external conditions. We consider three ways in which a chemical equilibrium can be disturbed: (1) adding or removing a reactant or product, (2) changing the pressure by changing the volume, and (3) changing the temperature.

## Change in Reactant or Product Concentration

A system at dynamic equilibrium is in a state of balance. When the concentrations of species in the reaction are altered, the equilibrium shifts until a new state of balance is attained. What does *shift* mean? It means that reactant and product concentrations change over time to accommodate the new situation. *Shift* does *not* mean that the equilibrium constant itself is altered; the equilibrium constant remains the same. Le Châtelier's principle states that the shift is in the direction that minimizes or reduces the effect of the change.

*If a chemical system is already at equilibrium and the concentration of any substance in the mixture is increased (either reactant or product), the system reacts to consume some of that substance. Conversely, if the concentration of a substance is decreased, the system reacts to produce some of that substance.*

There is no change in the equilibrium constant when we change the concentrations of reactants or products. As an example, consider our familiar equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$ :

Adding  $\text{H}_2$  causes the system to shift so as to reduce the increased concentration of  $\text{H}_2$  (Figure 15.11). This change can occur only if the reaction consumes  $\text{H}_2$  and simultaneously consumes  $\text{N}_2$  to form more  $\text{NH}_3$ . Adding  $\text{N}_2$  to the equilibrium mixture likewise causes the reaction to shift toward forming more  $\text{NH}_3$ . Removing  $\text{NH}_3$  also causes a shift toward producing more  $\text{NH}_3$ , whereas *adding*  $\text{NH}_3$  to the system at equilibrium causes the reaction to shift in the direction that reduces the increased  $\text{NH}_3$  concentration: Some of the added ammonia decomposes to form  $\text{N}_2$  and  $\text{H}_2$ . All of these “shifts” are entirely consistent with predictions that we would make by comparing the reaction quotient  $Q$  with the equilibrium constant  $K$ .

In the Haber reaction, therefore, removing  $\text{NH}_3$  from an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  causes the reaction to shift right to form more  $\text{NH}_3$ . If the  $\text{NH}_3$  can be removed continuously as it is produced, the yield can be increased dramatically. In the industrial production of ammonia, the  $\text{NH}_3$  is continuously removed by selectively

### Go Figure

Why does the nitrogen concentration decrease after hydrogen is added?

▲ **Figure 15.11** Effect of adding  $\text{H}_2$  to an equilibrium mixture of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$ . Adding  $\text{H}_2$  causes the reaction as written to shift to the right, consuming some  $\text{N}_2$  to produce more  $\text{NH}_3$ .

▲ **Figure 15.12** Diagram of the industrial production of ammonia. Incoming  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$  are heated to approximately  $500^\circ\text{C}$  and passed over a catalyst. When the resultant  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  mixture is cooled, the  $\text{NH}_3$  liquefies and is removed from the mixture, shifting the reaction to produce more  $\text{NH}_3$ .

liquefying it (Figure 15.12). (The boiling point of  $\text{NH}_3$ ,  $-33^\circ\text{C}$ , is much higher than those of  $\text{N}_2$ ,  $-196^\circ\text{C}$ , and  $\text{H}_2$ ,  $-253^\circ\text{C}$ .) The liquid  $\text{NH}_3$  is removed, and the  $\text{N}_2$  and  $\text{H}_2$  are recycled to form more  $\text{NH}_3$ . As a result of the product being continuously removed, the reaction is driven essentially to completion.

### Give It Some Thought

Does the equilibrium  $2\text{NO}(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2\text{NO}_2(\text{g})$  shift to the right (more products) or left (more reactants) if

- $\text{O}_2$  is added to the system?
- $\text{NO}$  is removed?

## Effects of Volume and Pressure Changes

If a system containing one or more gases is at equilibrium and its volume is decreased, thereby increasing its total pressure, Le Châtelier's principle indicates that the system responds by shifting its equilibrium position to reduce the pressure. A system can reduce its pressure by reducing the total number of gas molecules (fewer molecules of gas exert a lower pressure). Thus, at constant temperature, *reducing the volume of a gaseous equilibrium mixture causes the system to shift in the direction that reduces the number of moles of gas*. Increasing the volume causes a shift in the direction that produces more gas molecules (Figure 15.13).

▲ Figure 15.13 Pressure and Le Châtelier's principle.

### Give It Some Thought

What happens to the equilibrium  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2 \text{SO}_3(\text{g})$ , if the volume of the system is increased?

In the reaction  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ , four molecules of reactant are consumed for every two molecules of product produced. Consequently, an increase in pressure (caused by a decrease in volume) shifts the reaction in the direction that produces fewer gas molecules, which leads to the formation of more  $\text{NH}_3$ , as indicated in Figure 15.10. In the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ , the number of molecules of gaseous products (two) equals the number of molecules of gaseous reactants; therefore, changing the pressure does not influence the position of equilibrium.

Keep in mind that, as long as temperature remains constant, pressure-volume changes do *not* change the value of  $K$ . Rather, these changes alter the partial pressures of the gaseous substances. In Sample Exercise 15.7, we calculated  $K_p = 2.79 \times 10^{-5}$  for the Haber reaction,  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ , in an equilibrium mixture at  $472^\circ\text{C}$  containing 7.38 atm  $\text{H}_2$ , 2.46 atm  $\text{N}_2$ , and 0.166 atm  $\text{NH}_3$ . Consider what happens when we suddenly reduce the volume of the system by one-half. If there were no shift in equilibrium, this volume change would cause the partial pressures of all substances to double, giving  $P_{\text{H}_2} = 14.76$  atm,  $P_{\text{N}_2} = 4.92$  atm, and  $P_{\text{NH}_3} = 0.332$  atm. The reaction quotient would then no longer equal the equilibrium constant:

$$Q_p = \frac{(P_{\text{NH}_3})^2}{P_{\text{N}_2}(P_{\text{H}_2})^3} = \frac{(0.332)^2}{(4.92)(14.76)^3} = 6.97 \times 10^{-6} \neq K_p$$

Because  $Q_p < K_p$ , the system would no longer be at equilibrium. Equilibrium would be reestablished by increasing  $P_{\text{NH}_3}$  and decreasing both  $P_{\text{N}_2}$  and  $P_{\text{H}_2}$  until  $Q_p = K_p = 2.79 \times 10^{-5}$ . Therefore, the equilibrium shifts to the right in the reaction as written, as Le Châtelier's principle predicts.

It is possible to change the pressure of a system in which a chemical reaction is running without changing its volume. For example, pressure increases if additional amounts of any reacting components are added to the system. We have already seen how to deal with a change in concentration of a reactant or product. However, the *total* pressure in the reaction vessel might also be increased by adding a gas that is not involved in the equilibrium. For example, argon might be added to the ammonia equilibrium system. The argon would not alter the *partial* pressures of any of the reacting components and therefore would not cause a shift in equilibrium.

## Effect of Temperature Changes

Changes in concentrations or partial pressures shift equilibria without changing the value of the equilibrium constant. In contrast, almost every equilibrium constant changes as the temperature changes. For example, consider the equilibrium established when cobalt(II) chloride ( $\text{CoCl}_2$ ) is dissolved in hydrochloric acid,  $\text{HCl}(aq)$ , in the endothermic reaction

Because  $\text{Co}(\text{H}_2\text{O})_6^{2+}$  is pink and  $\text{CoCl}_4^{2-}$  is blue, the position of this equilibrium is readily apparent from the color of the solution (Figure 15.14). When the solution is heated it turns blue, indicating that the equilibrium has shifted to form more  $\text{CoCl}_4^{2-}$ . Cooling the solution leads to a pink solution, indicating that the equilibrium has shifted to produce more  $\text{Co}(\text{H}_2\text{O})_6^{2+}$ . We can monitor this reaction by spectroscopic methods, measuring the concentration of all species at the different temperatures. [∞ \(Section 14.2\)](#) We can then calculate the equilibrium constant at each temperature. How do we explain why the equilibrium constants and therefore the position of equilibrium both depend on temperature?

We can deduce the rules for the relationship between  $K$  and temperature from Le Châtelier's principle. We do this by treating heat as a chemical reagent. In an *endothermic* (heat-absorbing) reaction, we consider heat a *reactant*, and in an *exothermic* (heat-releasing) reaction, we consider heat a *product*:

Endothermic: Reactants + *heat*  $\rightleftharpoons$  products

Exothermic: Reactants  $\rightleftharpoons$  products + *heat*

$\Delta H > 0$ , endothermic reaction

Pink

Blue

▲ **Figure 15.14** Temperature and Le Châtelier's principle. In the molecular level views, only the  $\text{CoCl}_4^{2-}$  and  $\text{Co}(\text{H}_2\text{O})_6^{2+}$  ions are shown for clarity.

*When the temperature of a system at equilibrium is increased, the system reacts as if we added a reactant to an endothermic reaction or a product to an exothermic reaction. The equilibrium shifts in the direction that consumes the excess reactant (or product), namely heat.*

### Give It Some Thought

Is vaporization an exothermic or endothermic process? Based on Le Châtelier's principle, would you predict the vapor pressure of a gas will increase or decrease as the temperature increases?

In an endothermic reaction, such as Equation 15.25, heat is absorbed as reactants are converted to products. Thus, increasing the temperature causes the equilibrium to shift to the right, in the direction of making more products, and  $K$  increases. In an exothermic reaction, the opposite occurs: Heat is produced as reactants are converted to products. Thus, increasing the temperature in this case causes the equilibrium to shift to the left, in the direction of making more reactants, and  $K$  decreases.

*Endothermic:* Increasing  $T$  results in higher  $K$  value

*Exothermic:* Increasing  $T$  results in lower  $K$  value

Cooling a reaction has the opposite effect. As we lower the temperature, the equilibrium shifts in the direction that produces heat. Thus, cooling an endothermic reaction shifts the equilibrium to the left, decreasing  $K$ , as shown in Figure 15.14, and cooling an exothermic reaction shifts the equilibrium to the right, increasing  $K$ .

## Sample Exercise 15.12

### Using Le Châtelier's Principle to Predict Shifts in Equilibrium

Consider the equilibrium

In which direction will the equilibrium shift when (a)  $\text{N}_2\text{O}_4$  is added, (b)  $\text{NO}_2$  is removed, (c) the pressure is increased by addition of  $\text{N}_2(g)$ , (d) the volume is increased, (e) the temperature is decreased?

### SOLUTION

**Analyze** We are given a series of changes to be made to a system at equilibrium and are asked to predict what effect each change will have on the position of the equilibrium.

**Plan** Le Châtelier's principle can be used to determine the effects of each of these changes.

#### Solve

- (a) The system will adjust to decrease the concentration of the added  $\text{N}_2\text{O}_4$ , so the equilibrium shifts to the right, in the direction of the product.
- (b) The system will adjust to the removal of  $\text{NO}_2$  by shifting to the side that produces more  $\text{NO}_2$ ; thus, the equilibrium shifts to the right.
- (c) Adding  $\text{N}_2$  will increase the total pressure of the system, but  $\text{N}_2$  is not involved in the reaction. The partial pressures of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  are therefore unchanged, and there is no shift in the position of the equilibrium.
- (d) If the volume is increased, the system will shift in the direction that occupies a larger volume (more gas molecules); thus, the equilibrium shifts to the right.
- (e) The reaction is endothermic, so we can imagine heat as a reagent on the reactant side of the equation. Decreasing the

temperature will shift the equilibrium in the direction that produces heat, so the equilibrium shifts to the left, toward the formation of more  $\text{N}_2\text{O}_4$ . Note that only this last change also affects the value of the equilibrium constant,  $K$ .

#### Practice Exercise 1

For the reaction

which of the following changes will shift the equilibrium to the right, toward the formation of more products?

- (a) Adding more water vapor (b) Increasing the temperature
- (c) Increasing the volume of the reaction vessel (d) Removing  $\text{O}_2(g)$  (e) Adding 1 atm of Ne(g) to the reaction vessel.

#### Practice Exercise 2

For the reaction

in which direction will the equilibrium shift when (a)  $\text{Cl}_2(g)$  is removed, (b) the temperature is decreased, (c) the volume of the reaction system is increased, (d)  $\text{PCl}_3(g)$  is added?

## A CLOSER LOOK Temperature Changes and Le Châtelier's Principle

By thinking of heat as a chemical reagent, we can use Le Châtelier's principle to predict how an equilibrium mixture of reactants and products will respond to a change in temperature. For an endothermic reaction, the equilibrium constant  $K$  increases as the temperature rises and decreases as the temperature is lowered, while exothermic reactions respond in the opposite manner. The underlying reason for this behavior can be understood by taking a closer look at the relationships among the equilibrium constant, the forward and reverse reaction rates, and their activation energies.

To illustrate the underlying relationships consider an elementary reaction  $A \rightleftharpoons B$ . At equilibrium, the rates of the forward and reverse reactions are equal:

$$k_f[A] = k_r[B] \quad [15.26]$$

The equilibrium constant,  $K = [B]/[A]$  can be expressed in terms of reaction rates by rearranging Equation 15.26

$$K = \frac{[B]}{[A]} = \frac{k_f}{k_r} \quad [15.27]$$

It's instructive to consider shifts in equilibrium through the lens of Equation 15.27. If the reaction in question is an endothermic reaction, a decrease in temperature will lead to a decrease in  $K$ , thereby shifting the equilibrium to the left. Equation 15.27 tells us that in order for  $K$  to decrease, the rate constant of the forward reaction  $k_f$  must decrease by a larger amount than the rate constant of the reverse reaction  $k_r$ .

To understand why  $k_f$  decreases faster than  $k_r$  consider the relationship between reaction rate and activation energy,  $E_a$ . For the sake of illustration, consider the effect of decreasing the temperature from

$T_1 = 400 \text{ K}$  to  $T_2 = 300 \text{ K}$ . We can calculate the change in the forward rate constant using Equation 14.23:

$$\ln \frac{k_{f1}}{k_{f2}} = \frac{E_a(\text{forward})}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \quad [15.28]$$

$$\ln \frac{k_{f1}}{k_{f2}} = \frac{E_a(\text{forward})}{R} \left( \frac{1}{300 \text{ K}} - \frac{1}{400 \text{ K}} \right) = 1200 \frac{E_a(\text{forward})}{R} \quad [15.29]$$

Using the same approach, we can write an equation that gives the change in the reverse rate constant:

$$\ln \frac{k_{r1}}{k_{r2}} = \frac{E_a(\text{reverse})}{R} \left( \frac{1}{300 \text{ K}} - \frac{1}{400 \text{ K}} \right) = 1200 \frac{E_a(\text{reverse})}{R} \quad [15.30]$$

These equations are identical with one exception: the activation energies for the forward and reverse reactions are not the same, as shown on the left-hand side of Figure 15.15. For an endothermic reaction, the activation energy in the forward direction is always larger than that of the reverse reaction,  $E_a(\text{forward}) > E_a(\text{reverse})$ . Consequently, the decrease in the forward rate constant (Equation 15.29) will be larger than the decrease in the reverse rate constant (Equation 15.30), and the overall value of the equilibrium constant  $K$  must decrease.

For an exothermic reaction,  $E_a(\text{reverse}) > E_a(\text{forward})$  and the opposite relationships apply as shown on the right-hand side of Figure 15.15. As temperature is lowered, the reverse rate constant will decrease more rapidly than the forward rate constant and the equilibrium constant  $K$  will increase; that is, the equilibrium will shift to the right.

## The Effect of Catalysts

What happens if we add a catalyst to a chemical system that is at equilibrium? As shown in Figure 15.16, a catalyst lowers the activation barrier between reactants and products. The activation energies for both the forward and reverse reactions are lowered. The catalyst thereby increases the rates of both forward and reverse reactions. Since  $K$  is the ratio of the forward and reverse rate constants for a reaction, you can predict, correctly, that the presence of a catalyst, even though it changes the reaction *rate*, does not affect the numeric value of  $K$  (Figure 15.16). As a result, *a catalyst increases the rate at which equilibrium is achieved but does not change the composition of the equilibrium mixture.*

## Go Figure

What quantity dictates the speed of a reaction: (a) the energy difference between the initial state and the transition state or (b) the energy difference between the initial state and the final state?

▲ **Figure 15.16** An energy profile for the reaction  $A \rightleftharpoons B$  (left), and the change in concentration of B as a function of time (right), with and without a catalyst. Green curves show the reaction with a catalyst; black curves show the reaction without a catalyst.

**TABLE 15.2** Variation in  $K_p$  with Temperature for

| Temperature (°C) | $K_p$                 |
|------------------|-----------------------|
| 300              | $4.34 \times 10^{-3}$ |
| 400              | $1.64 \times 10^{-4}$ |
| 450              | $4.51 \times 10^{-5}$ |
| 500              | $1.45 \times 10^{-5}$ |
| 550              | $5.38 \times 10^{-6}$ |
| 600              | $2.25 \times 10^{-6}$ |

The rate at which a reaction approaches equilibrium is an important practical consideration. As an example, let's again consider the synthesis of ammonia from  $\text{N}_2$  and  $\text{H}_2$ . In designing his process, Haber had to deal with a rapid decrease in the equilibrium constant with increasing temperature, as you can see from [Table 15.2](#). At temperatures sufficiently high to give a satisfactory reaction rate, the amount of ammonia formed was too small. The solution to this dilemma was to develop a catalyst that would produce a reasonably rapid approach to equilibrium at a sufficiently low temperature, so that the equilibrium constant remained reasonably large. The development of a suitable catalyst thus became the focus of Haber's research efforts.

After trying different substances to see which would be most effective, Carl Bosch settled on iron mixed with metal oxides, and variants of this catalyst formulation are still used today. ∞ (Section 15.2, "The Haber Process") These catalysts make it possible to obtain a reasonably rapid approach to equilibrium at around 400 to 500 °C and 200 to 600 atm. The high pressures are needed to obtain a satisfactory equilibrium amount of  $\text{NH}_3$ . If a catalyst could be found that leads to sufficiently rapid reaction at temperatures lower than 400 °C, it would be possible to obtain the same extent of equilibrium conversion at pressures much lower than 200 to 600 atm. This would result in great savings in both the cost of the high-pressure equipment and the energy consumed in the production of ammonia. It is estimated that the Haber process consumes approximately 1% of the energy generated in the world each year. Not surprisingly, chemists and chemical engineers are actively searching for improved catalysts for the Haber process. A breakthrough in this field would not only increase the supply of ammonia for fertilizers, it would also reduce the global consumption of fossil fuels in a significant way.

## Give It Some Thought

If a reaction is carried out in the presence of a catalyst, will the amount of product present at equilibrium increase, decrease, or stay the same?

## Sample Integrative Exercise

### Putting Concepts Together

At temperatures near 800 °C, steam passed over hot coke (a form of carbon obtained from coal) reacts to form CO and H<sub>2</sub>:

The mixture of gases that results is an important industrial fuel called *water gas*. **(a)** At 800 °C the equilibrium constant for this reaction is  $K_p = 14.1$ . What are the equilibrium partial pressures of H<sub>2</sub>O, CO, and H<sub>2</sub> in the equilibrium mixture at this temperature if we start with solid carbon and 0.100 mol of H<sub>2</sub>O in a 1.00-L vessel? **(b)** What is the minimum amount of carbon required to achieve equilibrium under these conditions? **(c)** What is the total pressure in the vessel at equilibrium? **(d)** At 25 °C the value of  $K_p$  for this reaction is  $1.7 \times 10^{-21}$ . Is the reaction exothermic or endothermic? **(e)** To produce the maximum amount of CO and H<sub>2</sub> at equilibrium, should the pressure of the system be increased or decreased?

### SOLUTION

- (a)** To determine the equilibrium partial pressures, we use the ideal-gas equation, first determining the starting partial pressure of water.

$$P_{\text{H}_2\text{O}} = \frac{n_{\text{H}_2\text{O}}RT}{V} = \frac{(0.100 \text{ mol})(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(1073 \text{ K})}{1.00 \text{ L}} = 8.81 \text{ atm}$$

We then construct a table of initial partial pressures and their changes as equilibrium is achieved:

|                                    | $\text{C}(s) + \text{H}_2\text{O}(g) \rightleftharpoons \text{CO}(g) + \text{H}_2(g)$ |            |      |      |
|------------------------------------|---|------------|------|------|
| Initial partial pressure (atm)     |   | 8.81       | 0    | 0    |
| Change in partial pressure (atm)   |   | $-x$       | $+x$ | $+x$ |
| Equilibrium partial pressure (atm) |   | $8.81 - x$ | $x$  | $x$  |

There are no entries in the table under C(s) because the reactant, being a solid, does not appear in the equilibrium-constant expression. Substituting the equilibrium partial pressures of the other species into the equilibrium-constant expression for the reaction gives:

$$K_p = \frac{P_{\text{CO}}P_{\text{H}_2}}{P_{\text{H}_2\text{O}}} = \frac{(x)(x)}{(8.81 - x)} = 14.1$$

Multiplying through by the denominator gives a quadratic equation in  $x$ :

$$x^2 = (14.1)(8.81 - x)$$

Solving this equation for  $x$  using the quadratic formula yields  $x = 6.14$  atm. Hence, the equilibrium partial pressures are  $P_{\text{CO}} = x = 6.14$  atm,  $P_{\text{H}_2} = x = 6.14$  atm, and  $P_{\text{H}_2\text{O}} = (8.81 - x) = 2.67$  atm.

$$x^2 + 14.1x - 124.22 = 0$$

- (b)** Part (a) shows that  $x = 6.14$  atm of H<sub>2</sub>O must react for the system to achieve equilibrium. We can use the ideal-gas equation to convert this partial pressure into a mole amount.

Thus, 0.0697 mol of H<sub>2</sub>O and the same amount of C must react to achieve equilibrium. As a result, there must be at least 0.0697 mol of C (0.836 g C) present among the reactants at the start of the reaction.

$$\begin{aligned} n &= \frac{PV}{RT} \\ &= \frac{(6.14 \text{ atm})(1.00 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(1073 \text{ K})} = 0.0697 \text{ mol} \end{aligned}$$

- (c)** The total pressure in the vessel at equilibrium is simply the sum of the equilibrium partial pressures:

$$\begin{aligned} P_{\text{total}} &= P_{\text{H}_2\text{O}} + P_{\text{CO}} + P_{\text{H}_2} \\ &= 2.67 \text{ atm} + 6.14 \text{ atm} + 6.14 \text{ atm} = 14.95 \text{ atm} \end{aligned}$$

- (d)** In discussing Le Châtelier's principle, we saw that endothermic reactions exhibit an increase in  $K_p$  with increasing temperature. Because the equilibrium constant for this reaction increases as temperature increases, the reaction must be endothermic. From the enthalpies of formation given in Appendix C, we can verify our prediction by calculating the enthalpy change for the reaction: The positive sign for  $\Delta H^\circ$  indicates that the reaction is endothermic.

$$\begin{aligned} \Delta H^\circ &= \Delta H_f^\circ(\text{CO}(g)) + \Delta H_f^\circ(\text{H}_2(g)) - \Delta H_f^\circ(\text{C}(s, \text{graphite})) \\ &\quad - \Delta H_f^\circ(\text{H}_2\text{O}(g)) = +131.3 \text{ kJ} \end{aligned}$$

- (e)** According to Le Châtelier's principle, a decrease in the pressure causes a gaseous equilibrium to shift toward the side of the equation with the greater number of moles of gas. In this case, there are 2 mol of gas on the product side and only one on the reactant side. Therefore, the pressure should be decreased to maximize the yield of the CO and H<sub>2</sub>.

## CHEMISTRY PUT TO WORK Controlling Nitric Oxide Emissions

The formation of NO from N<sub>2</sub> and O<sub>2</sub>,

provides an interesting example of the practical importance of the fact that equilibrium constants and reaction rates change with temperature. By applying Le Châtelier's principle to this endothermic reaction and treating heat as a reactant, we deduce that an increase in temperature shifts the equilibrium in the direction of more NO. The equilibrium constant  $K_p$  for formation of 1 mol of NO from its elements at 300 K is only about  $1 \times 10^{-15}$  (Figure 15.17). At 2400 K, however, the equilibrium constant is about 0.05, which is  $10^{13}$  times larger than the 300 K value.

Figure 15.17 helps explain why NO is a pollution problem. In the cylinder of a modern high-compression automobile engine, the temperature during the fuel-burning part of the cycle is approximately 2400 K. Also, there is a fairly large excess of air in the cylinder. These conditions favor the formation of NO. After combustion, however, the gases cool quickly. As the temperature drops, the equilibrium in Equation 15.26 shifts to the left (because the reactant heat is being removed). However, the lower temperature also means that the reaction rate decreases, so the NO formed at 2400 K is essentially “trapped” in that form as the gas cools.

The gases exhausting from the cylinder are still quite hot, perhaps 1200 K. At this temperature, as shown in Figure 15.17, the equilibrium constant for formation of NO is about  $5 \times 10^{-4}$ , much smaller than the value at 2400 K. However, the rate of conversion of NO to N<sub>2</sub> and O<sub>2</sub> is too slow to permit much loss of NO before the gases are cooled further.

As discussed in the “Chemistry Put to Work” box in Section 14.7, one of the goals of automotive catalytic converters is to achieve rapid conversion of NO to N<sub>2</sub> and O<sub>2</sub> at the

## Go Figure

Estimate the value of  $K_p$  at 1200 K, the exhaust gas temperature.

▲ **Figure 15.17** Equilibrium and temperature. The equilibrium constant increases with increasing temperature because the reaction is endothermic. It is necessary to use a log scale for  $K_p$  because the values vary over such a large range.

temperature of the exhaust gas. Some catalysts developed for this reaction are reasonably effective under the grueling conditions in automotive exhaust systems. Nevertheless, scientists and engineers are continuously searching for new materials that provide even more effective catalysis of the decomposition of nitrogen oxides.

## Chapter Summary and Key Terms

**THE CONCEPT OF EQUILIBRIUM (SECTION 15.1)** A chemical reaction can achieve a state in which the forward and reverse processes are occurring at the same rate. This condition is called **chemical equilibrium**, and it results in the formation of an equilibrium mixture of reactants and products. The composition of an equilibrium mixture does not change with time if temperature is held constant.

**THE EQUILIBRIUM CONSTANT (SECTION 15.2)** An equilibrium that is used throughout this chapter is the reaction  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \rightleftharpoons 2 \text{NH}_3(\text{g})$ . This reaction is the basis of the **Haber process** for the production of ammonia. The relationship between the concentrations of the reactants and products of a system at equilibrium is given by the **law of mass action**. For an equilibrium equation of the form  $a \text{A} + b \text{B} \rightleftharpoons d \text{D} + e \text{E}$ , the **equilibrium-constant expression** is written as

$$K_c = \frac{[\text{D}]^d [\text{E}]^e}{[\text{A}]^a [\text{B}]^b}$$

where  $K_c$  is a dimensionless constant called the **equilibrium constant**. When the equilibrium system of interest consists of gases, it is often convenient to express the concentrations of reactants and products in terms of gas pressures:

$$K_p = \frac{(P_D)^d (P_E)^e}{(P_A)^a (P_B)^b}$$

$K_c$  and  $K_p$  are related by the expression  $K_p = K_c(RT)^{\Delta n}$ . To do this conversion properly, use  $R = 0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K}$  and temperature in kelvins.

**UNDERSTANDING AND WORKING WITH EQUILIBRIUM CONSTANTS (SECTION 15.3)** The value of the equilibrium constant changes with temperature. A large value of  $K_c$  indicates that the equilibrium mixture contains more products than reactants and therefore lies toward the product side of the equation. A small value for the equilibrium constant means that the equilibrium mixture

contains less products than reactants and therefore lies toward the reactant side. The equilibrium-constant expression and the equilibrium constant of the reverse of a reaction are the reciprocals of those of the forward reaction. If a reaction is the sum of two or more reactions, its equilibrium constant will be the product of the equilibrium constants for the individual reactions.

**HETEROGENEOUS EQUILIBRIA (SECTION 15.4)** Equilibria can be divided into two types: **homogeneous equilibria** where all of the reactants and products are in the same phase, and **heterogeneous equilibria** where more than one phase is present. Because their activities are exactly 1, the concentrations of pure solids and liquids are left out of the equilibrium-constant expression for a heterogeneous equilibrium.

**CALCULATING EQUILIBRIUM CONSTANTS (SECTION 15.5)** If the concentrations of all species in an equilibrium are known, the equilibrium-constant expression can be used to calculate the equilibrium constant. The changes in the concentrations of reactants and products on the way to achieving equilibrium are governed by the stoichiometry of the reaction.

**APPLICATIONS OF EQUILIBRIUM CONSTANTS (SECTION 15.6)** The **reaction quotient**,  $Q$ , is found by substituting reactant and product concentrations or partial pressures at any point during a reaction into the equilibrium-constant expression. If the system is at equilibrium,  $Q = K$ . If  $Q \neq K$ , however, the system is not at equilibrium. When

$Q < K$ , the reaction will move toward equilibrium by forming more products (the reaction proceeds from left to right); when  $Q > K$ , the reaction will move toward equilibrium by forming more reactants (the reaction proceeds from right to left). Knowing the value of  $K$  makes it possible to calculate the equilibrium amounts of reactants and products, often by the solution of an equation in which the unknown is the change in a partial pressure or concentration.

**LE CHÂTELIER'S PRINCIPLE (SECTION 15.7)** Le Châtelier's principle states that if a system at equilibrium is disturbed, the equilibrium will shift to minimize the disturbing influence. Therefore, if a reactant or product is added to a system at equilibrium, the equilibrium will shift to consume the added substance. The effects of removing reactants or products and of changing the pressure or volume of a reaction can be similarly deduced. For example, if the volume of the system is reduced, the equilibrium will shift in the direction that decreases the number of gas molecules. While changes in concentration or pressure lead to shifts in the equilibrium concentrations, they do not change the value of the equilibrium constant,  $K$ .

Changes in temperature affect both the equilibrium concentrations and the equilibrium constant. We can use the enthalpy change for a reaction to determine how an increase in temperature affects the equilibrium: For an endothermic reaction, an increase in temperature shifts the equilibrium to the right; for an exothermic reaction, a temperature increase shifts the equilibrium to the left. Catalysts affect the speed at which equilibrium is reached but do not affect the magnitude of  $K$ .

## Learning Outcomes After studying this chapter, you should be able to:

- Explain what is meant by chemical equilibrium and how it relates to reaction rates. (Section 15.1)  
*Related Exercises: 15.1, 15.13, 15.14*
- Write the equilibrium-constant expression for any reaction. (Section 15.2) *Related Exercises: 15.15, 15.16*
- Convert  $K_c$  to  $K_p$  and vice versa. (Section 15.2)  
*Related Exercises: 15.21, 15.22*
- Relate the magnitude of an equilibrium constant to the relative amounts of reactants and products present in an equilibrium mixture. (Section 15.3) *Related Exercises: 15.17–15.19*
- Manipulate the equilibrium constant to reflect changes in the chemical equation. (Section 15.3)  
*Related Exercises: 15.23, 15.25, 15.27, 15.28*
- Write the equilibrium-constant expression for a heterogeneous reaction. (Section 15.4) *Related Exercises: 15.7, 15.29, 15.30*
- Calculate an equilibrium constant from concentration measurements. (Section 15.5)  
*Related Exercises: 15.31–15.34*
- Predict the direction of a reaction given the equilibrium constant and the concentrations of reactants and products. (Section 15.6)  
*Related Exercises: 15.41–15.44*
- Calculate equilibrium concentrations given the equilibrium constant and all but one equilibrium concentration. (Section 15.6)  
*Related Exercises: 15.47–15.50*
- Calculate equilibrium concentrations, given the equilibrium constant and the starting concentrations. (Section 15.6)  
*Related Exercises: 15.51, 15.52, 15.57, 15.59*
- Use Le Châtelier's principle to predict how changing the concentrations, volume, or temperature of a system at equilibrium affects the equilibrium position. (Section 15.7)  
*Related Exercises: 15.61, 15.62, 15.65, 15.68*

## Key Equations

$$K_c = \frac{[D]^d[E]^e}{[A]^a[B]^b} \quad [15.8]$$

The equilibrium-constant expression for a general reaction of the type  $aA + bB \rightleftharpoons dD + eE$ , the concentrations are equilibrium concentrations only

$$K_p = \frac{(P_D)^d(P_E)^e}{(P_A)^a(P_B)^b} \quad [15.11]$$

The equilibrium-constant expression in terms of equilibrium partial pressures

$$K_p = K_c(RT)^{\Delta n} \quad [15.15]$$

Relating the equilibrium constant based on pressures to the equilibrium constant based on concentrations

$$Q_c = \frac{[D]^d[E]^e}{[A]^a[B]^b} \quad [15.24]$$

The reaction quotient. The concentrations are for any time during a reaction. If the concentrations are equilibrium concentrations, then  $Q_c = K_c$ .

## Exercises

## Visualizing Concepts

- 15.1** (a) Based on the following energy profile, predict whether  $k_f > k_r$  or  $k_f < k_r$ . (b) Using Equation 15.5, predict whether the equilibrium constant for the process is greater than 1 or less than 1. [Section 15.1]

- 15.2** The following diagrams represent a hypothetical reaction  $A \longrightarrow B$ , with A represented by red spheres and B represented by blue spheres. The sequence from left to right represents the system as time passes. Does the system reach equilibrium? If so, in which diagram(s) is the system in equilibrium? [Sections 15.1 and 15.2]

- 15.3** The following diagram represents an equilibrium mixture produced for a reaction of the type  $A + X \rightleftharpoons AX$ . Is  $K$  greater or smaller than 1 if the volume is 1 L and each atom/molecule in the diagram represents 1 mol? [Section 15.2]

- 15.4** The following diagram represents a reaction shown going to completion. Each molecule in the diagram represents 0.1 mol, and the volume of the box is 1.0 L. (a) Letting A = red spheres and B = blue spheres, write a balanced equation for the reaction. (b) Write the equilibrium-constant expression for the reaction. (c) Calculate the value of  $K_c$ . (d) Assuming that all of the molecules are in the gas phase, calculate  $\Delta n$ , the change in the number of gas molecules that accompanies the reaction. (e) Calculate the value of  $K_p$ . [Section 15.2]

- 15.5** Snapshots of two hypothetical reactions,  $A(g) + B(g) \rightleftharpoons AB(g)$  and  $X(g) + Y(g) \rightleftharpoons XY(g)$  at five different times are shown here. Which reaction has a larger equilibrium constant? [Sections 15.1 and 15.2]

- 15.6** Ethene ( $C_2H_4$ ) reacts with halogens ( $X_2$ ) by the following reaction:

The following figures represent the concentrations at equilibrium at the same temperature when  $X_2$  is  $Cl_2$  (green),  $Br_2$  (brown), and  $I_2$  (purple). List the equilibria from smallest to largest equilibrium constant. [Section 15.3]

(a) (b)

(c)

- 15.7** When lead(IV) oxide is heated above  $300^\circ\text{C}$ , it decomposes according to the following reaction  $\text{PbO}_2(\text{s}) \rightleftharpoons \text{PbO}(\text{s}) + \text{O}_2(\text{g})$ . Consider the two sealed vessels of  $\text{PbO}_2$  shown here. If both vessels are heated to  $400^\circ\text{C}$  and allowed to come to equilibrium, which of the following statements is true? **(a)** There will be less  $\text{PbO}_2$  remaining in vessel A, **(b)** There will be less  $\text{PbO}_2$  remaining in vessel B, **(c)** The amount of  $\text{PbO}_2$  remaining in each vessel will be the same. [Section 15.4]

- 15.8** The reaction  $\text{A}_2 + \text{B}_2 \rightleftharpoons 2\text{AB}$  has an equilibrium constant  $K_c = 1.5$ . The following diagrams represent reaction mixtures containing  $\text{A}_2$  molecules (red),  $\text{B}_2$  molecules (blue), and  $\text{AB}$  molecules. **(a)** Which reaction mixture is at equilibrium? **(b)** For those mixtures that are not at equilibrium, how will the reaction proceed to reach equilibrium? [Sections 15.5 and 15.6]

- 15.9** The reaction  $\text{A}_2(\text{g}) + \text{B}(\text{g}) \rightleftharpoons \text{A}(\text{g}) + \text{AB}(\text{g})$  has an equilibrium constant of  $K_p = 2$ . The accompanying diagram shows a mixture containing A atoms (red),  $\text{A}_2$  molecules, and  $\text{AB}$  molecules (red and blue). How many B atoms should be added to the diagram to illustrate an equilibrium mixture? [Section 15.6]

- 15.10** The diagram shown here represents the equilibrium state for the reaction  $\text{A}_2(\text{g}) + 2\text{B}(\text{g}) \rightleftharpoons 2\text{AB}(\text{g})$ . **(a)** Assuming the volume is 2 L, calculate the equilibrium constant  $K_c$  for the reaction. **(b)** If the volume of the equilibrium mixture is decreased, will the number of  $\text{AB}$  molecules increase or decrease? [Sections 15.5 and 15.7]

- 15.11** The following diagrams represent equilibrium mixtures for the reaction  $\text{A}_2 + \text{B} \rightleftharpoons \text{A} + \text{AB}$  at 300 K and 500 K. The A atoms are red, and the B atoms are blue. Is the reaction exothermic or endothermic? [Section 15.7]

- 15.12** The following graph represents the yield of the compound  $\text{AB}$  at equilibrium in the reaction  $\text{A}(\text{g}) + \text{B}(\text{g}) \rightleftharpoons \text{AB}(\text{g})$  at two different pressures,  $x$  and  $y$ , as a function of temperature.

- (a)** Is this reaction exothermic or endothermic? **(b)** Is  $P = x$  greater or smaller than  $P = y$ ? [Section 15.7]

### Equilibrium; The Equilibrium Constant (Sections 15.1–15.4)

- 15.13** Suppose that the gas-phase reactions  $\text{A} \rightarrow \text{B}$  and  $\text{B} \rightarrow \text{A}$  are both elementary processes with rate constants of  $4.7 \times 10^{-3} \text{ s}^{-1}$  and  $5.8 \times 10^{-1} \text{ s}^{-1}$ , respectively. **(a)** What is the value of the equilibrium constant for the equilibrium  $\text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g})$ ? **(b)** Which is greater at equilibrium, the partial pressure of A or the partial pressure of B?

- 15.14** The equilibrium constant for the dissociation of molecular iodine,  $I_2(g) \rightleftharpoons 2I(g)$ , at 800 K is  $K_c = 3.1 \times 10^{-5}$ .  
**(a)** Which species predominates at equilibrium  $I_2$  or  $I$ ?  
**(b)** Assuming both forward and reverse reactions are elementary processes, which reaction has the larger rate constant, the forward or the reverse reaction?

- 15.15** Write the expression for  $K_c$  for the following reactions. In each case indicate whether the reaction is homogeneous or heterogeneous.

- 15.16** Write the expressions for  $K_c$  for the following reactions. In each case indicate whether the reaction is homogeneous or heterogeneous.

- 15.17** When the following reactions come to equilibrium, does the equilibrium mixture contain mostly reactants or mostly products?

- 15.18** Which of the following reactions lies to the right, favoring the formation of products, and which lies to the left, favoring formation of reactants?

- 15.19** Which of the following statements are true and which are false? **(a)** The equilibrium constant can never be a negative number. **(b)** In reactions that we draw with a single-headed arrow, the equilibrium constant has a value that is very close to zero. **(c)** As the value of the equilibrium constant increases, the speed at which a reaction reaches equilibrium increases.

- 15.20** Which of the following statements are true and which are false? **(a)** For the reaction  $2A(g) + B(g) \rightleftharpoons A_2B(g)$   $K_c$  and  $K_p$  are numerically the same. **(b)** It is possible to distinguish  $K_c$  from  $K_p$  by comparing the units used to express the equilibrium constant. **(c)** For the equilibrium in (a), the value of  $K_c$  increases with increasing pressure.

- 15.21** If  $K_c = 0.042$  for  $PCl_3(g) + Cl_2(g) \rightleftharpoons PCl_5(g)$  at 500 K, what is the value of  $K_p$  for this reaction at this temperature?

- 15.22** Calculate  $K_c$  at 303 K for  $SO_2(g) + Cl_2(g) \rightleftharpoons SO_2Cl_2(g)$  if  $K_p = 34.5$  at this temperature.

- 15.23** The equilibrium constant for the reaction

is  $K_c = 1.3 \times 10^{-2}$  at 1000 K. **(a)** At this temperature does the equilibrium favor NO and  $Br_2$ , or does it favor NOBr? **(b)** Calculate  $K_c$  for  $2NOBr(g) \rightleftharpoons 2NO(g) + Br_2(g)$ . **(c)** Calculate  $K_c$  for  $NOBr(g) \rightleftharpoons NO(g) + \frac{1}{2}Br_2(g)$ .

- 15.24** Consider the following equilibrium:

**(a)** Calculate  $K_p$ . **(b)** Does the equilibrium mixture contain mostly  $H_2$  and  $S_2$  or mostly  $H_2S$ ? **(c)** Calculate the value of  $K_c$  if you rewrote the equation  $H_2(g) + \frac{1}{2}S_2(g) \rightleftharpoons H_2S(g)$ .

- 15.25** At 1000 K,  $K_p = 1.85$  for the reaction

**(a)** What is the value of  $K_p$  for the reaction  $SO_3(g) \rightleftharpoons SO_2(g) + \frac{1}{2}O_2(g)$ ? **(b)** What is the value of  $K_p$  for the reaction  $2SO_2(g) + O_2(g) \rightleftharpoons 2SO_3(g)$ ? **(c)** What is the value of  $K_c$  for the reaction in part (b)?

- 15.26** Consider the following equilibrium, for which  $K_p = 0.0752$  at  $480^\circ\text{C}$ :

**(a)** What is the value of  $K_p$  for the reaction  $4HCl(g) + O_2(g) \rightleftharpoons 2Cl_2(g) + 2H_2O(g)$ ?

**(b)** What is the value of  $K_p$  for the reaction  $Cl_2(g) + H_2O(g) \rightleftharpoons 2HCl(g) + \frac{1}{2}O_2(g)$ ?

**(c)** What is the value of  $K_c$  for the reaction in part (b)?

- 15.27** The following equilibria were attained at 823 K:

Based on these equilibria, calculate the equilibrium constant for  $H_2(g) + CO_2(g) \rightleftharpoons CO(g) + H_2O(g)$  at 823 K.

- 15.28** Consider the equilibrium

Calculate the equilibrium constant  $K_p$  for this reaction, given the following information (at 298 K):

- 15.29** Mercury(I) oxide decomposes into elemental mercury and elemental oxygen:  $2Hg_2O(s) \rightleftharpoons 4Hg(l) + O_2(g)$ .

**(a)** Write the equilibrium-constant expression for this reaction in terms of partial pressures. **(b)** Suppose you run this reaction in a solvent that dissolves elemental mercury and elemental oxygen. Rewrite the equilibrium-constant expression in terms of molarities for the reaction, using (solv) to indicate solvation.

- 15.30** Consider the equilibrium  $Na_2O(s) + SO_2(g) \rightleftharpoons Na_2SO_3(s)$ . **(a)** Write the equilibrium-constant expression for this reaction in terms of partial pressures. **(b)** All the compounds in this reaction are soluble in water. Rewrite the equilibrium-constant expression in terms of molarities for the aqueous reaction.

## Calculating Equilibrium Constants (Section 15.5)

- 15.31** Methanol ( $CH_3OH$ ) is produced commercially by the catalyzed reaction of carbon monoxide and hydrogen:  $CO(g) + 2H_2(g) \rightleftharpoons CH_3OH(g)$ . An equilibrium mixture in a 2.00-L vessel is found to contain 0.0406 mol  $CH_3OH$ , 0.170 mol  $CO$ , and 0.302 mol  $H_2$  at 500 K. Calculate  $K_c$  at this temperature.

- 15.32** Gaseous hydrogen iodide is placed in a closed container at  $425^\circ\text{C}$ , where it partially decomposes to hydrogen and iodine:  $2HI(g) \rightleftharpoons H_2(g) + I_2(g)$ . At equilibrium it is found that  $[HI] = 3.53 \times 10^{-3} M$ ,  $[H_2] = 4.79 \times 10^{-4} M$ , and  $[I_2] = 4.79 \times 10^{-4} M$ . What is the value of  $K_c$  at this temperature?

**15.33** The equilibrium  $2\text{NO}(g) + \text{Cl}_2(g) \rightleftharpoons 2\text{NOCl}(g)$  is established at 500 K. An equilibrium mixture of the three gases has partial pressures of 0.095 atm, 0.171 atm, and 0.28 atm for NO,  $\text{Cl}_2$ , and NOCl, respectively. **(a)** Calculate  $K_p$  for this reaction at 500.0 K. **(b)** If the vessel has a volume of 5.00 L, calculate  $K_c$  at this temperature.

**15.34** Phosphorus trichloride gas and chlorine gas react to form phosphorus pentachloride gas:  $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$ . A 7.5-L gas vessel is charged with a mixture of  $\text{PCl}_3(g)$  and  $\text{Cl}_2(g)$ , which is allowed to equilibrate at 450 K. At equilibrium the partial pressures of the three gases are  $P_{\text{PCl}_3} = 0.124$  atm,  $P_{\text{Cl}_2} = 0.157$  atm, and  $P_{\text{PCl}_5} = 1.30$  atm. **(a)** What is the value of  $K_p$  at this temperature? **(b)** Does the equilibrium favor reactants or products? **(c)** Calculate  $K_c$  for this reaction at 450 K.

**15.35** A mixture of 0.10 mol of NO, 0.050 mol of  $\text{H}_2$ , and 0.10 mol of  $\text{H}_2\text{O}$  is placed in a 1.0-L vessel at 300 K. The following equilibrium is established:

At equilibrium  $[\text{NO}] = 0.062$  M. **(a)** Calculate the equilibrium concentrations of  $\text{H}_2$ ,  $\text{N}_2$ , and  $\text{H}_2\text{O}$ . **(b)** Calculate  $K_c$ .

**15.36** A mixture of 1.374 g of  $\text{H}_2$  and 70.31 g of  $\text{Br}_2$  is heated in a 2.00-L vessel at 700 K. These substances react according to

At equilibrium, the vessel is found to contain 0.566 g of  $\text{H}_2$ . **(a)** Calculate the equilibrium concentrations of  $\text{H}_2$ ,  $\text{Br}_2$ , and HBr. **(b)** Calculate  $K_c$ .

**15.37** A mixture of 0.2000 mol of  $\text{CO}_2$ , 0.1000 mol of  $\text{H}_2$ , and 0.1600 mol of  $\text{H}_2\text{O}$  is placed in a 2.000-L vessel. The following equilibrium is established at 500 K:

**(a)** Calculate the initial partial pressures of  $\text{CO}_2$ ,  $\text{H}_2$ , and  $\text{H}_2\text{O}$ . **(b)** At equilibrium  $P_{\text{H}_2\text{O}} = 3.51$  atm. Calculate the equilibrium partial pressures of  $\text{CO}_2$ ,  $\text{H}_2$ , and CO. **(c)** Calculate  $K_p$  for the reaction. **(d)** Calculate  $K_c$  for the reaction.

**15.38** A flask is charged with 1.500 atm of  $\text{N}_2\text{O}_4(g)$  and 1.00 atm  $\text{NO}_2(g)$  at 25 °C, and the following equilibrium is achieved:

After equilibrium is reached, the partial pressure of  $\text{NO}_2$  is 0.512 atm. **(a)** What is the equilibrium partial pressure of  $\text{N}_2\text{O}_4$ ? **(b)** Calculate the value of  $K_p$  for the reaction. **(c)** Calculate  $K_c$  for the reaction.

**15.39** Two different proteins X and Y are dissolved in aqueous solution at 37 °C. The proteins bind in a 1:1 ratio to form XY. A solution that is initially 1.00 mM in each protein is allowed to reach equilibrium. At equilibrium, 0.20 mM of free X and 0.20 mM of free Y remain. What is  $K_c$  for the reaction?

**15.40** A chemist at a pharmaceutical company is measuring equilibrium constants for reactions in which drug candidate molecules bind to a protein involved in cancer. The drug molecules bind the protein in a 1:1 ratio to form a drug-protein complex. The protein concentration in aqueous solution at 25 °C is  $1.50 \times 10^{-6}$  M. Drug A is introduced into the protein solution at an initial concentration of  $2.00 \times 10^{-6}$  M. Drug B is introduced into a separate, identical protein solution at an initial concentration of  $2.00 \times 10^{-6}$  M. At equilibrium, the drug A-protein solution has an A-protein complex concentration of  $1.00 \times 10^{-6}$  M, and the drug B solution has a B-protein complex concentration of  $1.40 \times 10^{-6}$  M. Calculate the  $K_c$  value for the A-protein binding reaction and for the B-protein binding reaction. Assuming that the drug that binds more strongly will be more effective, which drug is the better choice for further research?

## Applications of Equilibrium Constants (Section 15.6)

**15.41** **(a)** If  $Q_c < K_c$ , in which direction will a reaction proceed in order to reach equilibrium? **(b)** What condition must be satisfied so that  $Q_c = K_c$ ?

**15.42** **(a)** If  $Q_c > K_c$ , how must the reaction proceed to reach equilibrium? **(b)** At the start of a certain reaction, only reactants are present; no products have been formed. What is the value of  $Q_c$  at this point in the reaction?

**15.43** At 100 °C, the equilibrium constant for the reaction  $\text{COCl}_2(g) \rightleftharpoons \text{CO}(g) + \text{Cl}_2(g)$  has the value  $K_c = 2.19 \times 10^{-10}$ . Are the following mixtures of  $\text{COCl}_2$ , CO, and  $\text{Cl}_2$  at 100 °C at equilibrium? If not, indicate the direction that the reaction must proceed to achieve equilibrium.

**(a)**  $[\text{COCl}_2] = 2.00 \times 10^{-3}$  M,  $[\text{CO}] = 3.3 \times 10^{-6}$  M,  $[\text{Cl}_2] = 6.62 \times 10^{-6}$  M

**(b)**  $[\text{COCl}_2] = 4.50 \times 10^{-2}$  M,  $[\text{CO}] = 1.1 \times 10^{-7}$  M,  $[\text{Cl}_2] = 2.25 \times 10^{-6}$  M

**(c)**  $[\text{COCl}_2] = 0.0100$  M,  $[\text{CO}] = [\text{Cl}_2] = 1.48 \times 10^{-6}$  M

**15.44** As shown in Table 15.2,  $K_p$  for the equilibrium

is  $4.51 \times 10^{-5}$  at 450 °C. For each of the mixtures listed here, indicate whether the mixture is at equilibrium at 450 °C. If it is not at equilibrium, indicate the direction (toward product or toward reactants) in which the mixture must shift to achieve equilibrium.

**(a)** 98 atm  $\text{NH}_3$ , 45 atm  $\text{N}_2$ , 55 atm  $\text{H}_2$

**(b)** 57 atm  $\text{NH}_3$ , 143 atm  $\text{N}_2$ , no  $\text{H}_2$

**(c)** 13 atm  $\text{NH}_3$ , 27 atm  $\text{N}_2$ , 82 atm  $\text{H}_2$

**15.45** At 100 °C,  $K_c = 0.078$  for the reaction

In an equilibrium mixture of the three gases, the concentrations of  $\text{SO}_2\text{Cl}_2$  and  $\text{SO}_2$  are 0.108 M and 0.052 M, respectively. What is the partial pressure of  $\text{Cl}_2$  in the equilibrium mixture?

**15.46** At 900 K, the following reaction has  $K_p = 0.345$ :

In an equilibrium mixture the partial pressures of  $\text{SO}_2$  and  $\text{O}_2$  are 0.135 atm and 0.455 atm, respectively. What is the equilibrium partial pressure of  $\text{SO}_3$  in the mixture?

**15.47** At 1285 °C, the equilibrium constant for the reaction  $\text{Br}_2(g) \rightleftharpoons 2\text{Br}(g)$  is  $K_c = 1.04 \times 10^{-3}$ . A 0.200-L vessel containing an equilibrium mixture of the gases has 0.245 g  $\text{Br}_2(g)$  in it. What is the mass of  $\text{Br}(g)$  in the vessel?

**15.48** For the reaction  $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2\text{HI}(g)$ ,  $K_c = 55.3$  at 700 K. In a 2.00-L flask containing an equilibrium mixture of the three gases, there are 0.056 g  $\text{H}_2$  and 4.36 g  $\text{I}_2$ . What is the mass of HI in the flask?

**15.49** At 800 K, the equilibrium constant for  $\text{I}_2(g) \rightleftharpoons 2\text{I}(g)$  is  $K_c = 3.1 \times 10^{-5}$ . If an equilibrium mixture in a 10.0-L vessel contains  $2.67 \times 10^{-2}$  g of  $\text{I}(g)$ , how many grams of  $\text{I}_2$  are in the mixture?

**15.50** For  $2\text{SO}_2(g) + \text{O}_2(g) \rightleftharpoons 2\text{SO}_3(g)$ ,  $K_p = 3.0 \times 10^4$  at 700 K. In a 2.00-L vessel, the equilibrium mixture contains 1.17 g of  $\text{SO}_3$  and 0.105 g of  $\text{O}_2$ . How many grams of  $\text{SO}_2$  are in the vessel?

- 15.51**
- At 2000 °C, the equilibrium constant for the reaction

is  $K_c = 2.4 \times 10^3$ . If the initial concentration of NO is 0.175 M, what are the equilibrium concentrations of NO,  $\text{N}_2$ , and  $\text{O}_2$ ?

- 15.52**
- For the equilibrium

at 400 K,  $K_c = 7.0$ . If 0.25 mol of  $\text{Br}_2$  and 0.55 mol of  $\text{Cl}_2$  are introduced into a 3.0-L container at 400 K, what will be the equilibrium concentrations of  $\text{Br}_2$ ,  $\text{Cl}_2$ , and  $\text{BrCl}$ ?

- 15.53**
- At 373 K,
- $K_p = 0.416$
- for the equilibrium

If the pressures of  $\text{NOBr}(g)$  and  $\text{NO}(g)$  are equal, what is the equilibrium pressure of  $\text{Br}_2(g)$ ?

- 15.54**
- At 218 °C,
- $K_c = 1.2 \times 10^{-4}$
- for the equilibrium

Calculate the equilibrium concentrations of  $\text{NH}_3$  and  $\text{H}_2\text{S}$  if a sample of solid  $\text{NH}_4\text{SH}$  is placed in a closed vessel at 218 °C and decomposes until equilibrium is reached.

- 15.55**
- Consider the reaction

At 25 °C, the equilibrium constant is  $K_c = 2.4 \times 10^{-5}$  for this reaction. **(a)** If excess  $\text{CaSO}_4(s)$  is mixed with water at 25 °C to produce a saturated solution of  $\text{CaSO}_4$ , what are the equilibrium concentrations of  $\text{Ca}^{2+}$  and  $\text{SO}_4^{2-}$ ? **(b)** If the resulting solution has a volume of 1.4 L, what is the minimum mass of  $\text{CaSO}_4(s)$  needed to achieve equilibrium?

- 15.56**
- At 80 °C,
- $K_c = 1.87 \times 10^{-3}$
- for the reaction

**(a)** Calculate the equilibrium concentrations of  $\text{PH}_3$  and  $\text{BCl}_3$  if a solid sample of  $\text{PH}_3\text{BCl}_3$  is placed in a closed vessel at 80 °C and decomposes until equilibrium is reached. **(b)** If the flask has a volume of 0.250 L, what is the minimum mass of  $\text{PH}_3\text{BCl}_3(s)$  that must be added to the flask to achieve equilibrium?

- 15.57**
- For the reaction
- $\text{I}_2(g) + \text{Br}_2(g) \rightleftharpoons 2\text{IBr}(g)$
- ,
- $K_c = 280$
- at 150 °C. Suppose that 0.500 mol IBr in a 2.00-L flask is allowed to reach equilibrium at 150 °C. What are the equilibrium concentrations of IBr,
- $\text{I}_2$
- , and
- $\text{Br}_2$
- ?

- 15.58**
- At 25 °C, the reaction

has an equilibrium constant  $K_c = 7.1 \times 10^{-4}$ . What are the equilibrium concentrations of  $\text{Ca}^{2+}$  and  $\text{CrO}_4^{2-}$  in a saturated solution of  $\text{CaCrO}_4$ ?

- 15.59**
- Methane,
- $\text{CH}_4$
- , reacts with
- $\text{I}_2$
- according to the reaction
- $\text{CH}_4(g) + \text{I}_2(g) \rightleftharpoons \text{CH}_3\text{I}(g) + \text{HI}(g)$
- . At 630 K,
- $K_p$
- for this reaction is
- $2.26 \times 10^{-4}$
- . A reaction was set up at 630 K with initial partial pressures of methane of 105.1 torr and of 7.96 torr for
- $\text{I}_2$
- . Calculate the pressures, in torr, of all reactants and products at equilibrium.

- 15.60**
- The reaction of an organic acid with an alcohol, in organic solvent, to produce an ester and water is commonly done in the pharmaceutical industry. This reaction is catalyzed by strong acid (usually
- $\text{H}_2\text{SO}_4$
- ). A simple example is the reaction of acetic acid with ethyl alcohol to produce ethyl acetate and water:

where “(solv)” indicates that all reactants and products are in solution but not an aqueous solution. The equilibrium constant for this reaction at 55 °C is 6.68. A pharmaceutical chemist makes up 15.0 L of a solution that is initially 0.275 M in acetic acid and 3.85 M in ethanol. At equilibrium, how many grams of ethyl acetate are formed?

## Le Châtelier's Principle (Section 15.7)

- 15.61**
- Consider the following equilibrium for which
- $\Delta H < 0$

How will each of the following changes affect an equilibrium mixture of the three gases: **(a)**  $\text{O}_2(g)$  is added to the system; **(b)** the reaction mixture is heated; **(c)** the volume of the reaction vessel is doubled; **(d)** a catalyst is added to the mixture; **(e)** the total pressure of the system is increased by adding a noble gas; **(f)**  $\text{SO}_3(g)$  is removed from the system?

- 15.62**
- Consider the reaction

Does each of the following increase, decrease, or leave unchanged the yield of NO at equilibrium? **(a)** increase  $[\text{NH}_3]$ ; **(b)** increase  $[\text{H}_2\text{O}]$ ; **(c)** decrease  $[\text{O}_2]$ ; **(d)** decrease the volume of the container in which the reaction occurs; **(e)** add a catalyst; **(f)** increase temperature.

- 15.63**
- How do the following changes affect the value of the equilibrium constant for a gas-phase exothermic reaction:
- (a)**
- removal of a reactant,
- (b)**
- removal of a product,
- (c)**
- decrease in the volume,
- (d)**
- decrease in the temperature,
- (e)**
- addition of a catalyst?

- 15.64**
- For a certain gas-phase reaction, the fraction of products in an equilibrium mixture is increased by either increasing the temperature or by increasing the volume of the reaction vessel.
- (a)**
- Is the reaction exothermic or endothermic?
- (b)**
- Does the balanced chemical equation have more molecules on the reactant side or product side?

- 15.65**
- Consider the following equilibrium between oxides of nitrogen

**(a)** Use data in Appendix C to calculate  $\Delta H^\circ$  for this reaction. **(b)** Will the equilibrium constant for the reaction increase or decrease with increasing temperature? **(c)** At constant temperature, would a change in the volume of the container affect the fraction of products in the equilibrium mixture?

- 15.66**
- Methanol (
- $\text{CH}_3\text{OH}$
- ) can be made by the reaction of CO with
- $\text{H}_2$
- :

**(a)** Use thermochemical data in Appendix C to calculate  $\Delta H^\circ$  for this reaction. **(b)** To maximize the equilibrium yield of methanol, would you use a high or low temperature? **(c)** To maximize the equilibrium yield of methanol, would you use a high or low pressure?

- 15.67**
- Ozone,
- $\text{O}_3$
- , decomposes to molecular oxygen in the stratosphere according to the reaction
- $2\text{O}_3(g) \longrightarrow 3\text{O}_2(g)$
- . Would an increase in pressure favor the formation of ozone or of oxygen?

- 15.68**
- The water–gas shift reaction
- $\text{CO}(g) + \text{H}_2\text{O}(g) \rightleftharpoons \text{CO}_2(g) + \text{H}_2(g)$
- is used industrially to produce hydrogen. The reaction enthalpy is
- $\Delta H^\circ = -41 \text{ kJ}$
- .
- (a)**
- To increase the equilibrium yield of hydrogen would you use high or low

temperature? (b) Could you increase the equilibrium yield of hydrogen by controlling the pressure of this reaction? If so would high or low pressure favor formation of  $\text{H}_2(\text{g})$ ?

- 15.69** (a) Is the dissociation of fluorine molecules into atomic fluorine,  $\text{F}_2(\text{g}) \rightleftharpoons 2\text{F}(\text{g})$  an exothermic or endothermic process? (b) If the temperature is raised by 100 K, does the equilibrium constant for this reaction increase or

decrease? (c) If the temperature is raised by 100 K, does the forward rate constant  $k_f$  increase by a larger or smaller amount than the reverse rate constant  $k_r$ ?

- 15.70** True or false: When the temperature of an exothermic reaction increases, the rate constant of the forward reaction decreases, which leads to a decrease in the equilibrium constant,  $K_c$ .

## Additional Exercises

- 15.71** Both the forward reaction and the reverse reaction in the following equilibrium are believed to be elementary steps:

At 25 °C, the rate constants for the forward and reverse reactions are  $1.4 \times 10^{-28} \text{ M}^{-1} \text{ s}^{-1}$  and  $9.3 \times 10^{10} \text{ M}^{-1} \text{ s}^{-1}$ , respectively. (a) What is the value for the equilibrium constant at 25 °C? (b) Are reactants or products more plentiful at equilibrium?

- 15.72** If  $K_c = 1$  for the equilibrium  $2\text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g})$ , what is the relationship between  $[\text{A}]$  and  $[\text{B}]$  at equilibrium?

- 15.73** A mixture of  $\text{CH}_4$  and  $\text{H}_2\text{O}$  is passed over a nickel catalyst at 1000 K. The emerging gas is collected in a 5.00-L flask and is found to contain 8.62 g of CO, 2.60 g of  $\text{H}_2$ , 43.0 g of  $\text{CH}_4$ , and 48.4 g of  $\text{H}_2\text{O}$ . Assuming that equilibrium has been reached, calculate  $K_c$  and  $K_p$  for the reaction  $\text{CH}_4(\text{g}) + \text{H}_2\text{O}(\text{g}) \rightleftharpoons \text{CO}(\text{g}) + 3\text{H}_2(\text{g})$ .

- 15.74** When 2.00 mol of  $\text{SO}_2\text{Cl}_2$  is placed in a 2.00-L flask at 303 K, 56% of the  $\text{SO}_2\text{Cl}_2$  decomposes to  $\text{SO}_2$  and  $\text{Cl}_2$ :

(a) Calculate  $K_c$  for this reaction at this temperature. (b) Calculate  $K_p$  for this reaction at 303 K. (c) According to Le Châtelier's principle, would the percent of  $\text{SO}_2\text{Cl}_2$  that decomposes increase, decrease or stay the same if the mixture were transferred to a 15.00-L vessel? (d) Use the equilibrium constant you calculated above to determine the percentage of  $\text{SO}_2\text{Cl}_2$  that decomposes when 2.00 mol of  $\text{SO}_2\text{Cl}_2$  is placed in a 15.00-L vessel at 303 K.

- 15.75** The value of the equilibrium constant  $K_c$  for the reaction  $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \rightleftharpoons 2\text{NH}_3(\text{g})$  changes in the following manner as a function of temperature

| Temperature (°C) | $K_c$ |
|------------------|-------|
| 300              | 9.6   |
| 400              | 0.50  |
| 500              | 0.058 |

(a) Based on the changes in  $K_c$  is this reaction exothermic or endothermic? (b) Use the standard enthalpies of formation given in Appendix C to determine the  $\Delta H$  for this reaction at standard conditions. Does this value agree with your prediction from part (a)? (c) If 0.025 mole of gaseous  $\text{NH}_3$  is added to a 1.00 L container and heated to 500 °C, what is the concentration of  $\text{NH}_3$  once the sample reaches equilibrium?

- 15.76** A sample of nitrosyl bromide ( $\text{NOBr}$ ) decomposes according to the equation

An equilibrium mixture in a 5.00-L vessel at 100 °C contains 3.22 g of  $\text{NOBr}$ , 3.08 g of  $\text{NO}$ , and 4.19 g of  $\text{Br}_2$ . (a) Calculate  $K_c$ . (b) What is the total pressure exerted by the mixture of gases? (c) What was the mass of the original sample of  $\text{NOBr}$ ?

- 15.77** Consider the hypothetical reaction  $\text{A}(\text{g}) \rightleftharpoons 2\text{B}(\text{g})$ . A flask is charged with 0.75 atm of pure A, after which it is allowed to reach equilibrium at 0 °C. At equilibrium, the partial pressure of A is 0.36 atm. (a) What is the total pressure in the flask at equilibrium? (b) What is the value of  $K_p$ ? (c) What could we do to maximize the yield of B?

- 15.78** As shown in Table 15.2, the equilibrium constant for the reaction  $\text{N}_2(\text{g}) + 3\text{H}_2(\text{g}) \rightleftharpoons 2\text{NH}_3(\text{g})$  is  $K_p = 4.34 \times 10^{-3}$  at 300 °C. Pure  $\text{NH}_3$  is placed in a 1.00-L flask and allowed to reach equilibrium at this temperature. There are 1.05 g  $\text{NH}_3$  in the equilibrium mixture. (a) What are the masses of  $\text{N}_2$  and  $\text{H}_2$  in the equilibrium mixture? (b) What was the initial mass of ammonia placed in the vessel? (c) What is the total pressure in the vessel?

- 15.79** For the equilibrium

$K_p = 8.5 \times 10^{-3}$  at 150 °C. If 0.025 atm of  $\text{IBr}$  is placed in a 2.0-L container, what is the partial pressure of all substances after equilibrium is reached?

- 15.80** For the equilibrium

$K_p = 0.052$  at 60 °C. (a) Calculate  $K_c$ . (b) After 3.00 g of solid  $\text{PH}_3\text{BCl}_3$  is added to a closed 1.500-L vessel at 60 °C, the vessel is charged with 0.0500 g of  $\text{BCl}_3(\text{g})$ . What is the equilibrium concentration of  $\text{PH}_3$ ?

- [15.81]** Solid  $\text{NH}_4\text{SH}$  is introduced into an evacuated flask at 24 °C. The following reaction takes place:

At equilibrium, the total pressure (for  $\text{NH}_3$  and  $\text{H}_2\text{S}$  taken together) is 0.614 atm. What is  $K_p$  for this equilibrium at 24 °C?

- [15.82]** A 0.831-g sample of  $\text{SO}_3$  is placed in a 1.00-L container and heated to 1100 K. The  $\text{SO}_3$  decomposes to  $\text{SO}_2$  and  $\text{O}_2$ :

At equilibrium, the total pressure in the container is 1.300 atm. Find the values of  $K_p$  and  $K_c$  for this reaction at 1100 K.

- 15.83** Nitric oxide ( $\text{NO}$ ) reacts readily with chlorine gas as follows:

At 700 K, the equilibrium constant  $K_p$  for this reaction is 0.26. Predict the behavior of each of the following mixtures at this temperature and indicate whether or not the mixtures are at equilibrium. If not, state whether the mixture will need to produce more products or reactants to reach equilibrium.

- (a)  $P_{\text{NO}} = 0.15 \text{ atm}$ ,  $P_{\text{Cl}_2} = 0.31 \text{ atm}$ ,  $P_{\text{NOCl}} = 0.11 \text{ atm}$   
 (b)  $P_{\text{NO}} = 0.12 \text{ atm}$ ,  $P_{\text{Cl}_2} = 0.10 \text{ atm}$ ,  $P_{\text{NOCl}} = 0.050 \text{ atm}$   
 (c)  $P_{\text{NO}} = 0.15 \text{ atm}$ ,  $P_{\text{Cl}_2} = 0.20 \text{ atm}$ ,  
 $P_{\text{NOCl}} = 5.10 \times 10^{-3} \text{ atm}$

- 15.84**
- At 900 °C,
- $K_c = 0.0108$
- for the reaction

A mixture of  $\text{CaCO}_3$ ,  $\text{CaO}$ , and  $\text{CO}_2$  is placed in a 10.0-L vessel at 900 °C. For the following mixtures, will the amount of  $\text{CaCO}_3$  increase, decrease, or remain the same as the system approaches equilibrium?

(a) 15.0 g  $\text{CaCO}_3$ , 15.0 g  $\text{CaO}$ , and 4.25 g  $\text{CO}_2$

(b) 2.50 g  $\text{CaCO}_3$ , 25.0 g  $\text{CaO}$ , and 5.66 g  $\text{CO}_2$

(a) 30.5 g  $\text{CaCO}_3$ , 25.5 g  $\text{CaO}$ , and 6.48 g  $\text{CO}_2$

- 15.85**
- When 1.50 mol
- $\text{CO}_2$
- and 1.50 mol
- $\text{H}_2$
- are placed in a 3.00-L container at 395 °C, the following reaction occurs:
- $\text{CO}_2(g) + \text{H}_2(g) \rightleftharpoons \text{CO}(g) + \text{H}_2\text{O}(g)$
- . If
- $K_c = 0.802$
- , what are the concentrations of each substance in the equilibrium mixture?

- 15.86**
- The equilibrium constant
- $K_c$
- for
- $\text{C}(s) + \text{CO}_2(g) \rightleftharpoons 2 \text{CO}(g)$
- is 1.9 at 1000 K and 0.133 at 298 K. (a) If excess C is allowed to react with 25.0 g of
- $\text{CO}_2$
- in a 3.00-L vessel at 1000 K, how many grams of CO are produced? (b) How many grams of C are consumed? (c) If a smaller vessel is used for the reaction, will the yield of CO be greater or smaller? (d) Is the reaction endothermic or exothermic?

- 15.87**
- NiO is to be reduced to nickel metal in an industrial process by use of the reaction

At 1600 K, the equilibrium constant for the reaction is  $K_p = 6.0 \times 10^2$ . If a CO pressure of 150 torr is to be employed in the furnace and total pressure never exceeds 760 torr, will reduction occur?

- 15.88**
- Le Châtelier noted that many industrial processes of his time could be improved by an understanding of chemical equilibria. For example, the reaction of iron oxide with carbon monoxide was used to produce elemental iron and
- $\text{CO}_2$
- according to the reaction

Even in Le Châtelier's time, it was noted that a great deal of CO was wasted, expelled through the chimneys over the furnaces. Le Châtelier wrote, "Because this incomplete reaction was thought to be due to an insufficiently prolonged contact between carbon monoxide and the iron ore [oxide], the dimensions of the furnaces have been increased. In England, they have been made as high as 30 m. But the proportion of carbon monoxide escaping has not diminished, thus demonstrating, by an experiment costing several hundred thousand francs, that the reduction of iron oxide by carbon monoxide is a limited reaction. Acquaintance with the laws of chemical equilibrium would have permitted the same conclusion to be reached more rapidly and far more economically." What does this anecdote tell us about the equilibrium constant for this reaction?

- [15.89]**
- At 700 K, the equilibrium constant for the reaction

is  $K_p = 0.76$ . A flask is charged with 2.00 atm of  $\text{CCl}_4$ , which then reaches equilibrium at 700 K. (a) What

fraction of the  $\text{CCl}_4$  is converted into C and  $\text{Cl}_2$ ? (b) What are the partial pressures of  $\text{CCl}_4$  and  $\text{Cl}_2$  at equilibrium?

- [15.90]**
- The reaction
- $\text{PCl}_3(g) + \text{Cl}_2(g) \rightleftharpoons \text{PCl}_5(g)$
- has
- $K_p = 0.0870$
- at 300 °C. A flask is charged with 0.50 atm
- $\text{PCl}_3$
- , 0.50 atm
- $\text{Cl}_2$
- , and 0.20 atm
- $\text{PCl}_5$
- at this temperature. (a) Use the reaction quotient to determine the direction the reaction must proceed to reach equilibrium. (b) Calculate the equilibrium partial pressures of the gases. (c) What effect will increasing the volume of the system have on the mole fraction of
- $\text{Cl}_2$
- in the equilibrium mixture? (d) The reaction is exothermic. What effect will increasing the temperature of the system have on the mole fraction of
- $\text{Cl}_2$
- in the equilibrium mixture?

- [15.91]**
- An equilibrium mixture of
- $\text{H}_2$
- ,
- $\text{I}_2$
- , and HI at 458 °C contains 0.112 mol
- $\text{H}_2$
- , 0.112 mol
- $\text{I}_2$
- , and 0.775 mol HI in a 5.00-L vessel. What are the equilibrium partial pressures when equilibrium is reestablished following the addition of 0.200 mol of HI?

- [15.92]**
- Consider the hypothetical reaction
- $\text{A}(g) + 2 \text{B}(g) \rightleftharpoons 2 \text{C}(g)$
- , for which
- $K_c = 0.25$
- at a certain temperature. A 1.00-L reaction vessel is loaded with 1.00 mol of compound C, which is allowed to reach equilibrium. Let the variable
- $x$
- represent the number of mol/L of compound A present at equilibrium. (a) In terms of
- $x$
- , what are the equilibrium concentrations of compounds B and C? (b) What limits must be placed on the value of
- $x$
- so that all concentrations are positive? (c) By putting the equilibrium concentrations (in terms of
- $x$
- ) into the equilibrium-constant expression, derive an equation that can be solved for
- $x$
- . (d) The equation from part (c) is a cubic equation (one that has the form
- $ax^3 + bx^2 + cx + d = 0$
- ). In general, cubic equations cannot be solved in closed form. However, you can estimate the solution by plotting the cubic equation in the allowed range of
- $x$
- that you specified in part (b). The point at which the cubic equation crosses the
- $x$
- axis is the solution. (e) From the plot in part (d), estimate the equilibrium concentrations of A, B, and C. (Hint: You can check the accuracy of your answer by substituting these concentrations into the equilibrium expression.)

- 15.93**
- At 1200 K, the approximate temperature of automobile exhaust gases (Figure 15.15),
- $K_p$
- for the reaction

is about  $1 \times 10^{-13}$ . Assuming that the exhaust gas (total pressure 1 atm) contains 0.2% CO, 12%  $\text{CO}_2$ , and 3%  $\text{O}_2$  by volume, is the system at equilibrium with respect to the  $\text{CO}_2$  reaction? Based on your conclusion, would the CO concentration in the exhaust be decreased or increased by a catalyst that speeds up the  $\text{CO}_2$  reaction? Recall that at a fixed pressure and temperature, volume % = mol %.

- 15.94**
- At a temperature of 700 K, the forward and reverse rate constants for the reaction
- $2 \text{HI}(g) \rightleftharpoons \text{H}_2(g) + \text{I}_2(g)$
- are
- $k_f = 1.8 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$
- and
- $k_r = 0.063 \text{ M}^{-1} \text{ s}^{-1}$
- . (a) What is the value of the equilibrium constant
- $K_c$
- at 700 K? (b) Is the forward reaction endothermic or exothermic if the rate constants for the same reaction have values of
- $k_f = 0.097 \text{ M}^{-1} \text{ s}^{-1}$
- and
- $k_r = 2.6 \text{ M}^{-1} \text{ s}^{-1}$
- at 800 K?

## Integrative Exercises

- 15.95**
- Consider the reaction
- $\text{IO}_4^-(aq) + 2 \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_4\text{IO}_6^-(aq)$
- ;
- $K_c = 3.5 \times 10^{-2}$
- . If you start with 25.0 mL of a 0.905 M solution of
- $\text{NaIO}_4$
- , and then dilute it with water to 500.0 mL, what is the concentration of
- $\text{H}_4\text{IO}_6^-$
- at equilibrium?

- 15.96**
- The following equilibria were measured at 823 K:

(a) Use these equilibria to calculate the equilibrium constant,  $K_c$ , for the reaction  $\text{CoO}(s) + \text{CO}(g) \rightleftharpoons \text{Co}(s) + \text{CO}_2(g)$  at 823 K. (b) Based on your answer to part (a), would you say that carbon monoxide is a stronger or weaker reducing agent than  $\text{H}_2$  at  $T = 823$  K? (c) If you were to place 5.00 g of  $\text{CoO}(s)$  in a sealed tube with a volume of 250 mL that contains  $\text{CO}(g)$  at a pressure of 1.00 atm and a temperature of 298 K, what is the concentration of the  $\text{CO}$  gas? Assume there is no reaction at this temperature and that the  $\text{CO}$  behaves as an ideal gas (you can neglect the volume of the solid). (d) If the reaction vessel from part (c) is heated to 823 K and allowed to come to equilibrium, how much  $\text{CoO}(s)$  remains?

**[15.97]** Consider the equilibrium  $A \rightleftharpoons B$  in which both the forward and reverse reactions are elementary (single-step) reactions. Assume that the only effect of a catalyst on the reaction is to lower the activation energies of the forward and reverse reactions, as shown in Figure 15.15. Using the Arrhenius equation (Section 14.5), prove that the equilibrium constant is the same for the catalyzed reaction as for the uncatalyzed one.

**[15.98]** The phase diagram for  $\text{SO}_2$  is shown here. (a) What does this diagram tell you about the enthalpy change in the reaction  $\text{SO}_2(l) \rightarrow \text{SO}_2(g)$ ? (b) Calculate the equilibrium constant for this reaction at 100 °C and at 0 °C. (c) Why is it not possible to calculate an equilibrium constant between the gas and liquid phases in the supercritical region? (d) At which of the three points marked in red does  $\text{SO}_2(g)$  most closely approach ideal-gas behavior? (e) At which of the three red points does  $\text{SO}_2(g)$  behave least ideally?

**15.99** At 800 K, the equilibrium constant for the reaction  $\text{A}_2(g) \rightleftharpoons 2 \text{A}(g)$  is  $K_c = 3.1 \times 10^{-4}$ . (a) Assuming both forward and reverse reactions are elementary reactions, which rate constant do you expect to be larger,  $k_f$  or  $k_r$ ? (b) If the value of  $k_f = 0.27 \text{ s}^{-1}$ , what is the value of  $k_r$  at 800 K? (c) Based on the nature of the reaction, do you expect the forward reaction to be endothermic or exothermic? (d) If the temperature is raised to 1000 K, will the reverse rate constant  $k_r$  increase or decrease? Will the change in  $k_r$  be larger or smaller than the change in  $k_f$ ?

**15.100** In Section 11.5, we defined the vapor pressure of a liquid in terms of an equilibrium. (a) Write the equation representing the equilibrium between liquid water and water vapor and the corresponding expression for  $K_p$ . (b) By using data in Appendix B, give the value of  $K_p$  for this reaction at 30 °C. (c) What is the value of  $K_p$  for any liquid in equilibrium with its vapor at the normal boiling point of the liquid?

**15.101** Water molecules in the atmosphere can form hydrogen-bonded dimers,  $(\text{H}_2\text{O})_2$ . The presence of these dimers is thought to be important in the nucleation of ice crystals in the atmosphere and in the formation of acid rain. (a) Using VSEPR theory, draw the structure of a water dimer, using dashed lines to indicate intermolecular interactions. (b) What kind of intermolecular forces are involved in water dimer formation? (c) The  $K_p$  for water dimer formation in the gas phase is 0.050 at 300 K and 0.020 at 350 K. Is water dimer formation endothermic or exothermic?

**15.102** The protein hemoglobin (Hb) transports  $\text{O}_2$  in mammalian blood. Each Hb can bind 4  $\text{O}_2$  molecules. The equilibrium constant for the  $\text{O}_2$  binding reaction is higher in fetal hemoglobin than in adult hemoglobin. In discussing protein oxygen-binding capacity, biochemists use a measure called the *P50 value*, defined as the partial pressure of oxygen at which 50% of the protein is saturated. Fetal hemoglobin has a P50 value of 19 torr, and adult hemoglobin has a P50 value of 26.8 torr. Use these data to estimate how much larger  $K_c$  is for the aqueous reaction  $4 \text{O}_2(g) + \text{Hb}(aq) \rightleftharpoons [\text{Hb}(\text{O}_2)_4(aq)]$  in a fetus, compared to  $K_c$  for the same reaction in an adult.

## Design an Experiment

The reaction between hydrogen and iodine to form hydrogen iodide was used to illustrate Beer's law in Chapter 14 (Figure 14.5). The reaction can be monitored using visible-light spectroscopy because  $\text{I}_2$  has a violet color while  $\text{H}_2$  and  $\text{HI}$  are colorless. At 300 K, the equilibrium constant for the reaction  $\text{H}_2(g) + \text{I}_2(g) \rightleftharpoons 2 \text{HI}(g)$  is  $K_c = 794$ . To answer the following questions assume you have access to hydrogen, iodine, hydrogen iodide, a transparent reaction vessel, a visible-light spectrometer, and a means for changing the temperature.

(a) Which gas or gases concentration could you readily monitor with the spectrometer? (b) To use Beer's law (Equation 14.5) you need to determine the extinction coefficient,  $\epsilon$ , for the substance in question. How would you determine  $\epsilon$ ? (c) Describe an experiment for determining the equilibrium constant at 600 K. (d) Use the bond enthalpies in Table 8.4 to estimate the enthalpy of this reaction. (e) Based on your answer to part (d), would you expect  $K_c$  at 600 K to be larger or smaller than at 300 K?

16

# ACID–BASE EQUILIBRIA

Acids and bases are common both in nature and in the laboratory. Citric acid and ascorbic acid (also known as Vitamin C) are what gives citrus fruits their characteristic tangy, sour tastes (Figure 16.1).

Acids and bases are among the most important substances in chemistry, and they affect our daily lives in innumerable ways. Not only are they present in our foods, but acids and bases are also crucial components of living systems, such as the amino acids that are used to synthesize proteins and the nucleic acids that code genetic information. Both citric and malic acids are among several acids involved in the Krebs cycle (also called the citric acid cycle) that is used to generate energy in aerobic organisms. The application of acid–base chemistry has also had critical roles in shaping modern society, including such human-driven activities as industrial manufacturing, the creation of advanced pharmaceuticals, and many aspects of the environment.

The impact of acids and bases depends not only on the type of acid or base, but also on how much is present. The time required for a metal object immersed in water to corrode, the ability of an aquatic environment to support fish and plant life, the fate of pollutants washed out of the air by rain, and even the rates of reactions that maintain our lives all critically depend on the acidity or basicity of solutions. We will thus explore in this chapter how we measure acidity and how the chemical reactions of acids and bases depend on their concentrations.

We first encountered acids and bases in Sections 2.8 and 4.3, in which we discussed the naming of acids and some simple acid–base reactions, respectively. In this chapter we take a closer look at how acids and bases are identified and characterized. In doing so, we consider their behavior both in terms of their structure and bonding and in terms of the chemical equilibria in which they participate.

◀ **CITRUS FRUITS.** Oranges, lemons, and other fruits contain several acids that contribute to their characteristic flavors.

## WHAT'S AHEAD

- 16.1 ▶ Arrhenius Acids and Bases** Recall that the *Arrhenius* definitions of acids and bases are the ones we learned early on: acids are compounds that increase the proton ion concentration in water, and bases are compounds that increase the hydroxide ion concentration in water.
- 16.2 ▶ Brønsted–Lowry Acids and Bases** Learn that a Brønsted–Lowry acid is a *proton donor* and a Brønsted–Lowry base is a *proton acceptor*. Two species that differ by the presence or absence of a proton are known as a *conjugate acid–base pair*.
- 16.3 ▶ The Autoionization of Water** Recognize that the *autoionization* of water produces small quantities of  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  ions. The *equilibrium constant* for autoionization,  $K_w = [\text{H}_3\text{O}^+][\text{OH}^-]$  defines the relationship between  $\text{H}_3\text{O}^+$  and  $\text{OH}^-$  concentrations in aqueous solutions.
- 16.4 ▶ The pH Scale** Use the pH scale to describe the acidity or basicity of an aqueous solution. Neutral solutions have  $\text{pH} = 7$ , acidic solutions have  $\text{pH}$  below 7, and basic solutions have  $\text{pH}$  above 7.
- 16.5 ▶ Strong Acids and Bases** Categorize acids and bases as being either strong or weak electrolytes. *Strong* acids and bases are strong electrolytes, ionizing or dissociating completely in aqueous solution. *Weak* acids and bases are weak electrolytes and ionize only partially.
- 16.6 ▶ Weak Acids** Learn that the ionization of a weak acid in water is an equilibrium process with an equilibrium constant  $K_a$  and be able to use it to calculate the  $\text{pH}$  of a weak acid solution.
- 16.7 ▶ Weak Bases** Learn that the ionization of a weak base in water is an equilibrium process with equilibrium constant  $K_b$  that can be used to calculate the  $\text{pH}$  of a weak base solution.
- 16.8 ▶ Relationship Between  $K_a$  and  $K_b$**  Recognize that  $K_a$  and  $K_b$  are related by the relationship  $K_a \times K_b = K_w$ . Hence, the stronger an acid, the weaker its conjugate base.
- 16.9 ▶ Acid–Base Properties of Salt Solutions** Learn the ions of a soluble ionic compound can serve as Brønsted–Lowry acids or bases.
- 16.10 ▶ Acid–Base Behavior and Chemical Structure** Explore the relationship between chemical structure and acid–base behavior.
- 16.11 ▶ Lewis Acids and Bases** Recognize the most general definition of acids and bases, namely, the Lewis acid–base definition. A Lewis acid is an *electron-pair acceptor*, and a Lewis base is an *electron-pair donor*.

► **Figure 16.1** Two organic acids: Citric acid,  $C_6H_8O_7$ , and ascorbic acid,  $C_6H_8O_6$ .

## 16.1 | Arrhenius Acids and Bases

From the earliest days of experimental chemistry, scientists have recognized acids and bases by their characteristic properties. Acids have a sour taste and cause certain dyes to change color, whereas bases have a bitter taste and feel slippery (soap is a good example). Use of the term *base* comes from the old English meaning of the word, “to bring low.” (We still use the word *debase* in this sense, meaning to lower the value of something.) When a base is added to an acid, the base “lowers” the amount of acid. Indeed, when acids and bases are mixed in the right proportions, their characteristic properties seem to disappear altogether. [∞ \(Section 4.3\)](#)

By 1830 it was evident that all acids contain hydrogen but not all hydrogen-containing substances are acids. During the 1880s, the Swedish chemist Svante Arrhenius (1859–1927) defined acids as substances that produce  $H^+$  ions in water and bases as substances that produce  $OH^-$  ions in water. Over time the Arrhenius concept of acids and bases came to be stated in the following way:

- An *acid* is a substance that, when dissolved in water, increases the concentration of  $H^+$  ions.
- A *base* is a substance that, when dissolved in water, increases the concentration of  $OH^-$  ions.

Hydrogen chloride gas, which is highly soluble in water, is an example of an Arrhenius acid. When it dissolves in water,  $HCl(g)$  produces hydrated  $H^+$  and  $Cl^-$  ions:

The aqueous solution of  $HCl$  is known as *hydrochloric acid*. Concentrated hydrochloric acid is about 37%  $HCl$  by mass and is 12 *M* in  $HCl$ .

Sodium hydroxide is an Arrhenius base. Because  $NaOH$  is an ionic compound, it dissociates into  $Na^+$  and  $OH^-$  ions when it dissolves in water, thereby increasing the concentration of  $OH^-$  ions in the solution.

### Give It Some Thought

Which two ions are central to the Arrhenius definitions of acids and bases?

## 16.2 | Brønsted–Lowry Acids and Bases

The Arrhenius concept of acids and bases, while useful, is rather limited. For one thing, it is restricted to aqueous solutions. In 1923 the Danish chemist Johannes Brønsted (1879–1947) and the English chemist Thomas Lowry (1874–1936) independently proposed a more general definition of acids and bases. Their concept is based on the fact that *acid–base reactions involve the transfer of  $H^+$  ions from one substance to another*. To understand this definition better, we need to examine the behavior of the  $H^+$  ion in water more closely.

### The $H^+$ Ion in Water

We might at first imagine that ionization of HCl in water produces just  $H^+$  and  $Cl^-$ . A hydrogen ion is no more than a bare proton—a very small particle with a positive charge. As such, an  $H^+$  ion interacts strongly with any source of electron density, such as the nonbonding electron pairs on the oxygen atoms of water molecules. For example, the interaction of a proton with water forms the **hydronium ion**,  $H_3O^+(aq)$ :

The behavior of  $H^+$  ions in liquid water is complex because hydronium ions interact with additional water molecules via the formation of hydrogen bonds.  (Section 11.2) For example, the  $H_3O^+$  ion bonds to additional  $H_2O$  molecules to generate such ions as  $H_5O_2^+$  and  $H_9O_4^+$  (Figure 16.2).

Chemists use the notations  $H^+(aq)$  and  $H_3O^+(aq)$  interchangeably to represent the hydrated proton responsible for the characteristic properties of aqueous solutions of acids. We often use the notation  $H^+(aq)$  for simplicity and convenience, as we did in Chapter 4 and Equation 16.1. The notation  $H_3O^+(aq)$ , however, more closely represents reality.

### Proton-Transfer Reactions

In the reaction that occurs when HCl dissolves in water, the HCl molecule transfers an  $H^+$  ion (a proton) to a water molecule. Thus, we can represent the reaction as occurring between an HCl molecule and a water molecule to form hydronium and chloride ions:

Notice that the reaction in Equation 16.3 involves a *proton donor* (HCl) and a *proton acceptor* ( $H_2O$ ). The notion of transfer from a proton donor to a proton acceptor is the key idea in the Brønsted–Lowry definition of acids and bases:

- **Brønsted–Lowry acid** An *acid* is a substance (molecule or ion) that *donates* a proton to another substance.
- **Brønsted–Lowry base** A *base* is a substance that *accepts* a proton.

### Go Figure

Which type of intermolecular force do the dotted lines in this figure represent?

▲ **Figure 16.2** Ball-and-stick models and Lewis structures for two hydrated hydronium ions.

Thus, when HCl dissolves in water (Equation 16.3), HCl acts as a Brønsted–Lowry acid (it donates a proton to H<sub>2</sub>O), and H<sub>2</sub>O acts as a Brønsted–Lowry base (it accepts a proton from HCl). We see that the H<sub>2</sub>O molecule serves as a proton acceptor by using one of the nonbonding pairs of electrons on the O atom to “attach” the proton.

Because the emphasis in the Brønsted–Lowry concept is on proton transfer, the concept also applies to reactions that do not occur in aqueous solution. In the reaction between gas phase HCl and NH<sub>3</sub>, for example, a proton is transferred from the acid HCl to the base NH<sub>3</sub>:

▲ **Figure 16.3** Fog of NH<sub>4</sub>Cl(s) caused by the reaction of HCl(g) and NH<sub>3</sub>(g).

The hazy film that forms on the windows of general chemistry laboratories and on glassware in the laboratory (**Figure 16.3**) is largely solid NH<sub>4</sub>Cl formed by the gas-phase reaction between HCl and NH<sub>3</sub>.

Let's consider another example that compares the relationship between the Arrhenius and Brønsted–Lowry definitions of acids and bases—an aqueous solution of ammonia, in which we have the equilibrium:

Ammonia is a Brønsted–Lowry base because it accepts a proton from H<sub>2</sub>O. Ammonia is also an Arrhenius base because adding it to water leads to an increase in the concentration of OH<sup>−</sup>(aq).

*The transfer of a proton always involves both an acid (donor) and a base (acceptor).*

In other words, a substance can function as an acid only if another substance simultaneously behaves as a base. To be a Brønsted–Lowry acid, a molecule or ion must have a hydrogen atom it can lose as an H<sup>+</sup> ion. To be a Brønsted–Lowry base, a molecule or ion must have a nonbonding pair of electrons it can use to bind the H<sup>+</sup> ion.

Some substances can act as an acid in one reaction and as a base in another. For example, H<sub>2</sub>O is a Brønsted–Lowry base in Equation 16.3 and a Brønsted–Lowry acid in Equation 16.5. A substance capable of acting as either an acid or a base is called **amphiprotic**. An amphiprotic substance acts as a base when combined with something more strongly acidic than itself and as an acid when combined with something more strongly basic than itself.

### Give It Some Thought

In the forward reaction of this equilibrium, which substance acts as the Brønsted–Lowry base?

## Conjugate Acid–Base Pairs

In any acid–base equilibrium, both the forward reaction (to the right) and the reverse reaction (to the left) involve proton transfer. For example, consider the reaction of an acid HA with water:

In the forward reaction, HA donates a proton to  $\text{H}_2\text{O}$ . Therefore, HA is the Brønsted–Lowry acid and  $\text{H}_2\text{O}$  is the Brønsted–Lowry base. In the reverse reaction, the  $\text{H}_3\text{O}^+$  ion donates a proton to the  $\text{A}^-$  ion, so  $\text{H}_3\text{O}^+$  is the acid and  $\text{A}^-$  is the base. When the acid HA donates a proton, it leaves behind a substance,  $\text{A}^-$ , that can act as a base. Likewise, when  $\text{H}_2\text{O}$  acts as a base, it generates  $\text{H}_3\text{O}^+$ , which can act as an acid.

An acid and a base such as HA and  $\text{A}^-$  that differ only in the presence or absence of a proton are called a **conjugate acid–base pair**. Every acid has a **conjugate base**, formed by removing a proton from the acid. For example,  $\text{OH}^-$  is the conjugate base of  $\text{H}_2\text{O}$ , and  $\text{A}^-$  is the conjugate base of HA. Every base has a **conjugate acid**, formed by adding a proton to the base. Thus,  $\text{H}_3\text{O}^+$  is the conjugate acid of  $\text{H}_2\text{O}$ , and HA is the conjugate acid of  $\text{A}^-$ .

In any acid–base (proton-transfer) reaction, we can identify two sets of conjugate acid–base pairs. For example, consider the reaction between nitrous acid and water:

Likewise, for the reaction between  $\text{NH}_3$  and  $\text{H}_2\text{O}$  (Equation 16.5), we have

## Sample Exercise 16.1

### Identifying Conjugate Acids and Bases

- (a) What is the conjugate base of  $\text{HClO}_4$ ,  $\text{H}_2\text{S}$ ,  $\text{PH}_4^+$ ,  $\text{HCO}_3^-$ ?  
 (b) What is the conjugate acid of  $\text{CN}^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{H}_2\text{O}$ ,  $\text{HCO}_3^-$ ?

### SOLUTION

**Analyze** We are asked to give the conjugate base for several acids and the conjugate acid for several bases.

**Plan** The conjugate base of a substance is simply the parent substance minus one proton, and the conjugate acid of a substance is the parent substance plus one proton.

#### Solve

- (a) If we remove a proton from  $\text{HClO}_4$ , we obtain  $\text{ClO}_4^-$ , which is its conjugate base. The other conjugate bases are  $\text{HS}^-$ ,  $\text{PH}_3$ , and  $\text{CO}_3^{2-}$ .  
 (b) If we add a proton to  $\text{CN}^-$ , we get  $\text{HCN}$ , its conjugate acid. The other conjugate acids are  $\text{HSO}_4^-$ ,  $\text{H}_3\text{O}^+$ , and  $\text{H}_2\text{CO}_3$ . Notice that the hydrogen carbonate ion ( $\text{HCO}_3^-$ ) is amphoteric. It can act as either an acid or a base.

### Practice Exercise 1

Consider the following equilibrium reaction:

Which substances are acting as acids in the reaction?

- (a)  $\text{HSO}_4^-$  and  $\text{OH}^-$   
 (b)  $\text{HSO}_4^-$  and  $\text{H}_2\text{O}$   
 (c)  $\text{OH}^-$  and  $\text{SO}_4^{2-}$   
 (d)  $\text{SO}_4^{2-}$  and  $\text{H}_2\text{O}$   
 (e) None of the substances are acting as acids in this reaction.

### Practice Exercise 2

Write the formula for the conjugate acid of each of the following:  $\text{HSO}_3^-$ ,  $\text{F}^-$ ,  $\text{PO}_4^{3-}$ ,  $\text{CO}$ .

Once you become proficient at identifying conjugate acid–base pairs it is not difficult to write equations for reactions involving Brønsted–Lowry acids and bases (proton-transfer reactions).

## Sample Exercise 16.2

### Writing Equations for Proton-Transfer Reactions

The hydrogen sulfite ion ( $\text{HSO}_3^-$ ) is amphiprotic. Write an equation for the reaction of  $\text{HSO}_3^-$  with water **(a)** in which the ion acts as an acid and **(b)** in which the ion acts as a base. In both cases identify the conjugate acid–base pairs.

### SOLUTION

**Analyze and Plan** We are asked to write two equations representing reactions between  $\text{HSO}_3^-$  and water, one in which  $\text{HSO}_3^-$  should donate a proton to water, thereby acting as a Brønsted–Lowry acid, and one in which  $\text{HSO}_3^-$  should accept a proton from water, thereby acting as a base. We are also asked to identify the conjugate pairs in each equation.

#### Solve

The conjugate pairs in this equation are  $\text{HSO}_3^-$  (acid) and  $\text{SO}_3^{2-}$  (conjugate base), and  $\text{H}_2\text{O}$  (base) and  $\text{H}_3\text{O}^+$  (conjugate acid).

The conjugate pairs in this equation are  $\text{H}_2\text{O}$  (acid) and  $\text{OH}^-$  (conjugate base), and  $\text{HSO}_3^-$  (base) and  $\text{H}_2\text{SO}_3$  (conjugate acid).

### Practice Exercise 1

The dihydrogen phosphate ion,  $\text{H}_2\text{PO}_4^-$ , is amphiprotic. In which of the following reactions is this ion serving as a base?

- (i)  $\text{H}_3\text{O}^+(aq) + \text{H}_2\text{PO}_4^-(aq) \rightleftharpoons \text{H}_3\text{PO}_4(aq) + \text{H}_2\text{O}(l)$   
 (ii)  $\text{H}_3\text{O}^+(aq) + \text{HPO}_4^{2-}(aq) \rightleftharpoons \text{H}_2\text{PO}_4^-(aq) + \text{H}_2\text{O}(l)$   
 (iii)  $\text{H}_3\text{PO}_4(aq) + \text{HPO}_4^{2-}(aq) \rightleftharpoons 2\text{H}_2\text{PO}_4^-(aq)$

- (a)** i only   **(b)** i and ii   **(c)** i and iii   **(d)** ii and iii  
**(e)** i, ii, and iii

### Practice Exercise 2

When lithium oxide ( $\text{Li}_2\text{O}$ ) is dissolved in water, the solution turns basic from the reaction of the oxide ion ( $\text{O}^{2-}$ ) with water. Write the equation for this reaction and identify the conjugate acid–base pairs.

## Relative Strengths of Acids and Bases

Some acids are better proton donors than others, and some bases are better proton acceptors than others. If we arrange acids in order of their ability to donate a proton, we find that the more easily a substance gives up a proton, the less easily its conjugate base accepts a proton. Similarly, the more easily a base accepts a proton, the less easily its conjugate acid gives up a proton. In other words, *the stronger an acid, the weaker its conjugate base, and the stronger a base, the weaker its conjugate acid*. Thus, if we know how readily an acid donates protons, we also know something about how readily its conjugate base accepts protons.

The inverse relationship between the strengths of acids and their conjugate bases is illustrated in **Figure 16.4**. Here we have grouped acids and bases into three broad categories based on their behavior in water:

1. A **strong acid** completely transfers its protons to water, leaving essentially no undissociated molecules in solution.  (Section 4.3) Its conjugate base has a negligible tendency to accept protons in aqueous solution. (*The conjugate base of a strong acid shows negligible basicity.*)
2. A **weak acid** only partially dissociates in aqueous solution and therefore exists in the solution as a mixture of the undissociated acid and its conjugate base. The conjugate base of a weak acid shows a slight ability to remove protons from water. (*The conjugate base of a weak acid is a weak base.*)
3. A substance with **negligible acidity** contains hydrogen but does not demonstrate any acidic behavior in water. Its conjugate base is a strong base, reacting completely with water, to form  $\text{OH}^-$  ions. (*The conjugate base of a substance with negligible acidity is a strong base.*)

The ions  $\text{H}_3\text{O}^+(aq)$  and  $\text{OH}^-(aq)$  are, respectively, the strongest possible acid and strongest possible base that can exist at equilibrium in aqueous solution. Stronger acids react with water to produce  $\text{H}_3\text{O}^+(aq)$  ions, and stronger bases react with water to produce  $\text{OH}^-(aq)$  ions, a phenomenon known as the *leveling effect*.

## Go Figure

If  $\text{O}^{2-}$  ions are added to water, what reaction, if any, occurs?

|                    | ACID                              |  | BASE                      |                     |
|--------------------|-----------------------------------|--|---------------------------|---------------------|
| Strong acids       | HCl                               | ↑<br>Base strength increasing<br>↓<br>Acid strength increasing | $\text{Cl}^-$             | Negligible basicity |
|                    | $\text{H}_2\text{SO}_4$           |  | $\text{HSO}_4^-$          |                     |
|                    | $\text{HNO}_3$                    |  | $\text{NO}_3^-$           |                     |
|                    | $\text{H}_3\text{O}^+(\text{aq})$ |  | $\text{H}_2\text{O}$      |                     |
|                    | $\text{HSO}_4^-$                  |  | $\text{SO}_4^{2-}$        |                     |
| Weak acids         | $\text{H}_3\text{PO}_4$           |  | $\text{H}_2\text{PO}_4^-$ | Weak bases          |
|                    | HF                                |  | $\text{F}^-$              |                     |
|                    | $\text{CH}_3\text{COOH}$          |  | $\text{CH}_3\text{COO}^-$ |                     |
|                    | $\text{H}_2\text{CO}_3$           |  | $\text{HCO}_3^-$          |                     |
|                    | $\text{H}_2\text{S}$              |  | $\text{HS}^-$             |                     |
|                    | $\text{H}_2\text{PO}_4^-$         |  | $\text{HPO}_4^{2-}$       |                     |
|                    | $\text{NH}_4^+$                   |  | $\text{NH}_3$             |                     |
|                    | $\text{HCO}_3^-$                  |  | $\text{CO}_3^{2-}$        |                     |
|                    | $\text{HPO}_4^{2-}$               |  | $\text{PO}_4^{3-}$        |                     |
|                    | $\text{H}_2\text{O}$              |  | $\text{OH}^-$             |                     |
| Negligible acidity | $\text{OH}^-$                     |  | $\text{O}^{2-}$           | Strong bases        |
|                    | $\text{H}_2$                      |  | $\text{H}^-$              |                     |
|                    | $\text{CH}_4$                     |  | $\text{CH}_3^-$           |                     |

▲ **Figure 16.4** Relative strengths of select conjugate acid–base pairs. The two members of each pair are listed opposite each other in the two columns.

## Give It Some Thought

Given that  $\text{HClO}_4$  is a strong acid, how would you classify the basicity of  $\text{ClO}_4^-$ ?

We can think of proton-transfer reactions as being governed by the relative abilities of two bases to abstract protons. For example, consider the proton transfer that occurs when an acid HA dissolves in water:

If  $\text{H}_2\text{O}$  (the base in the forward reaction) is a stronger base than  $\text{A}^-$  (the conjugate base of HA), it is favorable to transfer the proton from HA to  $\text{H}_2\text{O}$ , producing  $\text{H}_3\text{O}^+$  and  $\text{A}^-$ . As a result, the equilibrium lies to the right. This describes the behavior of a strong acid in water. For example, when HCl dissolves in water, the solution consists almost entirely of  $\text{H}_3\text{O}^+$  and  $\text{Cl}^-$  ions with a negligible concentration of HCl molecules:

$\text{H}_2\text{O}$  is a stronger base than  $\text{Cl}^-$  (Figure 16.4), so  $\text{H}_2\text{O}$  acquires the proton to become the hydronium ion. Because the reaction lies completely to the right, we write Equation 16.10 with only an arrow to the right rather than using the double arrows for an equilibrium.

When  $\text{A}^-$  is a stronger base than  $\text{H}_2\text{O}$ , the equilibrium lies to the left. This situation occurs when HA is a weak acid. For example, an aqueous solution of acetic acid consists mainly of  $\text{CH}_3\text{COOH}$  molecules with relatively few  $\text{H}_3\text{O}^+$  and  $\text{CH}_3\text{COO}^-$  ions:

The  $\text{CH}_3\text{COO}^-$  ion is a stronger base than  $\text{H}_2\text{O}$  (Figure 16.4) and therefore the reverse reaction is favored more than the forward reaction.

From these examples, we conclude that *in every acid–base reaction, equilibrium favors transfer of the proton from the stronger acid to the stronger base to form the weaker acid and the weaker base.*

## Sample Exercise 16.3

## Predicting the Position of a Proton-Transfer Equilibrium

For the following proton-transfer reaction, use Figure 16.4 to predict whether the equilibrium lies to the left ( $K_c < 1$ ) or to the right ( $K_c > 1$ ):

## SOLUTION

**Analyze** We are asked to predict whether an equilibrium lies to the right, favoring products, or to the left, favoring reactants.

**Plan** This is a proton-transfer reaction, and the position of the equilibrium will favor the proton going to the stronger of two bases. The two bases in the equation are  $\text{CO}_3^{2-}$ , the base in the forward reaction, and  $\text{SO}_4^{2-}$ , the conjugate base of  $\text{HSO}_4^-$ . We can find the relative positions of these two bases in Figure 16.4 to determine which is the stronger base.

**Solve** The  $\text{CO}_3^{2-}$  ion appears lower in the right-hand column in Figure 16.4 and is therefore a stronger base than  $\text{SO}_4^{2-}$ . Therefore,  $\text{CO}_3^{2-}$  will get the proton preferentially to become  $\text{HCO}_3^-$ , while  $\text{SO}_4^{2-}$  will remain mostly unprotonated. The resulting equilibrium lies to the right, favoring products (that is,  $K_c > 1$ ):

**Comment** Of the two acids  $\text{HSO}_4^-$  and  $\text{HCO}_3^-$ , the stronger one ( $\text{HSO}_4^-$ ) gives up a proton more readily, and the weaker one

( $\text{HCO}_3^-$ ) tends to retain its proton. Thus, the equilibrium favors the direction in which the proton moves from the stronger acid and becomes bonded to the stronger base.

## Practice Exercise 1

Based on information in Figure 16.4, place the following equilibria in order from smallest to largest value of  $K_c$ :

- (i)  $\text{CH}_3\text{COOH}(aq) + \text{HS}^-(aq) \rightleftharpoons \text{CH}_3\text{COO}^-(aq) + \text{H}_2\text{S}(aq)$   
 (ii)  $\text{F}^-(aq) + \text{NH}_4^+(aq) \rightleftharpoons \text{HF}(aq) + \text{NH}_3(aq)$   
 (iii)  $\text{H}_2\text{CO}_3(aq) + \text{Cl}^-(aq) \rightleftharpoons \text{HCO}_3^-(aq) + \text{HCl}(aq)$   
 (a)  $\text{i} < \text{ii} < \text{iii}$  (b)  $\text{ii} < \text{i} < \text{iii}$  (c)  $\text{iii} < \text{i} < \text{ii}$   
 (d)  $\text{ii} < \text{iii} < \text{i}$  (e)  $\text{iii} < \text{ii} < \text{i}$

## Practice Exercise 2

For each reaction, use Figure 16.4 to predict whether the equilibrium lies to the left or to the right:

- (a)  $\text{HPO}_4^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{PO}_4^-(aq) + \text{OH}^-(aq)$   
 (b)  $\text{NH}_4^+(aq) + \text{OH}^-(aq) \rightleftharpoons \text{NH}_3(aq) + \text{H}_2\text{O}(l)$

## 16.3 | The Autoionization of Water

One of the most important chemical properties of water is its ability to act as either a Brønsted–Lowry acid or a Brønsted–Lowry base. In the presence of an acid, it acts as a proton acceptor; in the presence of a base, it acts as a proton donor. In fact, one water molecule can donate a proton to another water molecule:

We call this process the **autoionization** of water.

Because the forward and reverse reactions in Equation 16.12 are extremely rapid, no water molecule remains ionized for long. At room temperature only about two out of every  $10^9$  water molecules are ionized at any given instant. Thus, pure water consists almost entirely of  $\text{H}_2\text{O}$  molecules and is an extremely poor conductor of electricity. Nevertheless, the autoionization of water is very important, as we will soon learn.

## The Ion Product of Water

The equilibrium-constant expression for the autoionization of water is

$$K_c = [\text{H}_3\text{O}^+][\text{OH}^-] \quad [16.13]$$

The term  $[\text{H}_2\text{O}]$  is excluded from the equilibrium-constant expression because we exclude the concentrations of pure solids and liquids.  $\infty$  (Section 15.4) Because this

expression refers specifically to the autoionization of water, we use the symbol  $K_w$  to denote the equilibrium constant, which we call the **ion-product constant** for water. At 25 °C,  $K_w$  equals  $1.0 \times 10^{-14}$ . Thus, we have

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \quad (\text{at } 25^\circ\text{C}) \quad [16.14]$$

Because we use  $\text{H}^+(\text{aq})$  and  $\text{H}_3\text{O}^+(\text{aq})$  interchangeably to represent the hydrated proton, the autoionization reaction for water can also be written as

Likewise, the expression for  $K_w$  can be written in terms of either  $\text{H}_3\text{O}^+$  or  $\text{H}^+$ , and  $K_w$  has the same value in either case:

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14} \quad (\text{at } 25^\circ\text{C}) \quad [16.16]$$

This equilibrium-constant expression and the value of  $K_w$  at 25 °C are extremely important, and you should commit them to memory.

A solution in which  $[\text{H}^+] = [\text{OH}^-]$  is said to be *neutral*. In most solutions, however, the  $\text{H}^+$  and  $\text{OH}^-$  concentrations are not equal. As the concentration of one of these ions increases, the concentration of the other must decrease, so that the product of their concentrations always equals  $1.0 \times 10^{-14}$  (Figure 16.5). Aqueous solutions in which  $[\text{H}^+] > [\text{OH}^-]$  are called *acidic*, and aqueous solutions in which  $[\text{OH}^-] > [\text{H}^+]$  are called *basic*.

## Sample Exercise 16.4

### Calculating $[\text{H}^+]$ for Pure Water

Calculate the values of  $[\text{H}^+]$  and  $[\text{OH}^-]$  in a neutral aqueous solution at 25 °C.

#### SOLUTION

**Analyze** We are asked to determine the concentrations of  $\text{H}^+$  and  $\text{OH}^-$  ions in a neutral solution at 25 °C.

**Plan** We will use Equation 16.16 and the fact that, by definition,  $[\text{H}^+] = [\text{OH}^-]$  in a neutral solution.

**Solve** We will represent the concentration of  $\text{H}^+$  and  $\text{OH}^-$  in neutral solution with  $x$ . This gives

$$\begin{aligned} [\text{H}^+][\text{OH}^-] &= (x)(x) = 1.0 \times 10^{-14} \\ x^2 &= 1.0 \times 10^{-14} \\ x &= 1.0 \times 10^{-7} \text{ M} = [\text{H}^+] = [\text{OH}^-] \end{aligned}$$

In an acid solution  $[\text{H}^+]$  is greater than  $1.0 \times 10^{-7} \text{ M}$ ; in a basic solution  $[\text{H}^+]$  is less than  $1.0 \times 10^{-7} \text{ M}$ .

#### Practice Exercise 1

In a certain acidic solution at 25 °C,  $[\text{H}^+]$  is 100 times greater than  $[\text{OH}^-]$ . What is the value for  $[\text{OH}^-]$  for the solution?

- (a)  $1.0 \times 10^{-8} \text{ M}$  (b)  $1.0 \times 10^{-7} \text{ M}$  (c)  $1.0 \times 10^{-6} \text{ M}$   
 (d)  $1.0 \times 10^{-2} \text{ M}$  (e)  $1.0 \times 10^{-9} \text{ M}$

#### Practice Exercise 2

Indicate whether solutions with each of the following ion concentrations are neutral, acidic, or basic at 25 °C:

- (a)  $[\text{H}^+] = 4 \times 10^{-9} \text{ M}$ ; (b)  $[\text{OH}^-] = 1 \times 10^{-7} \text{ M}$ ;  
 (c)  $[\text{OH}^-] = 1 \times 10^{-13} \text{ M}$ .

What makes Equation 16.16 particularly useful is that it is applicable both to pure water and to any aqueous solution. Although the equilibrium between  $\text{H}^+(\text{aq})$  and  $\text{OH}^-(\text{aq})$  as well as other ionic equilibria are affected somewhat by the presence of additional ions in solution, it is customary to ignore these ionic effects except in work requiring exceptional accuracy. Thus, Equation 16.16 is taken to be valid for any dilute aqueous solution and can be used to calculate either  $[\text{H}^+]$  (if  $[\text{OH}^-]$  is known) or  $[\text{OH}^-]$  (if  $[\text{H}^+]$  is known).

### Sample Exercise 16.5

#### Calculating $[\text{H}^+]$ from $[\text{OH}^-]$

Calculate the concentration of  $\text{H}^+(\text{aq})$  in (a) a solution in which  $[\text{OH}^-]$  is  $0.010\text{ M}$ , (b) a solution in which  $[\text{OH}^-]$  is  $1.8 \times 10^{-9}\text{ M}$ . *Note:* In this problem and all that follow, we assume, unless stated otherwise, that the temperature is  $25^\circ\text{C}$ .

#### SOLUTION

**Analyze** We are asked to calculate the  $[\text{H}^+]$  concentration in an aqueous solution where the hydroxide concentration is known.

**Plan** We can use the equilibrium-constant expression for the auto-ionization of water and the value of  $K_w$  to solve for each unknown concentration.

#### Solve

(a) Using Equation 16.16, we have

$$[\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$$

$$[\text{H}^+] = \frac{(1.0 \times 10^{-14})}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{0.010} = 1.0 \times 10^{-12}\text{ M}$$

This solution is basic because

$$[\text{OH}^-] > [\text{H}^+]$$

(b) In this instance

$$[\text{H}^+] = \frac{(1.0 \times 10^{-14})}{[\text{OH}^-]} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-9}} = 5.6 \times 10^{-6}\text{ M}$$

This solution is acidic because

$$[\text{H}^+] > [\text{OH}^-]$$

#### Practice Exercise 1

A solution has  $[\text{OH}^-] = 4.0 \times 10^{-8}$ . What is the value of  $[\text{H}^+]$  for the solution?

- (a)  $2.5 \times 10^{-8}\text{ M}$  (b)  $4.0 \times 10^{-8}\text{ M}$  (c)  $2.5 \times 10^{-7}\text{ M}$   
(d)  $2.5 \times 10^{-6}\text{ M}$  (e)  $4.0 \times 10^{-6}\text{ M}$

#### Practice Exercise 2

Calculate the concentration of  $\text{OH}^-(\text{aq})$  in a solution in which

- (a)  $[\text{H}^+] = 2 \times 10^{-6}\text{ M}$ ; (b)  $[\text{H}^+] = [\text{OH}^-]$ ;  
(c)  $[\text{H}^+] = 200 \times [\text{OH}^-]$ .

## 16.4 | The pH Scale

The molar concentration of  $\text{H}^+(\text{aq})$  in an aqueous solution is usually very small. For convenience, we therefore usually express  $[\text{H}^+]$  in terms of **pH**, which is the negative logarithm in base 10 of  $[\text{H}^+]$ .\*

$$\text{pH} = -\log[\text{H}^+] \quad [16.17]$$

If you need to review the use of logarithms, see Appendix A.

In Sample Exercise 16.4, we saw that  $[\text{H}^+] = 1.0 \times 10^{-7}\text{ M}$  for a neutral aqueous solution at  $25^\circ\text{C}$ . We can now use Equation 16.17 to calculate the pH of a neutral solution at  $25^\circ\text{C}$ :

$$\text{pH} = -\log(1.0 \times 10^{-7}) = -(-7.00) = 7.00$$

Notice that the pH is reported with two decimal places. We do so because *only the numbers to the right of the decimal point are the significant figures in a logarithm*. Because our original value for the concentration ( $1.0 \times 10^{-7}\text{ M}$ ) has two significant figures, the corresponding pH has two decimal places (7.00).

What happens to the pH of a solution as we make the solution more acidic, so that  $[\text{H}^+]$  increases? Because of the negative sign in the logarithm term of Equation 16.17,

\*Because  $[\text{H}^+]$  and  $[\text{H}_3\text{O}^+]$  are used interchangeably, you might see pH defined as  $-\log[\text{H}_3\text{O}^+]$ .

**TABLE 16.1 Relationships between  $[H^+]$ ,  $[OH^-]$ , and pH at 25 °C for Acidic, Neutral, and Basic Aqueous Solutions**

|             | Acidic                | Neutral              | Basic                 |
|-------------|-----------------------|----------------------|-----------------------|
| pH          | <7.00                 | 7.00                 | >7.00                 |
| $[H^+](M)$  | $>1.0 \times 10^{-7}$ | $1.0 \times 10^{-7}$ | $<1.0 \times 10^{-7}$ |
| $[OH^-](M)$ | $<1.0 \times 10^{-7}$ | $1.0 \times 10^{-7}$ | $>1.0 \times 10^{-7}$ |

the pH decreases as  $[H^+]$  increases. For example, when we add sufficient acid to make  $[H^+] = 1.0 \times 10^{-3} M$ , the pH is

$$\text{pH} = -\log(1.0 \times 10^{-3}) = -(-3.00) = 3.00$$

At 25 °C the pH of an acidic solution is less than 7.00.

We can also calculate the pH of a basic solution, one in which  $[OH^-] > 1.0 \times 10^{-7} M$ . Suppose  $[OH^-] = 2.0 \times 10^{-3} M$ . We can use Equation 16.16 to calculate  $[H^+]$  for this solution and Equation 16.17 to calculate the pH:

$$[H^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{2.0 \times 10^{-3}} = 5.0 \times 10^{-12} M$$

$$\text{pH} = -\log(5.0 \times 10^{-12}) = 11.30$$

At 25 °C the pH of a basic solution is greater than 7.00. The relationships among  $[H^+]$ ,  $[OH^-]$ , and pH are summarized in Table 16.1.

### Give It Some Thought

Is it possible for a solution to have a negative pH? If so, would that pH signify a basic or acidic solution?

One might think that when  $[H^+]$  is very small, as is often the case, it would be unimportant. That reasoning is quite incorrect! Remember that many chemical processes depend on the ratio of changes in concentration. For example, if a kinetic rate law is first order in  $[H^+]$ , doubling the  $H^+$  concentration doubles the rate even if the change is merely from  $1 \times 10^{-7} M$  to  $2 \times 10^{-7} M$ . (Section 14.3) In biological systems,

## Sample Exercise 16.6

### Calculating pH from $[H^+]$

Calculate the pH values for the two solutions of Sample Exercise 16.5.

#### SOLUTION

**Analyze** We are asked to determine the pH of aqueous solutions for which we have already calculated  $[H^+]$ .

**Plan** We can calculate pH using its defining equation, Equation 16.17.

#### Solve

(a) In the first instance we found  $[H^+]$  to be  $1.0 \times 10^{-12} M$ , so that

$$\text{pH} = -\log(1.0 \times 10^{-12}) = -(-12.00) = 12.00$$

Because  $1.0 \times 10^{-12}$  has two significant figures, the pH has two decimal places, 12.00.

(b) For the second solution,  $[H^+] = 5.6 \times 10^{-6} M$ . Before performing the calculation, it is helpful to estimate the pH. To do so, we note that  $[H^+]$  lies between  $1 \times 10^{-6}$  and  $1 \times 10^{-5}$ . Thus, we expect the pH to lie between 6.0 and 5.0. We use Equation 16.17 to calculate the pH:

$$\text{pH} = -\log(5.6 \times 10^{-6}) = 5.25$$

**Check** After calculating a pH, it is useful to compare it to your estimate. In this case the pH, as we predicted, falls between 6 and 5. Had the calculated pH and the estimate not agreed, we should have reconsidered our calculation or estimate or both.

#### Practice Exercise 1

A solution at 25 °C has  $[OH^-] = 6.7 \times 10^{-3}$ . What is the pH of the solution?

(a) 0.83 (b) 2.2 (c) 2.17 (d) 11.83 (e) 12

#### Practice Exercise 2

(a) In a sample of lemon juice,  $[H^+] = 3.8 \times 10^{-4} M$ . What is the pH?

(b) A commonly available window-cleaning solution has  $[OH^-] = 1.9 \times 10^{-6} M$ . What is the pH at 25 °C?

many reactions involve proton transfers and have rates that depend on  $[\text{H}^+]$ . Because the speeds of these reactions are crucial, the pH of biological fluids must be maintained within narrow limits. For example, human blood has a normal pH range of 7.35 to 7.45. Illness and even death can result if the pH varies much from this narrow range.

### pOH and Other “p” Scales

The negative logarithm is a convenient way of expressing the magnitudes of other small quantities. We use the convention that the negative logarithm of a quantity is labeled “p” (quantity). Thus, we can express the concentration of  $\text{OH}^-$  as pOH:

$$\text{pOH} = -\log [\text{OH}^-] \quad [16.18]$$

Likewise,  $\text{p}K_w$  equals  $-\log K_w$ .

By taking the negative logarithm of both sides of the equilibrium-constant expression for water,  $K_w = [\text{H}^+][\text{OH}^-]$ , we obtain

$$-\log [\text{H}^+] + (-\log [\text{OH}^-]) = -\log K_w \quad [16.19]$$

from which we obtain the useful expression

$$\text{pH} + \text{pOH} = 14.00 \quad (\text{at } 25^\circ\text{C}) \quad [16.20]$$

The pH and pOH values characteristic of a number of familiar solutions are shown in **Figure 16.6**. Notice that a change in  $[\text{H}^+]$  by a factor of 10 causes the pH to change by 1. Thus, the concentration of  $\text{H}^+(\text{aq})$  in a solution of pH 5 is 10 times the  $\text{H}^+(\text{aq})$  concentration in a solution of pH 6.

▲ **Figure 16.6** Concentrations of  $\text{H}^+$  and  $\text{OH}^-$ , and pH and pOH values of some common substances at  $25^\circ\text{C}$ .

## Give It Some Thought

If the pOH for a solution is 3.00, what is the pH? Is the solution acidic or basic?

## Sample Exercise 16.7

Calculating  $[H^+]$  from pOH

A sample of freshly pressed apple juice has a pOH of 10.24. Calculate  $[H^+]$ .

## SOLUTION

**Analyze** We need to calculate  $[H^+]$  from pOH.

**Plan** We will first use Equation 16.20,  $pH + pOH = 14.00$ , to calculate pH from pOH. Then we will use Equation 16.17 to determine the concentration of  $H^+$ .

**Solve** From Equation 16.20, we have

$$\begin{aligned} pH &= 14.00 - pOH \\ pH &= 14.00 - 10.24 = 3.76 \end{aligned}$$

Next we use Equation 16.17:

$$pH = -\log[H^+] = 3.76$$

Thus,

$$\log[H^+] = -3.76$$

To find  $[H^+]$ , we need to determine the *antilogarithm* of  $-3.76$ . Your calculator will show this command as  $10^x$  or INV log (these functions are usually above the log key). We use this function to perform the calculation:

$$[H^+] = \text{antilog}(-3.76) = 10^{-3.76} = 1.7 \times 10^{-4} M$$

**Comment** The number of significant figures in  $[H^+]$  is two because the number of decimal places in the pH is two.

**Check** Because the pH is between 3.0 and 4.0, we know that  $[H^+]$  will be between  $1.0 \times 10^{-3} M$  and  $1.0 \times 10^{-4} M$ . Our calculated  $[H^+]$  falls within this estimated range.

## ► Practice Exercise 1

A solution at 25 °C has  $pOH = 10.53$ . Which of the following statements is or are true?

- (i) The solution is acidic.
- (ii) The pH of the solution is  $14.00 - 10.53$ .
- (iii) For this solution,  $[OH^-] = 10^{-10.53} M$ .

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

## ► Practice Exercise 2

A solution formed by dissolving an antacid tablet has a pOH of 4.82. Calculate  $[H^+]$ .

## Measuring pH

The pH of a solution can be measured with a *pH meter* (Figure 16.7). A complete understanding of how this important device works requires knowledge of electrochemistry, a subject we take up in Chapter 20. In brief, a pH meter consists of a pair of electrodes connected to a meter capable of measuring small voltages, on the order of millivolts. A voltage, which varies with pH, is generated when the electrodes are placed in a solution. This voltage is read by the meter, which is calibrated to give pH.

Although less precise, acid–base indicators can be used to measure pH. An acid–base indicator is a colored substance that can exist in either an acid or a base form. The two forms have different colors. Thus, the indicator has one color at lower pH and another at higher pH. If you know the pH at which the indicator turns from one form to the other, you can determine whether a solution has a higher or lower pH than this value. Litmus, for example, changes color in the vicinity of pH 7. The color change, however, is not very sharp. Red litmus indicates a pH of about 5 or lower, and blue litmus indicates a pH of about 8 or higher.

Some common indicators are listed in Figure 16.8. The chart tells us, for instance, that methyl red changes color over the pH interval from about 4.5 to 6.0. Below pH 4.5 it is in the acid form, which is red. In the interval between 4.5 and 6.0, it is gradually converted to its basic form, which is yellow. Once the pH rises above 6 the conversion is complete, and the solution is yellow. This color change, along with that of the indicators bromthymol blue and phenolphthalein, is shown in Figure 16.9. Paper tape impregnated with several indicators is widely used for determining approximate pH values.

▲ **Figure 16.7** A digital pH meter. The electrodes immersed in a solution produce a voltage that depends on the pH of the solution.

### Go Figure

Which of these indicators is best suited to distinguish between a solution that is slightly acidic and one that is slightly basic?

Methyl red

Bromthymol blue

Phenolphthalein

▲ **Figure 16.9** Solutions containing three common acid–base indicators at various pH values.

### Go Figure

If a colorless solution turns pink when we add phenolphthalein, what can we conclude about the pH of the solution?

|                   | pH range for color change |     |        |        |        |           |        |      |
|-------------------|---------------------------|-----|--------|--------|--------|-----------|--------|------|
|                   | 0                         | 2   | 4      | 6      | 8      | 10        | 12     | 14   |
| Methyl violet     | Yellow                    |     | Violet |        |        |           |        |      |
| Thymol blue       |                           | Red |        | Yellow |        | Yellow    |        | Blue |
| Methyl orange     |                           |     | Red    |        | Yellow |           |        |      |
| Methyl red        |                           |     |        | Red    |        | Yellow    |        |      |
| Bromthymol blue   |                           |     |        |        | Yellow |           | Blue   |      |
| Phenolphthalein   |                           |     |        |        |        | Colorless |        | Pink |
| Alizarin yellow R |                           |     |        |        |        |           | Yellow | Red  |

▲ **Figure 16.8** pH ranges for common acid–base indicators. Most indicators have a useful range of about 2 pH units.

## 16.5 | Strong Acids and Bases

The chemistry of an aqueous solution often depends critically on pH. It is therefore important to examine how pH relates to acid and base concentrations. The simplest cases are those involving strong acids and strong bases. Strong acids and bases are *strong electrolytes*, existing in aqueous solution entirely as ions. There are relatively few common strong acids and bases (see Table 4.2).

### Strong Acids

The seven most common strong acids include six monoprotic acids (HCl, HBr, HI, HNO<sub>3</sub>, HClO<sub>3</sub>, and HClO<sub>4</sub>), and one diprotic acid (H<sub>2</sub>SO<sub>4</sub>). Nitric acid (HNO<sub>3</sub>) exemplifies the behavior of the monoprotic strong acids. For all practical purposes, an aqueous solution of HNO<sub>3</sub> consists entirely of H<sub>3</sub>O<sup>+</sup> and NO<sub>3</sub><sup>−</sup> ions:

We have not used equilibrium arrows for this equation because the reaction lies entirely to the right. ∞ (Section 4.1) As noted in Section 16.3, we use H<sub>3</sub>O<sup>+</sup>(aq) and H<sup>+</sup>(aq) interchangeably to represent the hydrated proton in water. Thus, we can simplify this acid ionization equation to

In an aqueous solution of a strong acid, the acid is normally the only significant source of H<sup>+</sup> ions.\* As a result, calculating the pH of a solution of a strong monoprotic acid is straightforward because [H<sup>+</sup>] equals the original concentration of acid. In a 0.20 M solution of HNO<sub>3</sub>(aq), for example, [H<sup>+</sup>] = [NO<sub>3</sub><sup>−</sup>] = 0.20 M. The situation with the diprotic acid H<sub>2</sub>SO<sub>4</sub> is somewhat more complex, as we will see in Section 16.6.

\*If the concentration of the acid is 10<sup>−6</sup> M or less, we also need to consider H<sup>+</sup> ions that result from H<sub>2</sub>O autoionization. Normally, the concentration of H<sup>+</sup> from H<sub>2</sub>O is so small that it can be neglected.

## Sample Exercise 16.8

### Calculating the pH of a Strong Acid Solution

What is the pH of a 0.040 *M* solution of HClO<sub>4</sub>?

#### SOLUTION

**Analyze and Plan** Because HClO<sub>4</sub> is a strong acid, it is completely ionized, giving  $[\text{H}^+] = [\text{ClO}_4^-] = 0.040 \text{ M}$ .

#### Solve

$$\text{pH} = -\log(0.040) = 1.40$$

**Check** Because  $[\text{H}^+]$  lies between  $1 \times 10^{-2}$  and  $1 \times 10^{-1}$ , the pH will be between 2.0 and 1.0. Our calculated pH falls within the estimated range. Furthermore, because the concentration has two significant figures, the pH has two decimal places.

#### Practice Exercise 1

Order the following three solutions from smallest to largest pH: (i) 0.20 *M* HClO<sub>3</sub> (ii) 0.0030 *M* HNO<sub>3</sub> (iii) 1.50 *M* HCl

- (a) i < ii < iii (b) ii < i < iii (c) iii < i < ii  
(d) ii < iii < i (e) iii < ii < i

#### Practice Exercise 2

An aqueous solution of HNO<sub>3</sub> has a pH of 2.34. What is the concentration of the acid?

## Strong Bases

The most common soluble strong bases are the ionic hydroxides of the alkali metals, such as NaOH, KOH, and the ionic hydroxides of heavier alkaline earth metals, such as Sr(OH)<sub>2</sub>. These compounds completely dissociate into ions in aqueous solution. Thus, a solution labeled 0.30 *M* NaOH consists of 0.30 *M* Na<sup>+</sup>(aq) and 0.30 *M* OH<sup>−</sup>(aq); there is essentially no undissociated NaOH.

### Give It Some Thought

Which solution has the higher pH, a 0.001 *M* solution of NaOH or a 0.001 *M* solution of Ba(OH)<sub>2</sub>?

## Sample Exercise 16.9

### Calculating the pH of a Strong Base

What is the pH of (a) a 0.028 *M* solution of NaOH, (b) a 0.0011 *M* solution of Ca(OH)<sub>2</sub>?

#### SOLUTION

**Analyze** We are asked to calculate the pH of two solutions of strong bases.

**Plan** We can calculate each pH by either of two equivalent methods. First, we could use Equation 16.16 to calculate  $[\text{H}^+]$  and then use Equation 16.17 to calculate the pH. Alternatively, we could use  $[\text{OH}^-]$  to calculate pOH and then use Equation 16.20 to calculate the pH.

#### Solve

(a) NaOH dissociates in water to give one OH<sup>−</sup> ion per formula unit. Therefore, the OH<sup>−</sup> concentration for the solution in (a) equals the stated concentration of NaOH, namely 0.028 *M*.

*Method 1:*

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.028} = 3.57 \times 10^{-13} \text{ M}$$

$$\text{pH} = -\log(3.57 \times 10^{-13}) = 12.45$$

*Method 2:*

$$\text{pOH} = -\log(0.028) = 1.55$$

$$\text{pH} = 14.00 - \text{pOH} = 12.45$$

(b) Ca(OH)<sub>2</sub> is a strong base that dissociates in water to give two OH<sup>−</sup> ions per formula unit. Thus, the concentration of OH<sup>−</sup>(aq) for the solution in part (b) is  $2 \times (0.0011 \text{ M}) = 0.0022 \text{ M}$ .

*Method 1:*

$$[\text{H}^+] = \frac{1.0 \times 10^{-14}}{0.0022} = 4.55 \times 10^{-12} \text{ M}$$

$$\text{pH} = -\log(4.55 \times 10^{-12}) = 11.34$$

*Method 2:*

$$\text{pOH} = -\log(0.0022) = 2.66$$

$$\text{pH} = 14.00 - \text{pOH} = 11.34$$

#### Practice Exercise 1

Order the following three solutions from smallest to largest pH: (i) 0.030 *M* Ba(OH)<sub>2</sub> (ii) 0.040 *M* KOH (iii) pure water.

- (a) i < ii < iii (b) ii < i < iii (c) iii < i < ii  
(d) ii < iii < i (e) iii < ii < i

#### Practice Exercise 2

What is the concentration of a solution of (a) KOH for which the pH is 11.89, (b) Ca(OH)<sub>2</sub> for which the pH is 11.68?

Although all of the alkali metal hydroxides are strong electrolytes, LiOH, RbOH, and CsOH are not commonly encountered in the laboratory. The hydroxides of the heavier alkaline earth metals—Ca(OH)<sub>2</sub>, Sr(OH)<sub>2</sub>, and Ba(OH)<sub>2</sub>—are also strong electrolytes. They have limited solubility, however, so they are used only when high solubility is not critical.

Strongly basic solutions are also created by certain substances that react with water to form OH<sup>−</sup>(aq). The most common of these contain the oxide ion. Ionic metal oxides, especially Na<sub>2</sub>O and CaO, are often used in industry when a strong base is needed. The O<sup>2−</sup> reacts very exothermically with water to form OH<sup>−</sup>, leaving virtually no O<sup>2−</sup> in the solution:

Thus, a solution formed by dissolving 0.010 mol of Na<sub>2</sub>O(s) in enough water to form 1.0 L of solution has [OH<sup>−</sup>] = 0.020 M and a pH of 12.30.

### Give It Some Thought

The CH<sub>3</sub><sup>−</sup> ion is the conjugate base of CH<sub>4</sub>, and CH<sub>4</sub> shows no evidence of being an acid in water. Write a balanced equation for the reaction of CH<sub>3</sub><sup>−</sup> and water.

## 16.6 | Weak Acids

Most acidic substances are weak acids and therefore only partially ionized in aqueous solution (Figure 16.10). We can use the equilibrium constant for the ionization reaction to express the extent to which a weak acid ionizes. If we represent a general weak acid as HA, we can write the equation for its ionization in either of the following ways, depending on whether the hydrated proton is represented as H<sub>3</sub>O<sup>+</sup>(aq) or H<sup>+</sup>(aq):

or

These equilibria are in aqueous solution, so we will use equilibrium-constant expressions based on concentrations. Because H<sub>2</sub>O is the solvent, it is omitted from the

► **Figure 16.10** Species present in solutions of a strong acid and a weak acid.

TABLE 16.2 Some Weak Acids in Water at 25 °C

| Acid  | Structural Formula*   | Conjugate Base                     | $K_a$                 |
|---|---|------------------------------------|-----------------------|
| Chlorous ( $\text{HClO}_2$ )                  | $\text{H}-\text{O}-\text{Cl}-\text{O}$  | $\text{ClO}_2^-$                   | $1.0 \times 10^{-2}$  |
| Hydrofluoric (HF)                             | $\text{H}-\text{F}$   | $\text{F}^-$                       | $6.8 \times 10^{-4}$  |
| Nitrous ( $\text{HNO}_2$ )                    | $\text{H}-\text{O}-\text{N}=\text{O}$   | $\text{NO}_2^-$                    | $4.5 \times 10^{-4}$  |
| Benzoic ( $\text{C}_6\text{H}_5\text{COOH}$ ) |  | $\text{C}_6\text{H}_5\text{COO}^-$ | $6.3 \times 10^{-5}$  |
| Acetic ( $\text{CH}_3\text{COOH}$ )           |  | $\text{CH}_3\text{COO}^-$          | $1.8 \times 10^{-5}$  |
| Hypochlorous ( $\text{HOCl}$ )                | $\text{H}-\text{O}-\text{Cl}$   | $\text{OCl}^-$                     | $3.0 \times 10^{-8}$  |
| Hydrocyanic ( $\text{HCN}$ )                  | $\text{H}-\text{C}\equiv\text{N}$   | $\text{CN}^-$                      | $4.9 \times 10^{-10}$ |
| Phenol ( $\text{HOC}_6\text{H}_5$ )           |  | $\text{C}_6\text{H}_5\text{O}^-$   | $1.3 \times 10^{-10}$ |

\*The proton that ionizes is shown in red.

equilibrium-constant expression.  $\infty$  (Section 15.4) Further, we add a subscript  $a$  on the equilibrium constant to indicate that it is an equilibrium constant for the ionization of an *acid*. Thus, we can write the equilibrium-constant expression as either:

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \quad \text{or} \quad K_a = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]} \quad [16.25]$$

$K_a$  is called the **acid-dissociation constant** for acid HA.

Table 16.2 shows the structural formulas, conjugate bases, and  $K_a$  values for a number of weak acids. Appendix D provides a more complete list. Many weak acids are organic compounds composed entirely of carbon, hydrogen, and oxygen. These compounds usually contain some hydrogen atoms bonded to carbon atoms and some bonded to oxygen atoms. In almost all cases, the hydrogen atoms bonded to carbon do not ionize in water; instead, the acidic behavior of these compounds is due to the hydrogen atoms attached to oxygen atoms.

The magnitude of  $K_a$  indicates the tendency of the acid to ionize in water: *The larger the value of  $K_a$ , the stronger the acid.* Chlorous acid ( $\text{HClO}_2$ ), for example, is the strongest acid in Table 16.2, and phenol ( $\text{HOC}_6\text{H}_5$ ) is the weakest. For most weak acids  $K_a$  values range from  $10^{-2}$  to  $10^{-10}$ .

### Give It Some Thought

Based on the entries in Table 16.2, which element is most commonly bonded to the acidic hydrogen?

## Calculating $K_a$ from pH

In order to calculate either the  $K_a$  value for a weak acid or the pH of its solutions, we will use many of the skills for solving equilibrium problems developed in Section 15.5. In many cases the small magnitude of  $K_a$  allows us to use approximations to simplify the problem. In doing these calculations, it is important to realize that proton-transfer reactions are generally very rapid. As a result, the measured or calculated pH for a weak acid always represents an equilibrium condition.

**Sample Exercise 16.10****Calculating  $K_a$  from Measured pH**

A student prepared a 0.10 *M* solution of formic acid (HCOOH) and found its pH at 25 °C to be 2.38. Calculate  $K_a$  for formic acid at this temperature.

**SOLUTION**

**Analyze** We are given the molar concentration of an aqueous solution of weak acid and the pH of the solution, and we are asked to determine the value of  $K_a$  for the acid.

**Plan** Although we are dealing specifically with the ionization of a weak acid, this problem is similar to the equilibrium problems in Chapter 15. We can solve this problem using the method outlined in Sample Exercise 15.8, starting with the chemical reaction and a tabulation of initial and equilibrium concentrations.

**Solve**

The first step in solving any equilibrium problem is to write the equation for the equilibrium reaction. The ionization of formic acid can be written as:

The equilibrium-constant expression is:

$$K_a = \frac{[\text{H}^+][\text{HCOO}^-]}{[\text{HCOOH}]}$$

From the measured pH, we can calculate  $[\text{H}^+]$ :

$$\begin{aligned}\text{pH} &= -\log [\text{H}^+] = 2.38 \\ \log [\text{H}^+] &= -2.38 \\ [\text{H}^+] &= 10^{-2.38} = 4.2 \times 10^{-3} M\end{aligned}$$

To determine the concentrations of the species involved in the equilibrium, we consider that the solution is initially 0.10 *M* in HCOOH molecules. We then consider the ionization of the acid into  $\text{H}^+$  and  $\text{HCOO}^-$ . For each HCOOH molecule that ionizes, one  $\text{H}^+$  ion and one  $\text{HCOO}^-$  ion are produced in solution. Because the pH measurement indicates that  $[\text{H}^+] = 4.2 \times 10^{-3} M$  at equilibrium, we can construct the following table:

|  |                               |                       |                       |
|--|-------------------------------|-----------------------|-----------------------|
| Initial concentration ( <i>M</i> )     | 0.10                          | 0                     | 0                     |
| Change in concentration ( <i>M</i> )   | $-4.2 \times 10^{-3}$         | $+4.2 \times 10^{-3}$ | $+4.2 \times 10^{-3}$ |
| Equilibrium concentration ( <i>M</i> ) | $(0.10 - 4.2 \times 10^{-3})$ | $4.2 \times 10^{-3}$  | $4.2 \times 10^{-3}$  |

Notice that we have neglected the very small concentration of  $\text{H}^+(aq)$  due to  $\text{H}_2\text{O}$  autoionization. Notice also that the amount of HCOOH that ionizes is very small compared with the initial concentration of the acid. To the number of significant figures we are using, the subtraction yields 0.10 *M*:

$$(0.10 - 4.2 \times 10^{-3}) M \approx 0.10 M$$

We can now insert the equilibrium concentrations into the expression for  $K_a$ :

$$K_a = \frac{(4.2 \times 10^{-3})(4.2 \times 10^{-3})}{0.10} = 1.8 \times 10^{-4}$$

**Check** The magnitude of our answer is reasonable because  $K_a$  for a weak acid is usually between  $10^{-2}$  and  $10^{-10}$ .

**Practice Exercise 1**

A 0.50 *M* solution of an acid HA has pH = 2.24. What is the value of  $K_a$  for the acid? (a)  $1.7 \times 10^{-12}$  (b)  $3.3 \times 10^{-5}$  (c)  $6.6 \times 10^{-5}$  (d)  $5.8 \times 10^{-3}$  (e)  $1.2 \times 10^{-2}$

**Practice Exercise 2**

Niacin, one of the B vitamins, has the molecular structure shown at the right. A 0.020 *M* solution of niacin has a pH of 3.26. What is the acid-dissociation constant for niacin?

**Percent Ionization**

We have seen that the magnitude of  $K_a$  indicates the strength of a weak acid. Another measure of acid strength is **percent ionization**, defined as

$$\text{Percent ionization} = \frac{\text{concentration of ionized HA}}{\text{original concentration of HA}} \times 100\% \quad [16.26]$$

The stronger the acid, the greater the percent ionization.

If we assume that the autoionization of  $\text{H}_2\text{O}$  is negligible, the concentration of acid that ionizes equals the concentration of  $\text{H}^+(\text{aq})$  that forms. Thus, the percent ionization for an acid HA can be expressed as

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HA}]_{\text{initial}}} \times 100\% \quad [16.27]$$

For example, a 0.035 M solution of  $\text{HNO}_2$  contains  $3.7 \times 10^{-3} \text{ M H}^+(\text{aq})$  and its percent ionization is

$$\text{Percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HNO}_2]_{\text{initial}}} \times 100\% = \frac{3.7 \times 10^{-3} \text{ M}}{0.035 \text{ M}} \times 100\% = 11\%$$

### Sample Exercise 16.11

#### Calculating Percent Ionization

As calculated in Sample Exercise 16.10, a 0.10 M solution of formic acid ( $\text{HCOOH}$ ) contains  $4.2 \times 10^{-3} \text{ M H}^+(\text{aq})$ . Calculate the percentage of the acid that is ionized.

#### SOLUTION

**Analyze** We are given the molar concentration of an aqueous solution of weak acid and the equilibrium concentration of  $\text{H}^+(\text{aq})$  and asked to determine the percent ionization of the acid.

**Plan** The percent ionization is given by Equation 16.27.

**Solve**

$$\begin{aligned} \text{Percent ionization} &= \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HCOOH}]_{\text{initial}}} \times 100\% \\ &= \frac{4.2 \times 10^{-3} \text{ M}}{0.10 \text{ M}} \times 100\% = 4.2\% \end{aligned}$$

#### Practice Exercise 1

A 0.077 M solution of an acid HA has  $\text{pH} = 2.16$ . What is the percentage of the acid that is ionized?

(a) 0.090% (b) 0.69% (c) 0.90% (d) 3.6% (e) 9.0%

#### Practice Exercise 2

A 0.020 M solution of niacin (see Sample Exercise 16.10) has a pH of 3.26. Calculate the percent ionization of the niacin.

## Using $K_a$ to Calculate pH

Knowing the value of  $K_a$  and the initial concentration of a weak acid, we can calculate the concentration of  $\text{H}^+(\text{aq})$  in a solution of the acid.

### How to Calculate pH Using $K_a$

1. Write the ionization equilibrium.
2. Write the equilibrium-constant expression and the value for the equilibrium constant.
3. Express the concentrations involved in the equilibrium reaction.
4. Substitute the equilibrium concentrations into the equilibrium-constant expression and solve for  $x$ .

Let's use this process to calculate the pH at 25 °C of a 0.30 M solution of acetic acid ( $\text{CH}_3\text{COOH}$ ).

1. The ionization equilibrium is:

Notice that the hydrogen that ionizes is the one attached to an oxygen atom.

2. Taking  $K_a = 1.8 \times 10^{-5}$  from Table 16.2, we write the equilibrium-constant expression and its value.

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = 1.8 \times 10^{-5} \quad [16.29]$$

3. Next we express the concentrations involved in the equilibrium reaction. This can be done with a little accounting, as described in Sample Exercise 16.10. Because we want to find the equilibrium value for  $[\text{H}^+]$ , let's call this quantity  $x$ . The concentration of acetic acid before any of it ionizes is 0.30 M. The chemical equation

tells us that for each molecule of  $\text{CH}_3\text{COOH}$  that ionizes, one  $\text{H}^+(\text{aq})$  and one  $\text{CH}_3\text{COO}^-(\text{aq})$  are formed. Consequently, if  $x$  moles per liter of  $\text{H}^+(\text{aq})$  form at equilibrium,  $x$  moles per liter of  $\text{CH}_3\text{COO}^-(\text{aq})$  must also form and  $x$  moles per liter of  $\text{CH}_3\text{COOH}$  must be ionized:

|                                   |              |      |      |
|-----------------------------------|--------------|------|------|
| Initial concentration ( $M$ )     | 0.30         | 0    | 0    |
| Change in concentration ( $M$ )   | $-x$         | $+x$ | $+x$ |
| Equilibrium concentration ( $M$ ) | $(0.30 - x)$ | $x$  | $x$  |

4. Finally, we substitute the equilibrium concentrations into the equilibrium-constant expression and solve for  $x$ :

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = \frac{(x)(x)}{0.30 - x} = 1.8 \times 10^{-5} \quad [16.30]$$

This expression leads to a quadratic equation in  $x$ , which we can solve by using either an equation-solving calculator or the quadratic formula. We can simplify the problem, however, by noting that the value of  $K_a$  is quite small. As a result, the equilibrium lies far to the left and  $x$  is much smaller than the initial concentration of acetic acid. Thus, we *assume* that  $x$  is negligible relative to 0.30, so that  $0.30 - x$  is essentially equal to 0.30. We can (and should!) check the validity of this assumption when we finish the problem. By using this assumption, Equation 16.30 becomes

$$K_a = \frac{x^2}{0.30} = 1.8 \times 10^{-5}$$

Solving for  $x$ , we have

$$\begin{aligned} x^2 &= (0.30)(1.8 \times 10^{-5}) = 5.4 \times 10^{-6} \\ x &= \sqrt{5.4 \times 10^{-6}} = 2.3 \times 10^{-3} \\ [\text{H}^+] &= x = 2.3 \times 10^{-3} M \\ \text{pH} &= -\log(2.3 \times 10^{-3}) = 2.64 \end{aligned}$$

Now we check the validity of our simplifying assumption that  $0.30 - x \approx 0.30$ . The value of  $x$  we determined is so small that, for this number of significant figures, the assumption is entirely valid. We are thus satisfied that the assumption was a reasonable one to make. Because  $x$  represents the moles per liter of acetic acid that ionize, we see that, in this particular case, less than 1% of the acetic acid molecules ionize:

$$\text{Percent ionization of } \text{CH}_3\text{COOH} = \frac{0.0023 M}{0.30 M} \times 100\% = 0.77\%$$

As a general rule, if  $x$  is more than about 5% of the initial concentration value, it is better to use the quadratic formula. You should always check the validity of any simplifying assumptions after you have finished solving a problem.

We have also made one other assumption, namely, that all of the  $\text{H}^+$  in the solution comes from ionization of  $\text{CH}_3\text{COOH}$ . Are we justified in neglecting the autoionization of  $\text{H}_2\text{O}$ ? The answer is yes—the additional  $[\text{H}^+]$  due to water, which would be on the order of  $10^{-7} M$ , is negligible compared to the  $[\text{H}^+]$  from the acid (which in this case is on the order of  $10^{-3} M$ ). In extremely precise work, or in cases involving very dilute solutions of acids, we would need to consider the autoionization of water more fully.

### Give It Some Thought

Would a  $1.0 \times 10^{-8} M$  solution of  $\text{HCl}$  have  $\text{pH} < 7$ ,  $\text{pH} = 7$ , or  $\text{pH} > 7$ ?

Finally, we can compare the pH value of this weak acid with the pH of a solution of a strong acid of the same concentration. The pH of the 0.30  $M$  acetic acid is 2.64, but the pH of a 0.30  $M$  solution of a strong acid such as  $\text{HCl}$  is  $-\log(0.30) = 0.52$ . As expected, the pH of a solution of a weak acid is higher than that of a solution of a strong acid of the same molarity. (Remember, the higher the pH value, the *less* acidic the solution.)

## Sample Exercise 16.12

### Using $K_a$ to Calculate pH

Calculate the pH of a 0.20  $M$  solution of HCN. (Refer to Table 16.2 or Appendix D for the value of  $K_a$ .)

### SOLUTION

**Analyze** We are given the molarity of a weak acid and are asked for the pH. From Table 16.2,  $K_a$  for HCN is  $4.9 \times 10^{-10}$ .

**Plan** We proceed as in the example just worked in the text, writing the chemical equation and constructing a table of initial and equilibrium concentrations in which the equilibrium concentration of  $H^+$  is our unknown.

**Solve** Writing both the chemical equation for the ionization reaction that forms  $H^+(aq)$  and the equilibrium-constant ( $K_a$ ) expression for the reaction:

$$K_a = \frac{[\text{H}^+][\text{CN}^-]}{[\text{HCN}]} = 4.9 \times 10^{-10}$$

Next, we tabulate the concentrations of the species involved in the equilibrium reaction, letting  $x = [H^+]$  at equilibrium:

|                                   | $\text{HCN}(aq) \rightleftharpoons \text{H}^+(aq) + \text{CN}^-(aq)$ |      |      |
|-----------------------------------|--|------|------|
| Initial concentration ( $M$ )     | 0.20   | 0    | 0    |
| Change in concentration ( $M$ )   | $-x$   | $+x$ | $+x$ |
| Equilibrium concentration ( $M$ ) | $(0.20 - x)$   | $x$  | $x$  |

Substituting the equilibrium concentrations into the equilibrium-constant expression yields:

$$K_a = \frac{(x)(x)}{0.20 - x} = 4.9 \times 10^{-10}$$

We next make the simplifying approximation that  $x$ , the amount of acid that dissociates, is small compared with the initial concentration of acid,  $0.20 - x \approx 0.20$ . Thus,

$$\frac{x^2}{0.20} = 4.9 \times 10^{-10}$$

Solving for  $x$ , we have:

$$\begin{aligned} x^2 &= (0.20)(4.9 \times 10^{-10}) = 0.98 \times 10^{-10} \\ x &= \sqrt{0.98 \times 10^{-10}} = 9.9 \times 10^{-6} M = [H^+] \end{aligned}$$

A concentration of  $9.9 \times 10^{-6} M$  is much smaller than 5% of 0.20  $M$ , the initial HCN concentration. Our simplifying approximation is therefore appropriate. We now calculate the pH of the solution:

$$\text{pH} = -\log[H^+] = -\log(9.9 \times 10^{-6}) = 5.00$$

#### Practice Exercise 1

What is the pH of a 0.40  $M$  solution of benzoic acid,  $\text{C}_6\text{H}_5\text{COOH}$ ? (The  $K_a$  value for benzoic acid is given in Table 16.2.)

(a) 2.30 (b) 2.10 (c) 1.90 (d) 4.20 (e) 4.60

#### Practice Exercise 2

The  $K_a$  for niacin (Sample Exercise 16.10) is  $1.5 \times 10^{-5}$ . What is the pH of a 0.010  $M$  solution of niacin?

The properties of an acid solution that relate directly to the concentration of  $H^+(aq)$ , such as electrical conductivity and rate of reaction with an active metal, are less evident for a solution of a weak acid than for a solution of a strong acid of the same concentration. **Figure 16.11** presents an experiment that demonstrates this difference with 1  $M$   $\text{CH}_3\text{COOH}$  and 1  $M$   $\text{HCl}$ . The concentration of  $H^+(aq)$  in 1  $M$   $\text{CH}_3\text{COOH}$  is only 0.004  $M$ , whereas the 1  $M$   $\text{HCl}$  solution contains 1  $M$   $H^+(aq)$ . As a result, the reaction rate with the metal is much faster in the  $\text{HCl}$  solution.

As the concentration of a weak acid increases, the equilibrium concentration of  $H^+(aq)$  increases, as expected. However, as shown in **Figure 16.12**, the percent ionization decreases as the concentration increases. Thus, the concentration of  $H^+(aq)$  is not directly proportional to the concentration of the weak acid. For example, doubling the concentration of a weak acid does not double the concentration of  $H^+(aq)$ .

▲ **Figure 16.11** The same reaction has different rates in a weak acid solution compared to a strong acid solution. The bubbles are  $\text{H}_2$  gas, which along with metal cations, is produced when a metal is oxidized by an acid. [∞](#) (Section 4.4)

### Sample Exercise 16.13

#### Using the Quadratic Equation to Calculate pH and Percent Ionization

Calculate the pH and percentage of HF molecules ionized in a 0.10 M HF solution.

#### SOLUTION

**Analyze** We are asked to calculate the percent ionization of a solution of HF. From Appendix D, we find  $K_a = 6.8 \times 10^{-4}$ .

**Plan** We approach this problem as for previous equilibrium problems: We write the chemical equation for the equilibrium and tabulate the known and unknown concentrations of all species. We then substitute the equilibrium concentrations into the equilibrium-constant expression and solve for the unknown concentration of  $\text{H}^+$ .

**Solve**

The equilibrium reaction and equilibrium concentrations are as follows:

$$\text{HF}(aq) \rightleftharpoons \text{H}^+(aq) + \text{F}^-(aq)$$

|                               |              |      |      |
|-------------------------------|--------------|------|------|
| Initial concentration (M)     | 0.10         | 0    | 0    |
| Change in concentration (M)   | $-x$         | $+x$ | $+x$ |
| Equilibrium concentration (M) | $(0.10 - x)$ | $x$  | $x$  |

The equilibrium-constant expression is:

$$K_a = \frac{[\text{H}^+][\text{F}^-]}{[\text{HF}]} = \frac{(x)(x)}{0.10 - x} = 6.8 \times 10^{-4}$$

When we try solving this equation using the approximation  $0.10 - x \approx 0.10$  (that is, by neglecting the concentration of acid that ionizes), we obtain:

$$x = 8.2 \times 10^{-3} M$$

Because this approximation is greater than 5% of 0.10 M, however, we should work the problem in standard quadratic form. Rearranging, we have:

$$\begin{aligned} x^2 &= (0.10 - x)(6.8 \times 10^{-4}) \\ &= 6.8 \times 10^{-5} - (6.8 \times 10^{-4})x \\ x^2 + (6.8 \times 10^{-4})x - 6.8 \times 10^{-5} &= 0 \end{aligned}$$

Substituting these values in the standard quadratic formula gives:

$$\begin{aligned} x &= \frac{-6.8 \times 10^{-4} \pm \sqrt{(6.8 \times 10^{-4})^2 - 4(-6.8 \times 10^{-5})}}{2} \\ &= \frac{-6.8 \times 10^{-4} \pm 1.6 \times 10^{-2}}{2} \end{aligned}$$

Of the two solutions, only the positive value for  $x$  is chemically reasonable. From that value, we can determine  $[\text{H}^+]$  and hence the pH:

$$x = [\text{H}^+] = [\text{F}^-] = 7.9 \times 10^{-3} M, \text{ so } \text{pH} = -\log[\text{H}^+] = 2.10$$

From our result, we can calculate the percent of molecules ionized:

$$\begin{aligned} \text{Percent ionization of HF} &= \frac{\text{concentration ionized}}{\text{original concentration}} \times 100\% \\ &= \frac{7.9 \times 10^{-3} M}{0.10 M} \times 100\% = 7.9\% \end{aligned}$$

**Practice Exercise 1**

What is the pH of a 0.010 M solution of HF?

(a) 1.58 (b) 2.10 (c) 2.30 (d) 2.58 (e) 2.64

**Practice Exercise 2**

In Practice Exercise 2 for Sample Exercise 16.11, we found that the percent ionization of niacin ( $K_a = 1.5 \times 10^{-5}$ ) in a 0.020 M solution is 2.7%. Calculate the percentage of niacin molecules ionized in a solution that is (a) 0.010 M, (b)  $1.0 \times 10^{-3} M$ .

**Polyprotic Acids**

Acids that have more than one ionizable H atom are known as **polyprotic acids**. Sulfurous acid ( $\text{H}_2\text{SO}_3$ ), for example, can undergo two successive ionizations:

Note that the acid-dissociation constants are labeled  $K_{a1}$  and  $K_{a2}$ . The numbers on the constants refer to the particular proton of the acid that is ionizing. Thus,  $K_{a2}$  always refers to the equilibrium involving removal of the second proton of a polyprotic acid.

We see that  $K_{a2}$  for sulfurous acid is much smaller than  $K_{a1}$ . Because of electrostatic attractions, we would expect a positively charged proton to be lost more readily from the neutral  $\text{H}_2\text{SO}_3$  molecule than from the negatively charged  $\text{HSO}_3^-$  ion. This observation is general: *It is always easier to remove the first proton from a polyprotic acid than to remove the second.* Similarly, for an acid with three ionizable protons, it is easier to remove the second proton than the third. Thus, the  $K_a$  values become successively smaller as successive protons are removed.

**TABLE 16.3** Acid-Dissociation Constants of Some Common Polyprotic Acids

| Name       | Formula   | $K_{a1}$             | $K_{a2}$              | $K_{a3}$              |
|------------|---|----------------------|-----------------------|-----------------------|
| Ascorbic   | $\text{H}_2\text{C}_6\text{H}_6\text{O}_6$      | $8.0 \times 10^{-5}$ | $1.6 \times 10^{-12}$ |                       |
| Carbonic   | $\text{H}_2\text{CO}_3$                         | $4.3 \times 10^{-7}$ | $5.6 \times 10^{-11}$ |                       |
| Citric     | $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$      | $7.4 \times 10^{-4}$ | $1.7 \times 10^{-5}$  | $4.0 \times 10^{-7}$  |
| Oxalic     | $\text{HOOC}-\text{COOH}$                       | $5.9 \times 10^{-2}$ | $6.4 \times 10^{-5}$  |                       |
| Phosphoric | $\text{H}_3\text{PO}_4$                         | $7.5 \times 10^{-3}$ | $6.2 \times 10^{-8}$  | $4.2 \times 10^{-13}$ |
| Sulfurous  | $\text{H}_2\text{SO}_3$                         | $1.7 \times 10^{-2}$ | $6.4 \times 10^{-8}$  |                       |
| Sulfuric   | $\text{H}_2\text{SO}_4$                         | Large                | $1.2 \times 10^{-2}$  |                       |
| Tartaric   | $\text{C}_2\text{H}_2\text{O}_2(\text{COOH})_2$ | $1.0 \times 10^{-3}$ | $4.6 \times 10^{-5}$  |                       |

**Give It Some Thought**

What is the equilibrium associated with  $K_{a3}$  for  $\text{H}_3\text{PO}_4$ ?

**Go Figure**

How many protons per citric acid molecule are ionizable?

▲ **Figure 16.13** The structure of citric acid.

The acid-dissociation constants for common polyprotic acids are listed in **Table 16.3**, and Appendix D provides a more complete list. The structure of citric acid illustrates the presence of multiple ionizable protons in **Figure 16.13**.

Notice in Table 16.3 that in most cases the  $K_a$  values for successive losses of protons differ by a factor of at least  $10^3$ . Notice also that the value of  $K_{a1}$  for sulfuric acid is listed simply as “large.” Sulfuric acid is a strong acid with respect to the removal of the first proton. Thus, the reaction for the first ionization step lies completely to the right:

However,  $\text{HSO}_4^-$  is a weak acid for which  $K_{a2} = 1.2 \times 10^{-2}$ .

For many polyprotic acids  $K_{a1}$  is much larger than subsequent dissociation constants, in which case the  $\text{H}^+(aq)$  in the solution comes almost entirely from the first ionization reaction. As long as successive  $K_a$  values differ by a factor of  $10^3$  or more, it is usually possible to obtain a satisfactory estimate of the pH of polyprotic acid solutions by treating the acids as if they were monoprotic, considering only  $K_{a1}$ .

**Sample Exercise 16.14****Calculating the pH of a Solution of a Polyprotic Acid**

The solubility of  $\text{CO}_2$  in water at  $25^\circ\text{C}$  and 0.1 atm is 0.0037  $M$ . The common practice is to assume that all the dissolved  $\text{CO}_2$  is in the form of carbonic acid ( $\text{H}_2\text{CO}_3$ ), which is produced in the reaction

What is the pH of a 0.0037  $M$  solution of  $\text{H}_2\text{CO}_3$ ?

**SOLUTION**

**Analyze** We are asked to determine the pH of a 0.0037  $M$  solution of a polyprotic acid.

**Plan**  $\text{H}_2\text{CO}_3$  is a diprotic acid; the two acid-dissociation constants,  $K_{a1}$  and  $K_{a2}$  (Table 16.3), differ by more than a factor of  $10^3$ . Consequently, the pH can be determined by considering only  $K_{a1}$ , thereby treating the acid as if it were a monoprotic acid.

**Solve**

Proceeding as in Sample Exercises 16.12 and 16.13, we can write the equilibrium reaction and equilibrium concentrations as:

|                               |                |      |      |
|-------------------------------|----------------|------|------|
| Initial concentration (M)     | 0.0037         | 0    | 0    |
| Change in concentration (M)   | $-x$           | $+x$ | $+x$ |
| Equilibrium concentration (M) | $(0.0037 - x)$ | $x$  | $x$  |

The equilibrium-constant expression is:

$$K_{a1} = \frac{[\text{H}^+][\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} = \frac{(x)(x)}{0.0037 - x} = 4.3 \times 10^{-7}$$

Solving this quadratic equation, we get:

$$x = 4.0 \times 10^{-5} M$$

Alternatively, because  $K_{a1}$  is small, we can make the simplifying approximation that  $x$  is small, so that:

$$0.0037 - x \approx 0.0037$$

Thus,

$$\frac{(x)(x)}{0.0037} = 4.3 \times 10^{-7}$$

Solving for  $x$ , we have:

$$\begin{aligned} x^2 &= (0.0037)(4.3 \times 10^{-7}) = 1.6 \times 10^{-9} \\ x &= [\text{H}^+] = [\text{HCO}_3^-] = \sqrt{1.6 \times 10^{-9}} = 4.0 \times 10^{-5} M \end{aligned}$$

Because we get the same value (to two significant figures) our simplifying assumption was justified. The pH is therefore:

$$\text{pH} = -\log[\text{H}^+] = -\log(4.0 \times 10^{-5}) = 4.40$$

**Comment** If we were asked for  $[\text{CO}_3^{2-}]$  we would need to use  $K_{a2}$ . Let's illustrate that calculation. Using our calculated values of  $[\text{HCO}_3^-]$  and  $[\text{H}^+]$  and setting  $[\text{CO}_3^{2-}] = y$ , we have:

|                               |                            |                            |      |
|-------------------------------|----------------------------|----------------------------|------|
| Initial concentration (M)     | $4.0 \times 10^{-5}$       | $4.0 \times 10^{-5}$       | 0    |
| Change in concentration (M)   | $-y$                       | $+y$                       | $+y$ |
| Equilibrium concentration (M) | $(4.0 \times 10^{-5} - y)$ | $(4.0 \times 10^{-5} + y)$ | $y$  |

Assuming that  $y$  is small relative to  $4.0 \times 10^{-5}$ , we have:

$$\begin{aligned} K_{a2} &= \frac{[\text{H}^+][\text{CO}_3^{2-}]}{[\text{HCO}_3^-]} = \frac{(4.0 \times 10^{-5})(y)}{4.0 \times 10^{-5}} = 5.6 \times 10^{-11} \\ y &= 5.6 \times 10^{-11} M = [\text{CO}_3^{2-}] \end{aligned}$$

We see that the value for  $y$  is indeed very small compared with  $4.0 \times 10^{-5}$ , showing that our assumption was justified. It also shows that the ionization of  $\text{HCO}_3^-$  is negligible relative to that of  $\text{H}_2\text{CO}_3$ , as far as production of  $\text{H}^+$  is concerned. However, it is the *only* source of  $\text{CO}_3^{2-}$ , which has a very low concentration in the solution. Our calculations thus tell us that in a solution of carbon dioxide in water, most of the  $\text{CO}_2$  is in the form of  $\text{CO}_2$  or  $\text{H}_2\text{CO}_3$ , only a small fraction ionizes to form  $\text{H}^+$  and  $\text{HCO}_3^-$ , and an even smaller fraction ionizes to give  $\text{CO}_3^{2-}$ . Notice also that  $[\text{CO}_3^{2-}]$  is numerically equal to  $K_{a2}$ .

► **Practice Exercise 1**

What is the pH of a 0.28 M solution of ascorbic acid (Vitamin C)? (See Table 16.3 for  $K_{a1}$  and  $K_{a2}$ .)

(a) 2.04 (b) 2.32 (c) 2.82 (d) 4.65 (e) 6.17

► **Practice Exercise 2**

(a) Calculate the pH of a 0.020 M solution of oxalic acid ( $\text{H}_2\text{C}_2\text{O}_4$ ). (See Table 16.3 for  $K_{a1}$  and  $K_{a2}$ .)

(b) Calculate the concentration of oxalate ion,  $[\text{C}_2\text{O}_4^{2-}]$ , in this solution.

## A CLOSER LOOK Polyprotic Acids

Different protonation states of polyprotic acids exist at different pH values. Shown in Figure 16.14 are the relative equilibrium concentrations of phosphoric acid and its successive conjugate bases as a function of pH.

We can learn many things from Figure 16.14. For instance, if the pH is greater than 4, there is essentially no  $\text{H}_3\text{PO}_4$  left in solution. At pH > 14, the major component is the phosphate ion,  $\text{PO}_4^{3-}$ . We can

also see that when the pH is equal to one of the  $\text{p}K_a$  values, the concentrations of the relevant conjugate acid-base pairs are equal. For instance, if you look at pH = 7.21,  $[\text{H}_2\text{PO}_4^{2-}] = [\text{HPO}_4^-]$ . This makes sense if we consider that the equilibrium reaction at that pH is:

*Continued*

And therefore  $K_{a2}$  corresponds to

$$K_{a2} = [\text{HPO}_4^{2-}][\text{H}_3\text{O}^+]/[\text{H}_2\text{PO}_4^-]$$

Using our log rules, we can see that

$$\text{p}K_{a2} = \log([\text{H}_2\text{PO}_4^-]/[\text{HPO}_4^{2-}]) + \text{pH}$$

and therefore if  $\text{p}K_{a2}$  has the same value as the pH, the ratio of  $[\text{H}_2\text{PO}_4^-]$  to  $[\text{HPO}_4^{2-}]$  must be one (since the log of 1 is equal to zero).

## 16.7 | Weak Bases

Many substances behave as weak bases in water. Weak bases react with water, abstracting protons from  $\text{H}_2\text{O}$ , thereby forming the conjugate acid of the base and  $\text{OH}^-$  ions:

The equilibrium-constant expression for this reaction can be written as

$$K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]} \quad [16.34]$$

Water is the solvent, so it is omitted from the equilibrium-constant expression. One of the most commonly encountered weak bases is ammonia,  $\text{NH}_3$ :

As with  $K_w$  and  $K_a$ , the subscript  $b$  in  $K_b$  denotes that the equilibrium constant refers to a particular type of reaction, namely, the ionization of a weak base in water. The constant  $K_b$ , the **base-dissociation constant**, always refers to the equilibrium in which a base reacts with  $\text{H}_2\text{O}$  to form the corresponding conjugate acid and  $\text{OH}^-$ .

Table 16.4 lists the Lewis structures, conjugate acids, and  $K_b$  values for a number of weak bases in water. Appendix D includes a more extensive list. These bases contain one or more lone pairs of electrons because a lone pair is necessary to form the bond with  $\text{H}^+$ . Notice that in the neutral molecules in Table 16.4, the lone pairs are on nitrogen atoms. The other bases listed are anions derived from weak acids.

### Types of Weak Bases

Weak bases fall into two general categories. The first category is neutral substances that have an atom with a nonbonding pair of electrons that can accept a proton. Most of these bases, including all uncharged bases in Table 16.4, contain a nitrogen atom. These substances include ammonia and a related class of compounds called **amines** (Figure 16.15).

TABLE 16.4 Some Weak Bases in Water at 25 °C

| Base  | Structural Formula* | Conjugate Acid                    | $K_b$                |
|---|---------------------|-----------------------------------|----------------------|
| Ammonia ( $\text{NH}_3$ )                   |                     | $\text{NH}_4^+$                   | $1.8 \times 10^{-5}$ |
| Pyridine ( $\text{C}_5\text{H}_5\text{N}$ ) |                     | $\text{C}_5\text{H}_5\text{NH}^+$ | $1.7 \times 10^{-9}$ |
| Hydroxylamine ( $\text{HONH}_2$ )           |                     | $\text{HONH}_3^+$                 | $1.1 \times 10^{-8}$ |
| Methylamine ( $\text{CH}_3\text{NH}_2$ )    |                     | $\text{CH}_3\text{NH}_3^+$        | $4.4 \times 10^{-4}$ |
| Hydrosulfide ion ( $\text{HS}^-$ )          |                     | $\text{H}_2\text{S}$              | $1.8 \times 10^{-7}$ |
| Carbonate ion ( $\text{CO}_3^{2-}$ )        |                     | $\text{HCO}_3^-$                  | $1.8 \times 10^{-4}$ |
| Hypochlorite ion ( $\text{ClO}^-$ )         |                     | $\text{HClO}$                     | $3.3 \times 10^{-7}$ |

\*The atom that accepts the proton is shown in blue.

### Sample Exercise 16.15

#### Using $K_b$ to Calculate $[\text{OH}^-]$

Calculate the concentration of  $\text{OH}^-$  in a 0.15 M solution of  $\text{NH}_3$ .

#### SOLUTION

**Analyze** We are given the concentration of a weak base and asked to determine the concentration of  $\text{OH}^-$ .

**Plan** We will use essentially the same procedure here as used in solving problems involving the ionization of weak acids—that is, write the chemical equation and tabulate initial and equilibrium concentrations.

#### Solve

The ionization reaction and equilibrium-constant expression are:

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = 1.8 \times 10^{-5}$$

Ignoring the concentration of  $\text{H}_2\text{O}$  because it is not involved in the equilibrium-constant expression, we see that the equilibrium concentrations are:

|                               |              |   |      |      |
|-------------------------------|--------------|---|------|------|
| Initial concentration (M)     | 0.15         | — | 0    | 0    |
| Change in concentration (M)   | $-x$         | — | $+x$ | $+x$ |
| Equilibrium concentration (M) | $(0.15 - x)$ | — | $x$  | $x$  |

Inserting these quantities into the equilibrium-constant expression gives:

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{(x)(x)}{0.15 - x} = 1.8 \times 10^{-5}$$

Continued

Because  $K_b$  is small, the amount of  $\text{NH}_3$  that reacts with water is much smaller than the  $\text{NH}_3$  concentration, and so we can neglect  $x$  relative to 0.15  $M$ . Then we have:

$$\frac{x^2}{0.15} = 1.8 \times 10^{-5}$$

$$x^2 = (0.15)(1.8 \times 10^{-5}) = 2.7 \times 10^{-6}$$

$$x = [\text{NH}_4^+] = [\text{OH}^-] = \sqrt{2.7 \times 10^{-6}} = 1.6 \times 10^{-3} M$$

**Check** The value obtained for  $x$  is only about 1% of the  $\text{NH}_3$  concentration, 0.15  $M$ . Therefore, neglecting  $x$  relative to 0.15 was justified.

**Comment** You may be asked to find the pH of a solution of a weak base. Once you have found  $[\text{OH}^-]$ , you can proceed as in Sample Exercise 16.9, where we calculated the pH of a strong base. In the present sample exercise, we have seen that the 0.15  $M$  solution of  $\text{NH}_3$  contains  $[\text{OH}^-] = 1.6 \times 10^{-3} M$ . Thus,  $\text{pOH} = -\log(1.6 \times 10^{-3}) = 2.80$ , and  $\text{pH} = 14.00 - 2.80 = 11.20$ . The pH of the solution is above 7 because we are dealing with a solution of a base.

### Practice Exercise 1

What is the pH of a 0.65  $M$  solution of pyridine,  $\text{C}_5\text{H}_5\text{N}$ ? (See Table 16.4 for  $K_b$ .)

(a) 4.48 (b) 8.96 (c) 9.52 (d) 9.62 (e) 9.71

### Practice Exercise 2

Which of the following compounds should produce the highest pH as a 0.05  $M$  solution: pyridine, methylamine, or nitrous acid?

In organic amines, at least one  $\text{N}-\text{H}$  bond in  $\text{NH}_3$  is replaced with an  $\text{N}-\text{C}$  bond. Like  $\text{NH}_3$ , amines can abstract a proton from a water molecule by forming an  $\text{N}-\text{H}$  bond, as shown here for methylamine:

Anions of weak acids make up the second general category of weak bases. In an aqueous solution of sodium hypochlorite ( $\text{NaClO}$ ), for example,  $\text{NaClO}$  dissociates to  $\text{Na}^+$  and  $\text{ClO}^-$  ions. The  $\text{Na}^+$  ion is always a spectator ion in acid–base reactions. [∞ \(Section 4.3\)](#) The  $\text{ClO}^-$  ion, however, is the conjugate base of a weak acid, hypochlorous acid. Consequently, the  $\text{ClO}^-$  ion acts as a weak base in water:

In Figure 16.6 we saw that bleach is quite basic (pH values of 12–13). Common chlorine bleach is typically a 5%  $\text{NaOCl}$  solution.

## Sample Exercise 16.16

### Using pH to Determine the Concentration of a Salt

A solution made by adding solid sodium hypochlorite ( $\text{NaClO}$ ) to enough water to make 2.00 L of solution has a pH of 10.50. Using the information in Equation 16.37, calculate the number of moles of  $\text{NaClO}$  added to the water.

### SOLUTION

**Analyze**  $\text{NaClO}$  is an ionic compound consisting of  $\text{Na}^+$  and  $\text{ClO}^-$  ions. As such, it is a strong electrolyte that completely dissociates in solution into  $\text{Na}^+$ , a spectator ion, and  $\text{ClO}^-$  ion, a weak base with  $K_b = 3.3 \times 10^{-7}$  (Equation 16.37). Given this information, we must calculate the number of moles of  $\text{NaClO}$  needed to increase the pH of 2.00 L of water to 10.50.

**Plan** From the pH, we can determine the equilibrium concentration of  $\text{OH}^-$ . We can then construct a table of initial and equilibrium concentrations in which the initial concentration of  $\text{ClO}^-$  is our unknown. We can calculate  $[\text{ClO}^-]$  using the expression for  $K_b$ .

**Solve**

We can calculate  $[\text{OH}^-]$  by using either Equation 16.16 or Equation 16.20; we will use the latter method here:

$$\text{pOH} = 14.00 - \text{pH} = 14.00 - 10.50 = 3.50$$

$$[\text{OH}^-] = 10^{-3.50} = 3.2 \times 10^{-4} \text{ M}$$

This concentration is high enough that we can assume that Equation 16.37 is the only source of  $\text{OH}^-$ ; that is, we can neglect any  $\text{OH}^-$  produced by the autoionization of  $\text{H}_2\text{O}$ . We now assume a value of  $x$  for the initial concentration of  $\text{ClO}^-$  and solve the equilibrium problem in the usual way.

| $\text{ClO}^-(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HClO}(aq) + \text{OH}^-(aq)$ |                            |   |                       |                       |
|---|----------------------------|---|-----------------------|-----------------------|
| Initial concentration (M)   | $x$                        | — | 0                     | 0                     |
| Change in concentration (M)   | $-3.2 \times 10^{-4}$      | — | $+3.2 \times 10^{-4}$ | $+3.2 \times 10^{-4}$ |
| Equilibrium concentration (M)   | $(x - 3.2 \times 10^{-4})$ | — | $3.2 \times 10^{-4}$  | $3.2 \times 10^{-4}$  |

We now use the expression for the base-dissociation constant to solve for  $x$ :

$$K_b = \frac{[\text{HClO}][\text{OH}^-]}{[\text{ClO}^-]} = \frac{(3.2 \times 10^{-4})^2}{x - 3.2 \times 10^{-4}} = 3.3 \times 10^{-7}$$

$$x = \frac{(3.2 \times 10^{-4})^2}{3.3 \times 10^{-7}} + (3.2 \times 10^{-4}) = 0.31 \text{ M}$$

We say that the solution is 0.31 M in NaClO even though some of the  $\text{ClO}^-$  ions have reacted with water. Because the solution is 0.31 M in NaClO and the total volume of solution is 2.00 L, 0.62 mol of NaClO is the amount of the salt that was added to the water.

**Practice Exercise 1**

The benzoate ion,  $\text{C}_6\text{H}_5\text{COO}^-$ , is a weak base with  $K_b = 1.6 \times 10^{-10}$ . How many moles of sodium benzoate are

present in 0.50 L of a solution of  $\text{NaC}_6\text{H}_5\text{COO}$  if the pH is 9.04?

(a) 0.38 (b) 0.66 (c) 0.76 (d) 1.5 (e) 2.9

**Practice Exercise 2**

What is the molarity of an aqueous  $\text{NH}_3$  solution that has a pH of 11.17?

## 16.8 | Relationship Between $K_a$ and $K_b$

We have seen in a qualitative way that the stronger an acid, the weaker its conjugate base. Let us be more quantitative and consider the  $\text{NH}_4^+$  and  $\text{NH}_3$  conjugate acid–base pair. Each species reacts with water. For the acid,  $\text{NH}_4^+$ , the equilibrium is

or written in its simpler form:

For the base,  $\text{NH}_3$ , the equilibrium is

Each equilibrium is expressed by a dissociation constant:

$$K_a = \frac{[\text{NH}_3][\text{H}^+]}{[\text{NH}_4^+]} \quad K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$$

When we add Equations 16.38 and 16.39, the  $\text{NH}_4^+$  and  $\text{NH}_3$  species cancel and we are left with the autoionization of water:

Recall that when two equations are added to give a third, the equilibrium constant associated with the third equation equals the product of the equilibrium constants of the first two equations. [∞ \(Section 15.3\)](#)

Applying this rule to our present example, we see that when we multiply  $K_a$  and  $K_b$ , we obtain

$$\begin{aligned} K_a \times K_b &= \left( \frac{[\text{NH}_3][\text{H}^+]}{[\text{NH}_4^+]} \right) \left( \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} \right) \\ &= [\text{H}^+][\text{OH}^-] = K_w \end{aligned}$$

Thus, the product of  $K_a$  and  $K_b$  is the ion-product constant for water,  $K_w$  (Equation 16.16). We expect this result because adding Equations 16.38 and 16.39 gave us the autoionization equilibrium for water, for which the equilibrium constant is  $K_w$ .

The above result holds for any conjugate acid–base pair. In general, *the product of the acid-dissociation constant for an acid and the base-dissociation constant for its conjugate base equals the ion-product constant for water:*

$$K_a \times K_b = K_w \quad (\text{for a conjugate acid–base pair}) \quad [16.40]$$

Note that this relationship only holds true for conjugate acid–base pairs. You should not use Equation 16.40 for any random pair of acids and bases! As the strength of an acid increases ( $K_a$  gets larger), the strength of its conjugate base must decrease ( $K_b$  gets smaller), so that the product  $K_a \times K_b$  remains  $1.0 \times 10^{-14}$  at 25 °C. [Table 16.5](#) demonstrates this relationship.

By using Equation 16.40, we can calculate  $K_b$  for any weak base if we know  $K_a$  for its conjugate acid. Similarly, we can calculate  $K_a$  for a weak acid if we know  $K_b$  for its conjugate base. As a practical consequence, ionization constants are often listed for only one member of a conjugate acid–base pair. For example, Appendix D does not contain  $K_b$  values for the anions of weak acids because they can be readily calculated from the tabulated  $K_a$  values for their conjugate acids.

Recall that we often express  $[\text{H}^+]$  as pH:  $\text{pH} = -\log [\text{H}^+]$ . [∞ \(Section 16.4\)](#) This “p” nomenclature is often used for other very small numbers. For example, if you look up the values for acid- or base-dissociation constants in a chemistry handbook, you may find them expressed as  $\text{p}K_a$  or  $\text{p}K_b$ :

$$\text{p}K_a = -\log K_a \quad \text{and} \quad \text{p}K_b = -\log K_b \quad [16.41]$$

Using this nomenclature, we can write Equation 16.40 in terms of  $\text{p}K_a$  and  $\text{p}K_b$  by taking the negative logarithm of both sides:

$$\text{p}K_a + \text{p}K_b = \text{p}K_w = 14.00 \quad \text{at } 25^\circ\text{C (conjugate acid–base pair)} \quad [16.42]$$

### Give It Some Thought

$K_a$  for acetic acid is  $1.8 \times 10^{-5}$ . What is the first digit of the  $\text{p}K_a$  value for acetic acid?

**TABLE 16.5 Some Conjugate Acid–Base Pairs**

| Acid                     | $K_a$                 | Base                      | $K_b$                 |
|--------------------------|-----------------------|---------------------------|-----------------------|
| $\text{HNO}_3$           | (Strong acid)         | $\text{NO}_3^-$           | (Negligible basicity) |
| HF                       | $6.8 \times 10^{-4}$  | $\text{F}^-$              | $1.5 \times 10^{-11}$ |
| $\text{CH}_3\text{COOH}$ | $1.8 \times 10^{-5}$  | $\text{CH}_3\text{COO}^-$ | $5.6 \times 10^{-10}$ |
| $\text{H}_2\text{CO}_3$  | $4.3 \times 10^{-7}$  | $\text{HCO}_3^-$          | $2.3 \times 10^{-8}$  |
| $\text{NH}_4^+$          | $5.6 \times 10^{-10}$ | $\text{NH}_3$             | $1.8 \times 10^{-5}$  |
| $\text{HCO}_3^-$         | $5.6 \times 10^{-11}$ | $\text{CO}_3^{2-}$        | $1.8 \times 10^{-4}$  |
| $\text{OH}^-$            | (Negligible acidity)  | $\text{O}^{2-}$           | (Strong base)         |

## CHEMISTRY PUT TO WORK Amines and Amine Hydrochlorides

Many low-molecular-weight amines have a fishy odor. Amines and  $\text{NH}_3$  are produced by the anaerobic (absence of  $\text{O}_2$ ) decomposition of dead animal or plant matter. Two such amines with very disagreeable aromas are  $\text{H}_2\text{N}(\text{CH}_2)_4\text{NH}_2$ , *putrescine*, and  $\text{H}_2\text{N}(\text{CH}_2)_5\text{NH}_2$ , *cadaverine*. The names of these substances are testaments to their repugnant odors!

Many drugs, including quinine, codeine, caffeine, and amphetamine, are amines. Like other amines, these substances are weak bases; the amine nitrogen is readily protonated upon treatment with an acid. The resulting products are called *acid salts*. If we use  $A$  as the abbreviation for an amine, the acid salt formed by reaction with hydrochloric acid can be written  $\text{AH}^+\text{Cl}^-$ . It can also be written as  $A \cdot \text{HCl}$  and referred to as a hydrochloride. Amphetamine hydrochloride, for example, is the acid salt formed by treating amphetamine with  $\text{HCl}$ :

Acid salts are much less volatile, more stable, and generally more water soluble than the corresponding amines. For this reason, many drugs that are amines are sold and administered as acid salts. Some examples of over-the-counter medications that contain amine hydrochlorides as active ingredients are shown in Figure 16.16.

**Related Exercises:** 16.9, 16.73, 16.74, 16.101, 16.114, 16.124

## Sample Exercise 16.17

Calculating  $K_a$  or  $K_b$  for a Conjugate Acid–Base Pair

Calculate (a)  $K_b$  for the fluoride ion, (b)  $K_a$  for the ammonium ion.

## SOLUTION

**Analyze** We are asked to determine dissociation constants for  $\text{F}^-$ , the conjugate base of  $\text{HF}$ , and  $\text{NH}_4^+$ , the conjugate acid of  $\text{NH}_3$ .

**Plan** We can use the tabulated  $K$  values for  $\text{HF}$  and  $\text{NH}_3$  and the relationship between  $K_a$  and  $K_b$  to calculate the dissociation constants for their conjugates,  $\text{F}^-$  and  $\text{NH}_4^+$ .

## Solve

(a) For the weak acid  $\text{HF}$ , Table 16.2 and Appendix D give  $K_a = 6.8 \times 10^{-4}$ . We can use Equation 16.40 to calculate  $K_b$  for the conjugate base,  $\text{F}^-$ :

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{6.8 \times 10^{-4}} = 1.5 \times 10^{-11}$$

(b) For  $\text{NH}_3$ , Table 16.4 and Appendix D give  $K_b = 1.8 \times 10^{-5}$ , and this value in Equation 16.40 gives us  $K_a$  for the conjugate acid,  $\text{NH}_4^+$ :

$$K_a = \frac{K_w}{K_b} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

**Check** The respective  $K$  values for  $\text{F}^-$  and  $\text{NH}_4^+$  are listed in Table 16.5, where we see that the values calculated here agree with those in Table 16.5.

## Practice Exercise 1

By using information from Appendix D, put the following three substances in order of weakest to strongest base:

(i)  $(\text{CH}_3)_3\text{N}$ , (ii)  $\text{HCOO}^-$ , (iii)  $\text{BrO}^-$ .

(a) i < ii < iii (b) ii < i < iii (c) iii < i < ii

(d) ii < iii < i (e) iii < ii < i

## Practice Exercise 2

(a) Based on information in Appendix D, which of these anions has the largest base-dissociation constant:  $\text{NO}_2^-$ ,  $\text{PO}_4^{3-}$ , or  $\text{N}_3^-$ ?  
(b) The base quinoline has the structure

Its conjugate acid is listed in handbooks as having a  $\text{p}K_a$  of 4.90. What is the base-dissociation constant for quinoline?

## 16.9 | Acid–Base Properties of Salt Solutions

Even before you began this chapter, you were undoubtedly aware of many substances that are acidic, such as  $\text{HNO}_3$ ,  $\text{HCl}$ , and  $\text{H}_2\text{SO}_4$ , and others that are basic, such as  $\text{NaOH}$  and  $\text{NH}_3$ . However, our discussion up to this point in the chapter has indicated that ions can also exhibit acidic or basic properties. For example, we calculated  $K_a$  for  $\text{NH}_4^+$  and  $K_b$  for  $\text{F}^-$  in Sample Exercise 16.17. Such behavior implies that salt solutions can be acidic or basic. Before proceeding with further discussions of acids and bases, let's examine the way dissolved salts can affect pH.

Because nearly all salts are strong electrolytes, we can assume that any salt dissolved in water is completely dissociated. Consequently, the acid–base properties of salt solutions are due to the behavior of the cations and anions. Many ions react with water to generate  $\text{H}^+(\text{aq})$  or  $\text{OH}^-(\text{aq})$  ions. This type of reaction is often called **hydrolysis**. The pH of an aqueous salt solution can be predicted qualitatively by considering the salt's cations and anions.

### An Anion's Ability to React with Water

In general, an anion  $\text{A}^-$  in solution can be considered the conjugate base of an acid. For example,  $\text{Cl}^-$  is the conjugate base of  $\text{HCl}$ , and  $\text{CH}_3\text{COO}^-$  is the conjugate base of  $\text{CH}_3\text{COOH}$ . Whether an anion reacts with water to produce hydroxide ions depends on the strength of the anion's conjugate acid. To identify the acid and assess its strength, we add a proton to the anion's formula. If the acid  $\text{HA}$  determined in this way is one of the seven strong acids listed at the beginning of Section 16.5, the anion has a negligible tendency to produce  $\text{OH}^-$  ions from water and does not affect the pH of the solution. The presence of  $\text{Cl}^-$  in an aqueous solution, for example, does not result in the production of any  $\text{OH}^-$  and does not affect the pH. Thus,  $\text{Cl}^-$  is always a spectator ion in acid–base chemistry.

If  $\text{HA}$  is *not* one of the seven common strong acids, it is a weak acid. In this case, the conjugate base  $\text{A}^-$  is a weak base, and it reacts to a small extent with water to produce the weak acid and hydroxide ions:

The  $\text{OH}^-$  ion generated in this way increases the pH of the solution, making it basic. Acetate ion, for example, being the conjugate base of a weak acid, reacts with water to produce acetic acid and hydroxide ions, thereby increasing the pH of the solution:

### Give It Some Thought

Will  $\text{NO}_3^-$  ions affect the pH of a solution? What about  $\text{CO}_3^{2-}$  ions?

The situation is more complicated for salts containing anions that have ionizable protons, such as  $\text{HSO}_3^-$ . These salts are amphiprotic (Section 16.2), and how they behave in water is determined by the relative magnitudes of  $K_a$  and  $K_b$  for the ion, as shown in Sample Exercise 16.19. If  $K_a > K_b$ , the ion causes the solution to be acidic. If  $K_b > K_a$ , the solution is made basic by the ion.

### A Cation's Ability to React with Water

Polyatomic cations containing one or more protons can be considered the conjugate acids of weak bases. The  $\text{NH}_4^+$  ion, for example, is the conjugate acid of the weak base  $\text{NH}_3$ . Thus,  $\text{NH}_4^+$  is a weak acid and will donate a proton to water, producing hydronium ions and thereby lowering the pH:

## Go Figure

Why do we need to use multiple acid–base indicators in this figure?

▲ **Figure 16.17** Effect of cations on solution pH. The pH values of 1.0 M solutions of four nitrate salts are estimated using acid–base indicators.

**TABLE 16.6** Acid-Dissociation Constants for Metal Cations in Aqueous Solution at 25 °C

| Cation           | $K_a$                 |
|------------------|-----------------------|
| $\text{Fe}^{3+}$ | $6.3 \times 10^{-3}$  |
| $\text{Cr}^{3+}$ | $1.6 \times 10^{-4}$  |
| $\text{Al}^{3+}$ | $1.4 \times 10^{-5}$  |
| $\text{Fe}^{2+}$ | $3.2 \times 10^{-10}$ |
| $\text{Zn}^{2+}$ | $2.5 \times 10^{-10}$ |
| $\text{Ni}^{2+}$ | $2.5 \times 10^{-11}$ |

A more unusual situation is encountered with some metal salts. For instance, if you dissolve  $\text{Fe}(\text{NO}_3)_3$  in water, the solution is quite acidic. Why would this be the case?

You might think that the nitrate ion is somehow producing nitric acid, but you would be wrong. Recall that nitrate is the conjugate base of a strong acid, and therefore its reaction with water is negligible. Instead, we have to consider what  $\text{Fe}^{3+}$  is doing in solution. It turns out that other small, highly charged metal cations like  $\text{Fe}^{3+}$  also create surprisingly acidic solutions in water (Table 16.6). A comparison of  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  values in the table illustrates how acidity increases as ionic charge increases.

Notice that  $K_a$  values for the 3+ ions in Table 16.6 are comparable to the values for familiar weak acids, such as acetic acid ( $K_a = 1.8 \times 10^{-5}$ ). In contrast, the ions of alkali and alkaline earth metals, being relatively large and not highly charged, do not react with water and therefore do not affect pH. Note that these are the same cations found in the strong bases (Section 16.5). The different tendencies of four cations to lower the pH of a solution are illustrated in Figure 16.17.

The mechanism by which metal ions produce acidic solutions is shown in Figure 16.18. Because metal ions are positively charged, they attract the unshared electron pairs of water molecules and become hydrated. ∞ (Section 13.1) The larger the charge on the metal ion, the stronger the interaction between the ion and the oxygen of its hydrating water molecules. As the strength of this interaction increases, the O—H bonds in the hydrating water molecules become weaker. This facilitates transfer of protons from the hydration water molecules to solvent water molecules.

## Combined Effect of Cation and Anion in Solution

To determine whether a salt forms an acidic, a basic, or a neutral solution when dissolved in water, we must consider the action of both cation and anion. There are four possible combinations.

1. If the salt contains an anion that does not react with water and a cation that does not react with water, we expect the pH to be neutral. Such is the case when the anion is a conjugate base of a strong acid and the cation is either from group 1A or one of the heavier members of group 2A ( $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , and  $\text{Ba}^{2+}$ ). Examples:  $\text{NaCl}$ ,  $\text{Ba}(\text{NO}_3)_2$ ,  $\text{RbClO}_4$ .

▲ **Figure 16.18** A hydrated  $\text{Fe}^{3+}$  ion acts as an acid by donating an  $\text{H}^+$  from a bound water molecule to a free  $\text{H}_2\text{O}$  molecule, forming  $\text{H}_3\text{O}^+$ .

- If the salt contains an anion that reacts with water to produce hydroxide ions and a cation that does not react with water, we expect the pH to be basic. Such is the case when the anion is the conjugate base of a weak acid and the cation is either from group 1A or one of the heavier members of group 2A ( $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , and  $\text{Ba}^{2+}$ ). *Examples:*  $\text{NaClO}$ ,  $\text{RbF}$ ,  $\text{BaSO}_3$ .
- If the salt contains a cation that reacts with water to produce hydronium ions and an anion that does not react with water, we expect the pH to be acidic. Such is the case when the cation is a conjugate acid of a weak base or a small cation with a charge of  $2+$  or greater. *Examples:*  $\text{NH}_4\text{NO}_3$ ,  $\text{AlCl}_3$ ,  $\text{Fe}(\text{NO}_3)_3$ .
- If the salt contains an anion and a cation *both* capable of reacting with water, both hydroxide ions and hydronium ions are produced. Whether the solution is basic, neutral, or acidic depends on the relative abilities of the ions to react with water. *Examples:*  $\text{NH}_4\text{ClO}$ ,  $\text{Al}(\text{CH}_3\text{COO})_3$ ,  $\text{CrF}_3$ .

### Sample Exercise 16.18

#### Determining Whether Salt Solutions Are Acidic, Basic, or Neutral

Determine whether aqueous solutions of each of these salts are acidic, basic, or neutral: (a)  $\text{Ba}(\text{CH}_3\text{COO})_2$ , (b)  $\text{NH}_4\text{Cl}$ , (c)  $\text{CH}_3\text{NH}_3\text{Br}$ , (d)  $\text{KNO}_3$ , (e)  $\text{Al}(\text{ClO}_4)_3$ .

#### SOLUTION

**Analyze** We are given the chemical formulas of five ionic compounds (salts) and asked whether their aqueous solutions will be acidic, basic, or neutral.

**Plan** We can determine whether a solution of a salt is acidic, basic, or neutral by identifying the ions in solution and by assessing how each ion will affect the pH.

#### Solve

- This solution contains barium ions and acetate ions. The cation is an ion of a heavy alkaline earth metal and will therefore not affect the pH. The anion,  $\text{CH}_3\text{COO}^-$ , is the conjugate base of the weak acid  $\text{CH}_3\text{COOH}$  and will hydrolyze to produce  $\text{OH}^-$  ions, thereby making the solution basic.
- In this solution,  $\text{NH}_4^+$  is the conjugate acid of a weak base ( $\text{NH}_3$ ) and is therefore acidic.  $\text{Cl}^-$  is the conjugate base of a strong acid ( $\text{HCl}$ ) and therefore has no influence on the pH

of the solution. Because the solution contains an ion that is acidic ( $\text{NH}_4^+$ ) and one that has no influence on pH ( $\text{Cl}^-$ ), the solution of  $\text{NH}_4\text{Cl}$  will be acidic.

- Here  $\text{CH}_3\text{NH}_3^+$  is the conjugate acid of a weak base ( $\text{CH}_3\text{NH}_2$ , an amine) and is therefore acidic, and  $\text{Br}^-$  is the conjugate base of a strong acid ( $\text{HBr}$ ) and therefore pH neutral. Because the solution contains one ion that is acidic and one that has no influence on pH, the solution of  $\text{CH}_3\text{NH}_3\text{Br}$  will be acidic.
- This solution contains the  $\text{K}^+$  ion, which is a cation of group 1A, and the  $\text{NO}_3^-$  ion, which is the conjugate base of the strong acid  $\text{HNO}_3$ . Neither of the ions will react with water to any appreciable extent, making the solution neutral.
- This solution contains  $\text{Al}^{3+}$  and  $\text{ClO}_4^-$  ions. Cations, such as  $\text{Al}^{3+}$ , that have a charge of  $3+$  or higher are acidic. The  $\text{ClO}_4^-$  ion is the conjugate base of a strong acid ( $\text{HClO}_4$ ) and therefore does not affect pH. Thus, the solution of  $\text{Al}(\text{ClO}_4)_3$  will be acidic.

► **Practice Exercise 1**

Order the following solutions from lowest to highest pH:

(i) 0.10 M NaClO, (ii) 0.10 M KBr, (iii) 0.10 M  $\text{NH}_4\text{ClO}_4$ .

- (a) i < ii < iii    (b) ii < i < iii    (c) iii < i < ii  
(d) ii < iii < i    (e) iii < ii < i

► **Practice Exercise 2**

Indicate which salt in each of the following pairs forms the more acidic (or less basic) 0.010 M solution:

- (a)  $\text{NaNO}_3$  or  $\text{Fe}(\text{NO}_3)_3$ , (b) KBr or  $\text{KBrO}_3$ ,  
(c)  $\text{CH}_3\text{NH}_3\text{Cl}$  or  $\text{BaCl}_2$ , (d)  $\text{NH}_4\text{NO}_2$  or  $\text{NH}_4\text{NO}_3$ .

**Sample Exercise 16.19****Predicting Whether the Solution of an Amphiprotic Anion Is Acidic or Basic**

Predict whether the salt  $\text{Na}_2\text{HPO}_4$  forms an acidic solution or a basic solution when dissolved in water.

**SOLUTION**

**Analyze** We are asked to predict whether a solution of  $\text{Na}_2\text{HPO}_4$  is acidic or basic. This substance is an ionic compound composed of  $\text{Na}^+$  and  $\text{HPO}_4^{2-}$  ions.

**Plan** We need to evaluate each ion, predicting whether it is acidic or basic. Because  $\text{Na}^+$  is a cation of group 1A, it has no influence on pH. Thus, our analysis of whether the solution is acidic or basic must focus on the behavior of the  $\text{HPO}_4^{2-}$  ion. We need to consider that  $\text{HPO}_4^{2-}$  can act as either an acid or a base:

Of these two reactions, the one with the larger equilibrium constant determines whether the solution is acidic or basic.

**Solve** The value of  $K_a$  for Equation 16.46 is  $K_{a3}$  for  $\text{H}_3\text{PO}_4$ ;  $4.2 \times 10^{-13}$  (Table 16.3). For Equation 16.47, we must calculate  $K_b$  for the base  $\text{HPO}_4^{2-}$  from the value of  $K_a$  for its conjugate acid,  $\text{H}_2\text{PO}_4^-$ , and the relationship

$K_a \times K_b = K_w$  (Equation 16.40). The relevant value of  $K_a$  for  $\text{H}_2\text{PO}_4^-$  is  $K_{a2}$  for  $\text{H}_3\text{PO}_4$ ;  $6.2 \times 10^{-8}$  (from Table 16.3). We therefore have

$$K_b(\text{HPO}_4^{2-}) \times K_a(\text{H}_2\text{PO}_4^-) = K_w = 1.0 \times 10^{-14}$$

$$K_b(\text{HPO}_4^{2-}) = \frac{1.0 \times 10^{-14}}{6.2 \times 10^{-8}} = 1.6 \times 10^{-7}.$$

This  $K_b$  value is more than  $10^5$  times larger than  $K_a$  for  $\text{HPO}_4^{2-}$ ; thus, the reaction in Equation 16.47 predominates over that in Equation 16.46, and the solution is basic.

► **Practice Exercise 1**

How many of the following salts are expected to produce acidic solutions (see Table 16.3 for data):  $\text{NaHSO}_4$ ,  $\text{NaHC}_2\text{O}_4$ ,  $\text{NaH}_2\text{PO}_4$ , and  $\text{NaHCO}_3$ ?

- (a) 0    (b) 1    (c) 2    (d) 3    (e) 4

► **Practice Exercise 2**

Predict whether the dipotassium salt of citric acid ( $\text{K}_2\text{HC}_6\text{H}_5\text{O}_7$ ) forms an acidic or basic solution in water (see Table 16.3 for data).

## 16.10 | Acid–Base Behavior and Chemical Structure

When a substance is dissolved in water, it may behave as an acid or a base, or exhibit no acid–base properties. How does the chemical structure of a substance determine which of these behaviors is exhibited by the substance? For example, why do some substances that contain OH groups behave as bases, releasing  $\text{OH}^-$  ions into solution, whereas others behave as acids, ionizing to release  $\text{H}^+$  ions? In this section we discuss briefly the effects of chemical structure on acid–base behavior.

**Factors That Affect Acid Strength**

The strength of an acid is often affected by three separate factors.

- **H—A Bond Polarity** A molecule containing H will act as a proton donor (an acid) only if the H—A bond is polarized such that the H atom has a partial positive charge.  (Section 8.4) Recall that we indicate such polarization in this way:

In ionic hydrides, such as NaH, the bond is polarized in the opposite way: The H atom possesses a negative charge and behaves as a proton acceptor (a base). Nonpolar H—A bonds, such as the H—C bond in  $\text{CH}_4$ , produce neither acidic nor basic aqueous

solutions. *In general, as the H—A bond polarity increases, to draw more electron density from H, the stronger the acid.*

- **H—A Bond Strength** The strength of the bond  $\infty$  (Section 8.8) also helps determine whether a molecule containing an H—A bond donates a proton. Very strong bonds are less easily broken than weaker ones. This factor is important, for example, in the hydrogen halides. The H—F bond is the most polar H—A bond. You therefore might expect HF to be a very strong acid if bond polarity were all that mattered. However, the H—A bond strength increases as you move up the group: 299 kJ/mol in HI, 366 kJ/mol in HBr, 431 kJ/mol in HCl, and 567 kJ/mol in HF. Because HF has the highest bond strength among the hydrogen halides, it is a weak acid, whereas all the other hydrogen halides are strong acids in water. *In general, as the H—A bond strength decreases, the stronger the acid.*
- **Conjugate Base Stability** A third factor that affects the ease with which a hydrogen atom ionizes from HA is the stability of the conjugate base,  $A^-$ . *In general, the greater the stability of the conjugate base, the stronger the acid.*

## Binary Acids

For a series of binary acids HA in which A represents members of the same *group* in the periodic table, the strength of the H—A bond is generally the most important factor determining acid strength. The strength of an H—A bond tends to decrease as the element A increases in size. As a result, the bond strength decreases and acidity increases down a group. Thus, HCl is a stronger acid than HF, and  $H_2S$  is a stronger acid than  $H_2O$ .

Bond polarity is the major factor determining acidity for binary acids HA when A represents members of the same *period*. Thus, acidity increases as the electronegativity of the element A increases, as it generally does moving from left to right across a period.  $\infty$  (Section 8.4) For example, the difference in acidity of the period 2 elements is  $CH_4 < NH_3 \ll H_2O < HF$ . Because the C—H bond is essentially nonpolar,  $CH_4$  shows no tendency to form  $H^+$  and  $CH_3^-$  ions. Although the N—H bond is polar,  $NH_3$  has a nonbonding pair of electrons on the nitrogen atom that dominates its chemistry, so  $NH_3$  acts as a base rather than an acid.

The periodic trends in the acid strengths of binary compounds of hydrogen and the nonmetals of periods 2 and 3 are summarized in Figure 16.19.

| 4A                                  | 5A  | 6A   | 7A  |                              |
|-------------------------------------|---|--|---|------------------------------|

| Increasing acid strength<br>        |   |  |   |                              |

▲ Figure 16.19 Trends in acid strength for the binary hydrides of periods 2–4.

## Oxyacids

Many common acids, such as sulfuric acid, contain one or more O—H bonds:

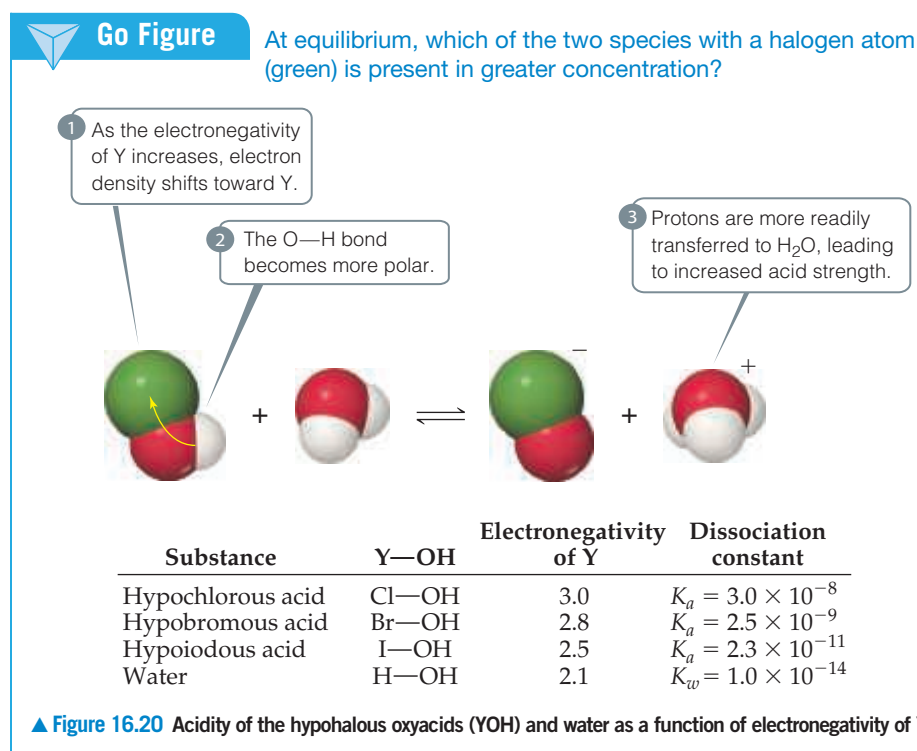

Acids in which OH groups and possibly additional oxygen atoms are bound to a central atom are called **oxyacids**. At first it may seem confusing that the OH group, which we know behaves as a base, is also present in some acids. Let's take a closer look at what factors determine whether a given OH group behaves as a base or as an acid.

Consider an OH group bound to some atom Y, which might in turn have other groups attached to it:

At one extreme, Y might be a metal, such as Na or Mg. Because of the low electronegativity of metals, the pair of electrons shared between Y and O is completely transferred to oxygen, and an ionic compound containing  $\text{OH}^-$  is formed. Such compounds are therefore sources of  $\text{OH}^-$  ions and behave as bases, as in NaOH and  $\text{Mg}(\text{OH})_2$ .

When Y is a nonmetal, the bond to O is covalent and the substance does not readily lose  $\text{OH}^-$ . Instead, these compounds are either acidic or neutral. *Generally, as the electronegativity of Y increases, so does the acidity of the substance.* This happens for two reasons: First, as electron density is drawn toward Y, the O—H bond becomes weaker and more polar, thereby favoring loss of  $\text{H}^+$ . Second, because the conjugate base of any acid YOH is usually an anion, its stability generally increases as the electronegativity of Y increases. This trend is illustrated by the  $K_a$  values of the hypohalous acids (YOH acids where Y is a halide ion), which decrease as the electronegativity of the halogen atom decreases (Figure 16.20).

Many oxyacids contain additional oxygen atoms bonded to the central atom Y. These atoms pull electron density from the O—H bond, further increasing its polarity. Increasing the number of oxygen atoms also helps stabilize the conjugate base by increasing its ability to “spread out” its negative charge. Thus, *the strength of an acid increases as additional electronegative atoms bond to the central atom Y*. For example, the strength of the chlorine oxyacids (Y = Cl) steadily increases as O atoms are added:

Because the oxidation number of Y increases as the number of attached O atoms increases, this correlation can be stated in an equivalent way: In a series of oxyacids, the acidity increases as the oxidation number of the central atom increases.

### Give It Some Thought

Which acid has the larger acid-dissociation constant,  $\text{HIO}_2$  or  $\text{HBrO}_3$ ?

## Sample Exercise 16.20

### Predicting Relative Acidities from Composition and Structure

Arrange the compounds in each series in order of increasing acid strength: (a)  $\text{AsH}_3$ ,  $\text{HBr}$ ,  $\text{KH}$ ,  $\text{H}_2\text{Se}$ ; (b)  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SeO}_3$ ,  $\text{H}_2\text{SeO}_4$ .

### SOLUTION

**Analyze** We are asked to arrange two sets of compounds in order from weakest acid to strongest acid. In (a), the substances are binary compounds containing H, and in (b) the substances are oxyacids.

**Plan** For the binary compounds, we will consider the electronegativities of As, Br, K, and Se relative to the electronegativity of H. The higher the electronegativity of these atoms, the higher the partial positive charge on H and so the more acidic the compound.

For the oxyacids, we will consider both the electronegativities of the central atom and the number of oxygen atoms bonded to the central atom.

### Solve

- (a) Because K is on the left side of the periodic table, it has a very low electronegativity (0.8, from Figure 8.8, p. 310). As a result, the hydrogen in  $\text{KH}$  carries a negative charge. Thus,  $\text{KH}$  should be the least acidic (most basic) compound in the series.

Arsenic and hydrogen have similar electronegativities, 2.0 and 2.1, respectively. This means that the As—H bond is nonpolar, and so  $\text{AsH}_3$  has little tendency to donate a proton in aqueous solution.

The electronegativity of Se is 2.4, and that of Br is 2.8. Consequently, the H—Br bond is more polar than the H—Se bond, giving  $\text{HBr}$  the greater tendency to donate a proton. (This expectation is confirmed by Figure 16.19, where we see

that  $\text{H}_2\text{Se}$  is a weak acid and  $\text{HBr}$  a strong acid.) Thus, the order of increasing acidity is  $\text{KH} < \text{AsH}_3 < \text{H}_2\text{Se} < \text{HBr}$ .

- (b) The acids  $\text{H}_2\text{SO}_4$  and  $\text{H}_2\text{SeO}_4$  have the same number of O atoms and the same number of OH groups. In such cases, the acid strength increases with increasing electronegativity of the central atom. Because S is slightly more electronegative than Se (2.5 vs 2.4), we predict that  $\text{H}_2\text{SO}_4$  is more acidic than  $\text{H}_2\text{SeO}_4$ .

For acids with the same central atom, the acidity increases as the number of oxygen atoms bonded to the central atom increases. Thus,  $\text{H}_2\text{SeO}_4$  should be a stronger acid than  $\text{H}_2\text{SeO}_3$ . We predict the order of increasing acidity to be  $\text{H}_2\text{SeO}_3 < \text{H}_2\text{SeO}_4 < \text{H}_2\text{SO}_4$ .

### Practice Exercise 1

Arrange the following substances in order from weakest to strongest acid:  $\text{HClO}_3$ ,  $\text{HOI}$ ,  $\text{HBrO}_2$ ,  $\text{HClO}_2$ ,  $\text{HIO}_2$ .

- (a)  $\text{HIO}_2 < \text{HOI} < \text{HClO}_3 < \text{HBrO}_2 < \text{HClO}_2$   
 (b)  $\text{HOI} < \text{HIO}_2 < \text{HBrO}_2 < \text{HClO}_2 < \text{HClO}_3$   
 (c)  $\text{HBrO}_2 < \text{HIO}_2 < \text{HClO}_2 < \text{HOI} < \text{HClO}_3$   
 (d)  $\text{HClO}_3 < \text{HClO}_2 < \text{HBrO}_2 < \text{HIO}_2 < \text{HOI}$   
 (e)  $\text{HOI} < \text{HClO}_2 < \text{HBrO}_2 < \text{HIO}_2 < \text{HClO}_3$

### Practice Exercise

In each pair, choose the compound that gives the more acidic (or less basic) solution: (a)  $\text{HBr}$ ,  $\text{HF}$ ; (b)  $\text{PH}_3$ ,  $\text{H}_2\text{S}$ ; (c)  $\text{HNO}_2$ ,  $\text{HNO}_3$ ; (d)  $\text{H}_2\text{SO}_3$ ,  $\text{H}_2\text{SeO}_3$ .

## Carboxylic Acids

Another large group of acids is illustrated by acetic acid, a weak acid ( $K_a = 1.8 \times 10^{-5}$ ):

The portion of the structure shown in red is called the *carboxyl group*, which is often written COOH. Thus, the chemical formula of acetic acid is written as  $\text{CH}_3\text{COOH}$ , where only the hydrogen atom in the carboxyl group can be ionized. Acids that contain a carboxyl group are called **carboxylic acids**, and they form the largest category of organic acids. Formic acid and benzoic acid are further examples of this large and important category of acids:

Two factors contribute to the acidic behavior of carboxylic acids. First, the additional oxygen atom attached to the carbon of the carboxyl group draws electron density from the O—H bond, increasing its polarity and helping to stabilize the conjugate base. Second, the conjugate base of a carboxylic acid (a *carboxylate anion*) can exhibit resonance (Section 8.6), which contributes to the stability of the anion by spreading the negative charge over several atoms:

### Give It Some Thought

Is a carboxylate salt likely to produce acidic or basic solutions in water?

## CHEMISTRY AND LIFE The Amphiprotic Behavior of Amino Acids

As we will discuss in greater detail in Chapter 24, *amino acids* are the building blocks of proteins. The general structure of amino acids is

where different amino acids have different R groups attached to the central carbon atom. For example, in *glycine*, the simplest amino acid, R is a hydrogen atom, and in *alanine* R is a  $\text{CH}_3$  group:

Amino acids contain a carboxyl group and can therefore serve as acids. They also contain an  $\text{NH}_2$  group, characteristic of amines (Section 16.7), and thus they can also act as bases. Amino acids, therefore, are amphiprotic. For glycine, we might expect the acid and base reactions with water to be

The pH of a solution of glycine in water is about 6.0, indicating that it is a slightly stronger acid than base.

The acid–base chemistry of amino acids is more complicated than shown in Equations 16.48 and 16.49, however. Because the COOH group can act as an acid and the  $\text{NH}_2$  group can act as a base, amino acids undergo a “self-contained” Brønsted–Lowry acid–base reaction in which the proton of the carboxyl group is transferred to the basic nitrogen atom:

*Continued*

Although the form of the amino acid on the right in this equation is electrically neutral overall, it has a positively charged end and a

negatively charged end. A molecule of this type is called a *zwitterion* (German for “hybrid ion”).

Do amino acids exhibit any properties indicating that they behave as zwitterions? If so, their behavior should be similar to that of ionic substances. [Section 8.2](#) Crystalline amino acids have relatively high melting points, usually above 200 °C, which is characteristic of ionic solids. Amino acids are far more soluble in water than in nonpolar solvents. In addition, the dipole moments of amino acids are large, consistent with a large separation of charge in the molecule. Thus, the ability of amino acids to act simultaneously as acids and bases has important effects on their properties.

**Related Exercise: 16.114**

## 16.11 | Lewis Acids and Bases

For a substance to be a proton acceptor (a Brønsted–Lowry base), it must have an unshared pair of electrons for binding the proton, as, for example, in  $\text{NH}_3$ . Using Lewis structures, we can write the reaction between  $\text{H}^+$  and  $\text{NH}_3$  as

G. N. Lewis was the first to notice this aspect of acid–base reactions. He proposed a more general definition of acids and bases that emphasizes the shared electron pair:

- A **Lewis acid** is an electron-pair acceptor.
- A **Lewis base** is an electron-pair donor.

Every base that we have discussed thus far—whether  $\text{OH}^-$ ,  $\text{H}_2\text{O}$ , an amine, or an anion—is an electron-pair donor. Everything that is a base in the Brønsted–Lowry sense (a proton acceptor) is also a base in the Lewis sense (an electron-pair donor). In the Lewis theory, however, a base can donate its electron pair to something other than  $\text{H}^+$ . The Lewis definition therefore greatly increases the number of species that can be considered acids; in other words,  $\text{H}^+$  is a Lewis acid but not the only one. For example, the reaction between  $\text{NH}_3$  and  $\text{BF}_3$  occurs because  $\text{BF}_3$  has a vacant orbital in its valence shell. [Section 8.7](#) It therefore acts as an electron-pair acceptor (a Lewis acid) toward  $\text{NH}_3$ , which donates the electron pair:

### Give It Some Thought

What feature must any molecule or ion have in order to act as a Lewis acid?

Our emphasis throughout this chapter has been on water as the solvent and on the proton as the source of acidic properties. In such cases we find the Brønsted–Lowry definition of acids and bases to be the most useful. In fact, when we speak of a substance as being acidic or basic, we are usually thinking of aqueous solutions and using these terms in the Arrhenius or Brønsted–Lowry sense. The advantage of the Lewis definitions of acid and base is that they allow us to treat a wider variety of reactions, including those that do not involve proton transfer, as acid–base reactions. To avoid confusion, a substance such as  $\text{BF}_3$  is rarely called an acid unless it is clear from the context that we are using the term in the sense of the Lewis definition. Instead, substances that function as electron-pair acceptors are referred to explicitly as “Lewis acids.”

Lewis acids include molecules that, like  $\text{BF}_3$ , have an incomplete octet of electrons. In addition, many simple cations can function as Lewis acids. For example,  $\text{Fe}^{3+}$  interacts strongly with cyanide ions to form the ferricyanide ion:

The  $\text{Fe}^{3+}$  ion has vacant orbitals that accept the electron pairs donated by the cyanide ions. (We will learn more in Chapter 23 about just which orbitals are used by the  $\text{Fe}^{3+}$  ion.) The metal ion is highly charged, too, which contributes to the interaction with  $\text{CN}^-$  ions.

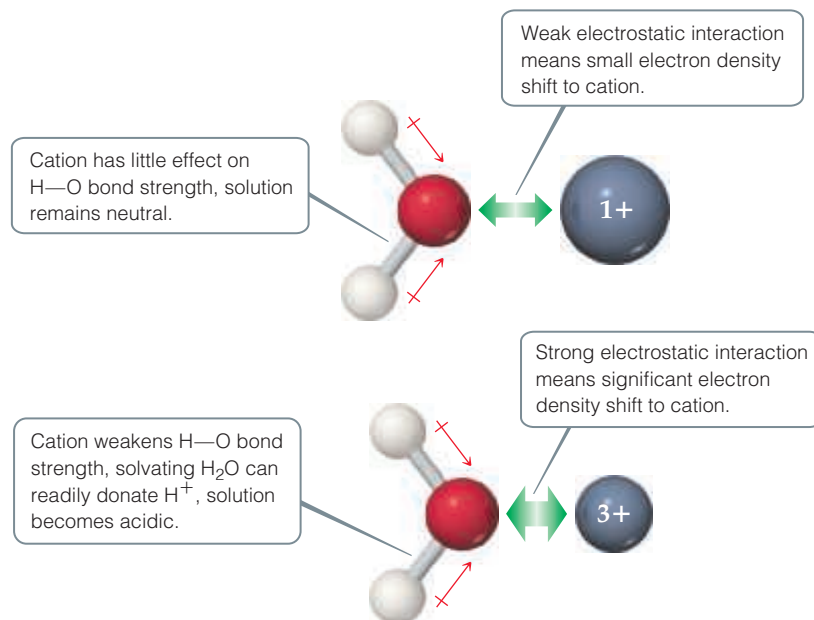

Some compounds containing multiple bonds can behave as Lewis acids. For example, the reaction of carbon dioxide with water to form carbonic acid ( $\text{H}_2\text{CO}_3$ ) can be pictured as an attack by a water molecule on  $\text{CO}_2$ , in which the water acts as an electron-pair donor and the  $\text{CO}_2$  as an electron-pair acceptor:

One electron pair of one of the carbon–oxygen double bonds is moved onto the oxygen, leaving a vacant orbital on the carbon, which means the carbon can accept an electron pair donated by  $\text{H}_2\text{O}$ . The initial acid–base product rearranges by transferring a proton from the water oxygen to a carbon dioxide oxygen, forming carbonic acid.

The hydrated cations we encountered in Section 16.9, such as  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$  in Figure 16.18, form through the reaction between the cation acting as a Lewis acid and the water molecules acting as Lewis bases. When a water molecule interacts with the positively charged metal ion, electron density is drawn from the oxygen (Figure 16.21). This flow of electron density causes the  $\text{O}—\text{H}$  bond to become more polarized; as a result, water molecules bound to the metal ion are more acidic than those in the bulk solvent. This effect becomes more pronounced as the charge of the cation increases, which explains why  $3+$  cations are much more acidic than cations with smaller charges.

The Lewis acid–base concept allows many ideas developed in this chapter to be used more broadly in chemistry, including reactions in solvents other than water. If you take a course in organic chemistry, you will see a number of important reactions that require the presence of a Lewis acid in order to proceed. The interaction of lone pairs on one molecule or ion with vacant orbitals on another molecule or ion is one of the most important concepts in chemistry, as you will see throughout your studies.

▲ **Figure 16.21** The acidity of a hydrated cation depends on cation charge.

## Sample Integrative Exercise

## Putting Concepts Together

Phosphorous acid ( $\text{H}_3\text{PO}_3$ ) has the Lewis structure shown at right.

(a) Explain why  $\text{H}_3\text{PO}_3$  is diprotic and not triprotic. (b) A 25.0-mL sample of an  $\text{H}_3\text{PO}_3$  solution titrated with 0.102 M NaOH requires 23.3 mL of NaOH to neutralize both acidic protons. What is the molarity of the  $\text{H}_3\text{PO}_3$  solution? (c) The original solution from part (b) has a pH of 1.59. Calculate the percent ionization and  $K_{a1}$  for  $\text{H}_3\text{PO}_3$ , assuming that  $K_{a1} \gg K_{a2}$ . (d) How does the osmotic pressure of a 0.050 M solution of HCl compare qualitatively with that of a 0.050 M solution of  $\text{H}_3\text{PO}_3$ ? Explain.

## SOLUTION

We will use what we have learned about molecular structure and its impact on acidic behavior to answer part (a). We will then use stoichiometry and the relationship between pH and  $[\text{H}^+]$  to

answer parts (b) and (c). Finally, we will consider percent ionization in order to compare the osmotic pressure of the two solutions in part (d).

(a) Acids have polar H—X bonds. From Figure 8.8 (p. 310) we see that the electronegativity of H is 2.1 and that of P is also 2.1. Because the two elements have the same electronegativity, the H—P bond is nonpolar. [∞∞ \(Section 8.4\)](#) Thus, this H cannot be acidic. The other two H atoms, however, are bonded to O, which has an electronegativity of 3.5. The H—O bonds are, therefore, polar with H having a partial positive charge. These two H atoms are consequently acidic.

(b) The chemical equation for the neutralization reaction is:

From the definition of molarity,  $M = \text{mol/L}$ , we see that moles =  $M \times L$ . [∞∞ \(Section 4.5\)](#) Thus, the number of moles of NaOH added to the solution is:

The balanced equation indicates that 2 mol of NaOH is consumed for each mole of  $\text{H}_3\text{PO}_3$ . Thus, the number of moles of  $\text{H}_3\text{PO}_3$  in the sample is:

The concentration of the  $\text{H}_3\text{PO}_3$  solution, therefore, equals  $(1.19 \times 10^{-3} \text{ mol}) / (0.0250 \text{ L}) = 0.0476 \text{ M}$ .

$$(0.0233 \text{ L})(0.102 \text{ mol/L}) = 2.38 \times 10^{-3} \text{ mol NaOH}$$

$$(2.38 \times 10^{-3} \text{ mol NaOH}) \left( \frac{1 \text{ mol H}_3\text{PO}_3}{2 \text{ mol NaOH}} \right) = 1.19 \times 10^{-3} \text{ mol H}_3\text{PO}_3$$

(c) From the pH of the solution, 1.59, we can calculate  $[\text{H}^+]$  at equilibrium:

Because  $K_{a1} \gg K_{a2}$ , the vast majority of the ions in solution are from the first ionization step of the acid.

Because one  $\text{H}_2\text{PO}_3^-$  ion forms for each  $\text{H}^+$  ion formed, the equilibrium concentrations of  $\text{H}^+$  and  $\text{H}_2\text{PO}_3^-$  are equal:  $[\text{H}^+] = [\text{H}_2\text{PO}_3^-] = 0.026 \text{ M}$ . The equilibrium concentration of  $\text{H}_3\text{PO}_3$  equals the initial concentration minus the amount that ionizes to form  $\text{H}^+$  and  $\text{H}_2\text{PO}_3^-$ :  $[\text{H}_3\text{PO}_3] = 0.0476 \text{ M} - 0.026 \text{ M} = 0.022 \text{ M}$  (two significant figures). These results can be tabulated as follows:

$$[\text{H}^+] = \text{antilog}(-1.59) = 10^{-1.59} = 0.026 \text{ M (two significant figures)}$$

|                               |        |        |        |
|-------------------------------|--------|--------|--------|
| Initial concentration (M)     | 0.0476 | 0      | 0      |
| Change in concentration (M)   | −0.026 | +0.026 | +0.026 |
| Equilibrium concentration (M) | 0.022  | 0.026  | 0.026  |

The percent ionization is:

$$\text{percent ionization} = \frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{H}_3\text{PO}_3]_{\text{initial}}} \times 100\% = \frac{0.026 \text{ M}}{0.0476 \text{ M}} \times 100\% = 55\%$$

The first acid-dissociation constant is:

$$K_{a1} = \frac{[\text{H}^+][\text{H}_2\text{PO}_3^-]}{[\text{H}_3\text{PO}_3]} = \frac{(0.026)(0.026)}{0.022} = 0.031$$

(d) Osmotic pressure is a colligative property and depends on the total concentration of particles in solution. [∞∞ \(Section 13.5\)](#) Because HCl is a strong acid, a 0.050 M solution will contain 0.050 M  $\text{H}^+(aq)$  and 0.050 M  $\text{Cl}^-(aq)$ , or a total of 0.100 mol/L of particles. Because  $\text{H}_3\text{PO}_3$  is a weak acid, it ionizes to a lesser extent than HCl and, hence, there are fewer particles in the  $\text{H}_3\text{PO}_3$  solution. As a result, the  $\text{H}_3\text{PO}_3$  solution will have the lower osmotic pressure.

## Chapter Summary and Key Terms

**ARRHENIUS ACIDS AND BASES (SECTION 16.1)** Acids and bases were first recognized by the properties of their aqueous solutions. For example, acids turn litmus red, whereas bases turn litmus blue. Arrhenius recognized that the properties of acidic solutions are due to  $\text{H}^+(\text{aq})$  ions and those of basic solutions are due to  $\text{OH}^-(\text{aq})$  ions.

**BRØNSTED-LOWRY ACIDS AND BASES (SECTION 16.2)** The Brønsted-Lowry concept of acids and bases is more general than the Arrhenius concept and emphasizes the transfer of a proton ( $\text{H}^+$ ) from an acid to a base. The  $\text{H}^+$  ion is strongly bound to water. For this reason, the **hydronium ion**,  $\text{H}_3\text{O}^+(\text{aq})$ , is often used to represent the predominant form of  $\text{H}^+$  in water instead of the simpler  $\text{H}^+(\text{aq})$ .

A **Brønsted-Lowry acid** is a substance that donates a proton to another substance; a **Brønsted-Lowry base** is a substance that accepts a proton from another substance. Water is an **amphiprotic** substance, one that can function as either a Brønsted-Lowry acid or base, depending on the substance with which it reacts.

The **conjugate base** of a Brønsted-Lowry acid is the species that remains when a proton is removed from the acid. The **conjugate acid** of a Brønsted-Lowry base is the species formed by adding a proton to the base. Together, an acid and its conjugate base (or a base and its conjugate acid) are called a **conjugate acid-base pair**.

The acid-base strengths of conjugate acid-base pairs are related: The stronger an acid, the weaker is its conjugate base; the weaker an acid, the stronger is its conjugate base. In every acid-base reaction, the position of the equilibrium favors the transfer of the proton from the stronger acid to the stronger base.

**AUTOIONIZATION OF WATER (SECTION 16.3)** Water ionizes to a slight degree, forming  $\text{H}^+(\text{aq})$  and  $\text{OH}^-(\text{aq})$ . The extent of this **autoionization** is expressed by the **ion-product constant** for water:  $K_w = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$  (25 °C). This relationship holds for both pure water and aqueous solutions. The  $K_w$  expression indicates that the product of  $[\text{H}^+]$  and  $[\text{OH}^-]$  is a constant. Thus, as  $[\text{H}^+]$  increases,  $[\text{OH}^-]$  decreases. Acidic solutions are those that contain more  $\text{H}^+(\text{aq})$  than  $\text{OH}^-(\text{aq})$ , whereas basic solutions contain more  $\text{OH}^-(\text{aq})$  than  $\text{H}^+(\text{aq})$ . When  $[\text{H}^+] = [\text{OH}^-]$ , the solution is neutral.

**THE pH SCALE (SECTION 16.4)** The concentration of  $\text{H}^+(\text{aq})$  can be expressed in terms of **pH**:  $\text{pH} = -\log[\text{H}^+]$ . At 25 °C the pH of a neutral solution is 7.00, whereas the pH of an acidic solution is below 7.00, and the pH of a basic solution is above 7.00. This p notation is also used to represent the negative logarithm of other small quantities, as in pOH and  $\text{p}K_w$ . The pH of a solution can be measured using a pH meter, or it can be estimated using acid-base indicators.

**STRONG ACIDS AND BASES (SECTION 16.5)** Strong acids are strong electrolytes, ionizing completely in aqueous solution. The common strong acids are HCl, HBr, HI,  $\text{HNO}_3$ ,  $\text{HClO}_3$ ,  $\text{HClO}_4$ , and  $\text{H}_2\text{SO}_4$ . The conjugate bases of strong acids have negligible basicity. Common strong bases are the ionic hydroxides of the alkali metals and the heavy alkaline earth metals.

**WEAK ACIDS AND BASES (SECTIONS 16.6 AND 16.7)** Weak acids are weak electrolytes; only a small fraction of the molecules exist in solution in ionized form. The extent of ionization is expressed by the **acid-dissociation constant**,  $K_a$ , which is the equilibrium constant for the reaction  $\text{HA}(\text{aq}) \rightleftharpoons \text{H}^+(\text{aq}) + \text{A}^-(\text{aq})$ , which can also be

written as  $\text{HA}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{A}^-(\text{aq})$ . The larger the value of  $K_a$ , the stronger is the acid. For solutions of the same concentration, a stronger acid also has a larger **percent ionization**. The concentration of a weak acid and its  $K_a$  value can be used to calculate the pH of a solution.

**Polyprotic acids**, such as  $\text{H}_3\text{PO}_4$ , have more than one ionizable proton. These acids have acid-dissociation constants that decrease in magnitude in the order  $K_{a1} > K_{a2} > K_{a3}$ . Because nearly all the  $\text{H}^+(\text{aq})$  in a polyprotic acid solution comes from the first dissociation step, the pH can usually be estimated satisfactorily by considering only  $K_{a1}$ . Weak bases include  $\text{NH}_3$ , **amines**, and the anions of weak acids. The extent to which a weak base reacts with water to generate the corresponding conjugate acid and  $\text{OH}^-$  is measured by the **base-dissociation constant**,  $K_b$ .  $K_b$  is the equilibrium constant for the reaction  $\text{B}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{HB}^+(\text{aq}) + \text{OH}^-(\text{aq})$ , where B is the base.

**RELATIONSHIP BETWEEN  $K_a$  AND  $K_b$  (SECTION 16.8)** The relationship between the strength of an acid and the strength of its conjugate base is expressed quantitatively by the equation  $K_a \times K_b = K_w$ , where  $K_a$  and  $K_b$  are dissociation constants for conjugate acid-base pairs. This equation explains the inverse relationship between the strength of an acid and the strength of its conjugate base.

**ACID-BASE PROPERTIES OF SALTS (SECTION 16.9)** The acid-base properties of salts can be ascribed to the behavior of their respective cations and anions. The reaction of ions with water, with a resulting change in pH, is called **hydrolysis**. The cations of the alkali metals and the alkaline earth metals as well as the anions of strong acids, such as  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{I}^-$ , and  $\text{NO}_3^-$ , do not undergo hydrolysis. They are always spectator ions in acid-base chemistry. A cation that is the conjugate acid of a weak base produces  $\text{H}^+$  upon hydrolysis. An anion that is the conjugate base of a weak acid produces  $\text{OH}^-$  upon hydrolysis. Highly charged metal cations, such as  $\text{Fe}^{3+}$ , are hydrated in water; the metal-bound water molecules undergo reaction with free water to make  $\text{H}_3\text{O}^+$  and therefore are acidic.

**ACID-BASE BEHAVIOR AND CHEMICAL STRUCTURE (SECTION 16.10)** The tendency of a substance to show acidic or basic characteristics in water can be correlated with its chemical structure. Acid character requires the presence of a highly polar  $\text{H}-\text{X}$  bond. Acidity is also favored when the  $\text{H}-\text{X}$  bond is weak and when the  $\text{X}^-$  ion is very stable.

For **oxyacids** with the same number of OH groups and the same number of O atoms, acid strength increases with increasing electronegativity of the central atom. For oxyacids with the same central atom, acid strength increases as the number of oxygen atoms attached to the central atom increases. **Carboxylic acids**, which are organic acids containing the  $\text{COOH}$  group, are the most important class of organic acids. The presence of delocalized  $\pi$  bonding in the conjugate base is a major factor responsible for the acidity of these compounds.

**LEWIS ACIDS AND BASES (SECTION 16.11)** The Lewis concept of acids and bases emphasizes the shared electron pair rather than the proton. A **Lewis acid** is an electron-pair acceptor, and a **Lewis base** is an electron-pair donor. The Lewis concept is more general than the Brønsted-Lowry concept because it can apply to cases in which the acid is some substance other than  $\text{H}^+$ , and to solvents other than water.

## Learning Outcomes After studying this chapter, you should be able to:

- Define and identify Arrhenius acids and bases. (Section 16.1)  
*Related Exercises:* 16.13, 16.14
- Define and identify Brønsted-Lowry acids and bases and identify conjugate acid-base pairs. (Section 16.2)  
*Related Exercises:* 16.17, 16.18
- Correlate the strength of an acid to the strength of its conjugate base. (Section 16.2) *Related Exercises:* 16.23, 16.24
- Explain how the equilibrium position of a proton-transfer reaction relates to the strengths of the acids and bases involved. (Section 16.3) *Related Exercises:* 16.25, 16.26

- Describe the autoionization of water and explain how  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  are related via  $K_w$ . (Section 16.3)

Related Exercises: 16.27, 16.28

- Calculate the pH of a solution given  $[\text{H}_3\text{O}^+]$  or  $[\text{OH}^-]$ . (Section 16.4) Related Exercises: 16.37, 16.38
- Calculate the pH of a strong acid or strong base given its concentration. (Section 16.5) Related Exercises: 16.43, 16.44
- Calculate  $K_a$  or  $K_b$  for a weak acid or weak base given its concentration and the pH of the solution, and vice versa. (Sections 16.6 and 16.7) Related Exercises: 16.51, 16.52, 16.69, 16.70
- Calculate the pH of a weak acid or weak base or its percent ionization given its concentration and  $K_a$  or  $K_b$ . (Sections 16.6 and 16.7) Related Exercises: 16.63, 16.64

- Calculate  $K_b$  for a weak base given  $K_a$  of its conjugate acid, and similarly calculate  $K_a$  from  $K_b$ . (Section 16.8)

Related Exercises: 16.77, 16.78

- Predict whether an aqueous solution of a salt will be acidic, basic, or neutral. (Section 16.9) Related Exercises: 16.83, 16.84
- Predict the relative strength of a series of acids from their molecular structures. (Section 16.10) Related Exercises: 16.91, 16.92
- Define and identify Lewis acids and bases. (Section 16.11) Related Exercises: 16.95, 16.96

## Key Equations

- $K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$
- $\text{pH} = -\log[\text{H}^+]$
- $\text{pOH} = -\log[\text{OH}^-]$
- $\text{pH} + \text{pOH} = 14.00$
- $K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$  or  $K_a = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]}$
- Percent ionization =  $\frac{[\text{H}^+]_{\text{equilibrium}}}{[\text{HA}]_{\text{initial}}} \times 100\%$
- $K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]}$
- $K_a \times K_b = K_w$
- $\text{p}K_a = -\log K_a$  and  $\text{p}K_b = -\log K_b$

## Exercises

### Visualizing Concepts

- 16.1** (a) Identify the Brønsted–Lowry acid and base in the reaction

- (b) Identify the Lewis acid and base in the reaction. [Sections 16.2 and 16.11]

- 16.2** The following diagrams represent aqueous solutions of two monoprotic acids, HA (A = X or Y). The water molecules have been omitted for clarity. (a) Which is the stronger acid, HX or HY? (b) Which is the stronger base,  $\text{X}^-$  or  $\text{Y}^-$ ? (c) If you mix equal concentrations of HX and NaY, will the equilibrium

lie mostly to the right ( $K_c > 1$ ) or to the left ( $K_c < 1$ )? [Section 16.2]

- 16.3** The indicator methyl orange has been added to both of the following solutions. Based on the colors, classify each statement as true or false:

- (a) The pH of solution A is definitely less than 7.00.
- (b) The pH of solution B is definitely greater than 7.00.
- (c) The pH of solution B is greater than that of solution A. [Section 16.4]

Solution A      Solution B

- 16.4** The probe of the pH meter shown here is sitting in a beaker that contains a clear liquid. **(a)** You are told the liquid is pure water, a solution of  $\text{HCl}(aq)$ , or a solution of  $\text{KOH}(aq)$ . Which one is it? **(b)** If the liquid is one of the solutions, what is its molarity? **(c)** Why is the temperature given on the pH meter? [Sections 16.4 and 16.5]

- 16.5** The following diagrams represent aqueous solutions of three acids, HX, HY, and HZ. The water molecules have been omitted for clarity, and the hydrated proton is represented as  $\text{H}^+$  rather than  $\text{H}_3\text{O}^+$ . **(a)** Which of the acids is a strong acid? Explain. **(b)** Which acid would have the smallest acid-dissociation constant,  $K_a$ ? **(c)** Which solution would have the highest pH? [Sections 16.5 and 16.6]

- 16.6** The graph given below shows  $[\text{H}^+]$  versus concentration for an aqueous solution of an unknown substance. **(a)** Is the substance a strong acid, a weak acid, a strong base, or a weak base? **(b)** Based on your answer to (a), can you determine the value of the pH of the solution when the concentration is  $0.18\text{ M}$ ? **(c)** Would the line go exactly through the origin of the plot? [Sections 16.5 and 16.6]

- 16.7** Which of these statements about how the percent ionization of a weak acid depends on acid concentration is true? [Section 16.6]

- (a)** Line A is most accurate because  $K_a$  does not depend on concentration.  
**(b)** Line A is the most accurate because the percent ionization of the acid does not depend on concentration.  
**(c)** Line B is the most accurate because as the acid concentration increases, a greater proportion of it is ionized.  
**(d)** Line B is the most accurate because as the acid concentration increases,  $K_a$  increases.  
**(e)** Line C is the most accurate because as the acid concentration increases, a lesser proportion of it ionized.  
**(f)** Line C is the most accurate because as the acid concentration increases,  $K_a$  decreases.

- 16.8** Each of the three molecules shown here contains an OH group, but one molecule acts as a base, one as an acid, and the third is neither acid nor base. **(a)** Which one acts as a base? **(b)** Which one acts as an acid? **(c)** Which one is neither acidic nor basic? [Sections 16.6 and 16.7]

- 16.9** Phenylephrine, an organic substance with molecular formula  $C_9H_{13}NO_2$ , is used as a nasal decongestant in over-the-counter medications. The molecular structure of phenylephrine is shown below using the usual shortcut organic structure. (a) Would you expect a solution of phenylephrine to be acidic, neutral, or basic? (b) One of the active ingredients in Alka-Seltzer PLUS® cold medication is phenylephrine hydrochloride. How does this ingredient differ from the structure shown below? (c) Would you expect a solution of phenylephrine hydrochloride to be acidic, neutral, or basic? [Sections 16.8 and 16.9]

- 16.10** Which of the following diagrams best represents an aqueous solution of NaF? (For clarity, the water molecules are not shown.) Will this solution be acidic, neutral, or basic? [Section 16.9]

- 16.11** Consider the molecular models shown here, where X represents a halogen atom. (a) If X is the same atom in both molecules, which molecule will be more acidic? (b) Does the acidity of each molecule increase or decrease as the electronegativity of the atom X increases? [Section 16.10]

- 16.12** For each of these reactions, identify the acid and base among the reactants, and state if the acids and bases are Lewis, Arrhenius, and/or Brønsted–Lowry:
- (a)  $PCl_4^+ + Cl^- \longrightarrow PCl_5$   
 (b)  $NH_3 + BF_3 \longrightarrow H_3NBF_3$   
 (c)  $[Al(H_2O)_6]^{3+} + H_2O \longrightarrow [Al(H_2O)_5OH]^{2+} + H_3O^+$

## Arrhenius and Brønsted–Lowry Acids and Bases (Sections 16.1 and 16.2)

- 16.13**  $NH_3(g)$  and  $HCl(g)$  react to form the ionic solid  $NH_4Cl(s)$ . Which substance is the Brønsted–Lowry acid in this reaction? Which is the Brønsted–Lowry base?

- 16.14** Which of the following statements is false?

- (a) An Arrhenius base increases the concentration of  $OH^-$  in water.  
 (b) A Brønsted–Lowry base is a proton acceptor.  
 (c) Water can act as a Brønsted–Lowry acid.  
 (d) Water can act as a Brønsted–Lowry base.  
 (e) Any compound that contains an  $-OH$  group acts as a Brønsted–Lowry base.

- 16.15** (a) Give the conjugate base of the following Brønsted–Lowry acids: (i)  $HIO_3$ , (ii)  $NH_4^+$ . (b) Give the conjugate acid of the following Brønsted–Lowry bases: (i)  $O^{2-}$ , (ii)  $H_2PO_4^-$ .

- 16.16** (a) Give the conjugate base of the following Brønsted–Lowry acids: (i)  $HCOOH$ , (ii)  $HPO_4^{2-}$ . (b) Give the conjugate acid of the following Brønsted–Lowry bases: (i)  $SO_4^{2-}$ , (ii)  $CH_3NH_2$ .

- 16.17** Identify the Brønsted–Lowry acid and the Brønsted–Lowry base on the left side of each of the following equations, and also identify the conjugate acid and conjugate base of each on the right side:

- 16.18** Identify the Brønsted–Lowry acid and the Brønsted–Lowry base on the left side of each equation, and also identify the conjugate acid and conjugate base of each on the right side.

- 16.19** (a) The hydrogen sulfite ion ( $HSO_3^-$ ) is amphoteric. Write a balanced chemical equation showing how it acts as an acid toward water and another equation showing how it acts as a base toward water. (b) What is the conjugate acid of  $HSO_3^-$ ? What is its conjugate base?

- 16.20** (a) Write an equation for the reaction in which  $H_2C_6H_7O_5^-(aq)$  acts as a base in  $H_2O(l)$ . (b) Write an equation for the reaction in which  $H_2C_6H_7O_5^-(aq)$  acts as an acid in  $H_2O(l)$ . (c) What is the conjugate acid of  $H_2C_6H_7O_5^-(aq)$ ? What is its conjugate base?

- 16.21** Label each of the following as being a strong base, a weak base, or a species with negligible basicity. In each case write the formula of its conjugate acid, and indicate whether the conjugate acid is a strong acid, a weak acid, or a species with negligible acidity: (a)  $CH_3COO^-$ , (b)  $HCO_3^-$ , (c)  $O^{2-}$ , (d)  $Cl^-$ , (e)  $NH_3$ .

- 16.22** Label each of the following as being a strong acid, a weak acid, or a species with negligible acidity. In each case write the formula of its conjugate base, and indicate whether the conjugate base is a strong base, a weak base, or a species with negligible basicity: (a)  $HCOOH$ , (b)  $H_2$ , (c)  $CH_4$ , (d)  $HF$ , (e)  $NH_4^+$ .

- 16.23** (a) Which of the following is the stronger Brønsted–Lowry acid,  $HBrO$  or  $HBr$ ? (b) Which is the stronger Brønsted–Lowry base,  $F^-$  or  $Cl^-$ ?

- 16.24** (a) Which of the following is the stronger Brønsted–Lowry acid,  $HClO_3$  or  $HClO_2$ ? (b) Which is the stronger Brønsted–Lowry base,  $HS^-$  or  $HSO_4^-$ ?

- 16.25** Predict the products of the following acid–base reactions, and predict whether the equilibrium lies to the left or to the right of the reaction arrow:

- (a)  $\text{O}^{2-}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons$   
 (b)  $\text{CH}_3\text{COOH}(\text{aq}) + \text{HS}^-(\text{aq}) \rightleftharpoons$   
 (c)  $\text{NO}_2^-(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons$

**16.26** Predict the products of the following acid-base reactions, and predict whether the equilibrium lies to the left or to the right of the reaction arrow:

- (a)  $\text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq}) \rightleftharpoons$   
 (b)  $\text{CH}_3\text{COO}^-(\text{aq}) + \text{H}_3\text{O}^+(\text{aq}) \rightleftharpoons$   
 (c)  $\text{HCO}_3^-(\text{aq}) + \text{F}^-(\text{aq}) \rightleftharpoons$

### Autoionization of Water (Section 16.3)

- 16.27** If a neutral solution of water, with  $\text{pH} = 7.00$ , is cooled to  $10^\circ\text{C}$ , the  $\text{pH}$  rises to  $7.27$ . Which of the following three statements is correct for the cooled water: (i)  $[\text{H}^+] > [\text{OH}^-]$ , (ii)  $[\text{H}^+] = [\text{OH}^-]$ , or (iii)  $[\text{H}^+] < [\text{OH}^-]$ ?
- 16.28** (a) Write a chemical equation that illustrates the autoionization of water. (b) Write the expression for the ion-product constant for water,  $K_w$ . (c) If a solution is described as basic, which of the following is true: (i)  $[\text{H}^+] > [\text{OH}^-]$ , (ii)  $[\text{H}^+] = [\text{OH}^-]$ , or (iii)  $[\text{H}^+] < [\text{OH}^-]$ ?
- 16.29** Calculate  $[\text{H}^+]$  for each of the following solutions, and indicate whether the solution is acidic, basic, or neutral: (a)  $[\text{OH}^-] = 0.00045\text{ M}$ ; (b)  $[\text{OH}^-] = 8.8 \times 10^{-9}\text{ M}$ ; (c) a solution in which  $[\text{OH}^-]$  is 100 times greater than  $[\text{H}^+]$ .
- 16.30** Calculate  $[\text{OH}^-]$  for each of the following solutions, and indicate whether the solution is acidic, basic, or neutral: (a)  $[\text{H}^+] = 0.0505\text{ M}$ ; (b)  $[\text{H}^+] = 2.5 \times 10^{-10}\text{ M}$ ; (c) a solution in which  $[\text{H}^+]$  is 1000 times greater than  $[\text{OH}^-]$ .
- 16.31** At the freezing point of water ( $0^\circ\text{C}$ ),  $K_w = 1.2 \times 10^{-15}$ . Calculate  $[\text{H}^+]$  and  $[\text{OH}^-]$  for a neutral solution at this temperature.
- 16.32** Deuterium oxide ( $\text{D}_2\text{O}$ , where D is deuterium, the hydrogen-2 isotope) has an ion-product constant,  $K_w$ , of  $8.9 \times 10^{-16}$  at  $20^\circ\text{C}$ . Calculate  $[\text{D}^+]$  and  $[\text{OD}^-]$  for pure (neutral)  $\text{D}_2\text{O}$  at this temperature.

### The pH Scale (Section 16.4)

- 16.33** By what factor does  $[\text{H}^+]$  change for a  $\text{pH}$  change of (a) 2.00 units, (b) 0.50 units?
- 16.34** Consider two solutions, solution A and solution B.  $[\text{H}^+]$  in solution A is 250 times greater than that in solution B. What is the difference in the  $\text{pH}$  values of the two solutions?
- 16.35** Complete the following table by calculating the missing entries and indicating whether the solution is acidic or basic.

| $[\text{H}^+]$                | $[\text{OH}^-]$                | $\text{pH}$ | $\text{pOH}$ | Acidic or Basic? |
|-------------------------------|--------------------------------|-------------|--------------|------------------|
| $7.5 \times 10^{-3}\text{ M}$ |                                |             |              |                  |
|                               | $3.6 \times 10^{-10}\text{ M}$ |             |              |                  |
|                               |                                | 8.25        |              |                  |
|                               |                                |             | 5.70         |                  |

**16.36** Complete the following table by calculating the missing entries. In each case indicate whether the solution is acidic or basic.

| $\text{pH}$ | $\text{pOH}$ | $[\text{H}^+]$                 | $[\text{OH}^-]$               | Acidic or Basic? |
|-------------|--------------|--------------------------------|-------------------------------|------------------|
| 5.25        |              |                                |                               |                  |
|             | 2.02         |                                |                               |                  |
|             |              | $4.4 \times 10^{-10}\text{ M}$ |                               |                  |
|             |              |                                | $8.5 \times 10^{-2}\text{ M}$ |                  |

**16.37** The average  $\text{pH}$  of normal arterial blood is 7.40. At normal body temperature ( $37^\circ\text{C}$ ),  $K_w = 2.4 \times 10^{-14}$ . Calculate  $[\text{H}^+]$ ,  $[\text{OH}^-]$ , and  $\text{pOH}$  for blood at this temperature.

**16.38** Carbon dioxide in the atmosphere dissolves in raindrops to produce carbonic acid ( $\text{H}_2\text{CO}_3$ ), causing the  $\text{pH}$  of clean, unpolluted rain to range from about 5.2 to 5.6. What are the ranges of  $[\text{H}^+]$  and  $[\text{OH}^-]$  in the raindrops?

**16.39** Addition of the indicator methyl orange to an unknown solution leads to a yellow color. The addition of bromthymol blue to the same solution also leads to a yellow color. (a) Is the solution acidic, neutral, or basic? (b) What is the range (in whole numbers) of possible  $\text{pH}$  values for the solution? (c) Is there another indicator you could use to narrow the range of possible  $\text{pH}$  values for the solution?

**16.40** Addition of phenolphthalein to an unknown colorless solution does not cause a color change. The addition of bromthymol blue to the same solution leads to a yellow color. (a) Is the solution acidic, neutral, or basic? (b) Which of the following can you establish about the solution: (i) A minimum  $\text{pH}$ , (ii) A maximum  $\text{pH}$ , or (iii) A specific range of  $\text{pH}$  values? (c) What other indicator or indicators would you want to use to determine the  $\text{pH}$  of the solution more precisely?

### Strong Acids and Bases (Section 16.5)

- 16.41** Is each of the following statements true or false? (a) All strong acids contain one or more H atoms. (b) A strong acid is a strong electrolyte. (c) A 1.0-M solution of a strong acid will have  $\text{pH} = 1.0$ .
- 16.42** Determine whether each of the following is true or false: (a) All strong bases are salts of the hydroxide ion. (b) The addition of a strong base to water produces a solution of  $\text{pH} > 7.0$ . (c) Because  $\text{Mg}(\text{OH})_2$  is not very soluble, it cannot be a strong base.
- 16.43** Calculate the  $\text{pH}$  of each of the following strong acid solutions: (a)  $8.5 \times 10^{-3}\text{ M HBr}$ , (b) 1.52 g of  $\text{HNO}_3$  in 575 mL of solution, (c) 5.00 mL of 0.250 M  $\text{HClO}_4$  diluted to 50.0 mL, (d) a solution formed by mixing 10.0 mL of 0.100 M  $\text{HBr}$  with 20.0 mL of 0.200 M  $\text{HCl}$ .
- 16.44** Calculate the  $\text{pH}$  of each of the following strong acid solutions: (a) 0.0167 M  $\text{HNO}_3$ , (b) 0.225 g of  $\text{HClO}_3$  in 2.00 L of solution, (c) 15.00 mL of 1.00 M  $\text{HCl}$  diluted to 0.500 L, (d) a mixture formed by adding 50.0 mL of 0.020 M  $\text{HCl}$  to 125 mL of 0.010 M  $\text{HI}$ .
- 16.45** Calculate  $[\text{OH}^-]$  and  $\text{pH}$  for (a)  $1.5 \times 10^{-3}\text{ M Sr}(\text{OH})_2$ , (b) 2.250 g of  $\text{LiOH}$  in 250.0 mL of solution, (c) 1.00 mL of 0.175 M  $\text{NaOH}$  diluted to 2.00 L, (d) a solution formed by adding 5.00 mL of 0.105 M  $\text{KOH}$  to 15.0 mL of  $9.5 \times 10^{-2}\text{ M Ca}(\text{OH})_2$ .
- 16.46** Calculate  $[\text{OH}^-]$  and  $\text{pH}$  for each of the following strong base solutions: (a) 0.182 M  $\text{KOH}$ , (b) 3.165 g of  $\text{KOH}$  in 500.0 mL of solution, (c) 10.0 mL of 0.0105 M  $\text{Ca}(\text{OH})_2$  diluted to 500.0 mL, (d) a solution formed by mixing 20.0 mL of 0.015 M  $\text{Ba}(\text{OH})_2$  with 40.0 mL of  $8.2 \times 10^{-3}\text{ M NaOH}$ .
- 16.47** Calculate the concentration of an aqueous solution of  $\text{NaOH}$  that has a  $\text{pH}$  of 11.50.
- 16.48** Calculate the concentration of an aqueous solution of  $\text{Ca}(\text{OH})_2$  that has a  $\text{pH}$  of 10.05.

### Weak Acids (Section 16.6)

**16.49** Write the chemical equation and the  $K_a$  expression for the ionization of each of the following acids in aqueous solution. First show the reaction with  $\text{H}^+(\text{aq})$  as a product and then with the hydronium ion: (a)  $\text{HBrO}_2$ , (b)  $\text{C}_2\text{H}_5\text{COOH}$ .

**16.50** Write the chemical equation and the  $K_a$  expression for the acid dissociation of each of the following acids in aqueous solution. First show the reaction with  $\text{H}^+(\text{aq})$  as a product and then with the hydronium ion: **(a)**  $\text{C}_6\text{H}_5\text{COOH}$ , **(b)**  $\text{HCO}_3^-$ .

**16.51** Lactic acid ( $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$ ) has one acidic hydrogen. A 0.10  $M$  solution of lactic acid has a pH of 2.44. Calculate  $K_a$ .

**16.52** Phenylacetic acid ( $\text{C}_6\text{H}_5\text{CH}_2\text{COOH}$ ) is one of the substances that accumulates in the blood of people with phenylketonuria, an inherited disorder that can cause mental retardation or even death. A 0.085  $M$  solution of  $\text{C}_6\text{H}_5\text{CH}_2\text{COOH}$  has a pH of 2.68. Calculate the  $K_a$  value for this acid.

**16.53** A 0.100  $M$  solution of chloroacetic acid ( $\text{ClCH}_2\text{COOH}$ ) is 11.0% ionized. Using this information, calculate  $[\text{ClCH}_2\text{COO}^-]$ ,  $[\text{H}^+]$ ,  $[\text{ClCH}_2\text{COOH}]$ , and  $K_a$  for chloroacetic acid.

**16.54** A 0.100  $M$  solution of bromoacetic acid ( $\text{BrCH}_2\text{COOH}$ ) is 13.2% ionized. Calculate  $[\text{H}^+]$ ,  $[\text{BrCH}_2\text{COO}^-]$ ,  $[\text{BrCH}_2\text{COOH}]$  and  $K_a$  for bromoacetic acid.

**16.55** A particular sample of vinegar has a pH of 2.90. If acetic acid is the only acid that vinegar contains ( $K_a = 1.8 \times 10^{-5}$ ), calculate the concentration of acetic acid in the vinegar.

**16.56** If a solution of  $\text{HF}$  ( $K_a = 6.8 \times 10^{-4}$ ) has a pH of 3.65, calculate the concentration of hydrofluoric acid.

**16.57** The acid-dissociation constant for benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) is  $6.3 \times 10^{-5}$ . Calculate the equilibrium concentrations of  $\text{H}_3\text{O}^+$ ,  $\text{C}_6\text{H}_5\text{COO}^-$ , and  $\text{C}_6\text{H}_5\text{COOH}$  in the solution if the initial concentration of  $\text{C}_6\text{H}_5\text{COOH}$  is 0.050  $M$ .

**16.58** The acid-dissociation constant for chlorous acid ( $\text{HClO}_2$ ) is  $1.1 \times 10^{-2}$ . Calculate the concentrations of  $\text{H}_3\text{O}^+$ ,  $\text{ClO}_2^-$ , and  $\text{HClO}_2$  at equilibrium if the initial concentration of  $\text{HClO}_2$  is 0.0125  $M$ .

**16.59** Calculate the pH of each of the following solutions ( $K_a$  and  $K_b$  values are given in Appendix D): **(a)** 0.095  $M$  propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$ ), **(b)** 0.100  $M$  hydrogen chromate ion ( $\text{HCrO}_4^-$ ), **(c)** 0.120  $M$  pyridine ( $\text{C}_5\text{H}_5\text{N}$ ).

**16.60** Determine the pH of each of the following solutions ( $K_a$  and  $K_b$  values are given in Appendix D): **(a)** 0.095  $M$  hypochlorous acid, **(b)** 0.0085  $M$  hydrazine, **(c)** 0.165  $M$  hydroxylamine.

**16.61** Saccharin, a sugar substitute, is a weak acid with  $\text{p}K_a = 2.32$  at 25 °C. It ionizes in aqueous solution as follows:

What is the pH of a 0.10  $M$  solution of this substance?

**16.62** The active ingredient in aspirin is acetylsalicylic acid ( $\text{HC}_9\text{H}_7\text{O}_4$ ), a monoprotic acid with  $K_a = 3.3 \times 10^{-4}$  at 25 °C. What is the pH of a solution obtained by dissolving two extra-strength aspirin tablets, containing 500 mg of acetylsalicylic acid each, in 250 mL of water?

**16.63** Calculate the percent ionization of hydrazoic acid ( $\text{HN}_3$ ) in solutions of each of the following concentrations ( $K_a$  is given in Appendix D): **(a)** 0.400  $M$ , **(b)** 0.100  $M$ , **(c)** 0.0400  $M$ .

**16.64** Calculate the percent ionization of propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$ ) in solutions of each of the following concentrations ( $K_a$  is given in Appendix D): **(a)** 0.250  $M$ , **(b)** 0.0800  $M$ , **(c)** 0.0200  $M$ .

**16.65** Citric acid, which is present in citrus fruits, is a triprotic acid (Table 16.3). **(a)** Calculate the pH of a 0.040  $M$  solution of citric acid. **(b)** Did you have to make any approximations or assumptions in completing your calculations? **(c)** Is the concentration of citrate ion ( $\text{C}_6\text{H}_5\text{O}_7^{3-}$ ) equal to, less than, or greater than the  $\text{H}^+$  ion concentration?

**16.66** Tartaric acid is found in many fruits, including grapes, and is partially responsible for the dry texture of certain wines. Calculate the pH and the tartrate ion ( $\text{C}_4\text{H}_4\text{O}_6^{2-}$ ) concentration for a 0.250  $M$  solution of tartaric acid, for which the acid-dissociation constants are listed in Table 16.3. Did you have to make any approximations or assumptions in your calculation?

## Weak Bases (Section 16.7)

**16.67** Consider the base hydroxylamine,  $\text{NH}_2\text{OH}$ . **(a)** What is the conjugate acid of hydroxylamine? **(b)** When it acts as a base, which atom in hydroxylamine accepts a proton? **(c)** There are two atoms in hydroxylamine that have nonbonding electron pairs that could act as proton acceptors. Use Lewis structures and formal charges (Section 8.5) to rationalize why one of these two atoms is a much better proton acceptor than the other.

**16.68** The hypochlorite ion,  $\text{ClO}^-$ , acts as a weak base. **(a)** Is  $\text{ClO}^-$  a stronger or weaker base than hydroxylamine? **(b)** When  $\text{ClO}^-$  acts as a base, which atom, Cl or O, acts as the proton acceptor? **(c)** Can you use formal charges to rationalize your answer to part (b)?

**16.69** Write the chemical equation and the  $K_b$  expression for the reaction of each of the following bases with water: **(a)** dimethylamine,  $(\text{CH}_3)_2\text{NH}$ ; **(b)** carbonate ion,  $\text{CO}_3^{2-}$ ; **(c)** formate ion,  $\text{CHO}_2^-$ .

**16.70** Write the chemical equation and the  $K_b$  expression for the reaction of each of the following bases with water: **(a)** propylamine,  $\text{C}_3\text{H}_7\text{NH}_2$ ; **(b)** monohydrogen phosphate ion,  $\text{HPO}_4^{2-}$ ; **(c)** benzoate ion,  $\text{C}_6\text{H}_5\text{CO}_2^-$ .

**16.71** Calculate the molar concentration of  $\text{OH}^-$  in a 0.075  $M$  solution of ethylamine ( $\text{C}_2\text{H}_5\text{NH}_2$ ;  $K_b = 6.4 \times 10^{-4}$ ). Calculate the pH of this solution.

**16.72** Calculate the molar concentration of  $\text{OH}^-$  in a 0.724  $M$  solution of hypobromite ion ( $\text{BrO}^-$ ;  $K_b = 4.0 \times 10^{-6}$ ). What is the pH of this solution?

**16.73** Ephedrine, a central nervous system stimulant, is used in nasal sprays as a decongestant. This compound is a weak organic base:

A 0.035  $M$  solution of ephedrine has a pH of 11.33. **(a)** What are the equilibrium concentrations of  $\text{C}_{10}\text{H}_{15}\text{ON}$ ,  $\text{C}_{10}\text{H}_{15}\text{ONH}^+$ , and  $\text{OH}^-$ ? **(b)** Calculate  $K_b$  for ephedrine.

**16.74** Codeine ( $\text{C}_{18}\text{H}_{21}\text{NO}_3$ ) is a weak organic base. A  $5.0 \times 10^{-3} M$  solution of codeine has a pH of 9.95. Calculate the value of  $K_b$  for this substance. What is the  $\text{p}K_b$  for this base?

## The $K_a - K_b$ Relationship; Acid–Base Properties of Salts (Sections 16.8 and 16.9)

**16.75** Phenol,  $\text{C}_6\text{H}_5\text{OH}$ , has a  $K_a$  of  $1.3 \times 10^{-10}$ .

**(a)** Write out the  $K_a$  reaction for phenol.

**(b)** Calculate  $K_b$  for phenol's conjugate base.

**(c)** Is phenol a stronger or weaker acid than water?

**16.76** Use the acid-dissociation constants in Table 16.3 to arrange these oxyanions from strongest base to weakest:  $\text{SO}_4^{2-}$ ,  $\text{CO}_3^{2-}$ ,  $\text{SO}_3^{2-}$ , and  $\text{PO}_4^{3-}$ .

**16.77** **(a)** Given that  $K_a$  for acetic acid is  $1.8 \times 10^{-5}$  and that for hypochlorous acid is  $3.0 \times 10^{-8}$ , which is the stronger acid? **(b)** Which is the stronger base, the acetate ion or the hypochlorite ion? **(c)** Calculate  $K_b$  values for  $\text{CH}_3\text{COO}^-$  and  $\text{ClO}^-$ .

**16.78** (a) Given that  $K_b$  for ammonia is  $1.8 \times 10^{-5}$  and that for hydroxylamine is  $1.1 \times 10^{-8}$ , which is the stronger base? (b) Which is the stronger acid, the ammonium ion or the hydroxylammonium ion? (c) Calculate  $K_a$  values for  $\text{NH}_4^+$  and  $\text{H}_3\text{NOH}^+$ .

**16.79** Using data from Appendix D, calculate  $[\text{OH}^-]$  and pH for each of the following solutions: (a) 0.10 M NaBrO, (b) 0.080 M NaHS, (c) a mixture that is 0.10 M in  $\text{NaNO}_2$  and 0.20 M in  $\text{Ca}(\text{NO}_2)_2$ .

**16.80** Using data from Appendix D, calculate  $[\text{OH}^-]$  and pH for each of the following solutions: (a) 0.105 M NaF, (b) 0.035 M  $\text{Na}_2\text{S}$ , (c) a mixture that is 0.045 M in  $\text{NaCH}_3\text{COO}$  and 0.055 M in  $\text{Ba}(\text{CH}_3\text{COO})_2$ .

**16.81** A solution of sodium acetate ( $\text{NaCH}_3\text{COO}$ ) has a pH of 9.70. What is the molarity of the solution?

**16.82** Pyridinium bromide ( $\text{C}_5\text{H}_5\text{NHBr}$ ) is a strong electrolyte that dissociates completely into  $\text{C}_5\text{H}_5\text{NH}^+$  and  $\text{Br}^-$ . An aqueous solution of pyridinium bromide has a pH of 2.95.

(a) Write out the reaction that leads to this acidic pH.

(b) Using Appendix D, calculate the  $K_a$  for pyridinium bromide.

(c) A solution of pyridinium bromide has a pH of 2.95. What is the concentration of the pyridinium cation at equilibrium, in units of molarity?

**16.83** Predict whether aqueous solutions of the following compounds are acidic, basic, or neutral: (a)  $\text{NH}_4\text{Br}$ , (b)  $\text{FeCl}_3$ , (c)  $\text{Na}_2\text{CO}_3$ , (d)  $\text{KClO}_4$ , (e)  $\text{NaHC}_2\text{O}_4$ .

**16.84** Predict whether aqueous solutions of the following substances are acidic, basic, or neutral: (a)  $\text{AlCl}_3$ , (b)  $\text{NaBr}$ , (c)  $\text{NaClO}$ , (d)  $[\text{CH}_3\text{NH}_3]\text{NO}_3$ , (e)  $\text{Na}_2\text{SO}_3$ .

**16.85** An unknown salt is either NaF, NaCl, or NaOCl. When 0.050 mol of the salt is dissolved in water to form 0.500 L of solution, the pH of the solution is 8.08. What is the identity of the salt?

**16.86** An unknown salt is either KBr,  $\text{NH}_4\text{Cl}$ , KCN, or  $\text{K}_2\text{CO}_3$ . If a 0.100 M solution of the salt is neutral, what is the identity of the salt?

## Acid–Base Character and Chemical Structure (Section 16.10)

**16.87** Predict the stronger acid in each pair: (a)  $\text{HNO}_3$  or  $\text{HNO}_2$ ; (b)  $\text{H}_2\text{S}$  or  $\text{H}_2\text{O}$ ; (c)  $\text{H}_2\text{SO}_4$  or  $\text{H}_2\text{SeO}_4$ ; (d)  $\text{CH}_3\text{COOH}$  or  $\text{CCl}_3\text{COOH}$ .

**16.88** Predict the stronger acid in each pair: (a) HCl or HF; (b)  $\text{H}_3\text{PO}_4$  or  $\text{H}_3\text{AsO}_4$ ; (c)  $\text{HBrO}_3$  or  $\text{HBrO}_2$ ; (d)  $\text{H}_2\text{C}_2\text{O}_4$  or  $\text{HC}_2\text{O}_4^-$ ; (e) benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) or phenol ( $\text{C}_6\text{H}_5\text{OH}$ ).

**16.89** Based on their compositions and structures and on conjugate acid–base relationships, select the stronger base in each of the following pairs: (a)  $\text{BrO}^-$  or  $\text{ClO}^-$ , (b)  $\text{BrO}^-$  or  $\text{BrO}_2^-$ , (c)  $\text{HPO}_4^{2-}$  or  $\text{H}_2\text{PO}_4^-$ .

**16.90** Based on their compositions and structures and on conjugate acid–base relationships, select the stronger base in each of the following pairs: (a)  $\text{NO}_3^-$  or  $\text{NO}_2^-$ , (b)  $\text{PO}_4^{3-}$  or  $\text{AsO}_4^{3-}$ , (c)  $\text{HCO}_3^-$  or  $\text{CO}_3^{2-}$ .

**16.91** Indicate whether each of the following statements is true or false. For each statement that is false, correct the statement to make it true. (a) In general, the acidity of binary acids increases from left to right in a given row of the periodic table. (b) In a series of acids that have the same central atom, acid strength increases with the number of hydrogen atoms bonded to the central atom. (c) Hydrotelluric acid ( $\text{H}_2\text{Te}$ ) is a stronger acid than  $\text{H}_2\text{S}$  because Te is more electronegative than S.

**16.92** Indicate whether each of the following statements is true or false. For each statement that is false, correct the statement to make it true. (a) Acid strength in a series of  $\text{H}-\text{A}$  molecules increases with increasing size of A. (b) For acids of the same general structure but differing electronegativities of the central atoms, acid strength decreases with increasing electronegativity of the central atom. (c) The strongest acid known is HF because fluorine is the most electronegative element.

## Lewis Acids and Bases (Section 16.11)

**16.93** Ammonia,  $\text{NH}_3$ , acts as an Arrhenius base, a Brønsted–Lowry base, and a Lewis base, in aqueous solution. Write out the reaction  $\text{NH}_3$  undergoes with water and explain what properties of ammonia correspond to each of the three definitions of “base.”

**16.94** The fluoride ion reacts with water to produce HF.

(a) Write out the chemical equation for this reaction.

(b) Will a concentrated solution of NaF in water be acidic, basic, or neutral?

(c) Is fluoride acting as a Lewis acid or as a Lewis base when reacting with water?

**16.95** Identify the Lewis acid and Lewis base among the reactants in each of the following reactions:

**16.96** Identify the Lewis acid and Lewis base in each of the following reactions:

**16.97** Predict which member of each pair produces the more acidic aqueous solution: (a)  $\text{K}^+$  or  $\text{Cu}^{2+}$ , (b)  $\text{Fe}^{2+}$  or  $\text{Fe}^{3+}$ , (c)  $\text{Al}^{3+}$  or  $\text{Ga}^{3+}$ .

**16.98** Which member of each pair produces the more acidic aqueous solution: (a)  $\text{ZnBr}_2$  or  $\text{CdCl}_2$ , (b)  $\text{CuCl}$  or  $\text{Cu}(\text{NO}_3)_2$ , (c)  $\text{Ca}(\text{NO}_3)_2$  or  $\text{NiBr}_2$ ?

## Additional Exercises

**16.99** Indicate whether each of the following statements is correct or incorrect.

(a) Every Brønsted–Lowry acid is also a Lewis acid.

(b) Every Lewis acid is also a Brønsted–Lowry acid.

(c) Conjugate acids of weak bases produce more acidic solutions than conjugate acids of strong bases.

(d)  $\text{K}^+$  ion is acidic in water because it causes hydrating water molecules to become more acidic.

(e) The percent ionization of a weak acid in water increases as the concentration of acid decreases.

**16.100** A solution is made by adding 0.300 g  $\text{Ca}(\text{OH})_2(\text{s})$ , 50.0 mL of 1.40 M  $\text{HNO}_3$ , and enough water to make a final volume

of 75.0 mL. Assuming that all of the solid dissolves, what is the pH of the final solution?

**16.101** The odor of fish is due primarily to amines, especially methylamine ( $\text{CH}_3\text{NH}_2$ ). Fish is often served with a wedge of lemon, which contains citric acid. The amine and the acid react forming a product with no odor, thereby making the less-than-fresh fish more appetizing. Using data from Appendix D, calculate the equilibrium constant for the reaction of citric acid with methylamine, if only the first proton of the citric acid ( $K_{a1}$ ) is important in the neutralization reaction.

**16.102** Which, if any, of the following statements are true?

- (a) The stronger the base, the smaller the  $\text{p}K_b$ .
- (b) The stronger the base, the larger the  $\text{p}K_b$ .
- (c) The stronger the base, the smaller the  $K_b$ .
- (d) The stronger the base, the larger the  $K_b$ .
- (e) The stronger the base, the smaller the  $\text{p}K_a$  of its conjugate acid.
- (f) The stronger the base, the larger the  $\text{p}K_a$  of its conjugate acid.

**16.103** Predict how each molecule or ion would act, in the Brønsted–Lowry sense, in aqueous solution by writing “acid,” “base,” “both,” or “neither” on the line provided.

(a)  $\text{HCO}_3^-$ , the bicarbonate ion: \_\_\_\_\_

(b) Prozac: \_\_\_\_\_

(c) PABA (formerly in sunscreen): \_\_\_\_\_

(d) TNT, trinitrotoluene: \_\_\_\_\_

(e) N-Methylpyridinium: \_\_\_\_\_

**[16.104]** Calculate the pH of a solution made by adding 2.50 g of lithium oxide ( $\text{Li}_2\text{O}$ ) to enough water to make 1.500 L of solution.

**16.105** Benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) and aniline ( $\text{C}_6\text{H}_5\text{NH}_2$ ) are both derivatives of benzene. Benzoic acid is an acid with  $K_a = 6.3 \times 10^{-5}$  and aniline is a base with  $K_b = 4.3 \times 10^{-10}$ .

Benzoic acid

Aniline

(a) What are the conjugate base of benzoic acid and the conjugate acid of aniline? (b) Anilinium chloride ( $\text{C}_6\text{H}_5\text{NH}_3\text{Cl}$ ) is a strong electrolyte that dissociates into anilinium ions ( $\text{C}_6\text{H}_5\text{NH}_3^+$ ) and chloride ions. Which will be more acidic, a 0.10 M solution of benzoic acid or a 0.10 M solution of anilinium chloride? (c) What is the value of the equilibrium constant for the following equilibrium?

**16.106** What is the pH of a solution that is  $2.5 \times 10^{-9}$  M in NaOH? Does your answer make sense? What assumption do we normally make that is not valid in this case?

**16.107** Oxalic acid ( $\text{H}_2\text{C}_2\text{O}_4$ ) is a diprotic acid. By using data in Appendix D as needed, determine whether each of the following statements is true: (a)  $\text{H}_2\text{C}_2\text{O}_4$  can serve as both a Brønsted–Lowry acid and a Brønsted–Lowry base. (b)  $\text{C}_2\text{O}_4^{2-}$  is the conjugate base of  $\text{HC}_2\text{O}_4^-$ . (c) An aqueous solution of the strong electrolyte  $\text{KHC}_2\text{O}_4$  will have  $\text{pH} < 7$ .

**16.108** Succinic acid ( $\text{H}_2\text{C}_4\text{H}_6\text{O}_4$ ), which we will denote  $\text{H}_2\text{Suc}$ , is a biologically relevant diprotic acid with the structure shown below. At 25 °C, the acid-dissociation constants for succinic acid are  $K_{a1} = 6.9 \times 10^{-5}$  and  $K_{a2} = 2.5 \times 10^{-6}$ . (a) Determine the pH of a 0.32 M solution of  $\text{H}_2\text{Suc}$  at 25 °C, assuming that only the first dissociation is relevant. (b) Determine the molar concentration of  $\text{Suc}^{2-}$  in the solution in part (a). (c) Is the assumption you made in part (a) justified by the result from part (b)? (d) Will a solution of the salt  $\text{NaHSuc}$  be acidic, neutral, or basic?

**16.109** Butyric acid is responsible for the foul smell of rancid butter. The  $\text{p}K_a$  of butyric acid is 4.84. (a) Calculate the  $\text{p}K_b$  for the butyrate ion. (b) Calculate the pH of a 0.050 M solution of butyric acid. (c) Calculate the pH of a 0.050 M solution of sodium butyrate.

**16.110** Arrange the following 0.10 M solutions in order of increasing acidity: (i)  $\text{NH}_4\text{NO}_3$ , (ii)  $\text{NaNO}_3$ , (iii)  $\text{CH}_3\text{COONH}_4$ , (iv)  $\text{NaF}$ , (v)  $\text{CH}_3\text{COONa}$ .

**16.111** A 0.25 M solution of a salt NaA has  $\text{pH} = 9.29$ . What is the value of  $K_a$  for the parent acid HA?

**[16.112]** The following observations are made about a diprotic acid  $\text{H}_2\text{A}$ : (i) A 0.10 M solution of  $\text{H}_2\text{A}$  has  $\text{pH} = 3.30$ . (ii) A 0.10 M solution of the salt  $\text{NaHA}$  is acidic. Which of the following could be the value of  $\text{p}K_{a2}$  for  $\text{H}_2\text{A}$ : (i) 3.22, (ii) 5.30, (iii) 7.47, or (iv) 9.82?

**16.113** Many moderately large organic molecules containing basic nitrogen atoms are not very soluble in water as neutral molecules, but they are frequently much more soluble as their acid salts. Assuming that pH in the stomach is 2.5, indicate whether each of the following compounds would be present in the stomach as the neutral base or in the protonated form: nicotine,  $K_b = 7 \times 10^{-7}$ ; caffeine,  $K_b = 4 \times 10^{-14}$ ; strychnine,  $K_b = 1 \times 10^{-6}$ ; quinine,  $K_b = 1.1 \times 10^{-6}$ .

**16.114** The amino acid glycine ( $\text{H}_2\text{N}-\text{CH}_2-\text{COOH}$ ) can participate in the following equilibria in water:

(a) Use the values of  $K_a$  and  $K_b$  to estimate the equilibrium constant for the intramolecular proton transfer to form a zwitterion:

(b) What is the pH of a 0.050 M aqueous solution of glycine?

(c) What would be the predominant form of glycine in a solution with pH 13? With pH 1?

**16.115** The  $pK_b$  of water is \_\_\_\_\_.

(a) 1 (b) 7 (c) 14 (d) not defined (e) none of the above

## Integrative Exercises

**16.116** Calculate the number of  $\text{H}^+(aq)$  ions in 1.0 mL of pure water at 25 °C.

**16.117** How many milliliters of concentrated hydrochloric acid solution (36.0% HCl by mass, density = 1.18 g/mL) are required to produce 10.0 L of a solution that has a pH of 2.05?

**16.118** The volume of an adult's stomach ranges from about 50 mL when empty to 1 L when full. If the stomach volume is 400 mL and its contents have a pH of 2, how many moles of  $\text{H}^+$  does the stomach contain? Assuming that all the  $\text{H}^+$  comes from HCl, how many grams of sodium hydrogen carbonate will totally neutralize the stomach acid?

**16.119** Atmospheric  $\text{CO}_2$  levels have risen by nearly 20% over the past 40 years from 320 ppm to 400 ppm. (a) Given that the average pH of clean, unpolluted rain today is 5.4, determine the pH of unpolluted rain 40 years ago. Assume that carbonic acid ( $\text{H}_2\text{CO}_3$ ) formed by the reaction of  $\text{CO}_2$  and water is the only factor influencing pH.

(b) What volume of  $\text{CO}_2$  at 25 °C and 1.0 atm is dissolved in a 20.0-L bucket of today's rainwater?

**16.120** At 50 °C, the ion-product constant for  $\text{H}_2\text{O}$  has the value  $K_w = 5.48 \times 10^{-14}$ . (a) What is the pH of pure water at 50 °C? (b) Based on the change in  $K_w$  with temperature, predict whether  $\Delta H$  is positive, negative, or zero for the autoionization reaction of water:

**16.121** In many reactions, the addition of  $\text{AlCl}_3$  produces the same effect as the addition of  $\text{H}^+$ .

(a) Draw a Lewis structure for  $\text{AlCl}_3$  in which no atoms carry formal charges, and determine its structure using the VSEPR method.

(b) What characteristic is notable about the structure in part (a) that helps us understand the acidic character of  $\text{AlCl}_3$ ?

(c) Predict the result of the reaction between  $\text{AlCl}_3$  and  $\text{NH}_3$  in a solvent that does not participate as a reactant.

(d) Which acid-base theory is most suitable for discussing the similarities between  $\text{AlCl}_3$  and  $\text{H}^+$ ?

**16.122** What is the boiling point of a 0.10 M solution of  $\text{NaHSO}_4$  if the solution has a density of 1.002 g/mL?

**16.123** Use average bond enthalpies from Table 8.4 to estimate the enthalpies of the following gas-phase reactions:

Are both reactions exothermic? How do these values relate to the different strengths of hydrofluoric and hydrochloric acid?

**16.124** Cocaine is a weak organic base whose molecular formula is  $\text{C}_{17}\text{H}_{21}\text{NO}_4$ . An aqueous solution of cocaine was found to have a pH of 8.53 and an osmotic pressure of 52.7 torr at 15 °C. Calculate  $K_b$  for cocaine.

**[16.125]** The iodate ion is reduced by sulfite according to the following reaction:

The rate of this reaction is found to be first order in  $\text{IO}_3^-$ , first order in  $\text{SO}_3^{2-}$ , and first order in  $\text{H}^+$ .

(a) Write the rate law for the reaction.

(b) By what factor will the rate of the reaction change if the pH is lowered from 5.00 to 3.50? Does the reaction proceed more quickly or more slowly at the lower pH?

(c) By using the concepts discussed in Section 14.6, explain how the reaction can be pH-dependent even though  $\text{H}^+$  does not appear in the overall reaction.

**16.126** (a) Using dissociation constants from Appendix D, determine the value for the equilibrium constant for each of the following reactions.

(b) We usually use single arrows for reactions when the forward reaction is appreciable ( $K$  much greater than 1) or when products escape from the system, so that equilibrium is never established. If we follow this convention, which of these equilibria might be written with a single arrow?

## Design an Experiment

Your professor gives you a bottle that contains a clear liquid. You are told that the liquid is a pure substance that is volatile, soluble in water, and might be an acid or a base. Design experiments to elucidate the following about this unknown sample. (a) Determine whether the substance in the sample is an acid or a base. (b) Suppose the substance is an acid. How would you determine whether it is a strong acid or a weak acid? (c) If the substance is a weak

acid, how would you determine the value of  $K_a$  for the substance?

(d) Suppose the substance were a weak acid and that you are also given a solution of  $\text{NaOH}(aq)$  of known molarity. What procedure would you use to isolate a pure sample of the sodium salt of the substance?

(e) Now suppose that the substance were a base rather than an acid. How would you adjust the procedures in parts (b) and (c) to determine if the substance were a strong or weak base, and, if weak, the value of  $K_b$ ?

An aerial photograph of a coral reef system. The foreground shows shallow, turquoise water with intricate, brownish-orange coral patterns. A small white boat is visible in the water. The reef extends towards the horizon, where the water transitions to a deeper blue. A semi-transparent blue triangle is overlaid on the upper left portion of the image, containing the white number 17.

17

# ADDITIONAL ASPECTS OF AQUEOUS EQUILIBRIA

Water, the most common and most important solvent on Earth, occupies its position of importance because of its abundance and its exceptional ability to dissolve a wide variety of substances. Coral reefs are a striking example of aqueous chemistry at work in nature. Coral reefs are built by tiny animals called stony corals, which secrete a hard calcium carbonate exoskeleton. Over time, the stony corals build up large networks of calcium carbonate upon which a reef is built. The size of such structures can be immense, as illustrated by the Great Barrier Reef.

Stony corals make their exoskeletons from dissolved  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  ions. This process is aided by the fact that the  $\text{CO}_3^{2-}$  concentration is supersaturated in most parts of the ocean. However, well-documented increases in the amount of  $\text{CO}_2$  in the atmosphere threaten to upset the aqueous chemistry that stony corals depend on. As atmospheric  $\text{CO}_2$  levels increase, the amount of  $\text{CO}_2$  dissolved in the ocean also increases. This lowers the pH of the ocean and leads to a decrease in the  $\text{CO}_3^{2-}$  concentration. As a result, it becomes more difficult for stony corals and other important ocean creatures to maintain their exoskeletons. We will take a closer look at the consequences of ocean acidification later in the Chapter 18.

◀ **GREAT BARRIER REEF** These structures are made of calcium carbonate,  $\text{CaCO}_3$ .

## WHAT'S AHEAD

- 17.1** ▶ **The Common-Ion Effect** Consider a specific example of Le Châtelier's principle known as the common-ion effect.
- 17.2** ▶ **Buffers** Recognize the composition of buffered solutions and learn how they resist pH change when small amounts of a strong acid or strong base are added to them.
- 17.3** ▶ **Acid–Base Titrations** Examine acid–base titrations and explore how to determine pH at any point in an acid–base titration.
- 17.4** ▶ **Solubility Equilibria** Use *solubility-product constants* to determine to what extent a sparingly soluble salt dissolves in water.
- 17.5** ▶ **Factors That Affect Solubility** Investigate some of the factors that affect solubility, including the common-ion effect and the effect of acids.
- 17.6** ▶ **Precipitation and Separation of Ions** Learn how differences in solubility can be used to separate ions through selective precipitation.
- 17.7** ▶ **Qualitative Analysis for Metallic Elements** Realize that the principles of solubility and complexation equilibria can be used to identify ions in solution.

To understand the chemistry that underlies coral reef formation and other processes in the ocean and in aqueous systems such as living cells, we must understand the concepts of aqueous equilibria. In this chapter, we take a step toward understanding such complex solutions by looking first at further applications of acid–base equilibria. The idea is to consider not only solutions in which there is a single solute but also those containing a mixture of solutes. We then broaden our discussion to include two additional types of aqueous equilibria: those involving slightly soluble salts and those involving the formation of metal complexes in solution. The discussions and calculations in this chapter are extensions of those in Chapters 15 and 16.

## 17.1 | The Common-Ion Effect

In Chapter 16, we examined the equilibrium concentrations of ions in solutions containing a weak acid or a weak base. We now consider solutions that contain a weak acid, such as acetic acid ( $\text{CH}_3\text{COOH}$ ), and a soluble salt of that acid, such as sodium acetate ( $\text{CH}_3\text{COONa}$ ). Notice that these solutions contain two substances that share a *common ion*,  $\text{CH}_3\text{COO}^-$ . It is instructive to view these solutions from the perspective of Le Châtelier’s principle. [∞ \(Section 15.7\)](#)

Sodium acetate is a soluble ionic compound and therefore a strong electrolyte. [∞ \(Section 4.1\)](#) Consequently, it dissociates completely in aqueous solution to form  $\text{Na}^+$  and  $\text{CH}_3\text{COO}^-$  ions:

In contrast,  $\text{CH}_3\text{COOH}$  is a weak electrolyte that ionizes only partially, represented by the dynamic equilibrium

The equilibrium constant for Equation 17.1 is  $K_a = 1.8 \times 10^{-5}$  at  $25^\circ\text{C}$  (Table 16.2). If we add sodium acetate to a solution of acetic acid in water, the  $\text{CH}_3\text{COO}^-$  from  $\text{CH}_3\text{COONa}$  causes the equilibrium concentrations of the substances in Equation 17.1 to shift to the left as expected from Le Châtelier’s principle, thereby decreasing the equilibrium concentration of  $\text{H}^+(aq)$ :

Addition of  $\text{CH}_3\text{COO}^-$  shifts equilibrium concentrations, lowering  $[\text{H}^+]$

In other words, the presence of the added acetate ion causes the acetic acid to ionize less than it normally would. We call this observation the **common-ion effect**.

*Whenever a weak electrolyte and a strong electrolyte containing a common ion are together in solution, the weak electrolyte ionizes less than it would if it were alone in solution.*

Note that the equilibrium constant itself does not change; it is the relative concentrations of products and reactants in the equilibrium expression that change.

### Sample Exercise 17.1

#### Calculating the pH When a Common Ion Is Involved

What is the pH of a solution made by adding 0.30 mol of acetic acid and 0.30 mol of sodium acetate to enough water to make 1.0 L of solution?

## SOLUTION

**Analyze** We are asked to determine the pH of a solution of a weak electrolyte ( $\text{CH}_3\text{COOH}$ ) and a strong electrolyte ( $\text{CH}_3\text{COONa}$ ) that share a common ion,  $\text{CH}_3\text{COO}^-$ .

**Plan** In any problem in which we must determine the pH of a solution containing a mixture of solutes, it is helpful to proceed by a series of logical steps:

- (1) Consider which solutes are strong electrolytes and which are weak electrolytes, and identify the major species in solution.

- (2) Identify the important equilibrium reaction that is the source of  $\text{H}^+$  and therefore determines pH.
- (3) Tabulate the concentrations of ions involved in the equilibrium.
- (4) Use the equilibrium-constant expression to calculate  $[\text{H}^+]$  and then pH.

### Solve

First, because  $\text{CH}_3\text{COOH}$  is a weak electrolyte and  $\text{CH}_3\text{COONa}$  is a strong electrolyte, the major species in the solution are  $\text{CH}_3\text{COOH}$  (a weak acid),  $\text{Na}^+$  (which is neither acidic nor basic and is therefore a spectator in the acid-base chemistry), and  $\text{CH}_3\text{COO}^-$  (which is the conjugate base of  $\text{CH}_3\text{COOH}$ ).

Second,  $[\text{H}^+]$  and, therefore, the pH are controlled by the dissociation equilibrium of  $\text{CH}_3\text{COOH}$ :

(We have written the equilibrium using  $\text{H}^+(aq)$  rather than  $\text{H}_3\text{O}^+(aq)$ , but both representations of the hydrated hydrogen ion are equally valid.)

Third, we tabulate the initial and equilibrium concentrations as we did in solving other equilibrium problems in Chapters 15 and 16:

The equilibrium concentration of  $\text{CH}_3\text{COO}^-$  (the common ion) is the initial concentration that is due to  $\text{CH}_3\text{COONa}$  (0.30 M) plus the change in concentration ( $x$ ) that is due to the ionization of  $\text{CH}_3\text{COOH}$ .

|                 |              |      |              |
|-----------------|--------------|------|--------------|
| Initial (M)     | 0.30         | 0    | 0.30         |
| Change (M)      | $-x$         | $+x$ | $+x$         |
| Equilibrium (M) | $(0.30 - x)$ | $x$  | $(0.30 + x)$ |

Now we can use the equilibrium-constant expression:

$$K_a = 1.8 \times 10^{-5} = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]}$$

The dissociation constant for  $\text{CH}_3\text{COOH}$  at 25 °C is from Table 16.2, or Appendix D; addition of  $\text{CH}_3\text{COONa}$  does not change the value of this constant. Substituting the equilibrium-constant concentrations from our table into the equilibrium expression gives:

$$K_a = 1.8 \times 10^{-5} = \frac{x(0.30 + x)}{0.30 - x}$$

Because  $K_a$  is small, we assume that  $x$  is small compared to the original concentrations of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$  (0.30 M each). Thus, we can ignore the very small  $x$  relative to 0.30 M, giving:

$$K_a = 1.8 \times 10^{-5} = \frac{x(0.30)}{0.30}$$

The resulting value of  $x$  is indeed small relative to 0.30, justifying the approximation made in simplifying the problem.

$$x = 1.8 \times 10^{-5} \text{ M} = [\text{H}^+]$$

Finally, we calculate the pH from the equilibrium concentration of  $\text{H}^+(aq)$ :

$$\text{pH} = -\log(1.8 \times 10^{-5}) = 4.74$$

**Comment** In Section 16.6, we calculated that a 0.30 M solution of  $\text{CH}_3\text{COOH}$  has a pH of 2.64, corresponding to  $[\text{H}^+] = 2.3 \times 10^{-3} \text{ M}$ . Thus, the addition of  $\text{CH}_3\text{COONa}$  has substantially decreased  $[\text{H}^+]$ , as we expect from Le Châtelier's principle.

### Practice Exercise 1

For the generic equilibrium  $\text{HA}(aq) \rightleftharpoons \text{H}^+(aq) + \text{A}^-(aq)$ , which of these statements is true?

- The equilibrium constant for this reaction changes as the pH changes.

- If you add the soluble salt KA to a solution of HA that is at equilibrium, the concentration of HA would decrease.
- If you add the soluble salt KA to a solution of HA that is at equilibrium, the concentration of  $\text{A}^-$  would decrease.
- If you add the soluble salt KA to a solution of HA that is at equilibrium, the pH would increase.

### Practice Exercise 2

Calculate the pH of a solution containing 0.085 M nitrous acid ( $\text{HNO}_2$ ,  $K_a = 4.5 \times 10^{-4}$ ) and 0.10 M potassium nitrite ( $\text{KNO}_2$ ).

## Sample Exercise 17.2

### Calculating Ion Concentrations When a Common Ion Is Involved

Calculate the fluoride ion concentration and pH of a solution that is 0.20 *M* in HF and 0.10 *M* in HCl.

#### SOLUTION

**Analyze** We are asked to determine the concentration of  $F^-$  and the pH in a solution containing the weak acid HF and the strong acid HCl. In this case the common ion is  $H^+$ .

**Plan** We can again use the four steps outlined in Sample Exercise 17.1.

#### Solve

Because HF is a weak acid and HCl is a strong acid, the major species in solution are HF,  $H^+$ , and  $Cl^-$ . The  $Cl^-$ , which is the conjugate base of a strong acid, is merely a spectator ion in any acid–base chemistry. The problem asks for  $[F^-]$ , which is formed by ionization of HF. Thus, this is the important equilibrium:

The common ion in this problem is the hydrogen (or hydronium) ion. Now we can tabulate the initial and equilibrium concentrations of each species involved in this equilibrium:

|                 | HF(aq)       | $H^+(aq)$    | $F^-(aq)$ |
|-----------------|--------------|--------------|-----------|
| Initial (M)     | 0.20         | 0.10         | 0         |
| Change (M)      | $-x$         | $+x$         | $+x$      |
| Equilibrium (M) | $(0.20 - x)$ | $(0.10 + x)$ | $x$       |

The equilibrium constant for the ionization of HF, from Appendix D, is  $6.8 \times 10^{-4}$ . Substituting the equilibrium-constant concentrations into the equilibrium expression gives:

$$K_a = 6.8 \times 10^{-4} = \frac{[H^+][F^-]}{[HF]} = \frac{(0.10 + x)(x)}{0.20 - x}$$

If we assume that  $x$  is small relative to 0.10 or 0.20 *M*, this expression simplifies to:

$$\frac{(0.10)(x)}{0.20} = 6.8 \times 10^{-4}$$

$$x = \frac{0.20}{0.10}(6.8 \times 10^{-4}) = 1.4 \times 10^{-3} M = [F^-]$$

This  $F^-$  concentration is substantially smaller than it would be in a 0.20 *M* solution of HF with no added HCl. The common ion,  $H^+$ , suppresses the ionization of HF. The concentration of  $H^+(aq)$  is:

$$[H^+] = (0.10 + x) M \approx 0.10 M$$

Thus,

$$pH = 1.00$$

**Comment** Notice that for all practical purposes, the hydrogen ion concentration is due entirely to the HCl; the HF makes a negligible contribution by comparison.

#### Practice Exercise 1

Calculate the concentration of the lactate ion in a solution that is 0.100 *M* in lactic acid ( $CH_3CH(OH)COOH$ ,  $pK_a = 3.86$ ) and 0.080 *M* in HCl.

- (a) 4.83 *M*      (b) 0.0800 *M*  
 (c)  $7.3 \times 10^{-3} M$       (d)  $3.65 \times 10^{-3} M$   
 (e)  $1.73 \times 10^{-4} M$

#### Practice Exercise 2

Calculate the formate ion concentration and pH of a solution that is 0.050 *M* in formic acid ( $HCOOH$ ,  $K_a = 1.8 \times 10^{-4}$ ) and 0.10 *M* in  $HNO_3$ .

Sample Exercises 17.1 and 17.2 both involve weak acids. The ionization of a weak base is also decreased by the addition of a common ion. For example, the addition of  $NH_4^+$  (as from the strong electrolyte  $NH_4Cl$ ) causes the equilibrium concentrations of the reagents in Equation 17.2 to shift to the left, decreasing the equilibrium concentration of  $OH^-$  and lowering the pH:

Addition of  $NH_4^+$  shifts equilibrium concentrations, lowering  $[OH^-]$

### Give It Some Thought

If solutions of  $\text{NH}_4\text{Cl}(aq)$  and  $\text{NH}_3(aq)$  are mixed, which ions in the resulting solution are spectator ions in any acid–base chemistry occurring in the solution? What equilibrium reaction determines  $[\text{OH}^-]$  and, therefore, the pH of the solution?

## 17.2 | Buffers

Solutions that contain high concentrations ( $10^{-3} M$  or more) of a weak conjugate acid–base pair and that resist drastic changes in pH when small amounts of strong acid or strong base are added to them are called **buffered solutions** (or merely **buffers**). Human blood, for example, is a complex buffered solution that maintains the blood pH at about 7.4 (The *Chemistry and Life* box, “Blood as a Buffered Solution” later in this section). Much of the chemical behavior of seawater is determined by its pH, buffered at about 8.1 to 8.3 near the surface due to the  $\text{HCO}_3^-/\text{CO}_3^{2-}$  acid–base pair. Buffers find many important applications in the laboratory and in medicine (Figure 17.1). Many biological reactions occur at the optimal rates only when properly buffered. If you ever work in a biochemistry lab, you will very likely have to prepare specific buffers in which to run your biochemical reactions.

### Composition and Action of Buffers

A buffer resists changes in pH because it contains both an acid to neutralize added  $\text{OH}^-$  ions and a base to neutralize added  $\text{H}^+$  ions. The acid and base that make up the buffer, however, must not consume each other through a neutralization reaction. (Section 4.3) These requirements are fulfilled by a weak acid–base conjugate pair, such as  $\text{CH}_3\text{COOH}/\text{CH}_3\text{COO}^-$  or  $\text{NH}_4^+/\text{NH}_3$ . The key is to have roughly equal concentrations of both the weak acid and its conjugate base. There are two ways to make a buffer.

- Mix a weak acid or a weak base with a salt of that acid or base. For example, the  $\text{CH}_3\text{COOH}/\text{CH}_3\text{COO}^-$  buffer can be prepared by adding  $\text{CH}_3\text{COONa}$  to a solution of  $\text{CH}_3\text{COOH}$ . Similarly, the  $\text{NH}_4^+/\text{NH}_3$  buffer can be prepared by adding  $\text{NH}_4\text{Cl}$  to a solution of  $\text{NH}_3$ .
- Make the conjugate acid or base from a solution of weak base or acid by the addition of a strong acid or base. For example, to make the  $\text{CH}_3\text{COOH}/\text{CH}_3\text{COO}^-$  buffer, you could start with a solution of  $\text{CH}_3\text{COOH}$  and add some  $\text{NaOH}$  to the solution—enough to neutralize about half of  $\text{CH}_3\text{COOH}$  according to the reaction

(Section 4.3) Neutralization reactions have very large equilibrium constants, and so the amount of acetate formed will only be limited by the relative amounts of the acid and strong base that are mixed. The resulting solution is the same as if you added sodium acetate to the acetic acid solution: You will have comparable quantities of both acetic acid and its conjugate base in solution.

By choosing appropriate components and adjusting their relative concentrations, we can buffer a solution at virtually any pH.

▲ **Figure 17.1** Standard buffers. For laboratory work, prepackaged buffers at specific pH values can be purchased.

To understand how a buffer works, let's consider one composed of a weak acid HA and one of its salts MA, where  $M^+$  could be  $Na^+$ ,  $K^+$ , or any other cation that does not react with water. The acid-dissociation equilibrium in this buffered solution involves both the acid and its conjugate base:

The corresponding acid-dissociation-constant expression is

$$K_a = \frac{[H^+][A^-]}{[HA]} \quad [17.4]$$

Solving this expression for  $[H^+]$ , we have

$$[H^+] = K_a \frac{[HA]}{[A^-]} \quad [17.5]$$

We see from this expression that  $[H^+]$  and, thus, the pH are determined by two factors:

- the value of  $K_a$  for the weak-acid component of the buffer;
- the ratio of the concentrations of the conjugate acid-base pair,  $[HA]/[A^-]$ .

If  $OH^-$  ions are added to this buffered solution, they react with the buffer acid component to produce water and  $A^-$ :

This neutralization reaction causes  $[HA]$  to decrease and  $[A^-]$  to increase. As long as the amounts of HA and  $A^-$  in the buffer are large relative to the amount of  $OH^-$  added, the ratio  $[HA]/[A^-]$  does not change much and, thus, the change in pH is small.

If  $H^+$  ions are added, they react with the base component of the buffer:

This reaction can also be represented using  $H_3O^+$ :

Using either equation, we see that this reaction causes  $[A^-]$  to decrease and  $[HA]$  to increase. As long as the change in the ratio  $[HA]/[A^-]$  is small, the change in pH will be small.

An example of an  $HA/A^-$  buffer is the  $HF/F^-$  buffered solution shown in **Figure 17.2**. The buffer consists of equal concentrations of hydrofluoric acid, HF, and fluoride ion,

▲ **Figure 17.2 Buffer action.** The pH of an  $HF/F^-$  buffered solution changes by only a small amount in response to addition of an acid or base.

$F^-$  (center). The addition of  $OH^-$  reduces  $[HF]$  and slightly increases  $[F^-]$ , whereas the addition of  $H^+$  reduces  $[F^-]$  and slightly increases  $[HF]$ .

It is possible to overwhelm a buffer by adding too much strong acid or strong base. We will examine this in more detail a little later in this chapter.

### Give It Some Thought

- What happens when NaOH is added to a buffer composed of  $CH_3COOH$  and  $CH_3COO^-$ ?
- What happens when HCl is added to this buffer?

## Calculating the pH of a Buffer

Because conjugate acid–base pairs share a common ion, we can use the same procedures to calculate the pH of a buffer that we used to treat the common-ion effect in Sample Exercise 17.1. Alternatively, we can take an approach based on an equation derived from Equation 17.5. Taking the negative logarithm of both sides of Equation 17.5, we have

$$-\log[H^+] = -\log\left(K_a \frac{[HA]}{[A^-]}\right) = -\log K_a - \log \frac{[HA]}{[A^-]}$$

Because  $-\log[H^+] = \text{pH}$  and  $-\log K_a = \text{p}K_a$ , we have

$$\text{pH} = \text{p}K_a - \log \frac{[HA]}{[A^-]} = \text{p}K_a + \log \frac{[A^-]}{[HA]} \quad [17.8]$$

(Remember the logarithm rules in Appendix A.2, if you are not sure how this calculation works.)

In general,

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \quad [17.9]$$

where [acid] and [base] refer to the equilibrium concentrations of the *conjugate acid–base pair*. Note that when  $[\text{base}] = [\text{acid}]$ , we have  $\text{pH} = \text{p}K_a$ .

Equation 17.9 is known as the **Henderson–Hasselbalch equation**. Biologists, biochemists, and others who work frequently with buffers often use this equation to calculate the pH of buffers. In doing equilibrium calculations, we have seen that we can normally neglect the amounts of the acid and base of the buffer that ionize. Therefore, we can usually use the initial concentrations of the acid and base components of the buffer directly in Equation 17.9, as seen in Sample Exercise 17.3. However, the assumption that the initial concentrations of the acid and base components in the buffer are equal to the equilibrium concentrations is just that: an assumption. There may be times when you will need to be more careful, as seen in Sample Exercise 17.4.

### Sample Exercise 17.3

#### Calculating the pH of a Buffer

What is the pH of a buffer that is 0.12 M in lactic acid  $[CH_3CH(OH)COOH]$ , or  $HC_3H_5O_3$ , and 0.10 M in sodium lactate  $[CH_3CH(OH)COONa]$  or  $NaC_3H_5O_3$ ? For lactic acid,  $K_a = 1.4 \times 10^{-4}$ .

#### SOLUTION

**Analyze** We are asked to calculate the pH of a buffer containing lactic acid ( $HC_3H_5O_3$ ) and its conjugate base, the lactate ion ( $C_3H_5O_3^-$ ).

**Plan** We will first determine the pH using the method described in Section 17.1. Because  $HC_3H_5O_3$  is a weak electrolyte and

$NaC_3H_5O_3$  is a strong electrolyte, the major species in solution are  $HC_3H_5O_3$ ,  $Na^+$ , and  $C_3H_5O_3^-$ . The  $Na^+$  ion is a spectator ion. The  $HC_3H_5O_3/C_3H_5O_3^-$  conjugate acid–base pair determines  $[H^+]$  and, thus, pH;  $[H^+]$  can be determined using the acid-dissociation equilibrium of lactic acid.

*Continued*

**Solve**

The initial and equilibrium concentrations of the species involved in this equilibrium are:

$$\text{CH}_3\text{CH}(\text{OH})\text{COOH}(\text{aq}) \rightleftharpoons \text{H}^+(\text{aq}) + \text{CH}_3\text{CH}(\text{OH})\text{COO}^-(\text{aq})$$

|                 |              |      |              |
|-----------------|--------------|------|--------------|
| Initial (M)     | 0.12         | 0    | 0.10         |
| Change (M)      | $-x$         | $+x$ | $+x$         |
| Equilibrium (M) | $(0.12 - x)$ | $x$  | $(0.10 + x)$ |

The equilibrium concentrations are governed by the equilibrium expression:

$$K_a = 1.4 \times 10^{-4} = \frac{[\text{H}^+][\text{C}_3\text{H}_5\text{O}_3^-]}{[\text{HC}_3\text{H}_5\text{O}_3]} = \frac{x(0.10 + x)}{0.12 - x}$$

Because  $K_a$  is small and a common ion is present, we expect  $x$  to be small relative to either 0.12 or 0.10 M. Thus, our equation can be simplified to give:

$$K_a = 1.4 \times 10^{-4} = \frac{x(0.10)}{0.12}$$

Solving for  $x$  gives a value that justifies our approximation:

$$[\text{H}^+] = x = \left(\frac{0.12}{0.10}\right)(1.4 \times 10^{-4}) = 1.7 \times 10^{-4} \text{ M}$$

Then, we can solve for pH:

$$\text{pH} = -\log(1.7 \times 10^{-4}) = 3.77$$

Alternatively, we can use the Henderson–Hasselbalch equation with the initial concentrations of acid and base to calculate pH directly:

$$\begin{aligned}\text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} = 3.85 + \log \left(\frac{0.10}{0.12}\right) \\ &= 3.85 + (-0.08) = 3.77\end{aligned}$$

**Practice Exercise 1**

If the pH of a buffer solution is equal to the  $\text{p}K_a$  of the acid in the buffer, what does this tell you about the relative concentrations of the acid and conjugate base forms of the buffer components?

(a) The acid concentration must be zero. (b) The base concentration must be zero. (c) The acid and base concentrations must

be equal. (d) The acid and base concentrations must be equal to the  $K_a$ . (e) The base concentration must be 2.3 times as large as the acid concentration.

**Practice Exercise 2**

Calculate the pH of a buffer composed of 0.12 M benzoic acid and 0.20 M sodium benzoate. (Refer to Appendix D.)

**Sample Exercise 17.4****Calculating pH When the Henderson–Hasselbalch Equation May Not Be Accurate**

Calculate the pH of a buffer that initially contains  $1.00 \times 10^{-3} \text{ M}$   $\text{CH}_3\text{COOH}$  and  $1.00 \times 10^{-4} \text{ M}$   $\text{CH}_3\text{COONa}$  in the following two ways: (i) using the Henderson–Hasselbalch equation and (ii) making no assumptions about quantities (which means you will need to use the quadratic equation). The  $K_a$  of  $\text{CH}_3\text{COOH}$  is  $1.80 \times 10^{-5}$ .

**SOLUTION**

**Analyze** We are asked to calculate the pH of a buffer two different ways. We know the initial concentrations of the weak acid and its conjugate base, and the  $K_a$  of the weak acid.

**Plan** We will first use the Henderson–Hasselbalch equation, which relates  $\text{p}K_a$  and ratio of acid–base concentrations to the pH. This will be straightforward. Then, we will redo the calculation making

no assumptions about any quantities, which means we will need to write out the initial/change/equilibrium concentrations, as we have done before. In addition, we will need to solve for quantities using the quadratic equation (since we cannot make assumptions about unknowns being small).

**Solve**

(i) The Henderson–Hasselbalch equation is:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

We know the  $K_a$  of the acid ( $1.8 \times 10^{-5}$ ), so we know  $\text{p}K_a$  ( $\text{p}K_a = -\log K_a = 4.74$ ).

We know the initial concentrations of the base, sodium acetate, and the acid, acetic acid, which we will assume are the same as the equilibrium concentrations.

Therefore, we have:

$$\begin{aligned}\text{pH} &= 4.74 + \log \frac{(1.00 \times 10^{-4})}{(1.00 \times 10^{-3})} \\ &= 4.74 - 1.00 = 3.74\end{aligned}$$

- (ii) Now we will redo the calculation, without making any assumptions at all. We will solve for  $x$ , which represents the  $\text{H}^+$  concentration at equilibrium, in order to calculate pH.

| $\text{CH}_3\text{COOH}(aq) \rightleftharpoons \text{CH}_3\text{COO}^-(aq) + \text{H}^+(aq)$ |                             |                             |      |
|--|-----------------------------|-----------------------------|------|
| Initial (M)  | $1.00 \times 10^{-3}$       | $1.00 \times 10^{-4}$       | 0    |
| Change (M)   | $-x$                        | $+x$                        | $+x$ |
| Equilibrium (M)  | $(1.00 \times 10^{-3} - x)$ | $(1.00 \times 10^{-4} + x)$ | $x$  |

$$\frac{[\text{CH}_3\text{COO}^-][\text{H}^+]}{[\text{CH}_3\text{COOH}]} = K_a$$

$$\frac{(1.00 \times 10^{-4} + x)(x)}{(1.00 \times 10^{-3} - x)} = 1.8 \times 10^{-5}$$

$$1.00 \times 10^{-4}x + x^2 = 1.8 \times 10^{-5}(1.00 \times 10^{-3} - x)$$

$$x^2 + 1.00 \times 10^{-4}x = 1.8 \times 10^{-8} - 1.8 \times 10^{-5}x$$

$$x^2 + 1.18 \times 10^{-4}x - 1.8 \times 10^{-8} = 0$$

$$x = \frac{-1.18 \times 10^{-4} \pm \sqrt{(1.18 \times 10^{-4})^2 - 4(1)(-1.8 \times 10^{-8})}}{2(1)}$$

$$= \frac{-1.18 \times 10^{-4} \pm \sqrt{8.5924 \times 10^{-8}}}{2}$$

$$= 8.76 \times 10^{-5} = [\text{H}^+]$$

$$\text{pH} = 4.06$$

**Comment** In Sample Exercise 17.3, the calculated pH is the same whether we solve exactly using the quadratic equation or make the simplifying assumption that the equilibrium concentrations of acid and base are equal to their initial concentrations. The simplifying assumption works because the concentrations of the acid–base conjugate pair are both a thousand times larger than  $K_a$ . In this Sample Exercise, the acid–base conjugate pair concentrations are only 10–100 as large as  $K_a$ . Therefore, we cannot assume that  $x$  is small compared to the initial concentrations (that is, that the initial concentrations are essentially equal to the equilibrium concentrations). The best answer to this Sample Exercise is  $\text{pH} = 4.06$ , obtained without assuming  $x$  is small. Therefore, we see that the assumptions behind the Henderson–Hasselbalch equation are not valid when the initial concentration of the weak acid (or base) is small compared to its  $K_a$  (or  $K_b$ ).

### Practice Exercise 1

A buffer is made with sodium acetate ( $\text{CH}_3\text{COONa}$ ) and acetic acid ( $\text{CH}_3\text{COOH}$ ); the  $K_a$  for acetic acid is  $1.80 \times 10^{-5}$ . The pH of the buffer is 3.98. What is the ratio of the equilibrium concentration of sodium acetate to that of acetic acid? (a) –0.760 (b) 0.174 (c) 0.840 (d) 5.75 (e) Not enough information is given to answer this question.

### Practice Exercise 2

Calculate the final, equilibrium pH of a buffer that initially contains  $6.50 \times 10^{-4} \text{ M HOCl}$  and  $7.50 \times 10^{-4} \text{ M NaOCl}$ . The  $K_a$  of  $\text{HOCl}$  is  $3.0 \times 10^{-8}$ .

In Sample Exercise 17.3 we calculated the pH of a buffered solution. Often we will need to work in the opposite direction by calculating the amounts of the acid and its conjugate base needed to achieve a specific pH. This calculation is illustrated in Sample Exercise 17.5.

## Sample Exercise 17.5

### Preparing a Buffer

How many moles of  $\text{NH}_4\text{Cl}$  must be added to 2.0 L of 0.10 M  $\text{NH}_3$  to form a buffer whose pH is 9.00? (Assume that the addition of  $\text{NH}_4\text{Cl}$  does not change the volume of the solution.)

### SOLUTION

**Analyze** We are asked to determine the amount of  $\text{NH}_4^+$  ion required to prepare a buffer of a specific pH.

**Plan** The major species in the solution will be  $\text{NH}_4^+$ ,  $\text{Cl}^-$ , and  $\text{NH}_3$ . Of these, the  $\text{Cl}^-$  ion is a spectator (it is the conjugate base of a strong acid). Thus, the  $\text{NH}_4^+/\text{NH}_3$  conjugate acid–base pair will determine the pH of the buffer. The equilibrium relationship

between  $\text{NH}_4^+$  and  $\text{NH}_3$  is given by the base-dissociation reaction for  $\text{NH}_3$ :

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = 1.8 \times 10^{-5}$$

The key to this exercise is to use this  $K_b$  expression to calculate  $[\text{NH}_4^+]$ .

*Continued*

**Solve**

We obtain  $[\text{OH}^-]$  from the given pH:

$$\text{pOH} = 14.00 - \text{pH} = 14.00 - 9.00 = 5.00$$

and so:

$$[\text{OH}^-] = 1.0 \times 10^{-5} M$$

Because  $K_b$  is small and the common ion  $[\text{NH}_4^+]$  is present, the equilibrium concentration of  $\text{NH}_3$  essentially equals its initial concentration:

$$[\text{NH}_3] = 0.10 M$$

We now use the expression for  $K_b$  to calculate  $[\text{NH}_4^+]$ :

$$[\text{NH}_4^+] = K_b \frac{[\text{NH}_3]}{[\text{OH}^-]} = (1.8 \times 10^{-5}) \frac{(0.10)}{(1.0 \times 10^{-5})} = 0.18 M$$

Thus, for the solution to have  $\text{pH} = 9.00$ ,  $[\text{NH}_4^+]$  must equal  $0.18 M$ . The number of moles of  $\text{NH}_4\text{Cl}$  needed to produce this concentration is given by the product of the volume of the solution and its molarity:

$$(2.0 L)(0.18 \text{ mol NH}_4\text{Cl}/L) = 0.36 \text{ mol NH}_4\text{Cl}$$

**Comment** Because  $\text{NH}_4^+$  and  $\text{NH}_3$  are a conjugate acid–base pair, we could use the Henderson–Hasselbalch equation (Equation 17.9) to solve this problem. To do so requires first using Equation 16.41 to calculate  $\text{p}K_a$  for  $\text{NH}_4^+$  from the value of  $\text{p}K_b$  for  $\text{NH}_3$ . We suggest you try this approach to convince yourself that you can use the Henderson–Hasselbalch equation for buffers for which you are given  $K_b$  for the conjugate base rather than  $K_a$  for the conjugate acid.

► **Practice Exercise 1**

Calculate the number of grams of ammonium chloride that must be added to 2.00 L of a 0.500 M ammonia solution to

obtain a buffer of  $\text{pH} = 9.20$ . Assume the volume of the solution does not change as the solid is added.  $K_b$  for ammonia is  $1.80 \times 10^{-5}$ .

(a) 60.7 g (b) 30.4 g (c) 1.52 g (d) 0.568 g  
(e)  $1.59 \times 10^{-5} \text{ g}$

► **Practice Exercise 2**

Calculate the concentration of sodium benzoate that must be present in a 0.20 M solution of benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ) to produce a pH of 4.00. Refer to Appendix D.

## Buffer Capacity and pH Range

Two important characteristics of a buffer are its capacity and its effective pH range. **Buffer capacity** is the amount of acid or base the buffer can neutralize before the pH begins to change to an appreciable degree. The buffer capacity depends on the amount of acid and base used to prepare the buffer. According to Equation 17.5, for example, the pH of a 1-L solution that is 1 M in  $\text{CH}_3\text{COOH}$  and 1 M in  $\text{CH}_3\text{COONa}$  is the same as the pH of a 1-L solution that is 0.1 M in  $\text{CH}_3\text{COOH}$  and 0.1 M in  $\text{CH}_3\text{COONa}$ . The first solution has a greater buffering capacity, however, because it contains more  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ .

The pH range of any buffer is the pH range over which the buffer acts effectively. Buffers most effectively resist a change in pH in *either* direction when the concentrations of weak acid and conjugate base are about the same. From Equation 17.9 we see that when the concentrations of weak acid and conjugate base are equal,  $\text{pH} = \text{p}K_a$ . This relationship gives the optimal pH of any buffer. Thus, we usually try to select a buffer whose acid form has a  $\text{p}K_a$  close to the desired pH. In practice, we find that if the concentration of one component of the buffer is more than 10 times the concentration of the other component, the buffering action is poor. Because  $\log 10 = 1$ , *buffers usually have a usable range within  $\pm 1$  pH unit of  $\text{p}K_a$*  (that is, a range of  $\text{pH} = \text{p}K_a \pm 1$ ).

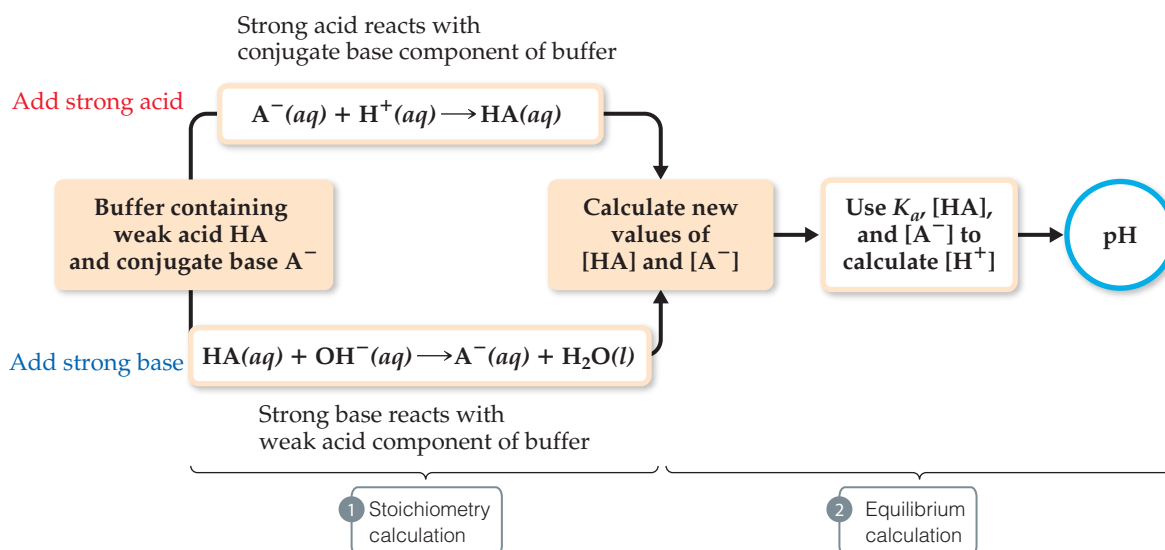

### Give It Some Thought

The  $K_a$  values for nitrous acid ( $\text{HNO}_2$ ) and hypochlorous ( $\text{HClO}$ ) acid are  $4.5 \times 10^{-4}$  and  $3.0 \times 10^{-8}$ , respectively. Which one would be more suitable for use in a solution buffered at  $\text{pH} = 7.0$ ? What other substances would be needed to make the buffer?

## Addition of Strong Acids or Bases to Buffers

Let's now consider in a more quantitative way how a buffered solution responds to addition of a strong acid or base. In this discussion, it is important to understand that

▲ **Figure 17.3** Calculating the pH of a buffer after addition of a strong acid or strong base.

neutralization reactions between strong acids and weak bases proceed essentially to completion, as do those between strong bases and weak acids. This is because water is a product of the reaction, and you have an equilibrium constant of  $1/K_w = 10^{14}$  in your favor when making water. ∞ (Section 16.3) Thus, as long as we do not exceed the buffering capacity of the buffer, we can assume that the strong acid or strong base is completely consumed by reaction with the buffer.

Consider a buffer that contains a weak acid HA and its conjugate base  $\text{A}^-$ . When a strong acid is added to this buffer, the added  $\text{H}^+$  is consumed by  $\text{A}^-$  to produce HA; thus,  $[\text{HA}]$  increases and  $[\text{A}^-]$  decreases. (See Equation 17.7.) Upon addition of a strong base, the added  $\text{OH}^-$  is consumed by HA to produce  $\text{A}^-$ ; in this case  $[\text{HA}]$  decreases and  $[\text{A}^-]$  increases. (See Equation 17.6.) These two situations are summarized in Figure 17.2.

To calculate how the pH of the buffer responds to the addition of a strong acid or a strong base, we follow the strategy outlined in Figure 17.3:

1. Consider the acid–base neutralization reaction and determine its effect on  $[\text{HA}]$  and  $[\text{A}^-]$ . This step is a *limiting reactant stoichiometry calculation*. ∞ (Sections 3.6 and 3.7)
2. Use the calculated values of  $[\text{HA}]$  and  $[\text{A}^-]$  along with  $K_a$  to calculate  $[\text{H}^+]$ . This step is an *equilibrium calculation* and is most easily done using the Henderson–Hasselbalch equation (if the concentrations of the weak acid–base pair are very large compared to  $K_a$  for the acid).

## Sample Exercise 17.6

### Calculating pH Changes in Buffers

A buffer is made by adding 0.300 mol  $\text{CH}_3\text{COOH}$  and 0.300 mol  $\text{CH}_3\text{COONa}$  to enough water to make 1.000 L of solution. The pH of the buffer is 4.74 (Sample Exercise 17.1). (a) Calculate the pH of this solution after 5.0 mL of 4.0 M  $\text{NaOH}(\text{aq})$  solution is added. (b) For comparison, calculate the pH of a solution made by adding 5.0 mL of 4.0 M  $\text{NaOH}(\text{aq})$  solution to 1.000 L of pure water.

### SOLUTION

**Analyze** We are asked to determine the pH of a buffer after addition of a small amount of strong base and to compare the pH change with the pH that would result if we were to add the same amount of strong base to pure water.

**Plan** Solving this problem involves the two steps outlined in Figure 17.3. First we do a stoichiometry calculation to determine how the added  $\text{OH}^-$  affects the buffer composition. Then we use the resulting buffer composition and either the Henderson–Hasselbalch equation or the equilibrium-constant expression for the buffer to determine the pH.

Continued

**Solve**

- (a) **Stoichiometry Calculation:** The  $\text{OH}^-$  provided by NaOH reacts with  $\text{CH}_3\text{COOH}$ , the weak acid component of the buffer. Since volumes are changing, it is prudent to figure out how many moles of reactants and products would be produced, then divide by the final volume later to obtain concentrations. Prior to this neutralization reaction, there are 0.300 mol each of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ . The amount of base added is  $0.0050 \text{ L} \times 4.0 \text{ mol/L} = 0.020 \text{ mol}$ . Neutralizing the 0.020 mol  $\text{OH}^-$  requires 0.020 mol of  $\text{CH}_3\text{COOH}$ . Consequently, the amount of  $\text{CH}_3\text{COOH}$  decreases by 0.020 mol, and the amount of the product of the neutralization,  $\text{CH}_3\text{COO}^-$ , increases by 0.020 mol. We can create a table to see how the composition of the buffer changes as a result of its reaction with  $\text{OH}^-$ :

$$\text{CH}_3\text{COOH}(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{CH}_3\text{COO}^-(aq)$$

|                                  |        |        |   |        |
|----------------------------------|--------|--------|---|--------|
| Before reaction (mol)            | 0.300  | 0.020  | — | 0.300  |
| Change (limiting reactant) (mol) | -0.020 | -0.020 | — | +0.020 |
| After reaction (mol)             | 0.280  | 0      | — | 0.320  |

**Equilibrium Calculation:** We now turn our attention to the equilibrium for the ionization of acetic acid, the relationship that determines the buffer pH:

Using the quantities of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$  remaining in the buffer after the reaction with strong base, we determine the pH using the Henderson-Hasselbalch equation. The volume of the solution is now  $1.000 \text{ L} + 0.0050 \text{ L} = 1.005 \text{ L}$  due to addition of the NaOH solution:

$$\text{pH} = 4.74 + \log \frac{0.320 \text{ mol} / 1.005 \text{ L}}{0.280 \text{ mol} / 1.005 \text{ L}} = 4.80$$

- (b) To determine the pH of a solution made by adding 0.020 mol of NaOH to 1.000 L of pure water, we first determine the concentration of  $\text{OH}^-$  ions in solution:

$$[\text{OH}^-] = 0.020 \text{ mol} / 1.005 \text{ L} = 0.020 \text{ M}$$

We use this value in Equation 16.18 to calculate pOH and then use our calculated pOH value to obtain pH:

$$\begin{aligned} \text{pOH} &= -\log[\text{OH}^-] = -\log(0.020) = +1.70 \\ \text{pH} &= 14 - (+1.70) = 12.30 \end{aligned}$$

▲ **Figure 17.4** Effect of adding a strong base to (a) a buffered solution and to (b) water.

**Comment** Note that the small amount of added NaOH changes the pH of water significantly. In contrast, the pH of the buffer changes very little when the NaOH is added, as summarized in **Figure 17.4**.

► **Practice Exercise 1**

Which of these statements is true? (a) If you add strong acid or base to a buffer, the pH will never change. (b) In order to do calculations in which strong acid or base is added to a buffer, you only need to use the Henderson-Hasselbalch equation. (c) Strong bases react with strong acids, but not

weak acids. (d) If you add a strong acid or base to a buffer, the buffer's  $\text{p}K_a$  or  $\text{p}K_b$  will change. (e) In order to do calculations in which a strong acid or base is added to a buffer, you need to calculate the amounts of substances from the neutralization reaction and then equilibrate.

► **Practice Exercise 2**

Determine (a) the pH of the original buffer described in Sample Exercise 17.6 after the addition of 0.020 mol HCl and (b) the pH of the solution that would result from the addition of 0.020 mol HCl to 1.000 L of pure water.

## CHEMISTRY AND LIFE Blood as a Buffered Solution

Chemical reactions that occur in living systems are often extremely sensitive to pH. Many of the enzymes that catalyze important biochemical reactions are effective only within a narrow pH range. For this reason, the human body maintains a remarkably intricate system of buffers, both within cells and in the fluids that transport cells. Blood, the fluid that transports oxygen to all parts of the body, is one of the most prominent examples of the importance of buffers in living beings.

Human blood has a normal pH of 7.35 to 7.45. Any deviation from this range can have extremely disruptive effects on the stability of cell membranes, the structures of proteins, and the activities of enzymes. Death may result if the blood pH falls below 6.8 or rises above 7.8. When the pH falls below 7.35, the condition is called *acidosis*; when it rises above 7.45, the condition is called *alkalosis*. Acidosis is the more common tendency because metabolism generates several acids in the body.

The major buffer system used to control blood pH is the *carbonic acid–bicarbonate buffer system*. Carbonic acid ( $\text{H}_2\text{CO}_3$ ) and bicarbonate ion ( $\text{HCO}_3^-$ ) are a conjugate acid–base pair. In addition, carbonic acid decomposes into carbon dioxide gas and water. The important equilibria in this buffer system are

Several aspects of these equilibria are notable. First, although carbonic acid is diprotic, the carbonate ion ( $\text{CO}_3^{2-}$ ) is unimportant in this system. Second, one component of this equilibrium,  $\text{CO}_2$ , is a gas, which provides a mechanism for the body to adjust the equilibria. Removal of  $\text{CO}_2$  via exhalation shifts the equilibria to the right, consuming  $\text{H}^+$  ions. Third, the buffer system in blood operates at pH 7.4, which is fairly far removed from the  $\text{p}K_{\text{a}1}$  value of  $\text{H}_2\text{CO}_3$  (6.1 at physiological temperatures). For the buffer to have a pH of 7.4, the ratio  $[\text{base}]/[\text{acid}]$  must be about 20. In normal blood plasma, the concentrations of  $\text{HCO}_3^-$  and  $\text{H}_2\text{CO}_3$  are about 0.024 M and 0.0012 M, respectively. Consequently, the buffer has a high capacity to neutralize additional acid but only a low capacity to neutralize additional base.

The principal organs that regulate the pH of the carbonic acid–bicarbonate buffer system are the lungs and kidneys. When the concentration of  $\text{CO}_2$  rises, the equilibrium concentrations in Equation 17.10 shift to the left, which leads to the formation of more  $\text{H}^+$  and a drop in pH. This change is detected by receptors in the brain that trigger a reflex to breathe faster and deeper, increasing the rate at which  $\text{CO}_2$  is expelled from the lungs and thereby shifting the equilibrium concentrations back to the right. When the blood pH becomes too high, the kidneys remove  $\text{HCO}_3^-$  from the blood. This shifts the equilibrium concentrations to the left, increasing the concentration of  $\text{H}^+$ . As a result, the pH decreases.

Regulation of blood pH relates directly to the effective transport of  $\text{O}_2$  throughout the body. The protein hemoglobin, found in red blood cells (Figure 17.5), carries oxygen. Hemoglobin (Hb) reversibly

binds both  $\text{O}_2$  and  $\text{H}^+$ . These two substances compete for the Hb, which can be represented approximately by the equilibrium

Oxygen enters the blood through the lungs, where it passes into the red blood cells and binds to Hb. When the blood reaches tissue in which the concentration of  $\text{O}_2$  is low, the equilibrium concentrations in Equation 17.11 shift to the left and  $\text{O}_2$  is released.

During periods of strenuous exertion, three factors work together to ensure delivery of  $\text{O}_2$  to active tissues. The role of each factor can be understood by applying Le Châtelier's principle to Equation 17.11:

1.  $\text{O}_2$  is consumed, causing the equilibrium concentrations to shift to the left, releasing more  $\text{O}_2$ .
2. Large amounts of  $\text{CO}_2$  are produced by metabolism, which increases  $[\text{H}^+]$  and causes the equilibrium concentrations to shift to the left, releasing  $\text{O}_2$ .
3. Body temperature rises. Because Equation 17.11 is exothermic, the increase in temperature shifts the equilibrium concentrations to the left, releasing  $\text{O}_2$ .

In addition to the factors causing release of  $\text{O}_2$  to tissues, the decrease in pH stimulates an increase in breathing rate, which furnishes more  $\text{O}_2$  and eliminates  $\text{CO}_2$ . Without this elaborate series of equilibrium shifts and pH changes, the  $\text{O}_2$  in tissues would be rapidly depleted, making further activity impossible. Under such conditions, the buffering capacity of the blood and the exhalation of  $\text{CO}_2$  through the lungs are essential to keep the pH from dropping too low, thereby triggering acidosis.

## 17.3 | Acid–Base Titrations

Titrations are procedures in which one reactant is slowly added into a solution of another reactant, while equilibrium concentrations along the way are monitored. ∞ (Section 4.6) There are two main reasons to do titrations:

- to determine the concentration of one of the reactants
- to determine the equilibrium constant for the reaction

In an acid–base titration, a solution containing a known concentration of base is slowly added to an acid (or the acid is added to the base). ∞ (Section 4.6) Acid–base

## Go Figure

In which direction do you expect the pH to change as NaOH is added to the HCl solution?

▲ Figure 17.6 Measuring pH during a titration.

indicators can be used to signal the *equivalence point* of a titration (the point at which stoichiometrically equivalent quantities of acid and base have been brought together). Alternatively, a pH meter can be used to monitor the progress of the reaction (Figure 17.6), producing a **pH titration curve**, a graph of the pH as a function of the volume of titrant added. The shape of the titration curve makes it possible to determine the equivalence point. The curve can also be used to select suitable indicators and to determine the  $K_a$  of the weak acid or the  $K_b$  of the weak base being titrated.

To understand why titration curves have certain characteristic shapes, we will examine the curves for three kinds of titrations: (1) strong acid–strong base, (2) weak acid–strong base, and (3) polyprotic acid–strong base. We will also briefly consider how these curves relate to those involving weak bases.

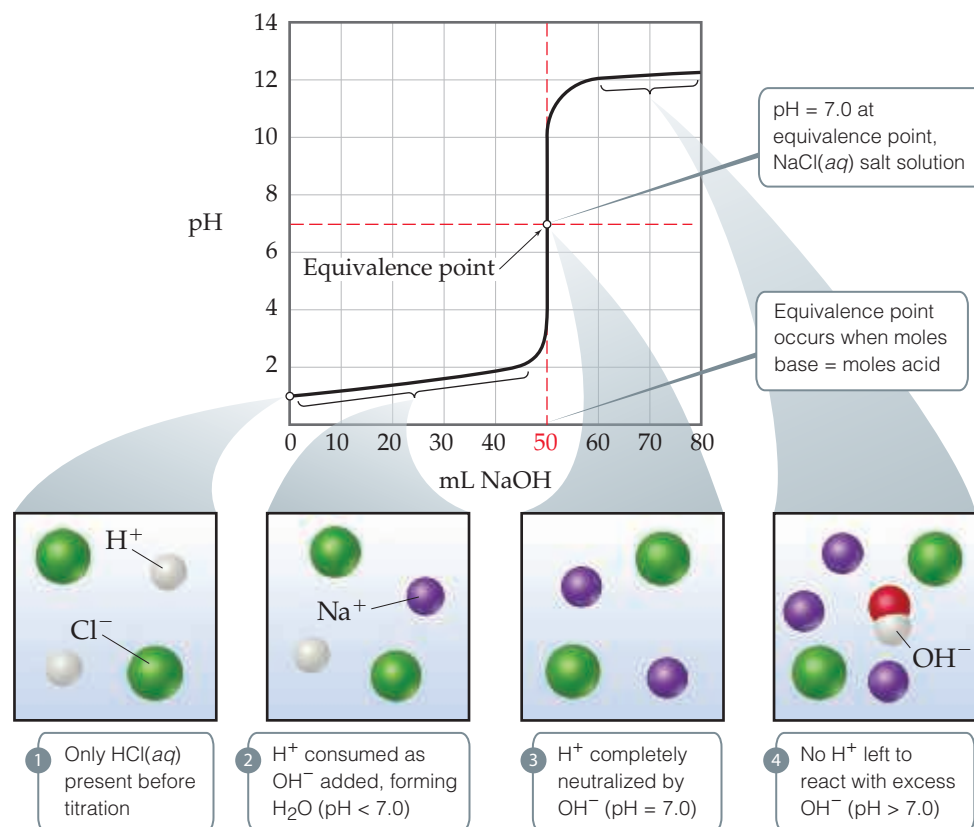

## Strong Acid–Strong Base Titrations

The titration curve produced when a strong base is added to a strong acid has the general shape shown in Figure 17.7, which depicts the pH change that occurs as 0.100 M NaOH is added to 50.0 mL of 0.100 M HCl. The pH can be calculated at various stages of the titration. To help understand these calculations, we can divide the curve into four regions:

- 1. Initial pH:** The pH of the solution before the addition of any base is determined by the initial concentration of the strong acid. For a solution of 0.100 M HCl,  $[H^+] = 0.100 M$  and  $pH = -\log(0.100) = 1.000$ . Thus, the initial pH is low.
- 2. Between initial pH and equivalence point:** As NaOH is added, the pH increases slowly at first and then rapidly in the vicinity of the equivalence point.

## Go Figure

What volume of NaOH(aq) would be needed to reach the equivalence point if the concentration of the added base were 0.200 M?

▲ Figure 17.7 Titration of a strong acid with a strong base. The pH curve for titration of 50.0 mL of a 0.100 M solution of hydrochloric acid with a 0.100 M solution of NaOH(aq). For clarity, water molecules have been omitted from the molecular art.

The pH before the equivalence point is determined by the concentration of acid not yet neutralized. This calculation is illustrated in Sample Exercise 17.7(a).

- 3. Equivalence point:** At the equivalence point an equal number of moles of NaOH and HCl have reacted, leaving only a solution of their salt, NaCl. The pH of the solution is 7.00 because the cation of a strong base (in this case  $\text{Na}^+$ ) and the anion of a strong acid (in this case  $\text{Cl}^-$ ) are neither acids nor bases and, therefore, have no appreciable effect on pH.  $\infty$  (Section 16.9)
- 4. After equivalence point:** The pH of the solution after the equivalence point is determined by the concentration of excess NaOH in the solution. This calculation is illustrated in Sample Exercise 17.7(b).

## Sample Exercise 17.7

### Calculations for a Strong Acid–Strong Base Titration

Calculate the pH when (a) 49.0 mL and (b) 51.0 mL of 0.100 M NaOH solution have been added to 50.0 mL of 0.100 M HCl solution.

### SOLUTION

**Analyze** We are asked to calculate the pH at two points in the titration of a strong acid with a strong base. The first point is just before the equivalence point, so we expect the pH to be determined by the small amount of strong acid that has not yet been neutralized. The second point is just after the equivalence point, so we expect this pH to be determined by the small amount of excess strong base.

**Plan** (a) As the NaOH solution is added to the HCl solution,  $\text{H}^+(aq)$  reacts with  $\text{OH}^-(aq)$  to form  $\text{H}_2\text{O}$ . Both  $\text{Na}^+$  and  $\text{Cl}^-$  are spectator ions, having negligible effect on the pH. To determine the pH of the solution, we must first determine how many moles

of  $\text{H}^+$  were originally present and how many moles of  $\text{OH}^-$  were added. We can then calculate how many moles of each ion remain after the neutralization reaction. To calculate  $[\text{H}^+]$ , and hence pH, we must also remember that the volume of the solution increases as we add titrant, thus diluting the concentration of all solutes present. Therefore, it is best to deal with moles first, and then convert to molarities using total solution volumes (volume of acid plus volume of base). (b) We proceed in the same way as in part (a) except we are now past the equivalence point and have more  $\text{OH}^-$  in the solution than  $\text{H}^+$ .

### Solve

- (a) The number of moles of  $\text{H}^+$  in the original HCl solution is given by the product of the volume of the solution and its molarity:

$$(0.0500 \text{ L soln}) \left( \frac{0.100 \text{ mol H}^+}{1 \text{ L soln}} \right) = 5.00 \times 10^{-3} \text{ mol H}^+$$

Likewise, the number of moles of  $\text{OH}^-$  in 49.0 mL of 0.100 M NaOH is:

$$(0.0490 \text{ L soln}) \left( \frac{0.100 \text{ mol OH}^-}{1 \text{ L soln}} \right) = 4.90 \times 10^{-3} \text{ mol OH}^-$$

Because we have not reached the equivalence point, there are more moles of  $\text{H}^+$  present than  $\text{OH}^-$ . Therefore,  $\text{OH}^-$  is the limiting reactant. Each mole of  $\text{OH}^-$  reacts with 1 mol of  $\text{H}^+$ . Using the convention introduced in Sample Exercise 17.6, we have:

|                                  | $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$ |                        |   |
|----------------------------------|--|------------------------|---|
| Before reaction (mol)            | $5.00 \times 10^{-3}$  | $4.90 \times 10^{-3}$  | — |
| Change (limiting reactant) (mol) | $-4.90 \times 10^{-3}$   | $-4.90 \times 10^{-3}$ | — |
| After reaction (mol)             | $0.10 \times 10^{-3}$  | 0                      | — |

The volume of the reaction mixture increases as the NaOH solution is added to the HCl solution. Thus, at this point in the titration, the volume in the titration flask is:

$$50.0 \text{ mL} + 49.0 \text{ mL} = 99.0 \text{ mL} = 0.0990 \text{ L}$$

Thus, the concentration of  $\text{H}^+(aq)$  in the flask is:

$$[\text{H}^+] = \frac{\text{moles H}^+(aq)}{\text{liters soln}} = \frac{0.10 \times 10^{-3} \text{ mol}}{0.09900 \text{ L}} = 1.0 \times 10^{-3} \text{ M}$$

The corresponding pH is:

$$-\log(1.0 \times 10^{-3}) = 3.00$$

- (b) As before, the initial number of moles of each reactant is determined from their volumes and concentrations. The reactant present in smaller stoichiometric amount (the limiting reactant) is consumed completely, leaving an excess of hydroxide ion.

|                                  | $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$ |                        |   |
|----------------------------------|--|------------------------|---|
| Before reaction (mol)            | $5.00 \times 10^{-3}$  | $5.10 \times 10^{-3}$  | — |
| Change (limiting reactant) (mol) | $-5.00 \times 10^{-3}$   | $-5.00 \times 10^{-3}$ | — |
| After reaction (mol)             | 0  | $0.10 \times 10^{-3}$  | — |

Continued

In this case, the volume in the titration flask is:  
Hence, the concentration of  $\text{OH}^-(aq)$  in the flask is:

and we have:

$$50.0 \text{ mL} + 51.0 \text{ mL} = 101.0 \text{ mL} = 0.1010 \text{ L}$$

$$[\text{OH}^-] = \frac{\text{moles } \text{OH}^-(aq)}{\text{liters soln}} = \frac{0.10 \times 10^{-3} \text{ mol}}{0.1010 \text{ L}} = 1.0 \times 10^{-3} \text{ M}$$

$$\text{pOH} = -\log(1.0 \times 10^{-3}) = 3.00$$

$$\text{pH} = 14.00 - \text{pOH} = 14.00 - 3.00 = 11.00$$

**Comment** Note that the pH increased by only two pH units, from 1.00 (Figure 17.7) to 3.00, after the first 49.0 mL of NaOH solution was added, but jumped by eight pH units, from 3.00 to 11.00, as 2.0 mL of base solution was added near the equivalence point. Such a rapid rise in pH near the equivalence point is a characteristic of titrations involving strong acids and strong bases.

### Practice Exercise 1

An acid–base titration is performed: 250.0 mL of an unknown concentration of HCl ( $aq$ ) is titrated to the equivalence point with 36.7 mL of a 0.1000 M aqueous solution of NaOH. Which of the following statements is *not* true of this titration?

(a) The HCl solution is less concentrated than the NaOH solution. (b) The pH is less than 7 after adding 25 mL of NaOH solution. (c) The pH at the equivalence point is 7.00. (d) If an additional 1.00 mL of NaOH solution is added beyond the equivalence point, the pH of the solution is more than 7.00. (e) At the equivalence point, the  $\text{OH}^-$  concentration in the solution is  $3.67 \times 10^{-3} \text{ M}$ .

### Practice Exercise 2

Calculate the pH when (a) 24.9 mL and (b) 25.1 mL of 0.100 M  $\text{HNO}_3$  have been added to 25.0 mL of 0.100 M KOH solution.

▲ **Figure 17.8** Titration of a strong base with a strong acid. The pH curve for titration of 50.0 mL of a 0.100 M solution of a strong base with a 0.100 M solution of a strong acid.

Titration of a solution of a strong base with a solution of a strong acid yields an analogous curve of pH versus added acid. In this case, however, the pH is high at the outset of the titration and low at its completion (Figure 17.8). The pH at the equivalence point is still 7.0 (at 25 °C), just like the strong acid–strong base titration.

### Give It Some Thought

What is the pH at the equivalence point when 0.10 M  $\text{HNO}_3$  is used to titrate a volume of solution containing 0.30 g of KOH?

## Weak Acid–Strong Base Titrations

The curve for titration of a weak acid by a strong base is similar to the curve in Figure 17.7. Consider, for example, the curve for titration of 50.0 mL of 0.100 M acetic acid with 0.100 M NaOH shown in Figure 17.9. We can calculate the pH at points along this curve, using principles we discussed earlier, which means again dividing the curve into four regions:

- 1. Initial pH:** We use  $K_a$  to calculate this pH, as shown in Section 16.6. The calculated pH of 0.100 M  $\text{CH}_3\text{COOH}$  is 2.89.
- 2. Between initial pH and equivalence point:** Prior to reaching the equivalence point, the acid is being neutralized, and its conjugate base is being formed:

Thus, the solution contains a mixture of  $\text{CH}_3\text{COOH}$  and  $\text{CH}_3\text{COO}^-$ . Calculating the pH in this region involves two steps. First, we consider the neutralization reaction between  $\text{CH}_3\text{COOH}$  and  $\text{OH}^-$  to determine  $[\text{CH}_3\text{COOH}]$  and  $[\text{CH}_3\text{COO}^-]$ . Next, we calculate the pH of this buffer pair using procedures developed in Sections 17.1 and 17.2. The general procedure is diagrammed in Figure 17.10 and illustrated in Sample Exercise 17.7.

- 3. Equivalence point:** The equivalence point is reached when 50.0 mL of 0.100 M NaOH has been added to the 50.0 mL of 0.100 M  $\text{CH}_3\text{COOH}$ . At this point, the  $5.00 \times 10^{-3} \text{ mol}$  of NaOH completely reacts with the  $5.00 \times 10^{-3} \text{ mol}$  of  $\text{CH}_3\text{COOH}$  to form  $5.00 \times 10^{-3} \text{ mol}$  of  $\text{CH}_3\text{COONa}$ . The  $\text{Na}^+$  ion of this salt has no significant effect on the pH. The  $\text{CH}_3\text{COO}^-$  ion, however, is a weak base whose

## Go Figure

If the acetic acid being titrated here were replaced by hydrochloric acid, would the amount of base needed to reach the equivalence point change? Would the pH at the equivalence point change?

**Figure 17.9** Titration of a weak acid with a strong base. The pH curve for titration of 50.0 mL of a 0.100 M solution of acetic acid with a 0.100 M solution of  $\text{NaOH}(aq)$ . For clarity, water molecules have been omitted from the molecular art.

reaction with water cannot be neglected, and the pH at the equivalence point is therefore greater than 7. In general, the pH at the equivalence point is always above 7 in a weak acid–strong base titration because the anion of the salt formed is a weak base. The procedure for calculating the pH of the solution of a weak base is described in Section 16.7 and is shown in Sample Exercise 17.8.

- 4. After equivalence point (excess base):** In this region,  $[\text{OH}^-]$  from the reaction of  $\text{CH}_3\text{COO}^-$  with water is negligible relative to  $[\text{OH}^-]$  from the excess  $\text{NaOH}$ . Thus, the pH is determined by the concentration of  $\text{OH}^-$  from the excess  $\text{NaOH}$ . The method for calculating pH in this region is therefore like that illustrated in Sample Exercise 17.7(b). Thus, the addition of 51.0 mL of 0.100 M  $\text{NaOH}$  to 50.0 mL of either 0.100 M  $\text{HCl}$  or 0.100 M  $\text{CH}_3\text{COOH}$  yields the same pH, 11.00. Notice by comparing Figures 17.7 and 17.9 that the titration curves for a strong acid and a weak acid are the same after the equivalence point.

▲ Figure 17.10 Procedure for calculating pH when a weak acid is partially neutralized by a strong base.

## Sample Exercise 17.8

### Calculations for a Weak Acid–Strong Base Titration

Calculate the pH of the solution formed when 45.0 mL of 0.100 M NaOH is added to 50.0 mL of 0.100 M CH<sub>3</sub>COOH ( $K_a = 1.8 \times 10^{-5}$ ).

#### SOLUTION

**Analyze** We are asked to calculate the pH before the equivalence point of the titration of a weak acid with a strong base.

**Plan** We first must determine the number of moles of CH<sub>3</sub>COOH and CH<sub>3</sub>COO<sup>-</sup> present after the neutralization

reaction (the stoichiometry calculation). We then calculate pH using  $K_a$ , [CH<sub>3</sub>COOH], and [CH<sub>3</sub>COO<sup>-</sup>] (the equilibrium calculation).

#### Solve

**Stoichiometry Calculation:** The product of the volume and concentration of each solution gives the number of moles of each reactant present before the neutralization:

$$(0.0500 \text{ L soln}) \left( \frac{0.100 \text{ mol CH}_3\text{COOH}}{1 \text{ L soln}} \right) = 5.00 \times 10^{-3} \text{ mol CH}_3\text{COOH}$$

$$(0.0450 \text{ L soln}) \left( \frac{0.100 \text{ mol NaOH}}{1 \text{ L soln}} \right) = 4.50 \times 10^{-3} \text{ mol NaOH}$$

The  $4.50 \times 10^{-3}$  mol of NaOH consumes  $4.50 \times 10^{-3}$  mol of CH<sub>3</sub>COOH:

|                                  |                        |                        |                        |   |
|----------------------------------|------------------------|------------------------|------------------------|---|
| Before reaction (mol)            | $5.00 \times 10^{-3}$  | $4.50 \times 10^{-3}$  | 0                      | — |
| Change (limiting reactant) (mol) | $-4.50 \times 10^{-3}$ | $-4.50 \times 10^{-3}$ | $+4.50 \times 10^{-3}$ |   |
| After reaction (mol)             | $0.50 \times 10^{-3}$  | 0                      | $4.50 \times 10^{-3}$  | — |

The total volume of the solution is:

$$45.0 \text{ mL} + 50.0 \text{ mL} = 95.0 \text{ mL} = 0.0950 \text{ L}$$

The resulting molarities of CH<sub>3</sub>COOH and CH<sub>3</sub>COO<sup>-</sup> after the reaction are therefore:

$$[\text{CH}_3\text{COOH}] = \frac{0.50 \times 10^{-3} \text{ mol}}{0.0950 \text{ L}} = 0.0053 \text{ M}$$

$$[\text{CH}_3\text{COO}^-] = \frac{4.50 \times 10^{-3} \text{ mol}}{0.0950 \text{ L}} = 0.0474 \text{ M}$$

**Equilibrium Calculation:** The equilibrium between CH<sub>3</sub>COOH and CH<sub>3</sub>COO<sup>-</sup> must obey the equilibrium-constant expression for CH<sub>3</sub>COOH:

$$K_a = \frac{[\text{H}^+][\text{CH}_3\text{COO}^-]}{[\text{CH}_3\text{COOH}]} = 1.8 \times 10^{-5}$$

Solving for [H<sup>+</sup>] gives:

$$[\text{H}^+] = K_a \times \frac{[\text{CH}_3\text{COOH}]}{[\text{CH}_3\text{COO}^-]} = (1.8 \times 10^{-5}) \times \left( \frac{0.0053}{0.0474} \right) = 2.0 \times 10^{-6} \text{ M}$$

$$\text{pH} = -\log(2.0 \times 10^{-6}) = 5.70$$

**Comment** We could have solved for pH equally well using the Henderson–Hasselbalch equation in the last step.

### ► Practice Exercise 1

If you think carefully about what happens during the course of a weak acid–strong base titration, you can learn some very interesting things. For example, let's look back at Figure 17.9 and pretend you did not know that acetic acid was the acid being titrated. You can figure out the  $pK_a$  of a weak acid just by thinking about the definition of  $K_a$  and looking at the right place on the titration curve! Which of the following choices is the best way to do this?

(a) At the equivalence point,  $pH = pK_a$ . (b) Halfway to the equivalence point,  $pH = pK_a$ . (c) Before any base is added,  $pH = pK_a$ . (d) At the top of the graph with excess base added,  $pH = pK_a$ .

### ► Practice Exercise 2

(a) Calculate the pH in the solution formed by adding 10.0 mL of 0.050 M NaOH to 40.0 mL of 0.0250 M benzoic acid ( $C_6H_5COOH$ ,  $K_a = 6.3 \times 10^{-5}$ ). (b) Calculate the pH in the solution formed by adding 10.0 mL of 0.100 M HCl to 20.0 mL of 0.100 M  $NH_3$ .

In order to further monitor the evolution of pH as a function of added base, we can calculate the pH at the equivalence point.

## Sample Exercise 17.9

### Calculating the pH at the Equivalence Point

Calculate the pH at the equivalence point in the titration of 50.0 mL of 0.100 M  $CH_3COOH$  with 0.100 M NaOH.

### SOLUTION

**Analyze** We are asked to determine the pH at the equivalence point of the titration of a weak acid with a strong base. Because the neutralization of a weak acid produces its anion, a conjugate base that can react with water, we expect the pH at the equivalence point to be greater than 7.

**Plan** The initial number of moles of acetic acid equals the number of moles of acetate ion at the equivalence point. We use the volume of the solution at the equivalence point to calculate the concentration of acetate ion. Because the acetate ion is a weak base, we can calculate the pH using  $K_b$  and  $[CH_3COO^-]$ .

### Solve

The number of moles of acetic acid in the initial solution is obtained from the volume and molarity of the solution:

$$\begin{aligned}\text{Moles} &= M \times V = (0.100 \text{ mol/L})(0.0500 \text{ L}) \\ &= 5.00 \times 10^{-3} \text{ mol } CH_3COOH\end{aligned}$$

Hence,  $5.00 \times 10^{-3}$  mol of  $CH_3COO^-$  is formed. It will take 50.0 mL of NaOH to reach the equivalence point (Figure 17.9). The volume of this salt solution at the equivalence point is the sum of the volumes of the acid and base,  $50.0 \text{ mL} + 50.0 \text{ mL} = 100.0 \text{ mL} = 0.1000 \text{ L}$ . Thus, the concentration of  $CH_3COO^-$  is:

$$[CH_3COO^-] = \frac{5.00 \times 10^{-3} \text{ mol}}{0.1000 \text{ L}} = 0.0500 \text{ M}$$

The  $CH_3COO^-$  ion is a weak base:

The  $K_b$  for  $CH_3COO^-$  can be calculated from the  $K_a$  value of its conjugate acid,  $K_b = K_w/K_a = (1.0 \times 10^{-14})/(1.8 \times 10^{-5}) = 5.6 \times 10^{-10}$ . Using the  $K_b$  expression, we have:

$$K_b = \frac{[CH_3COOH][OH^-]}{[CH_3COO^-]} = \frac{(x)(x)}{0.0500 - x} = 5.6 \times 10^{-10}$$

Making the approximation that  $0.0500 - x \approx 0.0500$ , and then solving for  $x$ , we have:

$$\begin{aligned}x = [OH^-] &= 5.3 \times 10^{-6} \text{ M}, \\ \text{which gives } pOH &= 5.28 \text{ and } pH = 8.72\end{aligned}$$

**Check** The pH is above 7, as expected for the salt of a weak acid and strong base.

### ► Practice Exercise 1

Why is pH at the equivalence point larger than 7 when you titrate a weak acid with a strong base? (a) There is excess strong base at the equivalence point. (b) There is excess weak acid at the equivalence point. (c) The conjugate base that is formed at the equivalence point is a strong base.

(d) The conjugate base that is formed at the equivalence point reacts with water. (e) This statement is false: the pH is always 7 at an equivalence point in a pH titration.

### ► Practice Exercise 2

Calculate the pH at the equivalence point when (a) 40.0 mL of 0.025 M benzoic acid ( $C_6H_5COOH$ ,  $K_a = 6.3 \times 10^{-5}$ ) is titrated with 0.050 M NaOH and (b) 40.0 mL of 0.100 M  $NH_3$  is titrated with 0.100 M HCl.

The titration curve for a weak acid–strong base titration (Figure 17.9) differs from the curve for a strong acid–strong base titration (Figure 17.7) in three noteworthy ways:

1. The solution of the weak acid has a higher initial pH than a solution of a strong acid of the same concentration.
2. The pH change in the rapid-rise portion of the curve near the equivalence point is smaller for the weak acid than for the strong acid.
3. The pH at the equivalence point is above 7.00 for the weak acid titration.

### Give It Some Thought

Describe the reasons why statement 3 above is true.

The weaker the acid, the more pronounced these differences become. To illustrate this consider the family of titration curves shown in **Figure 17.11**. Notice that as the acid becomes weaker (that is, as  $K_a$  becomes smaller), the initial pH increases and the pH change near the equivalence point becomes less marked. Furthermore, the pH at the equivalence point steadily increases as  $K_a$  decreases, because the strength of the conjugate base of the weak acid increases. It is virtually impossible to determine the equivalence point when  $pK_a$  is 10 or higher because the pH change is too small and gradual.

pH titration experiments are an excellent way to measure the  $pK_a$  of a weak acid. Look at Figure 17.11. Notice that for each acid solution, 50 mL of strong base is required to reach the equivalence point. This means, of course, that 50 mL of base is required to convert the HA molecules into  $A^-$  conjugate base anions. Also notice that halfway to each equivalence point (at 25 mL base added), the pH of the solution is nearly equal to the  $pK_a$  of the acid. Is this a coincidence? No! Recall that  $K_a = [H^+][A^-]/[HA]$ , where all concentrations are those at equilibrium. Halfway to the equivalence point, half of  $[HA]$  has been converted to  $[A^-]$ . In other words,  $[HA] = [A^-]$ . Therefore,  $[HA]/[A^-] = 1$ . In which case,  $K_a = [H^+]$ , and therefore  $pK_a = pH$ .

It becomes possible, then, to determine the  $pK_a$  of a weak acid from its pH titration curve. Once you identify the amount of base needed to reach the equivalence point, find the pH on the curve at halfway to the equivalence point. The pH you read off the graph at that point corresponds to the  $pK_a$  of the weak acid. If the acid's concentration is too low, however, the autoionization of water becomes significant, and this graphical way of measuring  $pK_a$  is not as accurate.

Often in an acid–base titration, an indicator is used rather than a pH meter. An indicator is a compound that changes color in solution over a specific pH range. Optimally, an indicator should change color at the equivalence point in a titration. In practice, however, an indicator need not precisely mark the equivalence point. The pH changes very rapidly near the equivalence point, and in this region one drop of titrant can change the pH by several units. Thus, an indicator beginning and ending its color change anywhere on the rapid-rise portion of the titration curve gives a sufficiently accurate measure of the titrant volume needed to reach the equivalence point. The point in a titration where the indicator changes color is called the *end point* to distinguish it from the equivalence point that it closely approximates.

### Go Figure

How does the pH at the equivalence point change as the acid being titrated becomes weaker? How does the volume of NaOH(aq) needed to reach the equivalence point change?

**Figure 17.11** A set of curves showing the effect of acid strength on the characteristics of the titration curve when a weak acid is titrated by a strong base. Each curve represents titration of 50.0 mL of 0.10 M acid with 0.10 M NaOH.

**Figure 17.12** shows the curve for titration of a strong base (NaOH) with a strong acid (HCl). We see from the vertical part of the curve that the pH changes rapidly from roughly 11 to 3 near the equivalence point. Consequently, an indicator for this titration can change color anywhere in this range. Most strong acid–strong base titrations are carried out using phenolphthalein as an indicator because it changes color in this range (see Figure 16.8, p. 678). Several other indicators would also be satisfactory, including methyl red, which, as the lower color band in Figure 17.12 shows, changes color in the pH range from about 4.2 to 6.0.

As noted in our discussion of Figure 17.11, because the pH change near the equivalence point becomes smaller as  $K_a$  decreases, the choice of indicator for a weak acid–strong base titration is more critical than it is for titrations where both acid and base are strong. When 0.100 M  $\text{CH}_3\text{COOH}$  ( $K_a = 1.8 \times 10^{-5}$ ) is titrated with 0.100 M NaOH, for example, the pH increases rapidly only over the pH range from about 7 to 11 (**Figure 17.13**). Phenolphthalein is therefore an ideal indicator because it changes color from pH 8.3 to 10.0, close to the pH at the equivalence point. Methyl red is a poor choice, however, because its color change, from 4.2 to 6.0, begins well before the equivalence point is reached.

Titration of a weak base (such as 0.100 M  $\text{NH}_3$ ) with a strong acid solution (such as 0.100 M HCl) leads to the titration curve shown in **Figure 17.14**. In this example, the equivalence point occurs at pH 5.28. Thus, methyl red is an ideal indicator, but phenolphthalein would be a poor choice.

### Go Figure

Is methyl red a suitable indicator when you are titrating a strong acid with a strong base? Explain your answer.

**Figure 17.12** Using color indicators for titration of a strong base with a strong acid. Both phenolphthalein and methyl red change color in the rapid-change portion of the titration curve.

Good choice. Suitable indicator for titration of a weak acid with a strong base because equivalence point falls within the color-change interval

Poor choice. Unsatisfactory indicator for titration of a weak acid with a strong base because color changes before reaching equivalence point

**Figure 17.13** Good and poor indicators for titration of a weak acid with a strong base.

▲ **Figure 17.14** Good and poor indicators for titration of a weak base with a strong acid.

## Titration of Polyprotic Acids

When weak acids contain more than one ionizable H atom, the reaction with  $\text{OH}^-$  occurs in a series of steps. Neutralization of phosphorous acid,  $\text{H}_3\text{PO}_3$ , for example, proceeds in two steps (the third H is bonded to the P and does not ionize):

When the neutralization steps of a polyprotic acid or polybasic base are sufficiently separated, the titration has multiple equivalence points. **Figure 17.15** shows the two equivalence points corresponding to Equations 17.13 and 17.14.

You can use titration data such as that shown in Figure 17.15 to figure out the  $\text{pK}_a$ s of the weak polyprotic acid. For example, let's write the  $K_{a1}$  and  $K_{a2}$  reactions for phosphorous acid:

If we rearrange these equilibrium expressions, you see that we obtain Henderson-Hasselbalch equations:

$$\text{pH} = \text{pK}_{a1} + \log \frac{[\text{H}_2\text{PO}_3^-]}{[\text{H}_3\text{PO}_3]}$$

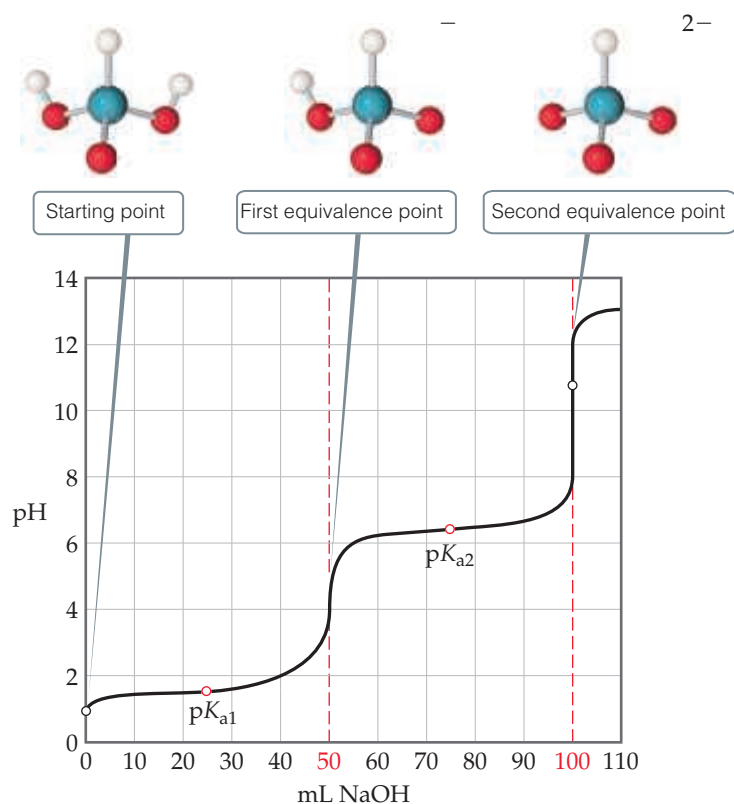

$$\text{pH} = \text{pK}_{a2} + \log \frac{[\text{HPO}_3^{2-}]}{[\text{H}_2\text{PO}_3^-]}$$

Therefore, if the concentrations of each acid and base conjugate pair are identical for each equilibrium,  $\log(1) = 0$  and so  $\text{pH} = \text{pK}_a$ . When does this happen during the titration? At the beginning of the titration, the acid is  $\text{H}_3\text{PO}_3$  initially; at the first equivalence point, it is all converted to  $\text{H}_2\text{PO}_3^-$ . Therefore, halfway to the first equivalence point, half of the  $\text{H}_3\text{PO}_3$  is converted to  $\text{H}_2\text{PO}_3^-$ . Thus, halfway to the equivalence point, the concentration

## Go Figure

What is/are the dominant species in solution at pH = 4:  $\text{H}_3\text{PO}_3$ ,  $\text{H}_2\text{PO}_3^-$ ,  $\text{HPO}_3^{2-}$ , and/or  $\text{PO}_3^{3-}$ ? At pH = 11?

▲ **Figure 17.15** Titration curve for a diprotic acid. The curve shows the pH change when 50.0 mL of 0.10 M  $\text{H}_3\text{PO}_3$  is titrated with 0.10 M NaOH.

of  $\text{H}_3\text{PO}_3$  is equal to that of  $\text{H}_2\text{PO}_3^-$ , and at that point,  $\text{pH} = \text{pK}_{a1}$ . Similar logic is true for the second equilibrium reaction: halfway toward its equivalence point,  $\text{pH} = \text{pK}_{a2}$ .

We can then just look at titration data and estimate the  $\text{pK}_a$ s for the polyprotic acid directly from the titration curve. This procedure is especially useful if you are trying to identify an unknown polyprotic acid. In Figure 17.15, for instance, the first equivalence point occurs for 50 mL NaOH added. Halfway to the equivalence point corresponds to 25 mL NaOH. Because the pH at 25 mL NaOH is about 1.5 we may estimate  $\text{pK}_{a1} = 1.5$  for phosphorous acid. The second equivalence point occurs at 100 mL NaOH added; halfway there (from the first equivalence point) is at 75 mL NaOH added. The graph indicates the pH at 75 mL NaOH added is about 6.5, and we therefore estimate that  $\text{pK}_{a2}$  for phosphorous acid is 6.5. The actual values for the two  $\text{pK}_a$ s are  $\text{pK}_{a1} = 1.3$  and  $\text{pK}_{a2} = 6.7$  (close to our estimates).

## Give It Some Thought

Sketch an approximate titration curve for the titration of  $\text{Na}_2\text{CO}_3$  with HCl and indicate where  $\text{HCO}_3^-$  is the dominant species.

## 17.4 | Solubility Equilibria

The equilibria we have considered thus far in this chapter have involved acids and bases. Furthermore, they have been homogeneous; that is, all the species have been in the same phase. Through the rest of the chapter, we will consider the equilibria involved in the dissolution or precipitation of ionic compounds. These reactions are heterogeneous.

Dissolution and precipitation occur both within us and around us. Tooth enamel dissolves in acidic solutions, for example, causing tooth decay, and the precipitation of certain salts in our kidneys produces kidney stones. The waters of Earth contain salts dissolved as water passes over and through the ground. Coral reefs are principally made of  $\text{CaCO}_3$ , as we saw in the beginning of this chapter. Precipitation of  $\text{CaCO}_3$  from groundwater is responsible for the formation of stalactites and stalagmites within limestone caves.

In our earlier discussion of precipitation reactions, we considered general rules for predicting the solubility of common salts in water. [Section 4.2](#) These rules give us a qualitative sense of whether a compound has a low or high solubility in water. By considering solubility equilibria, however, we can make quantitative predictions about solubility.

## The Solubility-Product Constant, $K_{sp}$

Recall that a *saturated solution* is one in which the solution is in contact with undissolved solute. [Section 13.2](#) Consider, for example, a saturated aqueous solution of  $\text{BaSO}_4$  in contact with solid  $\text{BaSO}_4$ . Because the solid is an ionic compound, it is a strong electrolyte and yields  $\text{Ba}^{2+}(\text{aq})$  and  $\text{SO}_4^{2-}(\text{aq})$  ions when dissolved in water, readily establishing the equilibrium

As with any other equilibrium, the extent to which this dissolution reaction occurs is expressed by the magnitude of the equilibrium constant. Because this equilibrium equation describes the dissolution of a solid, the equilibrium constant indicates how soluble the solid is in water and is referred to as the **solubility-product constant** (or simply the **solubility product**). It is denoted  $K_{sp}$ , where *sp* stands for solubility product.

The equilibrium-constant expression for the equilibrium between a solid and an aqueous solution of its component ions ( $K_{sp}$ ) is written according to the rules that apply to any other equilibrium-constant expression. Remember, however, that solids do not appear in the equilibrium-constant expressions for heterogeneous equilibrium. [Section 15.4](#)

Thus, the solubility-product expression for  $\text{BaSO}_4$ , which is based on Equation 17.15, is

$$K_{sp} = [\text{Ba}^{2+}][\text{SO}_4^{2-}] \quad [17.16]$$

The coefficient for each ion in the equilibrium equation also equals its subscript in the compound's chemical formula.

*In general, the solubility product  $K_{sp}$  of a compound equals the product of the concentration of the ions involved in the equilibrium, each raised to the power of its coefficient in the equilibrium equation.*

The values of  $K_{sp}$  at 25 °C for many ionic solids are tabulated in Appendix D. The value of  $K_{sp}$  for  $\text{BaSO}_4$  is  $1.1 \times 10^{-10}$ , a very small number indicating that only a very small amount of the solid dissolves in 25 °C water.

## Sample Exercise 17.10

### Writing Solubility-Product ( $K_{sp}$ ) Expressions

Write the expression for the solubility-product constant for  $\text{CaF}_2$ , and look up the corresponding  $K_{sp}$  value in Appendix D.

### SOLUTION

**Analyze** We are asked to write an equilibrium-constant expression for the process by which  $\text{CaF}_2$  dissolves in water.

**Plan** We apply the general rules for writing an equilibrium-constant expression, excluding the solid reactant from the expression. We assume that the compound dissociates completely into its component ions:

**Solve** The expression for  $K_{sp}$  is

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^{-}]^2$$

Appendix D gives  $3.9 \times 10^{-11}$  for this  $K_{sp}$ .

### Practice Exercise 1

Which of these expressions correctly expresses the solubility-product constant for  $\text{Ag}_3\text{PO}_4$  in water?

- (a)  $[\text{Ag}][\text{PO}_4]$  (b)  $[\text{Ag}^+][\text{PO}_4^{3-}]$  (c)  $[\text{Ag}^+]^3[\text{PO}_4^{3-}]$   
(d)  $[\text{Ag}^+][\text{PO}_4^{3-}]^3$  (e)  $[\text{Ag}^+]^3[\text{PO}_4^{3-}]^3$

### Practice Exercise 2

Give the solubility-product-constant expressions and  $K_{sp}$  values (from Appendix D) for (a) barium carbonate and (b) silver sulfate.

## Solubility and $K_{sp}$

It is important to distinguish carefully between solubility and the solubility-product constant. The solubility of a substance is the quantity that dissolves to form a saturated solution.  (Section 13.2) Solubility is often expressed as grams of solute per liter of solution (g/L). *Molar solubility* is the number of moles of solute that dissolve in forming 1 L of saturated solution of the solute (mol/L). The solubility-product constant ( $K_{sp}$ ) is the equilibrium constant for the equilibrium between an ionic solid and its saturated solution and is a unitless number. Thus, the magnitude of  $K_{sp}$  is a measure of how much of the solid dissolves to form a saturated solution.

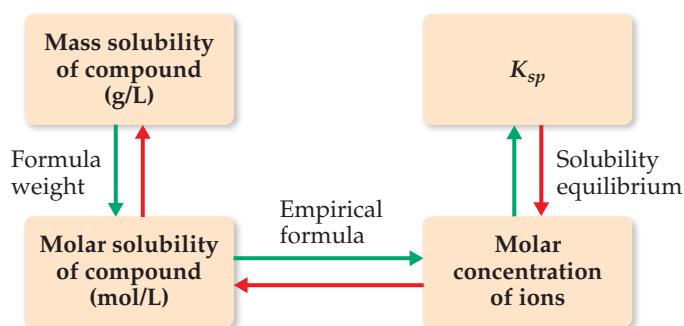

### Give It Some Thought

Without doing a calculation, predict which of these compounds has the greatest molar solubility in water: AgCl ( $K_{sp} = 1.8 \times 10^{-10}$ ), AgBr ( $K_{sp} = 5.0 \times 10^{-13}$ ), or AgI ( $K_{sp} = 8.3 \times 10^{-17}$ ).

The solubility of a substance can change considerably in response to a number of factors. For example, the solubilities of hydroxide salts, like  $\text{Mg}(\text{OH})_2$ , are dependent upon the pH of the solution. The solubility is also affected by concentrations of other ions in solution, especially common ions. In other words, the numeric value of the solubility of a given solute does change as the other species in solution change. In contrast, the solubility-product constant,  $K_{sp}$ , has only one value for a given solute at any specific temperature.\* **Figure 17.16** summarizes the relationships among various expressions of solubility and  $K_{sp}$ .

In principle, it is possible to use the  $K_{sp}$  value of a salt to calculate solubility under a variety of conditions. In practice, great care must be taken in doing so for the reasons indicated in “A Closer Look: Limitations of Solubility Products” at the end of this section. Agreement between the measured solubility and that calculated from  $K_{sp}$  is usually best for salts whose ions have low charges (1+ and 1−) and do not react with water.

**▲ Figure 17.16** Procedure for converting between solubility and  $K_{sp}$ . Starting from the mass solubility, follow the green arrows to determine  $K_{sp}$ . Starting from  $K_{sp}$ , follow the red arrows to determine either molar solubility or mass solubility.

## Sample Exercise 17.11

### Calculating $K_{sp}$ from Solubility

Solid silver chromate is added to pure water at 25 °C, and some of the solid remains undissolved. The mixture is stirred for several days to ensure that equilibrium is achieved between the undissolved  $\text{Ag}_2\text{CrO}_4(\text{s})$  and the solution. Analysis of the equilibrated solution shows that its silver ion concentration is  $1.3 \times 10^{-4} \text{ M}$ . Assuming that the  $\text{Ag}_2\text{CrO}_4$  solution is saturated and that there are no other important equilibria involving  $\text{Ag}^+$  or  $\text{CrO}_4^{2-}$  ions in the solution, calculate  $K_{sp}$  for this compound.

### SOLUTION

**Analyze** We are given the equilibrium concentration of  $\text{Ag}^+$  in a saturated solution of  $\text{Ag}_2\text{CrO}_4$  and asked to determine the value of  $K_{sp}$  for  $\text{Ag}_2\text{CrO}_4$ .

**Plan** The equilibrium equation and the expression for  $K_{sp}$  are

$$K_{sp} = [\text{Ag}^+]^2[\text{CrO}_4^{2-}]$$

To calculate  $K_{sp}$ , we need the equilibrium concentrations of  $\text{Ag}^+$  and  $\text{CrO}_4^{2-}$ . We know that at equilibrium  $[\text{Ag}^+] = 1.3 \times 10^{-4} \text{ M}$ . All the  $\text{Ag}^+$  and  $\text{CrO}_4^{2-}$  ions in the solution come from the  $\text{Ag}_2\text{CrO}_4$  that dissolves. Thus, we can use  $[\text{Ag}^+]$  to calculate  $[\text{CrO}_4^{2-}]$ .

**Solve** From the chemical formula of silver chromate, we know that there must be two  $\text{Ag}^+$  ions in solution for each  $\text{CrO}_4^{2-}$  ion in solution. Consequently, the concentration of  $\text{CrO}_4^{2-}$  is half the concentration of  $\text{Ag}^+$ :

*Continued*

\*This is strictly true only for very dilute solutions, for  $K_{sp}$  values change somewhat when the concentration of ionic substances in water is increased. However, we will ignore these effects, which are taken into consideration only for work that requires exceptional accuracy.

$$[\text{CrO}_4^{2-}] = \left( \frac{1.3 \times 10^{-4} \text{ mol Ag}^+}{\text{L}} \right) \left( \frac{1 \text{ mol CrO}_4^{2-}}{2 \text{ mol Ag}^+} \right) = 6.5 \times 10^{-5} \text{ M}$$

and  $K_{sp}$  is

$$K_{sp} = [\text{Ag}^+]^2[\text{CrO}_4^{2-}] = (1.3 \times 10^{-4})^2(6.5 \times 10^{-5}) = 1.1 \times 10^{-12}$$

**Check** We obtain a small value, as expected for a slightly soluble salt. Furthermore, the calculated value agrees well with the one given in Appendix D,  $1.2 \times 10^{-12}$ .

### Practice Exercise 1

You add 10.0 grams of solid copper(II) phosphate,  $\text{Cu}_3(\text{PO}_4)_2$ , to a beaker and then add 100.0 mL of water to the beaker at

$T = 298 \text{ K}$ . The solid does not appear to dissolve. You wait a long time, with occasional stirring and eventually measure the equilibrium concentration of  $\text{Cu}^{2+}(\text{aq})$  in the water to be  $5.01 \times 10^{-8} \text{ M}$ . What is the  $K_{sp}$  of copper(II) phosphate?

- (a)  $5.01 \times 10^{-8}$  (b)  $2.50 \times 10^{-15}$  (c)  $4.20 \times 10^{-15}$   
(d)  $3.16 \times 10^{-37}$  (e)  $1.40 \times 10^{-37}$

### Practice Exercise 2

A saturated solution of  $\text{Mg}(\text{OH})_2$  in contact with undissolved  $\text{Mg}(\text{OH})_2(\text{s})$  is prepared at  $25^\circ\text{C}$ . The pH of the solution is found to be 10.17. Assuming that there are no other simultaneous equilibria involving the  $\text{Mg}^{2+}$  or  $\text{OH}^-$  ions, calculate  $K_{sp}$  for this compound.

## Sample Exercise 17.12

### Calculating Solubility from $K_{sp}$

The  $K_{sp}$  for  $\text{CaF}_2$  is  $3.9 \times 10^{-11}$  at  $25^\circ\text{C}$ . Assuming equilibrium is established between solid and dissolved  $\text{CaF}_2$ , and that there are no other important equilibria affecting its solubility, calculate the solubility of  $\text{CaF}_2$  in grams per liter.

### SOLUTION

**Analyze** We are given  $K_{sp}$  for  $\text{CaF}_2$  and asked to determine solubility. Recall that the solubility of a substance is the quantity that can dissolve in solvent, whereas the solubility-product constant,  $K_{sp}$ , is an equilibrium constant.

**Plan** To go from  $K_{sp}$  to solubility, we follow the steps indicated by the red arrows in Figure 17.16. We first write the chemical equation

for the dissolution and set up a table of initial and equilibrium concentrations. We then use the equilibrium-constant expression. In this case we know  $K_{sp}$ , and so we solve for the concentrations of the ions in solution. Once we know these concentrations, we use the formula weight to determine solubility in g/L.

### Solve

Assume that initially no salt has dissolved, and then allow  $x$  mol/L of  $\text{CaF}_2$  to dissociate completely when equilibrium is achieved:

|                               |  |       |        |
|-------------------------------|--|-------|--------|
|                               | $\text{CaF}_2(\text{s}) \rightleftharpoons \text{Ca}^{2+}(\text{aq}) + 2\text{F}^{-}(\text{aq})$ |       |        |
| Initial concentration (M)     | —  | 0     | 0      |
| Change (M)                    | —  | + $x$ | + $2x$ |
| Equilibrium concentration (M) | —  | $x$   | $2x$   |

The stoichiometry of the equilibrium dictates that  $2x$  mol/L of  $\text{F}^-$  are produced for each  $x$  mol/L of  $\text{CaF}_2$  that dissolve. We now use the expression for  $K_{sp}$  and substitute the equilibrium concentrations to solve for the value of  $x$ :

$$K_{sp} = [\text{Ca}^{2+}][\text{F}^-]^2 = (x)(2x)^2 = 4x^3 = 3.9 \times 10^{-11}$$

(Remember that  $\sqrt[3]{y} = y^{1/3}$ .) Thus, the molar solubility of  $\text{CaF}_2$  is  $2.1 \times 10^{-4} \text{ mol/L}$ .

$$x = \frac{\sqrt[3]{3.9 \times 10^{-11}}}{4} = 2.1 \times 10^{-4}$$

The mass of  $\text{CaF}_2$  that dissolves in water to form 1 L of solution is:

$$\left( \frac{2.1 \times 10^{-4} \text{ mol CaF}_2}{1 \text{ L soln}} \right) \left( \frac{78.1 \text{ g CaF}_2}{1 \text{ mol CaF}_2} \right) = 1.6 \times 10^{-2} \text{ g CaF}_2/\text{L soln}$$

**Check** We expect a small number for the solubility of a slightly soluble salt. If we reverse the calculation, we should be able to recalculate the solubility product:  $K_{sp} = (2.1 \times 10^{-4})(4.2 \times 10^{-4})^2 = 3.7 \times 10^{-11}$ , close to the value given in the problem statement,  $3.9 \times 10^{-11}$ .

**Comment** Because  $\text{F}^-$  is the anion of a weak acid, you might expect hydrolysis of the ion to affect the solubility of  $\text{CaF}_2$ . The basicity of  $\text{F}^-$  is so small ( $K_b = 1.5 \times 10^{-11}$ ), however, that the hydrolysis occurs to only a slight extent and does not significantly influence the solubility. The reported solubility is 0.017 g/L at  $25^\circ\text{C}$ , in good agreement with our calculation.

### Practice Exercise 1

Of the five salts listed below, which has the highest concentration of its cation in water? Assume that all salt solutions are saturated and that the ions do not undergo any additional reactions in water.

- (a) lead(II) chromate,  $K_{sp} = 2.8 \times 10^{-13}$   
(b) cobalt(II) hydroxide,  $K_{sp} = 1.3 \times 10^{-15}$   
(c) cobalt(II) sulfide,  $K_{sp} = 5 \times 10^{-22}$   
(d) chromium(III) hydroxide,  $K_{sp} = 1.6 \times 10^{-30}$   
(e) silver sulfide,  $K_{sp} = 6 \times 10^{-51}$

### Practice Exercise 2

The  $K_{sp}$  for  $\text{LaF}_3$  is  $2 \times 10^{-19}$ . What is the solubility of  $\text{LaF}_3$  in water in moles per liter?

## A CLOSER LOOK Limitations of Solubility Products

Ion concentrations calculated from  $K_{sp}$  values sometimes deviate appreciably from those found experimentally. In part, these deviations are due to electrostatic interactions between ions in solution, which can lead to ion pairs.  $\infty$  (Section 13.5, “The van’t Hoff Factor”) These interactions increase in magnitude both as the concentrations of the ions increase and as their charges increase. The solubility calculated from  $K_{sp}$  tends to be low unless corrected to account for these interactions.

As an example of the effect of these interactions, consider  $\text{CaCO}_3$  (calcite), whose solubility product,  $4.5 \times 10^{-9}$ , gives a calculated solubility of  $6.7 \times 10^{-5} \text{ mol/L}$ ; correcting for ionic interactions in the solution yields  $7.3 \times 10^{-5} \text{ mol/L}$ . The reported solubility, however, is  $1.4 \times 10^{-4} \text{ mol/L}$ , indicating that there must be additional factors involved.

Another common source of error in calculating ion concentrations from  $K_{sp}$  is ignoring other equilibria that occur simultaneously

in the solution. It is possible, for example, that acid-base equilibria take place simultaneously with solubility equilibria. In particular, both basic anions and cations with high charge-to-size ratios undergo hydrolysis reactions that can measurably increase the solubilities of their salts. For example,  $\text{CaCO}_3$  contains the basic carbonate ion ( $K_b = 1.8 \times 10^{-4}$ ), which reacts with water:

If we consider the effect of ion-ion interactions as well as simultaneous solubility and  $K_b$  equilibria, we calculate a solubility of  $1.4 \times 10^{-4} \text{ mol/L}$ , in agreement with the measured value for calcite.

Finally, we generally assume that ionic compounds dissociate completely when they dissolve, but this assumption is not always valid. When  $\text{MgF}_2$  dissolves, for example, it yields not only  $\text{Mg}^{2+}$  and  $\text{F}^-$  ions but also  $\text{MgF}^+$  ions.

## 17.5 Factors That Affect Solubility

Solubility is affected by temperature and by the presence of other solutes. The presence of an acid, for example, can have a major influence on the solubility of a substance. In Section 17.4, we considered the dissolving of ionic compounds in pure water. In this section, we examine three factors that affect the solubility of ionic compounds: (1) presence of common ions, (2) solution pH, and (3) presence of complexing agents. We will also examine the phenomenon of *amphoterism*, which is related to the effects of both pH and complexing agents.

### The Common-Ion Effect

The presence of either  $\text{Ca}^{2+}(aq)$  or  $\text{F}^-(aq)$  in a solution reduces the solubility of  $\text{CaF}_2$ , shifting the equilibrium concentrations to the left:

Addition of  $\text{Ca}^{2+}$  or  $\text{F}^-$  shifts equilibrium concentrations, reducing solubility

This reduction in solubility is another manifestation of the common-ion effect we looked at in Section 17.1. In general, *the solubility of a slightly soluble salt is decreased by the presence of a second solute that furnishes a common ion*, as Figure 17.17 shows for  $\text{CaF}_2$ .

▲ **Figure 17.17** Common-ion effect. Notice that the  $\text{CaF}_2$  solubility is on a logarithmic scale.

### Sample Exercise 17.13

#### Calculating the Effect of a Common Ion on Solubility

Calculate the molar solubility of  $\text{CaF}_2$  at  $25^\circ\text{C}$  in a solution that is (a)  $0.010 \text{ M}$  in  $\text{Ca}(\text{NO}_3)_2$  and (b)  $0.010 \text{ M}$  in  $\text{NaF}$ .

#### SOLUTION

**Analyze** We are asked to determine the solubility of  $\text{CaF}_2$  in the presence of two strong electrolytes, each containing an ion common to  $\text{CaF}_2$ . In (a) the common ion is  $\text{Ca}^{2+}$ , and  $\text{NO}_3^-$  is a spectator ion. In (b) the common ion is  $\text{F}^-$ , and  $\text{Na}^+$  is a spectator ion.

**Plan** Because the slightly soluble compound is  $\text{CaF}_2$ , we need to use  $K_{sp}$  for this compound, which Appendix D gives as  $3.9 \times 10^{-11}$ . The value of  $K_{sp}$  is unchanged by the presence of

additional solutes. Because of the common-ion effect, however, the solubility of the salt decreases in the presence of common ions. We use our standard equilibrium techniques of starting with the equation for  $\text{CaF}_2$  dissolution, setting up a table of initial and equilibrium concentrations, and using the  $K_{sp}$  expression to determine the concentration of the ion that comes only from  $\text{CaF}_2$ .

Continued

**Solve**

- (a) The initial concentration of  $\text{Ca}^{2+}$  is  $0.010\text{ M}$  because of the dissolved  $\text{Ca}(\text{NO}_3)_2$ :

| Initial Concentration (M)     | — | 0.010       | 0   |
|-------------------------------|---|-------------|-----|
| Change (M)                    | — | +x          | +2x |
| Equilibrium Concentration (M) | — | (0.010 + x) | 2x  |

Substituting into the solubility-product expression gives:

$$K_{sp} = 3.9 \times 10^{-11} = [\text{Ca}^{2+}][\text{F}^-]^2 = (0.010 + x)(2x)^2$$

If we assume that  $x$  is small compared to  $0.010$ , we have:

$$3.9 \times 10^{-11} = (0.010)(2x)^2$$

This very small value for  $x$  validates the simplifying assumption we made. Our calculation indicates that  $3.1 \times 10^{-5}\text{ mol}$  of solid  $\text{CaF}_2$  dissolves per liter of  $0.010\text{ M Ca}(\text{NO}_3)_2$  solution.

$$x^2 = \frac{3.9 \times 10^{-11}}{4(0.010)} = 9.8 \times 10^{-10}$$

$$x = \sqrt{9.8 \times 10^{-10}} = 3.1 \times 10^{-5}\text{ M}$$

- (b) The common ion is  $\text{F}^-$ , and at equilibrium we have:

$$[\text{Ca}^{2+}] = x \quad \text{and} \quad [\text{F}^-] = 0.010 + 2x$$

Assuming that  $2x$  is much smaller than  $0.010\text{ M}$  (that is,  $0.010 + 2x \approx 0.010$ ), we have:

$$3.9 \times 10^{-11} = (x)(0.010 + 2x)^2 \approx x(0.010)^2$$

Thus,  $3.9 \times 10^{-7}\text{ mol}$  of solid  $\text{CaF}_2$  should dissolve per liter of  $0.010\text{ M NaF}$  solution.

$$x = \frac{3.9 \times 10^{-11}}{(0.010)^2} = 3.9 \times 10^{-7}\text{ M}$$

**Comment** The molar solubility of  $\text{CaF}_2$  in water is  $2.1 \times 10^{-4}\text{ M}$  (Sample Exercise 17.12). By comparison, our calculations here give a  $\text{CaF}_2$  solubility of  $3.1 \times 10^{-5}\text{ M}$  in the presence of  $0.010\text{ M Ca}^{2+}$  and  $3.9 \times 10^{-7}\text{ M}$  in the presence of  $0.010\text{ M F}^-$  ion. Thus, the addition of either  $\text{Ca}^{2+}$  or  $\text{F}^-$  to a solution of  $\text{CaF}_2$  decreases the solubility. However, the effect of  $\text{F}^-$  on the solubility is more pronounced than that of  $\text{Ca}^{2+}$  because  $[\text{F}^-]$  appears to the second power in the  $K_{sp}$  expression for  $\text{CaF}_2$ , whereas  $[\text{Ca}^{2+}]$  appears to the first power.

► **Practice Exercise 1**

Consider a saturated solution of the salt  $\text{MA}_3$ , in which M is a metal cation with a 3+ charge and A is an anion with a 1- charge, in water at 298 K. Which of the following will affect the  $K_{sp}$  of  $\text{MA}_3$  in water?

(a) The addition of more  $\text{M}^{3+}$  to the solution. (b) The addition of more  $\text{A}^-$  to the solution. (c) Diluting the solution. (d) Raising the temperature of the solution. (e) More than one of the above factors.

► **Practice Exercise 2**

For manganese(II) hydroxide,  $\text{Mn}(\text{OH})_2$ ,  $K_{sp} = 1.6 \times 10^{-13}$ . Calculate the molar solubility of  $\text{Mn}(\text{OH})_2$  in a solution that contains  $0.020\text{ M NaOH}$ .

## Solubility and pH

The solubility of almost any ionic compound is affected if the solution is made sufficiently acidic or basic. The effects are noticeable, however, only when one (or both) ions in the compound is at least moderately acidic or basic. The metal hydroxides, such as  $\text{Mg}(\text{OH})_2$ , are examples of compounds containing a strongly basic ion, the hydroxide ion. Let's look at  $\text{Mg}(\text{OH})_2$ , for which the solubility equilibrium is

A saturated solution of  $\text{Mg}(\text{OH})_2$  has a calculated pH of 10.52, and its  $\text{Mg}^{2+}$  concentration is  $1.7 \times 10^{-4}\text{ M}$ . Now suppose that solid  $\text{Mg}(\text{OH})_2$  is equilibrated with a solution buffered at pH 9.0. The pOH, therefore, is 5.0, so  $[\text{OH}^-] = 1.0 \times 10^{-5}$ . Inserting this value for  $[\text{OH}^-]$  into the solubility-product expression, we have

$$K_{sp} = [\text{Mg}^{2+}][\text{OH}^-]^2 = 1.8 \times 10^{-11}$$

$$[\text{Mg}^{2+}](1.0 \times 10^{-5})^2 = 1.8 \times 10^{-11}$$

$$[\text{Mg}^{2+}] = \frac{1.8 \times 10^{-11}}{(1.0 \times 10^{-5})^2} = 0.18\text{ M}$$

Thus, the  $\text{Mg}(\text{OH})_2$  dissolves until  $[\text{Mg}^{2+}] = 0.18\text{ M}$ . It is apparent that  $\text{Mg}(\text{OH})_2$  is much more soluble in this solution.

If  $[\text{OH}^-]$  were reduced further by making the solution even more acidic, the  $\text{Mg}^{2+}$  concentration would have to increase to maintain the equilibrium condition. Thus, a sample of  $\text{Mg}(\text{OH})_2(\text{s})$  dissolves completely if sufficient acid is added, as we saw in Figure 4.9 (page 135).

As we have seen, the solubility of  $\text{Mg}(\text{OH})_2$  greatly increases as the acidity of the solution increases. Based on this observation we can make the following generalization:

*In general, the solubility of a compound containing a basic anion (that is, the anion of a weak acid) increases as the solution becomes more acidic.*

The solubility of  $\text{PbF}_2$  increases as the solution becomes more acidic, too, because  $\text{F}^-$  is a base (it is the conjugate base of the weak acid  $\text{HF}$ ). As a result, the solubility equilibrium of  $\text{PbF}_2$  is shifted to the right as the concentration of  $\text{F}^-$  is reduced by protonation to form  $\text{HF}$ . Thus, the solution process can be understood in terms of two consecutive reactions:

The equation for the overall process is

The processes responsible for the increase in solubility of  $\text{PbF}_2$  in acidic solution are illustrated in Figure 17.18(a).

Other salts that contain basic anions, such as  $\text{CO}_3^{2-}$ ,  $\text{PO}_4^{3-}$ ,  $\text{CN}^-$ , or  $\text{S}^{2-}$ , behave similarly. These examples illustrate a general rule: *The solubility of slightly soluble salts containing basic anions increases as  $[\text{H}^+]$  increases (as pH is lowered).* The more basic the anion, the more the solubility is influenced by pH. The solubility of salts with anions of negligible basicity (the anions of strong acids), such as  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{I}^-$ , and  $\text{NO}_3^-$ , is unaffected by pH changes, as shown in Figure 17.18(b).

▲ **Figure 17.18** Response of two ionic compounds to addition of a strong acid. (a) The solubility of  $\text{PbF}_2$  increases upon addition of acid. (b) The solubility of  $\text{PbI}_2$  is not affected by the addition of acid. The water molecules and the anion of the strong acid have been omitted for clarity.

## Sample Exercise 17.14

## Predicting the Effect of Acid on Solubility

Which of these substances are more soluble in acidic solution than in basic solution:

(a)  $\text{Ni}(\text{OH})_2(s)$ , (b)  $\text{CaCO}_3(s)$ , (c)  $\text{BaF}_2(s)$ , (d)  $\text{AgCl}(s)$ ?

## SOLUTION

**Analyze** The problem lists four sparingly soluble salts, and we are asked to determine which are more soluble at low pH than at high pH.

**Plan** We will identify ionic compounds that dissociate to produce a basic anion, as these are especially soluble in acid solution.

## Solve

(a)  $\text{Ni}(\text{OH})_2(s)$  is more soluble in acidic solution because of the basicity of  $\text{OH}^-$ ; the  $\text{H}^+$  reacts with the  $\text{OH}^-$  ion, forming water:

(b) Similarly,  $\text{CaCO}_3(s)$  dissolves in acid solutions because  $\text{CO}_3^{2-}$  is a basic anion:  
The reaction between  $\text{CO}_3^{2-}$  and  $\text{H}^+$  occurs in steps, with  $\text{HCO}_3^-$  forming first and  $\text{H}_2\text{CO}_3$  forming in appreciable amounts only when  $[\text{H}^+]$  is sufficiently high.

(c) The solubility of  $\text{BaF}_2$  is enhanced by lowering the pH because  $\text{F}^-$  is a basic anion:

(d) The solubility of  $\text{AgCl}$  is unaffected by changes in pH because  $\text{Cl}^-$  is the anion of a strong acid and therefore has negligible basicity.

## Practice Exercise 1

Which of the following actions will increase the solubility of  $\text{AgBr}$  in water? (a) increasing the pH (b) decreasing the pH (c) adding  $\text{NaBr}$  (d) adding  $\text{NaNO}_3$  (e) none of the above

## Practice Exercise 2

Write the net ionic equation for the reaction between a strong acid and (a)  $\text{CuS}$ , (b)  $\text{Cu}(\text{N}_3)_2$ .

## CHEMISTRY AND LIFE Tooth Decay and Fluoridation

Tooth enamel consists mainly of the mineral hydroxyapatite,  $\text{Ca}_{10}(\text{PO}_4)_6(\text{OH})_2$ , the hardest substance in the body. Tooth cavities form when acids dissolve tooth enamel:

The  $\text{Ca}^{2+}$  and  $\text{HPO}_4^{2-}$  ions diffuse out of the enamel and are washed away by saliva. The acids that attack the hydroxyapatite are formed by the action of bacteria on sugars and other carbohydrates present in the plaque adhering to the teeth.

Fluoride ion, which is added to municipal water systems and toothpastes, can react with hydroxyapatite to form fluoroapatite,  $\text{Ca}_{10}(\text{PO}_4)_6\text{F}_2$ . This mineral, in which  $\text{F}^-$  has replaced  $\text{OH}^-$ , is much

more resistant to attack by acids because the fluoride ion is a much weaker Brønsted–Lowry base than the hydroxide ion.

The usual concentration of  $\text{F}^-$  in municipal water systems is 1 mg/L (1 ppm). The compound added may be  $\text{NaF}$  or  $\text{Na}_2\text{SiF}_6$ . The silicon-fluorine anion reacts with water to release fluoride ions:

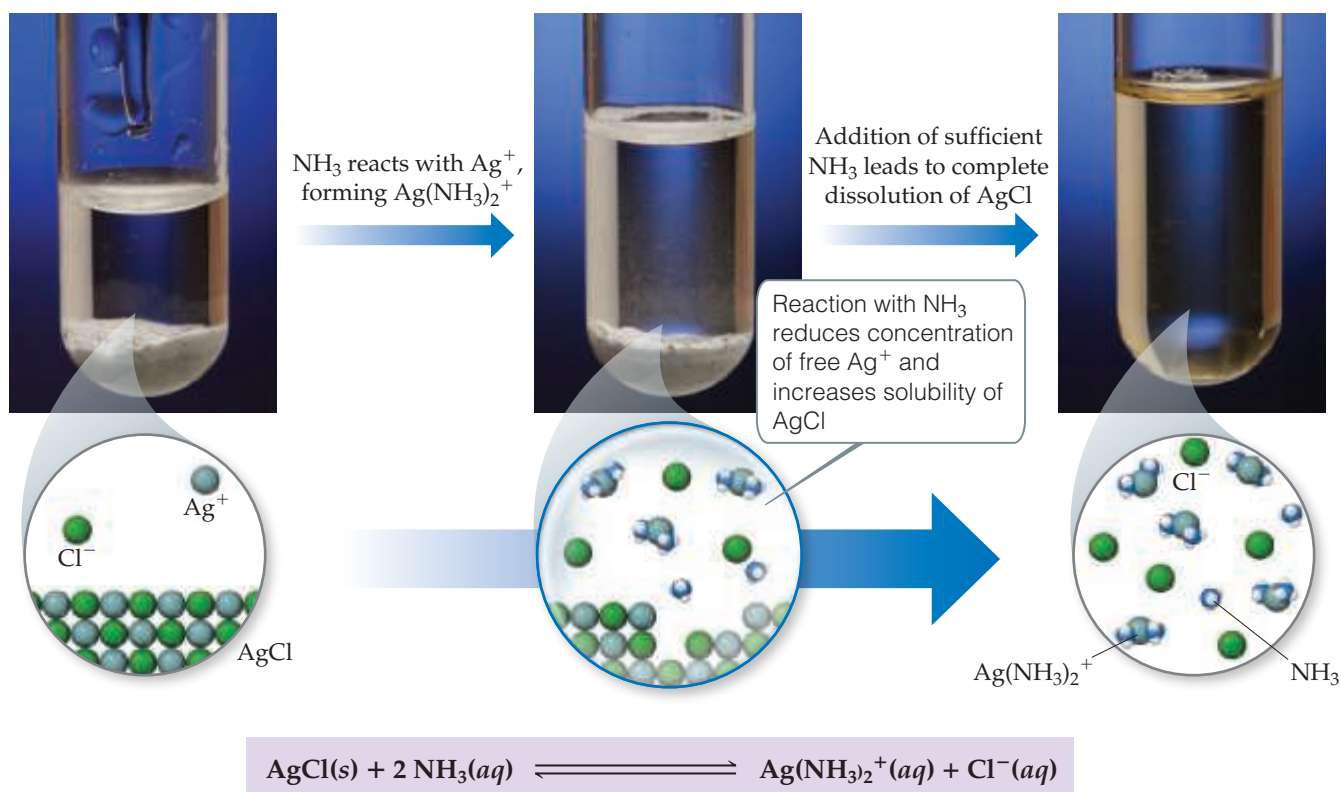

About 80% of all toothpastes now sold in the United States contain fluoride compounds, usually at the level of 0.1% fluoride by mass. The most common compounds in toothpastes are sodium fluoride ( $\text{NaF}$ ), sodium monofluorophosphate ( $\text{Na}_2\text{PO}_3\text{F}$ ), and stannous fluoride ( $\text{SnF}_2$ ).

## Formation of Complex Ions

A characteristic property of metal ions is their ability to act as Lewis acids toward water molecules, which act as Lewis bases.  $\infty$  (Section 16.11) Lewis bases other than water can also interact with metal ions, particularly transition-metal ions. Such interactions can dramatically affect the solubility of a metal salt. For example,  $\text{AgCl}$  ( $K_{sp} = 1.8 \times 10^{-10}$ )

▲ **Figure 17.19** Concentrated NH<sub>3</sub>(aq) dissolves AgCl(s), which otherwise has very low solubility in water.

dissolves in the presence of aqueous ammonia because Ag<sup>+</sup> interacts with the Lewis base NH<sub>3</sub>, as shown in **Figure 17.19**. This process can be viewed as the sum of two reactions:

The presence of NH<sub>3</sub> drives the reaction, the dissolution of AgCl, to the right as Ag<sup>+</sup>(aq) is consumed to form Ag(NH<sub>3</sub>)<sub>2</sub><sup>+</sup>, which is a very soluble species.

For a Lewis base such as NH<sub>3</sub> to increase the solubility of a metal salt, the base must be able to interact more strongly with the metal ion than water does. In other words, the NH<sub>3</sub> must displace solvating H<sub>2</sub>O molecules  $\rightleftharpoons$  (Sections 13.1 and 16.11) in order to form [Ag(NH<sub>3</sub>)<sub>2</sub>]<sup>+</sup>:

An assembly of a metal ion and the Lewis bases bonded to it, such as Ag(NH<sub>3</sub>)<sub>2</sub><sup>+</sup>, is called a **complex ion**. Complex ions are very soluble in water. The stability of a complex ion in aqueous solution can be judged by the size of the equilibrium constant for its formation from the hydrated metal ion. For example, the equilibrium constant for Equation 17.24 is

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2} = 1.7 \times 10^7 \quad [17.25]$$

Note that the equilibrium constant for this kind of reaction is called a **formation constant**,  $K_f$ . The formation constants for several complex ions are listed in **Table 17.1**.

The general rule is that the solubility of metal salts increases in the presence of suitable Lewis bases, such as NH<sub>3</sub>, CN<sup>-</sup>, or OH<sup>-</sup>, provided the metal forms a complex with the base. The ability of metal ions to form complexes is an extremely important aspect of their chemistry.

**TABLE 17.1 Formation Constants for Some Metal Complex Ions in Water at 25 °C**

| Complex Ion                              | $K_f$                | Chemical Equation   |
|--|----------------------|---|
| $\text{Ag}(\text{NH}_3)_2^+$             | $1.7 \times 10^7$    | $\text{Ag}^+(aq) + 2 \text{NH}_3(aq) \rightleftharpoons \text{Ag}(\text{NH}_3)_2^+(aq)$                           |
| $\text{Ag}(\text{CN})_2^-$               | $1 \times 10^{21}$   | $\text{Ag}^+(aq) + 2 \text{CN}^-(aq) \rightleftharpoons \text{Ag}(\text{CN})_2^-(aq)$                             |
| $\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$ | $2.9 \times 10^{13}$ | $\text{Ag}^+(aq) + 2 \text{S}_2\text{O}_3^{2-}(aq) \rightleftharpoons \text{Ag}(\text{S}_2\text{O}_3)_2^{3-}(aq)$ |
| $\text{Al}(\text{OH})_4^-$               | $1.1 \times 10^{33}$ | $\text{Al}^{3+}(aq) + 4 \text{OH}^-(aq) \rightleftharpoons \text{Al}(\text{OH})_4^-(aq)$                          |
| $\text{CdBr}_4^{2-}$                     | $5 \times 10^3$      | $\text{Cd}^{2+}(aq) + 4 \text{Br}^-(aq) \rightleftharpoons \text{CdBr}_4^{2-}(aq)$                                |
| $\text{Cr}(\text{OH})_4^-$               | $8 \times 10^{29}$   | $\text{Cr}^{3+}(aq) + 4 \text{OH}^-(aq) \rightleftharpoons \text{Cr}(\text{OH})_4^-(aq)$                          |
| $\text{Co}(\text{SCN})_4^{2-}$           | $1 \times 10^3$      | $\text{Co}^{2+}(aq) + 4 \text{SCN}^-(aq) \rightleftharpoons \text{Co}(\text{SCN})_4^{2-}(aq)$                     |
| $\text{Cu}(\text{NH}_3)_4^{2+}$          | $5 \times 10^{12}$   | $\text{Cu}^{2+}(aq) + 4 \text{NH}_3(aq) \rightleftharpoons \text{Cu}(\text{NH}_3)_4^{2+}(aq)$                     |
| $\text{Cu}(\text{CN})_4^{2-}$            | $1 \times 10^{25}$   | $\text{Cu}^{2+}(aq) + 4 \text{CN}^-(aq) \rightleftharpoons \text{Cu}(\text{CN})_4^{2-}(aq)$                       |
| $\text{Ni}(\text{NH}_3)_6^{2+}$          | $1.2 \times 10^9$    | $\text{Ni}^{2+}(aq) + 6 \text{NH}_3(aq) \rightleftharpoons \text{Ni}(\text{NH}_3)_6^{2+}(aq)$                     |
| $\text{Fe}(\text{CN})_6^{4-}$            | $1 \times 10^{35}$   | $\text{Fe}^{2+}(aq) + 6 \text{CN}^-(aq) \rightleftharpoons \text{Fe}(\text{CN})_6^{4-}(aq)$                       |
| $\text{Fe}(\text{CN})_6^{3-}$            | $1 \times 10^{42}$   | $\text{Fe}^{3+}(aq) + 6 \text{CN}^-(aq) \rightleftharpoons \text{Fe}(\text{CN})_6^{3-}(aq)$                       |
| $\text{Zn}(\text{OH})_4^{2-}$            | $4.6 \times 10^{17}$ | $\text{Zn}^{2+}(aq) + 4 \text{OH}^-(aq) \rightleftharpoons \text{Zn}(\text{OH})_4^{2-}(aq)$                       |

**Sample Exercise 17.15****Evaluating an Equilibrium Involving a Complex Ion**

Calculate the concentration of  $\text{Ag}^+$  present in solution at equilibrium when concentrated ammonia is added to a 0.010 M solution of  $\text{AgNO}_3$  to give an equilibrium concentration of  $[\text{NH}_3] = 0.20 \text{ M}$ . Neglect the small volume change that occurs when  $\text{NH}_3$  is added.

**SOLUTION**

**Analyze** Addition of  $\text{NH}_3(aq)$  to  $\text{Ag}^+(aq)$  forms  $\text{Ag}(\text{NH}_3)_2^+(aq)$ , as shown in Equation 17.22. We are asked to determine what concentration of  $\text{Ag}^+(aq)$  remains uncombined when the  $\text{NH}_3$  concentration is brought to 0.20 M in a solution originally 0.010 M in  $\text{AgNO}_3$ .

**Plan** We assume that the  $\text{AgNO}_3$  is completely dissociated, giving 0.010 M  $\text{Ag}^+$ . Because  $K_f$  for the formation of  $\text{Ag}(\text{NH}_3)_2^+$  is quite large, we assume that essentially all the  $\text{Ag}^+$  is converted to  $\text{Ag}(\text{NH}_3)_2^+$  and approach the problem as though we are concerned with the dissociation of  $\text{Ag}(\text{NH}_3)_2^+$  rather than its formation. To facilitate this approach, we need to reverse Equation 17.22 and make the corresponding change to the equilibrium constant:

$$\frac{1}{K_f} = \frac{1}{1.7 \times 10^7} = 5.9 \times 10^{-8}$$

**Solve** If  $[\text{Ag}^+]$  is 0.010 M initially,  $[\text{Ag}(\text{NH}_3)_2^+]$  will be 0.010 M following addition of the  $\text{NH}_3$ . We construct a table to solve this equilibrium problem. Note that the  $\text{NH}_3$  concentration given in the problem is an equilibrium concentration rather than an initial concentration.

|                 |               |      |      |
|-----------------|---------------|------|------|
| Initial (M)     | 0.010         | 0    | —    |
| Change (M)      | $-x$          | $+x$ | —    |
| Equilibrium (M) | $(0.010 - x)$ | $x$  | 0.20 |

Because  $[\text{Ag}^+]$  is very small, we can assume  $x$  is small compared to 0.010. Substituting these values into the equilibrium-constant expression for the dissociation of  $\text{Ag}(\text{NH}_3)_2^+$ , we obtain

$$\frac{[\text{Ag}^+][\text{NH}_3]^2}{[\text{Ag}(\text{NH}_3)_2^+]} = \frac{(x)(0.20)^2}{0.010} = 5.9 \times 10^{-8}$$

$$x = 1.5 \times 10^{-8} \text{ M} = [\text{Ag}^+]$$

Formation of the  $\text{Ag}(\text{NH}_3)_2^+$  complex drastically reduces the concentration of free  $\text{Ag}^+$  ion in solution.

**Practice Exercise 1**

You have an aqueous solution of chromium(III) nitrate that you titrate with an aqueous solution of sodium hydroxide. After a certain amount of titrant has been added, you observe a precipitate forming. You add more sodium hydroxide solution and the precipitate dissolves, leaving a solution again. What has happened? (a) The precipitate was sodium hydroxide, which redissolved in the larger volume. (b) The precipitate was chromium hydroxide, which dissolved once more solution was added, forming  $\text{Cr}^{3+}(aq)$ . (c) The precipitate was chromium hydroxide, which then reacted with more hydroxide to produce a soluble complex ion,  $\text{Cr}(\text{OH})_4^-(aq)$ . (d) The precipitate was sodium nitrate, which reacted with more nitrate to produce the soluble complex ion  $\text{Na}(\text{NO}_3)_2^-(aq)$ .

**Practice Exercise 2**

Calculate  $[\text{Cr}^{3+}]$  in equilibrium with  $\text{Cr}(\text{OH})_4^-(aq)$  when 0.010 mol of  $\text{Cr}(\text{NO}_3)_3$  is dissolved in 1 L of solution buffered at pH 10.0.

▲ **Figure 17.20 Amphoterism.** Some metal oxides and hydroxides, such as  $\text{Al}(\text{OH})_3$ , are amphoteric, which means they dissolve in both strongly acidic and strongly basic solutions.

## Amphoterism

Some metal oxides and hydroxides that are relatively insoluble in water dissolve in strongly acidic and strongly basic solutions. These substances, called **amphoteric oxides** and **amphoteric hydroxides**,\* are soluble in strong acids and bases because they themselves are capable of behaving as either an acid or base. Examples of amphoteric substances include the oxides and hydroxides of  $\text{Al}^{3+}$ ,  $\text{Cr}^{3+}$ ,  $\text{Zn}^{2+}$ , and  $\text{Sn}^{2+}$ .

Like other metal oxides and hydroxides, amphoteric species dissolve in acidic solutions because their anions,  $\text{O}^{2-}$  or  $\text{OH}^{-}$ , react with acids. What makes amphoteric oxides and hydroxides special, though, is that they also dissolve in strongly basic solutions. This behavior results from the formation of complex anions containing several (typically four) hydroxides bound to the metal ion (**Figure 17.20**):

The extent to which an insoluble metal hydroxide reacts with either acid or base varies with the particular metal ion involved. Many metal hydroxides—such as  $\text{Ca}(\text{OH})_2$ ,  $\text{Fe}(\text{OH})_2$ , and  $\text{Fe}(\text{OH})_3$ —are capable of dissolving in acidic solution but do not react with excess base. These hydroxides are not amphoteric.

The purification of aluminum ore in the manufacture of aluminum metal provides an interesting application of amphoterism. As we have seen,  $\text{Al}(\text{OH})_3$  is amphoteric, whereas  $\text{Fe}(\text{OH})_3$  is not. Aluminum occurs in large quantities as the ore *bauxite*, which is essentially hydrated  $\text{Al}_2\text{O}_3$  contaminated with  $\text{Fe}_2\text{O}_3$ . When bauxite is added to a strongly basic solution, the  $\text{Al}_2\text{O}_3$  dissolves because the aluminum forms complex ions, such as  $\text{Al}(\text{OH})_4^{-}$ . The  $\text{Fe}_2\text{O}_3$  impurity, however, is not amphoteric and remains as a solid. The solution is filtered, getting rid of the iron impurity. Aluminum hydroxide is then precipitated by addition of acid. The purified hydroxide receives further treatment and eventually yields aluminum metal.

\*Notice that the term *amphoteric* is applied to the behavior of insoluble oxides and hydroxides that dissolve in acidic or basic solutions. The similar term *amphiprotic* (Section 16.2) relates more generally to any molecule or ion that can either gain or lose a proton.

## A CLOSER LOOK Lead Contamination in Drinking Water

Access to clean drinking water is something most people in the industrialized world take for granted. Unfortunately, there are rare instances in which tap water is not safe to drink, as illustrated by the discovery in 2015 of elevated levels of lead in the municipal water supply of Flint, Michigan.

Lead is detrimental to many organs in the human body, but the brain and central nervous system are particularly sensitive to its presence. In the brain,  $\text{Pb}^{2+}$  ions interfere with cell communication and growth by mimicking  $\text{Ca}^{2+}$  ions. One of the most serious side effects of lead poisoning occurs in young children, where it leads to cognitive impairment. Although lead compounds were once used in a variety of applications—as a gasoline additive, in pigments, shotgun pellets, glass, and water pipes—our daily exposure to lead dropped dramatically once governmental agencies started regulating its use in the 1970s. According to the National Health and Nutrition Examination Survey, the mean concentration of lead in the blood for an average U.S. resident dropped from 150 ppb in 1976 to 16 ppb by 2002, nearly an order-of-magnitude decrease.

The regulatory limit set by the U.S. Environmental Protection Agency (EPA) for lead in drinking water is 15 parts per billion (ppb). According to EPA regulations, utilities serving more than 50,000 people must monitor the level of lead in their water and take corrective action if more than 10% of the homes sampled exceed the 15 ppb limit. Tests performed on samples collected in September 2015 by researchers from Virginia Tech found that in 10% of the 252 Flint homes tested the lead concentration exceeded 25 ppb, and in several homes the concentration exceeded 100 ppb. At the same time, a local pediatrician analyzed the results of infant blood tests and found that the percentage of children with elevated concentrations of lead in their bloodstream ( $>50$  ppb) had doubled from 2.4% in the 2013 to 4.9% in 2015.

The troubles began in April 2014 when the city began using the nearby Flint River as the natural source of its municipal water. Prior to that, Flint obtained water from Detroit, where water taken from Lake Huron was treated before piping it to Flint. The source of the lead was not the Flint River itself, but corrosion from lead pipes that are present in the underground water distribution network. Why did the change in water supply dramatically increase the leaching of lead from the old pipes? Many factors were at play, but basically they all came down to solubility considerations.

When water is properly treated, a passivation layer of insoluble lead salts builds up on the inner surface of the lead pipes (Figure 17.21).

This layer prevents corrosion that would otherwise allow lead to be oxidized and dissolve into the water as  $\text{Pb}^{2+}$  ions. The water treatment facility in Detroit was adding phosphate ions,  $\text{PO}_4^{3-}$ , to their water to inhibit corrosion, whereas the people managing water treatment in Flint elected not to do so. The presence of  $\text{PO}_4^{3-}$  ions promotes the formation of highly insoluble phosphate salts on the inner surface of the pipes that helps prevent corrosion.

Another factor that appears to have contributed to the problem is a drop in the pH of the water, from 8.0 in December 2014 to 7.3 in August 2015. Because the insoluble lead salts that form the passivating layer, like  $\text{Pb}_3(\text{PO}_4)_2$ ,  $\text{PbHSO}_4$ , and  $\text{PbCO}_3$ , contain anions that can act as weak bases, anything that makes the water more acidic increases their solubility.

Another contributing factor was the presence of high levels of chloride ions. The treated water from Detroit had chloride levels of about 11 ppm, whereas the treated Flint water had chloride levels of 85 ppm in August 2015. While  $\text{PbCl}_2$  is fairly insoluble ( $K_{\text{sp}} = 1.7 \times 10^{-5}$ ), high concentrations of chloride ions can lead to the formation of soluble complex ions such as  $\text{PbCl}_3^-$  and  $\text{PbCl}_4^{2-}$ . The increased chloride levels were due in part to the addition of  $\text{FeCl}_3$ , which was used to help coagulate and filter out unwanted organic matter that was leading to problems with *E. coli* contamination. Chloride ions are also produced when unwanted organic matter is oxidized by hypochlorite ions, which are added to kill bacteria. Run-off containing chloride salts used to treat icy roads in the winter may have also contributed.

In the face of mounting evidence that the lead in Flint's drinking water was at unsafe levels, in October of 2015 the city switched back to water piped in from Detroit. Over a period of many months, the circulation of properly treated water should restore the passivating layers inside the pipes. However, cleanup costs are expected to be in excess of \$120 million and possibly much more, a large sum compared to the estimated \$50,000 per year that it would have cost to treat the water with phosphates. More importantly, the damage done to people who drank the contaminated water, especially children, cannot be undone.

Although the use of lead in plumbing has been banned in the United States since 1986, it is estimated that millions of miles of buried lead pipe are still in use in America's cities. Vigilance by water treatment facilities and environmental protection agencies is needed to avoid a repeat of the tragedy in Flint.

**Related Exercises:** 17.97, 17.101

**▲ Figure 17.21 Protected and unprotected lead pipes.** (a) A lead pipe that has a protective passivation layer, and (b) a lead pipe where the lack of a phosphate corrosion inhibitor causes the passivation layer to dissolve and fall off, exposing the lead to oxidizing agents such as  $\text{O}_2$  and  $\text{OCl}^-$ .

## 17.6 | Precipitation and Separation of Ions

Equilibrium can be achieved starting with the substances on either side of a chemical equation. For example, the equilibrium that exists between  $\text{BaSO}_4(s)$ ,  $\text{Ba}^{2+}(aq)$ , and  $\text{SO}_4^{2-}(aq)$  (Equation 17.15), can be achieved by starting either with  $\text{BaSO}_4(s)$  or with solutions containing  $\text{Ba}^{2+}$  and  $\text{SO}_4^{2-}$ . If we mix, say, a  $\text{BaCl}_2$  aqueous solution with a  $\text{Na}_2\text{SO}_4$  aqueous solution,  $\text{BaSO}_4$  might precipitate out. How can we predict whether a precipitate will form under various conditions?

Recall that we used the reaction quotient  $Q$  in Section 15.6 to determine the direction in which a reaction must proceed to reach equilibrium. The form of  $Q$  is the same as the equilibrium-constant expression for a reaction, but instead of only equilibrium concentrations, you can use whatever concentrations are being considered. The direction in which a reaction proceeds to reach equilibrium depends on the relationship between  $Q$  and  $K$  for the reaction. If  $Q < K$ , the product concentrations are too low and reactant concentrations are too high relative to the equilibrium concentrations, and so the reaction will proceed to the right (toward products) to achieve equilibrium. If  $Q > K$ , product concentrations are too high and reactant concentrations are too low, and so the reaction will proceed to the left to achieve equilibrium. If  $Q = K$ , the reaction is at equilibrium.

For solubility-product equilibria, the relationship between  $Q$  and  $K_{sp}$  is exactly like that for other equilibria. For  $K_{sp}$  reactions, products are always the soluble ions, and the reactant is always the solid.

Therefore, for solubility equilibria,

- If  $Q = K_{sp}$ , the system is at equilibrium, which means the solution is saturated; this is the highest concentration the solution can have without precipitating.
- If  $Q < K_{sp}$ , the reaction will proceed to the right, toward the soluble ions; no precipitate will form.
- If  $Q > K_{sp}$ , the reaction will proceed to the left, toward the solid; precipitate will form.

For the case of the barium sulfate solution, then we would calculate  $Q = [\text{Ba}^{2+}][\text{SO}_4^{2-}]$ , and compare this quantity to the  $K_{sp}$  for barium sulfate.

### Sample Exercise 17.16

#### Predicting Whether a Precipitate Forms

Does a precipitate form when 0.10 L of  $8.0 \times 10^{-3} \text{ M Pb(NO}_3)_2$  is added to 0.40 L of  $5.0 \times 10^{-3} \text{ M Na}_2\text{SO}_4$ ?

#### SOLUTION

**Analyze** The problem asks us to determine whether a precipitate forms when two salt solutions are combined.

**Plan** We should determine the concentrations of all ions just after the solutions are mixed and compare the value of  $Q$  with  $K_{sp}$  for any potentially insoluble product. The possible metathesis

products are  $\text{PbSO}_4$  and  $\text{NaNO}_3$ . Like all sodium salts  $\text{NaNO}_3$  is soluble, but  $\text{PbSO}_4$  has a  $K_{sp}$  of  $6.3 \times 10^{-7}$  (Appendix D) and will precipitate if the  $\text{Pb}^{2+}$  and  $\text{SO}_4^{2-}$  concentrations are high enough for  $Q$  to exceed  $K_{sp}$ .

#### Solve

When the two solutions are mixed, the volume is  $0.10 \text{ L} + 0.40 \text{ L} = 0.50 \text{ L}$ . The number of moles of  $\text{Pb}^{2+}$  in 0.10 L of  $8.0 \times 10^{-3} \text{ M Pb(NO}_3)_2$  is:

$$(0.10 \text{ L}) \left( \frac{8.0 \times 10^{-3} \text{ mol}}{\text{L}} \right) = 8.0 \times 10^{-4} \text{ mol}$$

The concentration of  $\text{Pb}^{2+}$  in the 0.50-L mixture is therefore:

$$[\text{Pb}^{2+}] = \frac{8.0 \times 10^{-4} \text{ mol}}{0.50 \text{ L}} = 1.6 \times 10^{-3} \text{ M}$$

*Continued*

The number of moles of  $\text{SO}_4^{2-}$  in 0.40 L of  $5.0 \times 10^{-3} \text{ M Na}_2\text{SO}_4$  is:

$$(0.40 \text{ L}) \left( \frac{5.0 \times 10^{-3} \text{ mol}}{\text{L}} \right) = 2.0 \times 10^{-3} \text{ mol}$$

Therefore:

$$[\text{SO}_4^{2-}] = \frac{2.0 \times 10^{-3} \text{ mol}}{0.50 \text{ L}} = 4.0 \times 10^{-3} \text{ M}$$

and:

$$Q = [\text{Pb}^{2+}][\text{SO}_4^{2-}] = (1.6 \times 10^{-3})(4.0 \times 10^{-3}) = 6.4 \times 10^{-6}$$

Because  $Q > K_{sp}$ ,  $\text{PbSO}_4$  precipitates.

### Practice Exercise 1

An insoluble salt MA has a  $K_{sp}$  of  $1.0 \times 10^{-16}$ . Two solutions,  $\text{MNO}_3$  and  $\text{NaA}$  are mixed, to yield a final solution that is  $1.0 \times 10^{-8} \text{ M}$  in  $\text{M}^+(aq)$  and  $1.00 \times 10^{-7} \text{ M}$  in  $\text{A}^-(aq)$ . Will a precipitate form?

(a) Yes (b) No

### Practice Exercise 2

Does a precipitate form when 0.050 L of  $2.0 \times 10^{-2} \text{ M NaF}$  is mixed with 0.010 L of  $1.0 \times 10^{-2} \text{ M Ca(NO}_3)_2$ ?

## Selective Precipitation of Ions

Ions can be separated from each other based on the solubilities of their salts. Consider a solution containing both  $\text{Ag}^+$  and  $\text{Cu}^{2+}$ . If  $\text{HCl}$  is added to the solution,  $\text{AgCl}$  ( $K_{sp} = 1.8 \times 10^{-10}$ ) precipitates, while  $\text{Cu}^{2+}$  remains in solution because  $\text{CuCl}_2$  is soluble. Separation of ions in an aqueous solution by using a reagent that forms a precipitate with one or more (but not all) of the ions is called *selective precipitation*.

Sulfide ion is often used to separate metal ions because the solubilities of sulfide salts span a wide range and depend greatly on solution pH. For example,  $\text{Cu}^{2+}$  and  $\text{Zn}^{2+}$  can be separated by bubbling  $\text{H}_2\text{S}$  gas through an acidified solution containing these two cations. Because  $\text{CuS}$  ( $K_{sp} = 6 \times 10^{-37}$ ) is less soluble than  $\text{ZnS}$  ( $K_{sp} = 2 \times 10^{-25}$ ),  $\text{CuS}$  precipitates from an acidified solution ( $\text{pH} \approx 1$ ) while  $\text{ZnS}$  does not (Figure 17.22):

The  $\text{CuS}$  can be separated from the  $\text{Zn}^{2+}$  solution by filtration. The separated  $\text{CuS}$  can then be dissolved by raising the concentration of  $\text{H}^+$  even further, shifting the equilibrium concentrations of the compounds in Equation 17.27 to the left.

## Sample Exercise 17.17

### Selective Precipitation

A solution contains  $1.0 \times 10^{-2} \text{ M Ag}^+(aq)$  and  $2.0 \times 10^{-2} \text{ M Pb}^{2+}(aq)$ . When  $\text{Cl}^-(aq)$  is added, both  $\text{AgCl}$  ( $K_{sp} = 1.8 \times 10^{-10}$ ) and  $\text{PbCl}_2$  ( $K_{sp} = 1.7 \times 10^{-5}$ ) can precipitate. What concentration of  $\text{Cl}^-(aq)$  is necessary to begin the precipitation of each salt? Which salt precipitates first?

### SOLUTION

**Analyze** We are asked to determine the concentration of  $\text{Cl}^-(aq)$  necessary to begin the precipitation from a solution containing  $\text{Ag}^+(aq)$  and  $\text{Pb}^{2+}(aq)$  ions, and to predict which metal chloride will begin to precipitate first.

**Plan** We are given  $K_{sp}$  values for the two precipitates. Using these and the metal ion concentrations, we can calculate what  $\text{Cl}^-(aq)$  concentration is necessary to precipitate each salt. The salt requiring the lower  $\text{Cl}^-(aq)$  ion concentration precipitates first.

**Solve** For  $\text{AgCl}$  we have  $K_{sp} = [\text{Ag}^+][\text{Cl}^-] = 1.8 \times 10^{-10}$ .

Because  $[\text{Ag}^+] = 1.0 \times 10^{-2} \text{ M}$ , the greatest concentration of  $\text{Cl}^-(aq)$  that can be present without causing precipitation of  $\text{AgCl}$  can be calculated from the  $K_{sp}$  expression:

$$K_{sp} = (1.0 \times 10^{-2})[\text{Cl}^-] = 1.8 \times 10^{-10}$$

$$[\text{Cl}^-] = \frac{1.8 \times 10^{-10}}{1.0 \times 10^{-2}} = 1.8 \times 10^{-8} \text{ M}$$

Any  $\text{Cl}^-(aq)$  in excess of this very small concentration will cause  $\text{AgCl}$  to precipitate from solution. Proceeding similarly for  $\text{PbCl}_2$ , we have

$$K_{sp} = [\text{Pb}^{2+}][\text{Cl}^-]^2 = 1.7 \times 10^{-5}$$

$$(2.0 \times 10^{-2})[\text{Cl}^-]^2 = 1.7 \times 10^{-5}$$

$$[\text{Cl}^-]^2 = \frac{1.7 \times 10^{-5}}{2.0 \times 10^{-2}} = 8.5 \times 10^{-4}$$

$$[\text{Cl}^-] = \sqrt{8.5 \times 10^{-4}} = 2.9 \times 10^{-2} M$$

Thus, a concentration of  $\text{Cl}^-(aq)$  in excess of  $2.9 \times 10^{-2} M$  causes  $\text{PbCl}_2$  to precipitate.

Comparing the  $\text{Cl}^-(aq)$  concentration required to precipitate each salt, we see that as  $\text{Cl}^-(aq)$  is added,  $\text{AgCl}$  precipitates first because it requires a much smaller concentration of  $\text{Cl}^-$ . Thus,  $\text{Ag}^+(aq)$  can be separated from  $\text{Pb}^{2+}(aq)$  by slowly adding  $\text{Cl}^-(aq)$  so that the chloride ion concentration remains between  $1.8 \times 10^{-8} M$  and  $2.9 \times 10^{-2} M$ .

**Comment** Precipitation of  $\text{AgCl}$  will keep the  $\text{Cl}^-(aq)$  concentration low until the number of moles of  $\text{Cl}^-(aq)$  added exceeds the number of moles of  $\text{Ag}^+(aq)$  in the solution. Once past this point,  $[\text{Cl}^-]$  rises sharply and  $\text{PbCl}_2$  will soon begin to precipitate.

### Practice Exercise 1

Under what conditions does an ionic compound precipitate from a solution of the constituent ions?

(a) always (b) when  $Q = K_{sp}$  (c) when  $Q$  exceeds  $K_{sp}$  (d) when  $Q$  is less than  $K_{sp}$  (e) never, if it is very soluble

### Practice Exercise 2

A solution consists of  $0.050 M \text{Mg}^{2+}(aq)$  and  $\text{Cu}^{2+}(aq)$ . Which ion precipitates first as  $\text{OH}^-(aq)$  is added? What concentration of  $\text{OH}^-(aq)$  is necessary to begin the precipitation of each cation? [ $K_{sp} = 1.8 \times 10^{-11}$  for  $\text{Mg}(\text{OH})_2$ , and  $K_{sp} = 4.8 \times 10^{-20}$  for  $\text{Cu}(\text{OH})_2$ .]

## Go Figure

Why is the sulfide reagent  $\text{HS}^-$  in the third test tube and not  $\text{H}_2\text{S}$ ?

▲ **Figure 17.22** Selective precipitation. In this example,  $\text{Cu}^{2+}$  ions are separated from  $\text{Zn}^{2+}$  ions.

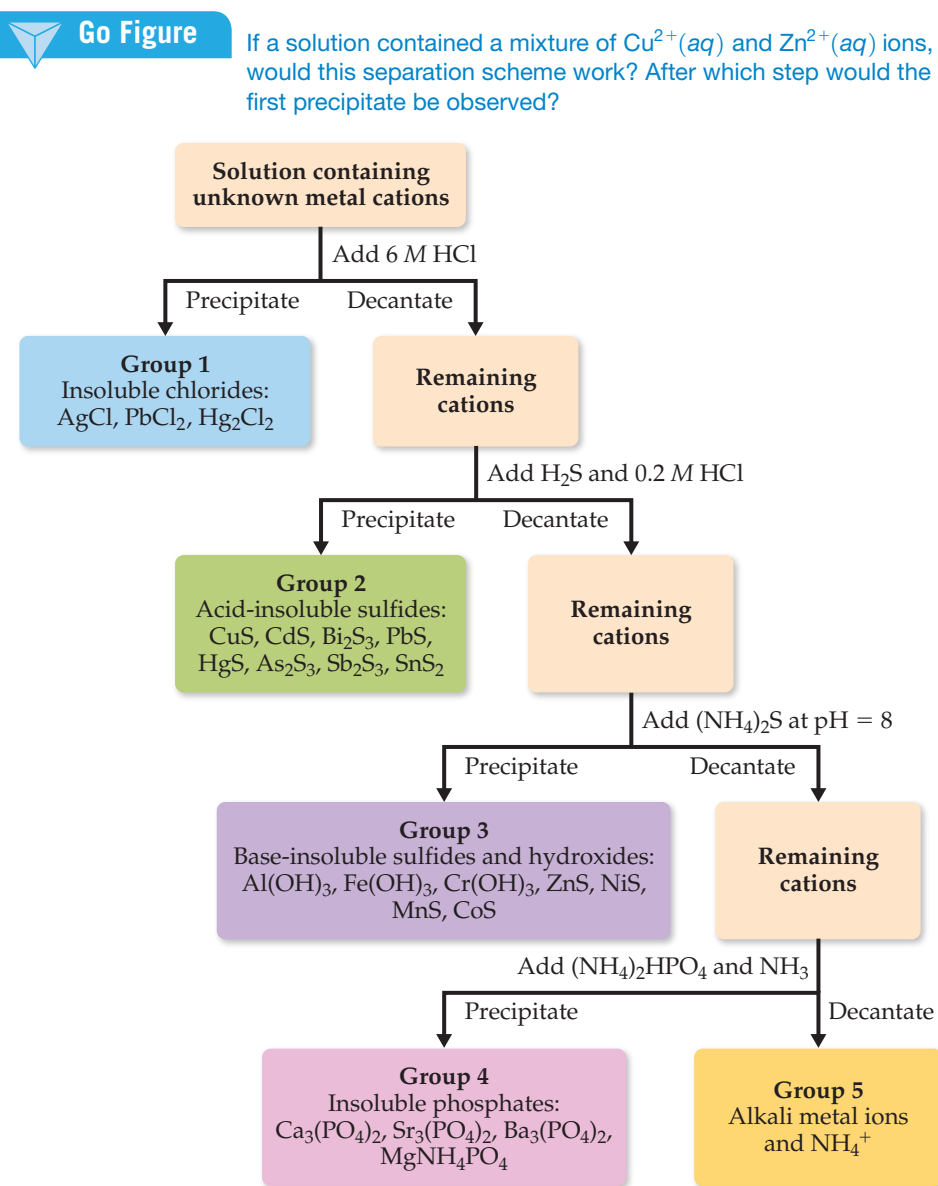

## 17.7 | Qualitative Analysis for Metallic Elements

In this final section, we look at how solubility equilibria and complex-ion formation can be used to detect the presence of particular metal ions in solution. Before the development of modern analytical instrumentation, it was necessary to analyze mixtures of metals in

a sample by what were called *wet chemical methods*. For example, an ore sample that might contain several metallic elements was dissolved in a concentrated acid solution that was then tested in a systematic way for the presence of various metal ions.

**Qualitative analysis** determines only the presence or absence of a particular metal ion relative to some threshold, whereas **quantitative analysis** determines how much of a given substance is present. Even though wet methods of qualitative analysis have become less important in the chemical industry, they are frequently used in general chemistry laboratory programs to illustrate equilibria, to teach the properties of common metal ions in solution, and to develop laboratory skills. Typically, such analyses proceed in three stages: (1) The ions are separated into broad groups on the basis of solubility properties. (2) The ions in each group are separated by selectively dissolving members in the group. (3) The ions are identified by means of specific tests.

A scheme in general use divides the common cations into five groups (Figure 17.23). The order in which reagents are added is important in this scheme. The most selective separations—those that involve the smallest number of ions—are carried out first. The

▲ **Figure 17.23** Qualitative analysis. A flowchart showing a common scheme for identifying cations.

reactions used must proceed so far toward completion that any concentration of cations remaining in the solution is too small to interfere with subsequent tests.

Let's look at each of these five groups of cations, briefly examining the logic used in this qualitative analysis scheme.

**Group 1. Insoluble chlorides:** Of the common metal ions, only  $\text{Ag}^+(aq)$ ,  $\text{Hg}_2^{2+}(aq)$ , and  $\text{Pb}^{2+}(aq)$  form insoluble chlorides. When  $\text{HCl}$  is added to a mixture of cations, therefore, only  $\text{AgCl}$ ,  $\text{Hg}_2\text{Cl}_2$ , and  $\text{PbCl}_2$  precipitate, leaving the other cations in solution. The absence of a precipitate indicates that the starting solution contains no  $\text{Ag}^+(aq)$ ,  $\text{Hg}_2^{2+}(aq)$ , or  $\text{Pb}^{2+}(aq)$ .

**Group 2. Acid-insoluble sulfides:** After any insoluble chlorides have been removed, the remaining solution, now acidic from  $\text{HCl}$  treatment, is treated with  $\text{H}_2\text{S}$ . Since  $\text{H}_2\text{S}$  is a weak acid compared to  $\text{HCl}$ , its role here is to act as a source for small amounts of sulfide. Only the most insoluble metal sulfides— $\text{CuS}$ ,  $\text{Bi}_2\text{S}_3$ ,  $\text{CdS}$ ,  $\text{PbS}$ ,  $\text{HgS}$ ,  $\text{As}_2\text{S}_3$ ,  $\text{Sb}_2\text{S}_3$ , and  $\text{SnS}_2$ —precipitate. (Note the very small values of  $K_{sp}$  for some of these sulfides in Appendix D.) Those metal ions whose sulfides are somewhat more soluble—for example,  $\text{ZnS}$  or  $\text{NiS}$ —remain in solution.

**Group 3. Base-insoluble sulfides and hydroxides:** After the solution is filtered to remove any acid-insoluble sulfides, it is made slightly basic, and  $(\text{NH}_4)_2\text{S}$  is added. In basic solutions the concentration of  $\text{S}^{2-}(aq)$  is higher than in acidic solutions. Under these conditions, the ion products for many of the more soluble sulfides exceed their  $K_{sp}$  values and thus precipitation occurs. The metal ions precipitated at this stage are  $\text{Al}^{3+}(aq)$ ,  $\text{Cr}^{3+}(aq)$ ,  $\text{Fe}^{3+}(aq)$ ,  $\text{Zn}^{2+}(aq)$ ,  $\text{Ni}^{2+}(aq)$ ,  $\text{Co}^{2+}(aq)$ , and  $\text{Mn}^{2+}(aq)$ . (The  $\text{Al}^{3+}(aq)$ ,  $\text{Fe}^{3+}(aq)$ , and  $\text{Cr}^{3+}(aq)$  ions do not form insoluble sulfides; instead they precipitate as insoluble hydroxides, as Figure 17.23 shows.)

**Group 4. Insoluble phosphates:** At this point, the solution contains only metal ions from groups 1A and 2A of the periodic table. Adding  $(\text{NH}_4)_2\text{HPO}_4$  to a basic solution precipitates the group 2A elements  $\text{Mg}^{2+}(aq)$ ,  $\text{Ca}^{2+}(aq)$ ,  $\text{Sr}^{2+}(aq)$ , and  $\text{Ba}^{2+}(aq)$  because these metals form insoluble phosphates.

**Group 5. The alkali metal ions and  $\text{NH}_4^+(aq)$ :** The ions that remain after removing the insoluble phosphates are tested for individually. A flame test can be used to determine the presence of  $\text{K}^+(aq)$ , for example, because the flame turns a characteristic violet color if  $\text{K}^+(aq)$  is present (Figure 7.22).

### Give It Some Thought

An aqueous solution contains a soluble compound of either silver, barium, or copper. If a precipitate forms when  $\text{HCl}$  is added to the solution, which ion must be present?

### Sample Integrative Exercise

#### Putting Concepts Together

A sample of 1.25 L of  $\text{HCl}$  gas at  $21^\circ\text{C}$  and 0.950 atm is bubbled through 0.500 L of 0.150 M  $\text{NH}_3$  solution. Calculate the pH of the resulting solution assuming that all the  $\text{HCl}$  dissolves and that the volume of the solution remains 0.500 L.

#### SOLUTION

The number of moles of  $\text{HCl}$  gas is calculated from the ideal-gas law:

$$n = \frac{PV}{RT} = \frac{(0.950 \text{ atm})(1.25 \text{ L})}{(0.0821 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(294 \text{ K})} = 0.0492 \text{ mol HCl}$$

The number of moles of  $\text{NH}_3$  in the solution is given by the product of the volume of the solution and its concentration:

$$\text{Moles NH}_3 = (0.500 \text{ L})(0.150 \text{ mol NH}_3/\text{L}) = 0.0750 \text{ mol NH}_3$$

Continued

The acid HCl and base NH<sub>3</sub> react, transferring a proton from HCl to NH<sub>3</sub>, producing NH<sub>4</sub><sup>+</sup> and Cl<sup>-</sup> ions:

To determine the pH of the solution, we first calculate the amount of each reactant and each product present at the completion of the reaction. Because you can assume this neutralization reaction proceeds as far toward the product side as possible, this is a limiting reactant problem.

|                                  | $\text{HCl}(g) + \text{NH}_3(aq) \longrightarrow \text{NH}_4^+(aq) + \text{Cl}^-(aq)$ |         |         |         |
|----------------------------------|---|---------|---------|---------|
| Before reaction (mol)            | 0.0492  | 0.0750  | 0       | 0       |
| Change (limiting reactant) (mol) | -0.0492   | -0.0492 | +0.0492 | +0.0492 |
| After reaction (mol)             | 0   | 0.0258  | 0.0492  | 0.0492  |

Thus, the reaction produces a solution containing a mixture of NH<sub>3</sub>, NH<sub>4</sub><sup>+</sup>, and Cl<sup>-</sup>. The NH<sub>3</sub> is a weak base ( $K_b = 1.8 \times 10^{-5}$ ), NH<sub>4</sub><sup>+</sup> is its conjugate acid, and Cl<sup>-</sup> is neither acidic nor basic. Consequently, the pH depends on [NH<sub>3</sub>] and [NH<sub>4</sub><sup>+</sup>]:

$$[\text{NH}_3] = \frac{0.0258 \text{ mol NH}_3}{0.500 \text{ L soln}} = 0.0516 \text{ M}$$

$$[\text{NH}_4^+] = \frac{0.0492 \text{ mol NH}_4^+}{0.500 \text{ L soln}} = 0.0984 \text{ M}$$

We can calculate the pH using either  $K_b$  for NH<sub>3</sub> or  $K_a$  for NH<sub>4</sub><sup>+</sup>. Using the  $K_b$  expression, we have:

|                 | $\text{NH}_3(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_4^+(aq) + \text{OH}^-(aq)$ |   |              |    |
|-----------------|--|---|--------------|----|
| Initial (M)     | 0.0516   | — | 0.0984       | 0  |
| Change (M)      | -x   | — | +x           | +x |
| Equilibrium (M) | (0.0516 - x)   | — | (0.0984 + x) | x  |

$$K_b = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} = \frac{(0.0984 + x)(x)}{(0.0516 - x)} \cong \frac{(0.0984)x}{0.0516} = 1.8 \times 10^{-5}$$

$$x = [\text{OH}^-] = \frac{(0.0516)(1.8 \times 10^{-5})}{0.0984} = 9.4 \times 10^{-6} \text{ M}$$

$$\text{Hence, pOH} = -\log(9.4 \times 10^{-6}) = 5.03$$

$$\text{and pH} = 14.00 - \text{pOH} = 14.00 - 5.03 = 8.97.$$

## Chapter Summary and Key Terms

**THE COMMON ION EFFECT (SECTION 17.1)** In this chapter, we have considered several types of important equilibria that occur in aqueous solution. Our primary emphasis has been on acid-base equilibria in solutions containing two or more solutes and on solubility equilibria. The dissociation of a weak acid or weak base is repressed by the presence of a strong electrolyte that provides an ion common to the equilibrium (the **common-ion effect**).

**BUFFERS (SECTION 17.2)** A particularly important type of acid-base mixture is that of a weak conjugate acid-base pair that functions as a **buffered solution (buffer)**. Addition of small amounts of a strong acid or a strong base to a buffered solution causes only small changes in pH because the buffer reacts with the added acid or base. (Strong acid-strong base, strong acid-weak base, and weak acid-strong base reactions proceed essentially to completion.) Buffered solutions are usually prepared from a weak acid and a salt of that acid or from a weak base and a salt of that base. Two important characteristics of a buffered solution are its **buffer capacity** and its pH range. The optimal pH of a buffer is equal to

$\text{p}K_a$  (or  $\text{p}K_b$ ) of the acid (or base) used to prepare the buffer. The relationship between pH,  $\text{p}K_a$ , and the concentrations of an acid and its conjugate base can be expressed by the **Henderson-Hasselbalch equation**. It is important to realize that the Henderson-Hasselbalch equation is an approximation, and more detailed calculations may need to be performed to obtain equilibrium concentrations.

**ACID-BASE TITRATIONS (SECTION 17.3)** The plot of the pH of an acid (or base) as a function of the volume of added base (or acid) is called a **pH titration curve**. The titration curve of a strong acid-strong base titration exhibits a large change in pH in the immediate vicinity of the equivalence point; at the equivalence point for such a titration  $\text{pH} = 7$ . For strong acid-weak base or weak acid-strong base titrations, the pH change in the vicinity of the equivalence point is not as large as for a strong acid-strong base titration, nor will the pH equal 7 at the equivalence point in these cases. Instead, what determines the pH at the equivalence point is the conjugate base or acid salt solution that results from the

neutralization reaction. For this reason, it is important to choose an indicator whose color change is near the pH at the equivalence point for titrations involving either weak acids or weak bases. It is possible to calculate the pH at any point of the titration curve by first considering the effects of the acid–base reaction on solution concentrations and then examining equilibria involving the remaining solute species.

**SOLUBILITY EQUILIBRIA (SECTION 17.4)** The equilibrium between a solid compound and its ions in solution provides an example of heterogeneous equilibrium. The **solubility-product constant** (or simply the **solubility product**),  $K_{sp}$ , is an equilibrium constant that expresses quantitatively the extent to which the compound dissolves. The  $K_{sp}$  can be used to calculate the solubility of an ionic compound, and the solubility can be used to calculate  $K_{sp}$ .

**FACTORS THAT AFFECT SOLUBILITY (SECTION 17.5)** Several experimental factors, including temperature, affect the solubilities of ionic compounds in water. The solubility of a slightly soluble ionic compound is decreased by the presence of a second solute that furnishes a common ion (the common-ion effect). The solubility of compounds containing basic anions increases as the solution is made more acidic (as pH decreases). Salts with anions of negligible basicity (the anions of strong acids) are unaffected by pH changes.

The solubility of metal salts is also affected by the presence of certain Lewis bases that react with metal ions to form stable **complex**

**ions**. Complex-ion formation in aqueous solution involves the displacement by Lewis bases (such as  $\text{NH}_3$  and  $\text{CN}^-$ ) of water molecules attached to the metal ion. The extent to which such complex formation occurs is expressed quantitatively by the **formation constant** for the complex ion. **Amphoteric oxides** and **hydroxides** are those that are only slightly soluble in water but dissolve on addition of either acid or base.

#### PRECIPITATION AND SEPARATION OF IONS (SECTION 17.6)

Comparison of the reaction quotient,  $Q$ , with the value of  $K_{sp}$  can be used to judge whether a precipitate will form when solutions are mixed or whether a slightly soluble salt will dissolve under various conditions. Precipitates form when  $Q > K_{sp}$ . If two salts have sufficiently different solubilities, selective precipitation can be used to precipitate one ion while leaving the other in solution, effectively separating the two ions.

#### QUALITATIVE ANALYSIS FOR METALLIC ELEMENTS (SECTION 17.7)

Metallic elements vary a great deal in the solubilities of their salts, in their acid–base behavior, and in their tendencies to form complex ions. These differences can be used to separate and detect the presence of metal ions in mixtures. **Qualitative analysis** determines the presence or absence of species in a sample, whereas **quantitative analysis** determines how much of each species is present. The qualitative analysis of metal ions in solution can be carried out by separating the ions into groups on the basis of precipitation reactions and then analyzing each group for individual metal ions.

## Learning Outcomes After studying this chapter, you should be able to:

- Describe the common-ion effect. (Section 17.1)  
*Related Exercises: 17.13, 17.14*
- Explain how a buffer functions and calculate the pH of a buffered solution. (Section 17.2) *Related Exercises: 17.19, 17.20*
- Calculate the pH of a buffer after the addition of small amounts of a strong acid or a strong base. (Section 17.2)  
*Related Exercises: 17.27, 17.28*
- Calculate the appropriate quantities of compounds to make a buffer at a given pH. (Section 17.2) *Related Exercises: 17.31, 17.32*
- Calculate the pH at any point for an acid–base titration curve. (Section 17.3) *Related Exercises: 17.45, 17.46*
- Estimate the  $\text{p}K_a$  for monoprotic or polyprotic acids from their titration curves. (Section 17.3) *Related Exercises: 17.33, 17.34*
- Given either  $K_{sp}$ , molar solubility, or mass solubility for a substance, calculate the other two quantities. (Section 17.4)  
*Related Exercises: 17.49, 17.50, 17.53, 17.54*
- Qualitatively predict, and quantitatively calculate, the molar solubility of a substance in the presence of a common ion or at different pH values. (Section 17.5)  
*Related Exercises: 17.55, 17.56, 17.63, 17.64, 17.67, 17.68*
- Qualitatively predict whether a precipitate will form when solutions are mixed, and quantitatively calculate the ion concentrations required to initiate precipitation. (Section 17.6)  
*Related Exercises: 17.69, 17.70, 17.73, 17.74*
- Explain the effect of complex-ion formation on solubility. (Section 17.6) *Related Exercises: 17.65, 17.66*
- Predict how to separate and identify cations based on their solubility characteristics. (Section 17.7)  
*Related Exercises: 17.79, 17.80*

## Key Equations

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \quad [17.9]$$

The Henderson–Hasselbalch equation, used to estimate the pH of a buffer from the concentrations of a conjugate acid–base pair

## Exercises

## Visualizing Concepts

- 17.1** The following boxes represent aqueous solutions containing a weak acid, HA, and its conjugate base,  $A^-$ . Water molecules, hydronium ions, and cations are not shown. Which solution has the highest pH? Explain. [Section 17.1]

- 17.2** The beaker on the right contains 0.1 M acetic acid solution with methyl orange as an indicator. The beaker on the left contains a mixture of 0.1 M acetic acid and 0.1 M sodium acetate with methyl orange. (a) Using Figures 16.8 and 16.9, which solution has a higher pH? (b) Which solution is better able to maintain its pH when small amounts of NaOH are added? Explain. [Sections 17.1 and 17.2]

- 17.3** A buffer contains a weak acid, HA, and its conjugate base. The weak acid has a  $pK_a$  of 4.5, and the buffer has a pH of 4.3. Without doing a calculation, state which of these possibilities are correct at pH 4.3. (a)  $[HA] = [A^-]$ , (b)  $[HA] > [A^-]$ , or (c)  $[HA] < [A^-]$ . [Section 17.2]
- 17.4** The following diagram represents a buffer composed of equal concentrations of a weak acid, HA, and its conjugate base,  $A^-$ . The heights of the columns are proportional to the concentrations of the components of the buffer. (a) Which of the three drawings, (1), (2), or (3), represents the buffer after the addition of a strong acid? (b) Which of the three represents the buffer after the addition of a strong base? (c) Which of the three represents a situation that cannot arise from the addition of either an acid or a base? [Section 17.2]

- 17.5** The following figure represents solutions at various stages of the titration of a weak acid, HA, with NaOH. (The  $Na^+$  ions and water molecules have been omitted for clarity.) To which of the following regions of the titration curve does each drawing correspond: (a) before addition of NaOH, (b) after addition of NaOH but before the equivalence point, (c) at the equivalence point, (d) after the equivalence point? [Section 17.3]

- 17.6** Match the following descriptions of titration curves with the diagrams: (a) strong acid added to strong base, (b) strong base added to weak acid, (c) strong base added to strong acid, (d) strong base added to polyprotic acid. [Section 17.3]

- 17.7** Equal volumes of two acids are titrated with 0.10 M NaOH resulting in the two titration curves shown in the following figure. (a) Which curve corresponds to the more concentrated acid solution? (b) Which corresponds to the acid with the larger  $K_a$ ? [Section 17.3]

- 17.8** A saturated solution of  $Cd(OH)_2$  is shown in the middle beaker. If hydrochloric acid solution is added, the solubility of  $Cd(OH)_2$  will increase, causing additional solid to

dissolve. Which of the two choices, Beaker A or Beaker B, accurately represents the solution after equilibrium is reestablished? (The water molecules and Cl<sup>-</sup> ions are omitted for clarity.) [Sections 17.4 and 17.5]

- 17.9** The following graphs represent the behavior of BaCO<sub>3</sub> under different circumstances. In each case, the vertical axis indicates the solubility of the BaCO<sub>3</sub> and the horizontal axis represents the concentration of some other reagent. (a) Which graph represents what happens to the solubility of BaCO<sub>3</sub> as HNO<sub>3</sub> is added? (b) Which graph represents what happens to the BaCO<sub>3</sub> solubility as Na<sub>2</sub>CO<sub>3</sub> is added? (c) Which represents what happens to the BaCO<sub>3</sub> solubility as NaNO<sub>3</sub> is added? [Section 17.5]

- 17.10** Ca(OH)<sub>2</sub> has a  $K_{sp}$  of  $6.5 \times 10^{-6}$ . (a) If 0.370 g of Ca(OH)<sub>2</sub> is added to 500 mL of water and the mixture is allowed to come to equilibrium, will the solution be saturated? (b) If 50 mL of the solution from part (a) is added to each of the beakers shown here, in which beakers, if any, will a precipitate form? In those cases where a precipitate forms, what is its identity? [Section 17.6]

- 17.11** The graph below shows the solubility of a salt as a function of pH. Which of the following choices explain the shape of this graph? (a) None; this behavior is not possible. (b) A soluble salt reacts with acid to form a precipitate, and additional acid reacts with this product to dissolve it. (c) A soluble salt forms an insoluble hydroxide, then additional base reacts with this product to dissolve it. (d) The solubility of the salt increases with pH, then decreases because of the heat generated from the neutralization reactions. [Section 17.5]

- 17.12** Three cations, Ni<sup>2+</sup>, Cu<sup>2+</sup>, and Ag<sup>+</sup>, are separated using two different precipitating agents. Based on Figure 17.23, what two precipitating agents could be used? Using these agents, indicate which of the cations is A, which is B, and which is C. [Section 17.7]

### The Common-Ion Effect (Section 17.1)

- 17.13** Which of these statements about the common-ion effect is most correct? (a) The solubility of a salt MA is decreased in a solution that already contains either M<sup>+</sup> or A<sup>-</sup>. (b) Common ions alter the equilibrium constant for the reaction of an ionic solid with water. (c) The common-ion effect does not apply to unusual ions like SO<sub>3</sub><sup>2-</sup>. (d) The solubility of a salt MA is affected equally by the addition of either A<sup>-</sup> or a noncommon ion.

- 17.14** Consider the equilibrium

Suppose that a salt of HB<sup>+</sup>(aq) is added to a solution of B(aq) at equilibrium. (a) Will the equilibrium constant for the reaction increase, decrease, or stay the same? (b) Will the concentration of B(aq) increase, decrease, or stay the same? (c) Will the pH of the solution increase, decrease, or stay the same?

- 17.15** Use information from Appendix D to calculate the pH of (a) a solution that is 0.060 M in potassium propionate (C<sub>2</sub>H<sub>5</sub>COOK or KC<sub>2</sub>H<sub>5</sub>O<sub>2</sub>) and 0.085 M in propionic acid (C<sub>2</sub>H<sub>5</sub>COOH or HC<sub>2</sub>H<sub>5</sub>O<sub>2</sub>); (b) a solution that is 0.075 M in

trimethylamine,  $(\text{CH}_3)_3\text{N}$ , and 0.10 *M* in trimethylammonium chloride,  $(\text{CH}_3)_3\text{NHCl}$ ; (c) a solution that is made by mixing 50.0 mL of 0.15 *M* acetic acid and 50.0 mL of 0.20 *M* sodium acetate.

- 17.16** Use information from Appendix D to calculate the pH of (a) a solution that is 0.250 *M* in sodium formate ( $\text{HCOONa}$ ) and 0.100 *M* in formic acid ( $\text{HCOOH}$ ), (b) a solution that is 0.510 *M* in pyridine ( $\text{C}_5\text{H}_5\text{N}$ ) and 0.450 *M* in pyridinium chloride ( $\text{C}_5\text{H}_5\text{NHCl}$ ), (c) a solution that is made by combining 55 mL of 0.050 *M* hydrofluoric acid with 125 mL of 0.10 *M* sodium fluoride.
- 17.17** (a) Calculate the percent ionization of 0.0075 *M* butanoic acid ( $K_a = 1.5 \times 10^{-5}$ ). (b) Calculate the percent ionization of 0.0075 *M* butanoic acid in a solution containing 0.085 *M* sodium butanoate.
- 17.18** (a) Calculate the percent ionization of 0.125 *M* lactic acid ( $K_a = 1.4 \times 10^{-4}$ ). (b) Calculate the percent ionization of 0.125 *M* lactic acid in a solution containing 0.0075 *M* sodium lactate.

### Buffers (Section 17.2)

- 17.19** Which of the following solutions is a buffer? (a) 0.10 *M*  $\text{CH}_3\text{COOH}$  and 0.10 *M*  $\text{CH}_3\text{COONa}$ , (b) 0.10 *M*  $\text{CH}_3\text{COOH}$ , (c) 0.10 *M*  $\text{HCl}$  and 0.10 *M*  $\text{NaCl}$ , (d) both a and c, (e) all of a, b, and c.
- 17.20** Which of the following solutions is a buffer? (a) A solution made by mixing 100 mL of 0.100 *M*  $\text{CH}_3\text{COOH}$  and 50 mL of 0.100 *M*  $\text{NaOH}$ , (b) a solution made by mixing 100 mL of 0.100 *M*  $\text{CH}_3\text{COOH}$  and 500 mL of 0.100 *M*  $\text{NaOH}$ , (c) A solution made by mixing 100 mL of 0.100 *M*  $\text{CH}_3\text{COOH}$  and 50 mL of 0.100 *M*  $\text{HCl}$ , (d) A solution made by mixing 100 mL of 0.100 *M*  $\text{CH}_3\text{COOK}$  and 50 mL of 0.100 *M*  $\text{KCl}$ .
- 17.21** (a) Calculate the pH of a buffer that is 0.12 *M* in lactic acid and 0.11 *M* in sodium lactate. (b) Calculate the pH of a buffer formed by mixing 85 mL of 0.13 *M* lactic acid with 95 mL of 0.15 *M* sodium lactate.
- 17.22** (a) Calculate the pH of a buffer that is 0.105 *M* in  $\text{NaHCO}_3$  and 0.125 *M* in  $\text{Na}_2\text{CO}_3$ . (b) Calculate the pH of a solution formed by mixing 65 mL of 0.20 *M*  $\text{NaHCO}_3$  with 75 mL of 0.15 *M*  $\text{Na}_2\text{CO}_3$ .
- 17.23** A buffer is prepared by adding 20.0 g of sodium acetate ( $\text{CH}_3\text{COONa}$ ) to 500 mL of a 0.150 *M* acetic acid ( $\text{CH}_3\text{COOH}$ ) solution. (a) Determine the pH of the buffer. (b) Write the complete ionic equation for the reaction that occurs when a few drops of hydrochloric acid are added to the buffer. (c) Write the complete ionic equation for the reaction that occurs when a few drops of sodium hydroxide solution are added to the buffer.
- 17.24** A buffer is prepared by adding 10.0 g of ammonium chloride ( $\text{NH}_4\text{Cl}$ ) to 250 mL of 1.00 *M*  $\text{NH}_3$  solution. (a) What is the pH of this buffer? (b) Write the complete ionic equation for the reaction that occurs when a few drops of nitric acid are added to the buffer. (c) Write the complete ionic equation for the reaction that occurs when a few drops of potassium hydroxide solution are added to the buffer.
- 17.25** You are asked to prepare a pH = 3.00 buffer solution starting from 1.25 L of a 1.00 *M* solution of hydrofluoric acid ( $\text{HF}$ ) and any amount you need of sodium fluoride ( $\text{NaF}$ ). (a) What is the pH of the hydrofluoric acid solution prior to adding sodium fluoride? (b) How many grams of sodium fluoride should be added to prepare the buffer solution? Neglect the small volume change that occurs when the sodium fluoride is added.
- 17.26** You are asked to prepare a pH = 4.00 buffer starting from 1.50 L of 0.0200 *M* solution of benzoic acid

( $\text{C}_6\text{H}_5\text{COOH}$ ) and any amount you need of sodium benzoate ( $\text{C}_6\text{H}_5\text{COONa}$ ). (a) What is the pH of the benzoic acid solution prior to adding sodium benzoate? (b) How many grams of sodium benzoate should be added to prepare the buffer? Neglect the small volume change that occurs when the sodium benzoate is added.

- 17.27** A buffer contains 0.10 mol of acetic acid and 0.13 mol of sodium acetate in 1.00 L. (a) What is the pH of this buffer? (b) What is the pH of the buffer after the addition of 0.02 mol of  $\text{KOH}$ ? (c) What is the pH of the buffer after the addition of 0.02 mol of  $\text{HNO}_3$ ?
- 17.28** A buffer contains 0.15 mol of propionic acid ( $\text{C}_2\text{H}_5\text{COOH}$ ) and 0.10 mol of sodium propionate ( $\text{C}_2\text{H}_5\text{COONa}$ ) in 1.20 L. (a) What is the pH of this buffer? (b) What is the pH of the buffer after the addition of 0.01 mol of  $\text{NaOH}$ ? (c) What is the pH of the buffer after the addition of 0.01 mol of  $\text{HI}$ ?
- 17.29** (a) What is the ratio of  $\text{HCO}_3^-$  to  $\text{H}_2\text{CO}_3$  in blood of pH 7.4? (b) What is the ratio of  $\text{HCO}_3^-$  to  $\text{H}_2\text{CO}_3$  in an exhausted marathon runner whose blood pH is 7.1?
- 17.30** A buffer, consisting of  $\text{H}_2\text{PO}_4^-$  and  $\text{HPO}_4^{2-}$ , helps control the pH of physiological fluids. Many carbonated soft drinks also use this buffer system. What is the pH of a soft drink in which the major buffer ingredients are 6.5 g of  $\text{NaH}_2\text{PO}_4$  and 8.0 g of  $\text{Na}_2\text{HPO}_4$  per 355 mL of solution?
- 17.31** You have to prepare a pH = 3.50 buffer, and you have the following 0.10 *M* solutions available:  $\text{HCOOH}$ ,  $\text{CH}_3\text{COOH}$ ,  $\text{H}_3\text{PO}_4$ ,  $\text{HCOONa}$ ,  $\text{CH}_3\text{COONa}$ , and  $\text{NaH}_2\text{PO}_4$ . Which solutions would you use? How many milliliters of each solution would you use to make approximately 1 L of the buffer?
- 17.32** You have to prepare a pH = 5.00 buffer, and you have the following 0.10 *M* solutions available:  $\text{HCOOH}$ ,  $\text{HCOONa}$ ,  $\text{CH}_3\text{COOH}$ ,  $\text{CH}_3\text{COONa}$ ,  $\text{HCN}$ , and  $\text{NaCN}$ . Which solutions would you use? How many milliliters of each solution would you use to make approximately 1 L of the buffer?

### Acid–Base Titrations (Section 17.3)

- 17.33** The accompanying graph shows the titration curves for two monoprotic acids. (a) Which curve is that of a strong acid? (b) What is the approximate pH at the equivalence point of each titration? (c) 40.0 mL of each acid was titrated with a 0.100 *M* base. Which acid is more concentrated? (d) Estimate the  $\text{p}K_a$  of the weak acid.

- 17.34** Compare the titration of a strong, monoprotic acid with a strong base to the titration of a weak, monoprotic acid with a strong base. Assume the strong and weak acid solutions initially have the same concentrations. Indicate whether the following statements are true or false. (a) More base is

required to reach the equivalence point for the strong acid than the weak acid. (b) The pH at the beginning of the titration is lower for the weak acid than the strong acid. (c) The pH at the equivalence point is 7 no matter which acid is titrated.

- 17.35** The samples of nitric and acetic acids shown here are both titrated with a 0.100 M solution of NaOH(aq).

25.0 mL of 1.0 M  $\text{HNO}_3(\text{aq})$     25.0 mL of 1.0 M  $\text{CH}_3\text{COOH}(\text{aq})$

Determine whether each of the following statements concerning these titrations is true or false.

- (a) A larger volume of NaOH(aq) is needed to reach the equivalence point in the titration of  $\text{HNO}_3$ .
  - (b) The pH at the equivalence point in the  $\text{HNO}_3$  titration will be lower than the pH at the equivalence point in the  $\text{CH}_3\text{COOH}$  titration.
  - (c) Phenolphthalein would be a suitable indicator for both titrations.
- 17.36** Determine whether each of the following statements concerning the titrations in Problem 17.35 is true or false.
- (a) The pH at the beginning of the two titrations will be the same.
  - (b) The titration curves will both be essentially the same after passing the equivalence point.
  - (c) Methyl red would be a suitable indicator for both titrations.
- 17.37** Predict whether the equivalence point of each of the following titrations is below, above, or at pH 7: (a)  $\text{NaHCO}_3$  titrated with NaOH, (b)  $\text{NH}_3$  titrated with HCl, (c) KOH titrated with HBr.
- 17.38** Predict whether the equivalence point of each of the following titrations is below, above, or at pH 7: (a) formic acid titrated with NaOH, (b) calcium hydroxide titrated with perchloric acid, (c) pyridine titrated with nitric acid.
- 17.39** As shown in Figure 16.8, the indicator thymol blue has two color changes. Which color change will generally be more suitable for the titration of a weak acid with a strong base?
- 17.40** Assume that 30.0 mL of a 0.10 M solution of a weak base B that accepts one proton is titrated with a 0.10 M solution of the monoprotic strong acid HA. (a) How many moles of HA have been added at the equivalence point? (b) What is the predominant form of B at the equivalence point? (c) Is the pH 7, less than 7, or more than 7 at the equivalence point? (d) Which indicator, phenolphthalein or methyl red, is likely to be the better choice for this titration?
- 17.41** How many milliliters of 0.0850 M NaOH are required to titrate each of the following solutions to the equivalence point: (a) 40.0 mL of 0.0900 M  $\text{HNO}_3$ , (b) 35.0 mL of 0.0850 M  $\text{CH}_3\text{COOH}$ , (c) 50.0 mL of a solution that contains 1.85 g of HCl per liter?
- 17.42** How many milliliters of 0.105 M HCl are needed to titrate each of the following solutions to the equivalence point: (a) 45.0 mL of 0.0950 M NaOH, (b) 22.5 mL of 0.118 M  $\text{NH}_3$ , (c) 125.0 mL of a solution that contains 1.35 g of NaOH per liter?

- 17.43** A 20.0-mL sample of 0.200 M HBr solution is titrated with 0.200 M NaOH solution. Calculate the pH of the solution after the following volumes of base have been added: (a) 15.0 mL, (b) 19.9 mL, (c) 20.0 mL, (d) 20.1 mL, (e) 35.0 mL.
- 17.44** A 20.0-mL sample of 0.150 M KOH is titrated with 0.125 M  $\text{HClO}_4$  solution. Calculate the pH after the following volumes of acid have been added: (a) 20.0 mL, (b) 23.0 mL, (c) 24.0 mL, (d) 25.0 mL, (e) 30.0 mL.
- 17.45** A 35.0-mL sample of 0.150 M acetic acid ( $\text{CH}_3\text{COOH}$ ) is titrated with 0.150 M NaOH solution. Calculate the pH after the following volumes of base have been added: (a) 0 mL, (b) 17.5 mL, (c) 34.5 mL, (d) 35.0 mL, (e) 35.5 mL, (f) 50.0 mL.
- 17.46** Consider the titration of 30.0 mL of 0.050 M  $\text{NH}_3$  with 0.025 M HCl. Calculate the pH after the following volumes of titrant have been added: (a) 0 mL, (b) 20.0 mL, (c) 59.0 mL, (d) 60.0 mL, (e) 61.0 mL, (f) 65.0 mL.
- 17.47** Calculate the pH at the equivalence point for titrating 0.200 M solutions of each of the following bases with 0.200 M HBr: (a) sodium hydroxide (NaOH), (b) hydroxylamine ( $\text{NH}_2\text{OH}$ ), (c) aniline ( $\text{C}_6\text{H}_5\text{NH}_2$ ).
- 17.48** Calculate the pH at the equivalence point in titrating 0.100 M solutions of each of the following with 0.080 M NaOH: (a) hydrobromic acid (HBr), (b) chlorous acid ( $\text{HClO}_2$ ), (c) benzoic acid ( $\text{C}_6\text{H}_5\text{COOH}$ ).

## Solubility Equilibria and Factors Affecting Solubility (Sections 17.4 and 17.5)

- 17.49** For each statement, indicate whether it is true or false.
- (a) The solubility of a slightly soluble salt can be expressed in units of moles per liter.
  - (b) The solubility product of a slightly soluble salt is simply the square of the solubility.
  - (c) The solubility of a slightly soluble salt is independent of the presence of a common ion.
  - (d) The solubility product of a slightly soluble salt is independent of the presence of a common ion.
- 17.50** The solubility of two slightly soluble salts of  $\text{M}^{2+}$ , MA and  $\text{MZ}_2$ , is the same,  $4 \times 10^{-4}$  mol/L. (a) Which has the larger numerical value for the solubility product constant? (b) In a saturated solution of each salt in water, which has the higher concentration of  $\text{M}^{2+}$ ? (c) If you added an equal volume of a solution saturated in MA to one saturated in  $\text{MZ}_2$ , what would be the equilibrium concentration of the cation,  $\text{M}^{2+}$ ?
- 17.51** Write the expression for the solubility-product constant for each of the following ionic compounds: AgI,  $\text{SrSO}_4$ ,  $\text{Fe}(\text{OH})_2$ , and  $\text{Hg}_2\text{Br}_2$ .
- 17.52** (a) True or false: “solubility” and “solubility-product constant” are the same number for a given compound. (b) Write the expression for the solubility-product constant for each of the following ionic compounds:  $\text{MnCO}_3$ ,  $\text{Hg}(\text{OH})_2$ , and  $\text{Cu}_3(\text{PO}_4)_2$ .
- 17.53** (a) If the molar solubility of  $\text{CaF}_2$  at 35 °C is  $1.24 \times 10^{-3}$  mol/L, what is  $K_{sp}$  at this temperature? (b) It is found that  $1.1 \times 10^{-2}$  g  $\text{SrF}_2$  dissolves per 100 mL of aqueous solution at 25 °C. Calculate the solubility product for  $\text{SrF}_2$ . (c) The  $K_{sp}$  of  $\text{Ba}(\text{IO}_3)_2$  at 25 °C is  $6.0 \times 10^{-10}$ . What is the molar solubility of  $\text{Ba}(\text{IO}_3)_2$ ?
- 17.54** (a) The molar solubility of  $\text{PbBr}_2$  at 25 °C is  $1.0 \times 10^{-2}$  mol/L. Calculate  $K_{sp}$ . (b) If 0.0490 g of  $\text{AgIO}_3$  dissolves per liter of solution, calculate the solubility-product constant. (c) Using the appropriate  $K_{sp}$  value from Appendix D, calculate the pH of a saturated solution of  $\text{Ca}(\text{OH})_2$ .

- 17.55** A 1.00-L solution saturated at 25 °C with calcium oxalate ( $\text{CaC}_2\text{O}_4$ ) contains 0.0061 g of  $\text{CaC}_2\text{O}_4$ . Calculate the solubility-product constant for this salt at 25 °C.
- 17.56** A 1.00-L solution saturated at 25 °C with lead(II) iodide contains 0.54 g of  $\text{PbI}_2$ . Calculate the solubility-product constant for this salt at 25 °C.
- 17.57** Using Appendix D, calculate the molar solubility of  $\text{AgBr}$  in (a) pure water, (b)  $3.0 \times 10^{-2} \text{ M AgNO}_3$  solution, (c) 0.10 M  $\text{NaBr}$  solution.
- 17.58** Calculate the solubility of  $\text{LaF}_3$  in grams per liter in (a) pure water, (b) 0.010 M  $\text{KF}$  solution, (c) 0.050 M  $\text{LaCl}_3$  solution.
- 17.59** Consider a beaker containing a saturated solution of  $\text{CaF}_2$  in equilibrium with undissolved  $\text{CaF}_2(\text{s})$ . Solid  $\text{CaCl}_2$  is then added to the solution. (a) Will the amount of solid  $\text{CaF}_2$  at the bottom of the beaker increase, decrease, or remain the same? (b) Will the concentration of  $\text{Ca}^{2+}$  ions in solution increase or decrease? (c) Will the concentration of  $\text{F}^-$  ions in solution increase or decrease?
- 17.60** Consider a beaker containing a saturated solution of  $\text{PbI}_2$  in equilibrium with undissolved  $\text{PbI}_2(\text{s})$ . Now solid  $\text{KI}$  is added to this solution. (a) Will the amount of solid  $\text{PbI}_2$  at the bottom of the beaker increase, decrease, or remain the same? (b) Will the concentration of  $\text{Pb}^{2+}$  ions in solution increase or decrease? (c) Will the concentration of  $\text{I}^-$  ions in solution increase or decrease?
- 17.61** Calculate the solubility of  $\text{Mn}(\text{OH})_2$  in grams per liter when buffered at pH (a) 7.0, (b) 9.5, (c) 11.8.
- 17.62** Calculate the molar solubility of  $\text{Ni}(\text{OH})_2$  when buffered at pH (a) 8.0, (b) 10.0, (c) 12.0.
- 17.63** Which of the following salts will be substantially more soluble in acidic solution than in pure water: (a)  $\text{ZnCO}_3$ , (b)  $\text{ZnS}$ , (c)  $\text{BiI}_3$ , (d)  $\text{AgCN}$ , (e)  $\text{Ba}_3(\text{PO}_4)_2$ ?
- 17.64** For each of the following slightly soluble salts, write the net ionic equation, if any, for reaction with a strong acid: (a)  $\text{MnS}$ , (b)  $\text{PbF}_2$ , (c)  $\text{AuCl}_3$ , (d)  $\text{Hg}_2\text{C}_2\text{O}_4$ , (e)  $\text{CuBr}$ .
- 17.65** From the value of  $K_f$  listed in Table 17.1, calculate the concentration of  $\text{Ni}^{2+}(\text{aq})$  and  $\text{Ni}(\text{NH}_3)_6^{2+}$  that are present at equilibrium after dissolving 1.25 g  $\text{NiCl}_2$  in 100.0 mL of 0.20 M  $\text{NH}_3(\text{aq})$ .
- 17.66** From the value of  $K_f$  listed in Table 17.1, calculate the concentration of  $\text{NH}_3$  required to just dissolve 0.020 mol of  $\text{NiC}_2\text{O}_4$  ( $K_{sp} = 4 \times 10^{-10}$ ) in 1.00 L of solution? (Hint: You can neglect the hydrolysis of  $\text{C}_2\text{O}_4^{2-}$  because the solution will be quite basic.)
- 17.67** Use values of  $K_{sp}$  for  $\text{AgI}$  and  $K_f$  for  $\text{Ag}(\text{CN})_2^-$  to (a) calculate the molar solubility of  $\text{AgI}$  in pure water, (b) calculate the equilibrium constant for the reaction  $\text{AgI}(\text{s}) + 2 \text{CN}^-(\text{aq}) \rightleftharpoons \text{Ag}(\text{CN})_2^-(\text{aq}) + \text{I}^-(\text{aq})$ , (c) determine the molar solubility of  $\text{AgI}$  in a 0.100 M  $\text{NaCN}$  solution.
- 17.68** Using the value of  $K_{sp}$  for  $\text{Ag}_2\text{S}$ ,  $K_{a1}$  and  $K_{a2}$  for  $\text{H}_2\text{S}$ , and  $K_f = 1.1 \times 10^5$  for  $\text{AgCl}_2^-$ , calculate the equilibrium constant for the following reaction:

## Precipitation and Separation of Ions (Section 17.6)

- 17.69** (a) Will  $\text{Ca}(\text{OH})_2$  precipitate from solution if the pH of a 0.050 M solution of  $\text{CaCl}_2$  is adjusted to 8.0? (b) Will  $\text{Ag}_2\text{SO}_4$  precipitate when 100 mL of 0.050 M  $\text{AgNO}_3$  is mixed with 10 mL of  $5.0 \times 10^{-2} \text{ M Na}_2\text{SO}_4$  solution?
- 17.70** (a) Will  $\text{Co}(\text{OH})_2$  precipitate from solution if the pH of a 0.020 M solution of  $\text{Co}(\text{NO}_3)_2$  is adjusted to 8.5? (b) Will  $\text{AgIO}_3$  precipitate when 20 mL of 0.010 M  $\text{AgIO}_3$  is mixed with 10 mL of 0.015 M  $\text{NaIO}_3$ ? ( $K_{sp}$  of  $\text{AgIO}_3$  is  $3.1 \times 10^{-8}$ .)
- 17.71** Calculate the minimum pH needed to precipitate  $\text{Mn}(\text{OH})_2$  so completely that the concentration of  $\text{Mn}^{2+}(\text{aq})$  is less than 1  $\mu\text{g}$  per liter [1 part per billion (ppb)].
- 17.72** Suppose that a 10-mL sample of a solution is to be tested for  $\text{I}^-$  ion by addition of 1 drop (0.2 mL) of 0.10 M  $\text{Pb}(\text{NO}_3)_2$ . What is the minimum number of grams of  $\text{I}^-$  that must be present for  $\text{PbI}_2(\text{s})$  to form?
- 17.73** A solution contains  $2.0 \times 10^{-4} \text{ M Ag}^+(\text{aq})$  and  $1.5 \times 10^{-3} \text{ M Pb}^{2+}(\text{aq})$ . If  $\text{NaI}$  is added, will  $\text{AgI}$  ( $K_{sp} = 8.3 \times 10^{-17}$ ) or  $\text{PbI}_2$  ( $K_{sp} = 7.9 \times 10^{-9}$ ) precipitate first? Specify the concentration of  $\text{I}^-(\text{aq})$  needed to begin precipitation.
- 17.74** A solution of  $\text{Na}_2\text{SO}_4$  is added dropwise to a solution that is 0.010 M in  $\text{Ba}^{2+}(\text{aq})$  and 0.010 M in  $\text{Sr}^{2+}(\text{aq})$ . (a) What concentration of  $\text{SO}_4^{2-}$  is necessary to begin precipitation? (Neglect volume changes.  $\text{BaSO}_4$ :  $K_{sp} = 1.1 \times 10^{-10}$ ;  $\text{SrSO}_4$ :  $K_{sp} = 3.2 \times 10^{-7}$ .) (b) Which cation precipitates first? (c) What is the concentration of  $\text{SO}_4^{2-}(\text{aq})$  when the second cation begins to precipitate?
- 17.75** A solution contains three anions with the following concentrations: 0.20 M  $\text{CrO}_4^{2-}$ , 0.10 M  $\text{CO}_3^{2-}$ , and 0.010 M  $\text{Cl}^-$ . If a dilute  $\text{AgNO}_3$  solution is slowly added to the solution, what is the first compound to precipitate:  $\text{Ag}_2\text{CrO}_4$  ( $K_{sp} = 1.2 \times 10^{-12}$ ),  $\text{Ag}_2\text{CO}_3$  ( $K_{sp} = 8.1 \times 10^{-12}$ ), or  $\text{AgCl}$  ( $K_{sp} = 1.8 \times 10^{-10}$ )?
- 17.76** A 1.0 M  $\text{Na}_2\text{SO}_4$  solution is slowly added to 10.0 mL of a solution that is 0.20 M in  $\text{Ca}^{2+}$  and 0.30 M in  $\text{Ag}^+$ . (a) Which compound will precipitate first:  $\text{CaSO}_4$  ( $K_{sp} = 2.4 \times 10^{-5}$ ) or  $\text{Ag}_2\text{SO}_4$  ( $K_{sp} = 1.5 \times 10^{-5}$ )? (b) How much  $\text{Na}_2\text{SO}_4$  solution must be added to initiate the precipitation?

## Qualitative Analysis for Metallic Elements (Section 17.7)

- 17.77** A solution containing several metal ions is treated with dilute  $\text{HCl}$ ; no precipitate forms. The pH is adjusted to about 1, and  $\text{H}_2\text{S}$  is bubbled through. Again, no precipitate forms. The pH of the solution is then adjusted to about 8. Again,  $\text{H}_2\text{S}$  is bubbled through. This time a precipitate forms. The filtrate from this solution is treated with  $(\text{NH}_4)_2\text{HPO}_4$ . No precipitate forms. Which of these metal cations are either possibly present or definitely absent:  $\text{Al}^{3+}$ ,  $\text{Na}^+$ ,  $\text{Ag}^+$ ,  $\text{Mg}^{2+}$ ?
- 17.78** An unknown solid is entirely soluble in water. On addition of dilute  $\text{HCl}$ , a precipitate forms. After the precipitate is filtered off, the pH is adjusted to about 1 and  $\text{H}_2\text{S}$  is bubbled in; a precipitate again forms. After filtering off this precipitate, the pH is adjusted to 8 and  $\text{H}_2\text{S}$  is again added; no precipitate forms. No precipitate forms upon addition of  $(\text{NH}_4)_2\text{HPO}_4$ . The remaining solution shows a yellow color in a flame test (see Figure 7.22). Based on these observations, which of the following compounds might be present, which are definitely present, and which are definitely absent:  $\text{CdS}$ ,  $\text{Pb}(\text{NO}_3)_2$ ,  $\text{HgO}$ ,  $\text{ZnSO}_4$ ,  $\text{Cd}(\text{NO}_3)_2$ , and  $\text{Na}_2\text{SO}_4$ ?
- 17.79** In the course of various qualitative analysis procedures, the following mixtures are encountered: (a)  $\text{Zn}^{2+}$  and  $\text{Cd}^{2+}$ , (b)  $\text{Cr}(\text{OH})_3$  and  $\text{Fe}(\text{OH})_3$ , (c)  $\text{Mg}^{2+}$  and  $\text{K}^+$ , (d)  $\text{Ag}^+$  and  $\text{Mn}^{2+}$ . Suggest how each mixture might be separated.
- 17.80** Suggest how the cations in each of the following solution mixtures can be separated: (a)  $\text{Na}^+$  and  $\text{Cd}^{2+}$ , (b)  $\text{Cu}^{2+}$  and  $\text{Mg}^{2+}$ , (c)  $\text{Pb}^{2+}$  and  $\text{Al}^{3+}$ , (d)  $\text{Ag}^+$  and  $\text{Hg}^{2+}$ .

- 17.81** (a) Precipitation of the group 4 cations of Figure 17.23 requires a basic medium. Why is this so? (b) What is the most significant difference between the sulfides precipitated in group 2 and those precipitated in group 3? (c) Suggest a procedure that would serve to redissolve the group 3 cations following their precipitation.

## Additional Exercises

- 17.83** Derive an equation similar to the Henderson–Hasselbalch equation relating the pOH of a buffer to the  $pK_b$  of its base component.
- [17.84]** Rainwater is acidic because  $\text{CO}_2(\text{g})$  dissolves in the water, creating carbonic acid,  $\text{H}_2\text{CO}_3$ . If the rainwater is too acidic, it will react with limestone and seashells (which are principally made of calcium carbonate,  $\text{CaCO}_3$ ). Calculate the concentrations of carbonic acid, bicarbonate ion ( $\text{HCO}_3^-$ ) and carbonate ion ( $\text{CO}_3^{2-}$ ) that are in a raindrop that has a pH of 5.60, assuming that the sum of all three species in the raindrop is  $1.0 \times 10^{-5} \text{ M}$ .
- 17.85** Furoic acid ( $\text{HC}_5\text{H}_3\text{O}_3$ ) has a  $K_a$  value of  $6.76 \times 10^{-4}$  at  $25^\circ\text{C}$ . Calculate the pH at  $25^\circ\text{C}$  of (a) a solution formed by adding 25.0 g of furoic acid and 30.0 g of sodium furoate ( $\text{NaC}_5\text{H}_3\text{O}_3$ ) to enough water to form 0.250 L of solution, (b) a solution formed by mixing 30.0 mL of 0.250 M  $\text{HC}_5\text{H}_3\text{O}_3$  and 20.0 mL of 0.22 M  $\text{NaC}_5\text{H}_3\text{O}_3$  and diluting the total volume to 125 mL, (c) a solution prepared by adding 50.0 mL of 1.65 M NaOH solution to 0.500 L of 0.0850 M  $\text{HC}_5\text{H}_3\text{O}_3$ .
- 17.86** The acid–base indicator bromocresol green is a weak acid. The yellow acid and blue base forms of the indicator are present in equal concentrations in a solution when the pH is 4.68. What is the  $pK_a$  for bromocresol green?
- 17.87** Equal quantities of 0.010 M solutions of an acid HA and a base B are mixed. The pH of the resulting solution is 9.2. (a) Write the chemical equation and equilibrium-constant expression for the reaction between HA and B. (b) If  $K_a$  for HA is  $8.0 \times 10^{-5}$ , what is the value of the equilibrium constant for the reaction between HA and B? (c) What is the value of  $K_b$  for B?
- 17.88** Two buffers are prepared by adding an equal number of moles of formic acid ( $\text{HCOOH}$ ) and sodium formate ( $\text{HCOONa}$ ) to enough water to make 1.00 L of solution. Buffer A is prepared using 1.00 mol each of formic acid and sodium formate. Buffer B is prepared by using 0.010 mol of each. (a) Calculate the pH of each buffer. (b) Which buffer will have the greater buffer capacity? (c) Calculate the change in pH for each buffer upon the addition of 1.0 mL of 1.00 M HCl. (d) Calculate the change in pH for each buffer upon the addition of 10 mL of 1.00 M HCl.
- 17.89** A biochemist needs 750 mL of an acetic acid–sodium acetate buffer with pH 4.50. Solid sodium acetate ( $\text{CH}_3\text{COONa}$ ) and glacial acetic acid ( $\text{CH}_3\text{COOH}$ ) are available. Glacial acetic acid is 99%  $\text{CH}_3\text{COOH}$  by mass and has a density of 1.05 g/mL. If the buffer is to be 0.15 M in  $\text{CH}_3\text{COOH}$ , how many grams of  $\text{CH}_3\text{COONa}$  and how many milliliters of glacial acetic acid must be used?
- 17.90** A sample of 0.2140 g of an unknown monoprotic acid was dissolved in 25.0 mL of water and titrated with 0.0950 M NaOH. The acid required 30.0 mL of base to reach the equivalence point. (a) What is the molar mass of the acid? (b) After 15.0 mL of base had been added in the titration, the pH was found to be 6.50. What is the  $K_a$  for the unknown acid?
- 17.82** A student who is in a great hurry to finish his laboratory work decides that his qualitative analysis unknown contains a metal ion from group 4 of Figure 17.23. He therefore tests his sample directly with  $(\text{NH}_4)_2\text{HPO}_4$ , skipping earlier tests for the metal ions in groups 1, 2, and 3. He observes a precipitate and concludes that a metal ion from group 4 is indeed present. Why is this possibly an erroneous conclusion?
- 17.91** A sample of 0.1687 g of an unknown monoprotic acid was dissolved in 25.0 mL of water and titrated with 0.1150 M NaOH. The acid required 15.5 mL of base to reach the equivalence point. (a) What is the molar mass of the acid? (b) After 7.25 mL of base had been added in the titration, the pH was found to be 2.85. What is the  $K_a$  for the unknown acid?
- 17.92** Mathematically prove that the pH at the halfway point of a titration of a weak acid with a strong base (where the volume of added base is half of that needed to reach the equivalence point) is equal to  $pK_a$  for the acid.
- 17.93** A weak monoprotic acid is titrated with 0.100 M NaOH. It requires 50.0 mL of the NaOH solution to reach the equivalence point. After 25.0 mL of base is added, the pH of the solution is 3.62. Estimate the  $pK_a$  of the weak acid.
- 17.94** What is the pH of a solution made by mixing 0.30 mol NaOH, 0.25 mol  $\text{Na}_2\text{HPO}_4$ , and 0.20 mol  $\text{H}_3\text{PO}_4$  with water and diluting to 1.00 L?
- 17.95** Suppose you want to do a physiological experiment that calls for a pH 6.50 buffer. You find that the organism with which you are working is not sensitive to the weak acid  $\text{H}_2\text{A}$  ( $K_{a1} = 2 \times 10^{-2}$ ;  $K_{a2} = 5.0 \times 10^{-7}$ ) or its sodium salts. You have available a 1.0 M solution of this acid and a 1.0 M solution of NaOH. How much of the NaOH solution should be added to 1.0 L of the acid to give a buffer at pH 6.50? (Ignore any volume change.)
- 17.96** How many microliters of 1.000 M NaOH solution must be added to 25.00 mL of a 0.1000 M solution of lactic acid [ $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$  or  $\text{HC}_3\text{H}_5\text{O}_3$ ] to produce a buffer with  $\text{pH} = 3.75$ ?
- 17.97** Lead(II) carbonate,  $\text{PbCO}_3$ , is one of the components of the passivating layer that forms inside lead pipes. (a) If the  $K_{sp}$  for  $\text{PbCO}_3$  is  $7.4 \times 10^{-14}$  what is the molarity of  $\text{Pb}^{2+}$  in a saturated solution of lead(II) carbonate? (b) What is the concentration in ppb of  $\text{Pb}^{2+}$  ions in a saturated solution? (c) Will the solubility of  $\text{PbCO}_3$  increase or decrease as the pH is lowered? (d) The EPA threshold for acceptable levels of lead ions in water is 15 ppb. Does a saturated solution of lead(II) carbonate produce a solution that exceeds the EPA limit?
- 17.98** For each pair of compounds, use  $K_{sp}$  values to determine which has the greater molar solubility: (a) CdS or CuS, (b)  $\text{PbCO}_3$  or  $\text{BaCrO}_4$ , (c)  $\text{Ni}(\text{OH})_2$  or  $\text{NiCO}_3$ , (d) AgI or  $\text{Ag}_2\text{SO}_4$ .
- 17.99** The solubility of  $\text{CaCO}_3$  is pH dependent. (a) Calculate the molar solubility of  $\text{CaCO}_3$  ( $K_{sp} = 4.5 \times 10^{-9}$ ) neglecting the acid–base character of the carbonate ion. (b) Use the  $K_b$  expression for the  $\text{CO}_3^{2-}$  ion to determine the equilibrium constant for the reaction
- $$\text{CaCO}_3(\text{s}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{Ca}^{2+}(\text{aq}) + \text{HCO}_3^-(\text{aq}) + \text{OH}^-(\text{aq})$$
- (c) If we assume that the only sources of  $\text{Ca}^{2+}$ ,  $\text{HCO}_3^-$ , and  $\text{OH}^-$  ions are from the dissolution of  $\text{CaCO}_3$ , what is

the molar solubility of  $\text{CaCO}_3$  using the equilibrium expression from part (b)? (d) What is the molar solubility of  $\text{CaCO}_3$  at the pH of the ocean (8.3)? (e) If the pH is buffered at 7.5, what is the molar solubility of  $\text{CaCO}_3$ ?

- 17.100** Tooth enamel is composed of hydroxyapatite, whose simplest formula is  $\text{Ca}_5(\text{PO}_4)_3\text{OH}$ , and whose corresponding  $K_{sp} = 6.8 \times 10^{-27}$ . As discussed in the Chemistry and Life box on page 746, fluoride in fluorinated water or in toothpaste reacts with hydroxyapatite to form fluoroapatite,  $\text{Ca}_5(\text{PO}_4)_3\text{F}$ , whose  $K_{sp} = 1.0 \times 10^{-60}$ . (a) Write the expression for the solubility-constant for hydroxyapatite and for fluoroapatite. (b) Calculate the molar solubility of each of these compounds.
- 17.101** Salts containing the phosphate ion are added to municipal water supplies to prevent the corrosion of lead pipes. (a) Based on the  $\text{p}K_a$  values for phosphoric acid ( $\text{p}K_{a1} = 7.5 \times 10^{-3}$ ,  $\text{p}K_{a2} = 6.2 \times 10^{-8}$ ,  $\text{p}K_{a3} = 4.2 \times 10^{-13}$ ) what is the  $K_b$  value for the  $\text{PO}_4^{3-}$  ion? (b) What is the pH of a  $1 \times 10^{-3} M$  solution of  $\text{Na}_3\text{PO}_4$  (you can ignore the formation of  $\text{H}_2\text{PO}_4^-$  and  $\text{H}_3\text{PO}_4$ )?
- 17.102** Calculate the solubility of  $\text{Mg}(\text{OH})_2$  in  $0.50 M \text{NH}_4\text{Cl}$ .
- 17.103** The solubility-product constant for barium permanganate,  $\text{Ba}(\text{MnO}_4)_2$ , is  $2.5 \times 10^{-10}$ . Assume that solid  $\text{Ba}(\text{MnO}_4)_2$  is in equilibrium with a solution of  $\text{KMnO}_4$ . What concentration of  $\text{KMnO}_4$  is required to establish a concentration of  $2.0 \times 10^{-8} M$  for the  $\text{Ba}^{2+}$  ion in solution?
- 17.104** Calculate the ratio of  $[\text{Ca}^{2+}]$  to  $[\text{Fe}^{2+}]$  in a lake in which the water is in equilibrium with deposits of both  $\text{CaCO}_3$

and  $\text{FeCO}_3$ . Assume that the water is slightly basic and that the hydrolysis of the carbonate ion can therefore be ignored.

- 17.105** The solubility product constants of  $\text{PbSO}_4$  and  $\text{SrSO}_4$  are  $6.3 \times 10^{-7}$  and  $3.2 \times 10^{-7}$ , respectively. What are the values of  $[\text{SO}_4^{2-}]$ ,  $[\text{Pb}^{2+}]$ , and  $[\text{Sr}^{2+}]$  in a solution at equilibrium with both substances?
- 17.106** A buffer of what pH is needed to give a  $\text{Mg}^{2+}$  concentration of  $3.0 \times 10^{-2} M$  in equilibrium with solid magnesium oxalate?
- 17.107** The value of  $K_{sp}$  for  $\text{Mg}_3(\text{AsO}_4)_2$  is  $2.1 \times 10^{-20}$ . The  $\text{AsO}_4^{3-}$  ion is derived from the weak acid  $\text{H}_3\text{AsO}_4$  ( $\text{p}K_{a1} = 2.22$ ;  $\text{p}K_{a2} = 6.98$ ;  $\text{p}K_{a3} = 11.50$ ). (a) Calculate the molar solubility of  $\text{Mg}_3(\text{AsO}_4)_2$  in water. (b) Calculate the pH of a saturated solution of  $\text{Mg}_3(\text{AsO}_4)_2$  in water.
- 17.108** The solubility product for  $\text{Zn}(\text{OH})_2$  is  $3.0 \times 10^{-16}$ . The formation constant for the hydroxo complex,  $\text{Zn}(\text{OH})_4^{2-}$ , is  $4.6 \times 10^{17}$ . What concentration of  $\text{OH}^-$  is required to dissolve  $0.015 \text{ mol}$  of  $\text{Zn}(\text{OH})_2$  in a liter of solution?
- 17.109** The value of  $K_{sp}$  for  $\text{Cd}(\text{OH})_2$  is  $2.5 \times 10^{-14}$ . (a) What is the molar solubility of  $\text{Cd}(\text{OH})_2$ ? (b) The solubility of  $\text{Cd}(\text{OH})_2$  can be increased through formation of the complex ion  $\text{CdBr}_4^{2-}$  ( $K_f = 5 \times 10^3$ ). If solid  $\text{Cd}(\text{OH})_2$  is added to a  $\text{NaBr}$  solution, what is the initial concentration of  $\text{NaBr}$  needed to increase the molar solubility of  $\text{Cd}(\text{OH})_2$  to  $1.0 \times 10^{-3} \text{ mol/L}$ ?

## Integrative Exercises

- 17.110** (a) Write the net ionic equation for the reaction that occurs when a solution of hydrochloric acid ( $\text{HCl}$ ) is mixed with a solution of sodium formate ( $\text{NaCHO}_2$ ). (b) Calculate the equilibrium constant for this reaction. (c) Calculate the equilibrium concentrations of  $\text{Na}^+$ ,  $\text{Cl}^-$ ,  $\text{H}^+$ ,  $\text{CHO}_2^-$ , and  $\text{HCHO}_2$  when  $50.0 \text{ mL}$  of  $0.15 M \text{HCl}$  is mixed with  $50.0 \text{ mL}$  of  $0.15 M \text{NaCHO}_2$ .
- 17.111** (a) A  $0.1044\text{-g}$  sample of an unknown monoprotic acid requires  $22.10 \text{ mL}$  of  $0.0500 M \text{NaOH}$  to reach the end point. What is the molar mass of the unknown? (b) As the acid is titrated, the pH of the solution after the addition of  $11.05 \text{ mL}$  of the base is  $4.89$ . What is the  $K_a$  for the acid? (c) Using Appendix D, suggest the identity of the acid.
- 17.112** A sample of  $7.5 \text{ L}$  of  $\text{NH}_3$  gas at  $22^\circ\text{C}$  and  $735 \text{ torr}$  is bubbled into a  $0.50\text{-L}$  solution of  $0.40 M \text{HCl}$ . Assuming that all the  $\text{NH}_3$  dissolves and that the volume of the solution remains  $0.50 \text{ L}$ , calculate the pH of the resulting solution.
- 17.113** Aspirin has the structural formula

At body temperature ( $37^\circ\text{C}$ ),  $K_a$  for aspirin equals  $3 \times 10^{-5}$ . If two aspirin tablets, each having a mass of  $325 \text{ mg}$ , are dissolved in a full stomach whose volume is  $1 \text{ L}$  and whose pH is  $2$ , what percent of the aspirin is in the form of neutral molecules?

- 17.114** What is the pH at  $25^\circ\text{C}$  of water saturated with  $\text{CO}_2$  at a partial pressure of  $1.10 \text{ atm}$ ? The Henry's law constant for  $\text{CO}_2$  at  $25^\circ\text{C}$  is  $3.1 \times 10^{-2} \text{ mol/L}\cdot\text{atm}$ .
- 17.115** Excess  $\text{Ca}(\text{OH})_2$  is shaken with water to produce a saturated solution. The solution is filtered, and a  $50.00\text{-mL}$  sample titrated with  $\text{HCl}$  requires  $11.23 \text{ mL}$  of  $0.0983 M \text{HCl}$  to reach the end point. Calculate  $K_{sp}$  for  $\text{Ca}(\text{OH})_2$ . Compare your result with that in Appendix D. Suggest a reason for any differences you find between your value and the one in Appendix D.
- 17.116** The osmotic pressure of a saturated solution of strontium sulfate at  $25^\circ\text{C}$  is  $21 \text{ torr}$ . What is the solubility product of this salt at  $25^\circ\text{C}$ ?
- 17.117** A concentration of  $10\text{--}100$  parts per billion (by mass) of  $\text{Ag}^+$  is an effective disinfectant in swimming pools. However, if the concentration exceeds this range, the  $\text{Ag}^+$  can cause adverse health effects. One way to maintain an appropriate concentration of  $\text{Ag}^+$  is to add a slightly soluble salt to the pool. Using  $K_{sp}$  values from Appendix D, calculate the equilibrium concentration of  $\text{Ag}^+$  in parts per billion that would exist in equilibrium with (a)  $\text{AgCl}$ , (b)  $\text{AgBr}$ , (c)  $\text{AgI}$ .
- 17.118** Fluoridation of drinking water is employed in many places to aid in the prevention of tooth decay. Typically, the  $\text{F}^-$  ion concentration is adjusted to about  $1 \text{ ppm}$ . Some water supplies are also "hard"; that is, they contain certain cations such as  $\text{Ca}^{2+}$  that interfere with the action of soap. Consider a case where the concentration of  $\text{Ca}^{2+}$  is  $8 \text{ ppm}$ . Could a precipitate of  $\text{CaF}_2$  form under these conditions? (Make any necessary approximations.)
- 17.119** Baking soda (sodium bicarbonate,  $\text{NaHCO}_3$ ) reacts with acids in foods to form carbonic acid ( $\text{H}_2\text{CO}_3$ ), which in turn decomposes to water and carbon dioxide gas. In a

cake batter, the  $\text{CO}_2(\text{g})$  forms bubbles and causes the cake to rise. **(a)** A rule of thumb in baking is that 1/2 teaspoon of baking soda is neutralized by one cup of sour milk. The acid component in sour milk is lactic acid,  $\text{CH}_3\text{CH}(\text{OH})\text{COOH}$ . Write the chemical equation for this neutralization reaction. **(b)** The density of baking soda is  $2.16 \text{ g/cm}^3$ . Calculate the concentration of lactic acid in one cup of sour milk (assuming the rule of thumb applies), in units of mol/L. (One cup =  $236.6 \text{ mL} = 48$  teaspoons). **(c)** If 1/2 teaspoon of baking soda is indeed completely neutralized by the

lactic acid in sour milk, calculate the volume of carbon dioxide gas that would be produced at 1 atm pressure, in an oven set to  $350^\circ\text{F}$ .

- 17.120** In nonaqueous solvents, it is possible to react HF to create  $\text{H}_2\text{F}^+$ . Which of these statements follows from this observation? **(a)** HF can act like a strong acid in nonaqueous solvents, **(b)** HF can act like a base in nonaqueous solvents, **(c)** HF is thermodynamically unstable, **(d)** There is an acid in the nonaqueous medium that is a stronger acid than HF.

## Design an Experiment

You are cleaning up an old chemistry lab and find a glass bottle labeled “ $6.00 \text{ M NaOH}$ .” The bottle looks like it holds about  $5 \text{ mL}$  of solution. However, it is possible that sodium hydroxide, over a long period of time, has reacted with glass ( $\text{SiO}_2$ ). It is also possible that the bottle was not well sealed, and some water evaporated.

Design an experiment to determine the concentration of the  $\text{NaOH}$ , using a very small amount from the bottle (less than  $1 \text{ mL}$ ). Consider that you have unlimited water available, a stock solution of  $2.00 \text{ M HCl}$ , and any pH indicators you need. Also consider that your equipment only allows you to measure volumes to the nearest  $\text{mL}$ .

# CHEMISTRY OF THE ENVIRONMENT

The richness of life on Earth, represented in the chapter-opening photograph, is made possible by our planet's supportive atmosphere, the energy received from the Sun, and an abundance of water. These are the signature environmental features believed to be necessary for life.

As technology has advanced and human population has increased, humans have put new and greater stresses on the environment. Paradoxically, the very technology that enables population growth also provides the tools to help understand and manage the environment in a beneficial way. Chemistry is often at the heart of environmental issues. The economic growth of both developed and developing nations depends critically on chemical processes that range from treatment of water supplies to the extraction of fossil fuels. Some of these processes produce products or by-products that are harmful to the environment.

We are now in a position to apply the principles we have learned in preceding chapters to an understanding of how our environment operates and how human activities affect it. To understand and protect the environment in which we live, we must understand how human-made and natural chemical compounds interact on land and in the sea and sky. Our daily actions as consumers turn on the same choices made by leading experts and governmental leaders: Each decision should reflect the costs versus the benefits of our choices. Unfortunately, the environmental impacts of our decisions are often subtle and not immediately evident.

◀ **THE OKAVANGO DELTA IN BOTSWANA** is formed when water from the Okavango River floods a large area of the Kalahari desert. In Botswana's winter months, the size of the delta swells to more than three times its normal size attracting a wide variety of animals.

## WHAT'S AHEAD

- 18.1** ▶ **Earth's Atmosphere** Investigate the temperature profile, pressure profile, and chemical composition of Earth's atmosphere. Examine *photoionization* and *photodissociation*, reactions that result from atmospheric absorption of solar radiation.
- 18.2** ▶ **Human Activities and Earth's Atmosphere** Consider the effect human activities have on the atmosphere, including how atmospheric ozone is depleted by reactions involving human-made gases and how acid rain and smog are produced.
- 18.3** ▶ **Earth's Water** Examine the global water cycle, which describes how water moves from the ground to the surface to the atmosphere and back into the ground. We compare the chemical compositions of *seawater*, *freshwater*, and *groundwater*.
- 18.4** ▶ **Human Activities and Water Quality** Consider the relationship between Earth's water and its climate and examine one measure of water quality: dissolved oxygen concentration. Water for drinking and for irrigation must be free of salts and pollutants.
- 18.5** ▶ **Green Chemistry** Become familiar with *green chemistry*, an international initiative to make industrial products, processes, and chemical reactions compatible with a sustainable society and environment.

## 18.1 | Earth's Atmosphere

Because most of us have never been very far from Earth's surface, we often take for granted the many ways in which the atmosphere determines the environment in which we live. In this section we examine some of the important characteristics of our planet's atmosphere.

The temperature of the atmosphere varies with altitude (Figure 18.1), and the atmosphere is divided into four regions based on this temperature profile. Just above the surface, in the **troposphere**, the temperature normally decreases with increasing altitude, reaching a minimum of about 215 K at about 10 km. Nearly all of us live our entire lives in the troposphere. Howling winds and soft breezes, rain, and sunny skies—all that we normally think of as “weather”—occur in this region. Commercial jet aircraft typically fly about 10 km (33,000 ft) above Earth, an altitude that defines the upper limit of the troposphere, which we call the *tropopause*.

Above the tropopause, air temperature increases with altitude, reaching a maximum of about 275 K at about 50 km. The region from 10 km to 50 km is the **stratosphere**, and above it are the *mesosphere* and *thermosphere*. Notice in Figure 18.1 that the temperature extremes that form the boundaries between adjacent regions are denoted by the suffix *-pause*. The boundaries are important because gases mix across them relatively slowly. For example, pollutant gases generated in the troposphere pass through the tropopause and find their way into the stratosphere only very slowly.

### Go Figure

At what altitude is the atmospheric temperature lowest?

▲ **Figure 18.1** Temperature and pressure in the atmosphere vary as a function of altitude above sea level.

Atmospheric pressure decreases with increasing elevation (Figure 18.1), declining much more rapidly at lower elevations than at higher ones because of the atmosphere's compressibility. Thus, the pressure decreases from an average value of 760 torr at sea level to  $2.3 \times 10^{-3}$  torr at 100 km, to only  $1.0 \times 10^{-6}$  torr at 200 km.

The troposphere and stratosphere together account for 99.9% of the mass of the atmosphere, 75% of which is the mass in the troposphere. Nevertheless, the thin upper atmosphere plays many important roles in determining the conditions of life at the surface.

## Composition of the Atmosphere

Earth's atmosphere is constantly bombarded by radiation and energetic particles from the Sun. This barrage of energy has profound chemical and physical effects, especially in the upper regions of the atmosphere, above about 80 km (Figure 18.2). In addition, because of Earth's gravitational field, heavier atoms and molecules tend to sink in the atmosphere, leaving lighter atoms and molecules at the top of the atmosphere. (This is why, as just noted, 75% of the atmosphere's mass is in the troposphere.) Because of all these factors, the composition of the atmosphere is not uniform.

Table 18.1 shows the composition of dry air near sea level. Note that although traces of many substances are present,  $\text{N}_2$  and  $\text{O}_2$  make up about 99% of sea-level air. The noble gases and  $\text{CO}_2$  make up most of the remainder.

### Give It Some Thought

Would you expect the ratio of atmospheric helium to argon to be larger in the troposphere or the mesosphere?

When applied to substances in aqueous solution, the concentration unit *parts per million* (ppm) refers to grams of substance per million grams of solution. (Section 13.4) When dealing with gases, however, 1 ppm means one part by *volume* in 1 million volumes of the whole. Because volume is proportional to number of moles of gas via the ideal-gas equation ( $PV = nRT$ ), volume fraction and mole fraction are the same. Thus, 1 ppm of a trace constituent of the atmosphere amounts to 1 mol of that constituent in 1 million moles of air; that is, the concentration in parts per million is equal to the mole fraction times  $10^6$ . For example, Table 18.1 lists the mole fraction of  $\text{CO}_2$  in the atmosphere as 0.000400, which means its concentration in parts per million is  $0.000400 \times 10^6 = 400$  ppm.

**TABLE 18.1 The Major Components of Dry Air near Sea Level**

| Component*     | Content (mole fraction) | Molar Mass (g/mol) |
|----------------|-------------------------|--------------------|
| Nitrogen       | 0.78084                 | 28.013             |
| Oxygen         | 0.20948                 | 31.998             |
| Argon          | 0.00934                 | 39.948             |
| Carbon dioxide | 0.000400                | 44.0099            |
| Neon           | 0.00001818              | 20.183             |
| Helium         | 0.00000524              | 4.003              |
| Methane        | 0.000002                | 16.043             |
| Krypton        | 0.00000114              | 83.80              |
| Hydrogen       | 0.0000005               | 2.0159             |
| Nitrous oxide  | 0.0000005               | 44.0128            |
| Xenon          | 0.000000087             | 131.30             |

\*Ozone, sulfur dioxide, nitrogen dioxide, ammonia, and carbon monoxide are present as trace gases in variable amounts.

**▲ Figure 18.2** The aurora borealis (northern lights).

**TABLE 18.2 Sources and Typical Concentrations of Some Minor Atmospheric Constituents**

| Constituent                     | Sources  | Typical Concentration   |
|---------------------------------|--|---|
| Carbon dioxide, CO <sub>2</sub> | Decomposition of organic matter, release from oceans, fossil fuel combustion                 | 400 ppm throughout troposphere                                  |
| Carbon monoxide, CO             | Decomposition of organic matter, industrial processes, fossil fuel combustion                | 0.05 ppm in unpolluted air; 1–50 ppm in urban areas             |
| Methane, CH <sub>4</sub>        | Decomposition of organic matter, natural-gas seepage, livestock emissions                    | 1.82 ppm throughout troposphere                                 |
| Nitric oxide, NO                | Atmospheric electrical discharges, internal combustion engines, combustion of organic matter | 0.01 ppm in unpolluted air; 0.2 ppm in smog                     |
| Ozone, O <sub>3</sub>           | Atmospheric electrical discharges, diffusion from the stratosphere, photochemical smog       | 0–0.01 ppm in unpolluted air; 0.5 ppm in photochemical smog     |
| Sulfur dioxide, SO <sub>2</sub> | Volcanic gases, forest fires, bacterial action, fossil fuel combustion, industrial processes | 0–0.01 ppm in unpolluted air; 0.1–2 ppm in polluted urban areas |

Other minor constituents of the troposphere, in addition to CO<sub>2</sub>, are listed in [Table 18.2](#).

Before we consider the chemical processes that occur in the atmosphere, let's review some of the properties of the two major components, N<sub>2</sub> and O<sub>2</sub>. Recall that the N<sub>2</sub> molecule possesses a triple bond between the nitrogen atoms.  (Section 8.3) This very strong bond (bond energy 941 kJ/mol) is largely responsible for the very low reactivity of N<sub>2</sub>. The bond energy in O<sub>2</sub> is only 495 kJ/mol, making O<sub>2</sub> much more reactive than N<sub>2</sub>. For example, oxygen reacts with many substances to form oxides.

### Sample Exercise 18.1

#### Calculating Concentration from Partial Pressure

What is the concentration, in parts per million, of water vapor in a sample of air if the partial pressure of the water is 0.80 torr and the total pressure of the air is 735 torr?

#### SOLUTION

**Analyze** We are given the partial pressure of water vapor and the total pressure of an air sample and asked to determine the water vapor concentration.

**Plan** Recall that the partial pressure of a component in a mixture of gases is given by the product of its mole fraction and the total pressure of the mixture  (Section 10.6):

$$P_{\text{H}_2\text{O}} = X_{\text{H}_2\text{O}} P_t$$

**Solve** Solving for the mole fraction of water vapor in the mixture,  $X_{\text{H}_2\text{O}}$ , gives

$$X_{\text{H}_2\text{O}} = \frac{P_{\text{H}_2\text{O}}}{P_t} = \frac{0.80 \text{ torr}}{735 \text{ torr}} = 0.0011$$

The concentration in ppm is the mole fraction times 10<sup>6</sup>:

$$0.0011 \times 10^6 = 1100 \text{ ppm}$$

#### Practice Exercise 1

From the data in Table 18.1, the partial pressure of argon in dry air at an atmospheric pressure of 668 mm Hg is (a) 3.12 mm Hg, (b) 7.09 mm Hg, (c) 6.24 mm Hg, (d) 9.34 mm Hg, (e) 39.9 mm Hg.

#### Practice Exercise 2

The concentration of CO in a sample of air is 4.3 ppm. What is the partial pressure of the CO if the total air pressure is 695 torr?

## Photochemical Reactions in the Atmosphere

Although the atmosphere beyond the stratosphere contains only a small fraction of the atmospheric mass, it forms the outer defense against the hail of radiation and high-energy particles that continuously bombard Earth. As the bombarding radiation passes through the upper atmosphere, it causes two kinds of chemical changes: *photodissociation* and *photoionization*. These processes protect us from high-energy radiation by absorbing most of the radiation before it reaches the troposphere. If it were not for these photochemical processes, plant and animal life as we know it could not exist on Earth.

## Go Figure

Why doesn't the solar spectrum at sea level perfectly match the solar spectrum outside the atmosphere?

▲ **Figure 18.3** The solar spectrum above Earth's atmosphere compared to that at sea level.

The more structured curve at sea level is due to gases in the atmosphere absorbing specific wavelengths of light. "Flux," the unit on the vertical axis, is light energy per area per unit of time.

The Sun emits radiant energy over a wide range of wavelengths (Figure 18.3). To understand the connection between the wavelength of radiation and its effect on atoms and molecules, recall that electromagnetic radiation can be pictured as a stream of photons. ∞ (Section 6.2) The energy of each photon is given by  $E = h\nu$ , where  $h$  is Planck constant and  $\nu$  is the radiation frequency. For a chemical change to occur when radiation strikes atoms or molecules, two conditions must be met. First, the incoming photons must have sufficient energy to break a chemical bond or remove an electron from the atom or molecule. Second, the atoms or molecules being bombarded must absorb these photons. When these requirements are met, the energy of the photons is used to do the work associated with some chemical change.

**Photodissociation** The rupture of a chemical bond resulting from absorption of a photon by a molecule is called **photodissociation**. No ions are formed when the bond between two atoms is cleaved by photodissociation. Instead, half the bonding electrons stay with one atom and half stay with the other atom. The result is two electrically neutral particles.

One of the most important processes occurring above an altitude of about 120 km is photodissociation of the oxygen molecule:

The minimum energy required to cause this change is determined by the bond energy (or *dissociation energy*) of  $\text{O}_2$ , 495 kJ/mol.

## Sample Exercise 18.2

## Calculating the Wavelength Required to Break a Bond

What is the maximum wavelength of light, in nanometers, that has enough energy per photon to dissociate the  $\text{O}_2$  molecule?

## SOLUTION

**Analyze** We are asked to determine the wavelength of a photon that has just enough energy to break the  $\text{O}=\text{O}$  double bond in  $\text{O}_2$ .

**Plan** We first need to calculate the energy required to break the  $\text{O}=\text{O}$  double bond in one molecule and then find the wavelength of a photon of this energy.

## Solve

The dissociation energy of  $\text{O}_2$  is 495 kJ/mol. Using this value and Avogadro's number, we can calculate the amount of energy needed to break the bond in a single  $\text{O}_2$  molecule:

$$\begin{aligned} & \left( 495 \times 10^3 \frac{\text{J}}{\text{mol}} \right) \left( \frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ molecules}} \right) \\ &= 8.22 \times 10^{-19} \frac{\text{J}}{\text{molecule}} \end{aligned}$$

Continued

We next use the Planck relationship,  $E = h\nu$ , (Equation 6.2) to calculate the frequency  $\nu$  of a photon that has this amount of energy:

$$\nu = \frac{E}{h} = \frac{8.22 \times 10^{-19} \text{ J}}{6.626 \times 10^{-34} \text{ J}\cdot\text{s}} = 1.24 \times 10^{15} \text{ s}^{-1}$$

Finally, we use the relationship between frequency and wavelength (Section 6.1) to calculate the wavelength of the light:

$$\lambda = \frac{c}{\nu} = \left( \frac{3.00 \times 10^8 \text{ m/s}}{1.24 \times 10^{15} / \text{s}} \right) \left( \frac{10^9 \text{ nm}}{1 \text{ m}} \right) = 242 \text{ nm}$$

**Comment** Thus, light of wavelength 242 nm, which is in the ultraviolet region of the electromagnetic spectrum, has sufficient energy per photon to photodissociate an  $\text{O}_2$  molecule. Because photon energy increases as wavelength *decreases*, any photon of wavelength *shorter* than 242 nm will have sufficient energy to dissociate  $\text{O}_2$ .

#### Practice Exercise 1

The bond dissociation energy of the Br—Br bond is 193 kJ/mol. What wavelength of light has just enough energy to cause Br—Br bond dissociation?

(a) 620 nm (b) 310 nm (c) 148 nm (d) 6200 nm (e) 563 nm

#### Practice Exercise 2

The bond energy in  $\text{N}_2$  is 941 kJ/mol. What is the longest wavelength a photon can have and still have sufficient energy to dissociate  $\text{N}_2$ ?

Fortunately for us,  $\text{O}_2$  absorbs much of the high-energy, short-wavelength radiation from the solar spectrum before that radiation reaches the lower atmosphere. As it does, atomic oxygen, O, is formed. The dissociation of  $\text{O}_2$  is very extensive at higher elevations. At 400 km, for example, only 1% of the oxygen is in the form of  $\text{O}_2$ ; 99% is atomic oxygen. At 130 km,  $\text{O}_2$  and atomic oxygen are just about equally abundant. Below 130 km,  $\text{O}_2$  is more abundant than atomic oxygen because most of the solar energy has been absorbed in the upper atmosphere.

The dissociation energy of  $\text{N}_2$  is very high, 941 kJ/mol. As you should have seen in working out Practice Exercise 2 of Sample Exercise 18.2, only photons having a wavelength shorter than 127 nm possess sufficient energy to dissociate  $\text{N}_2$ . Furthermore,  $\text{N}_2$  does not readily absorb photons, even when they possess sufficient energy. As a result, very little atomic nitrogen is formed in the upper atmosphere by photodissociation of  $\text{N}_2$ .

**Photoionization** Other photochemical processes besides photodissociation occur in the upper atmosphere, although their discovery has taken many twists and turns. In 1901, Guglielmo Marconi received a radio signal in St. John's, Newfoundland, that had been transmitted from Land's End, England, 2900 km away. Because people at the time thought radio waves traveled in straight lines, they assumed that the curvature of Earth's surface would make radio communication over large distances impossible. Marconi's successful experiment suggested that Earth's atmosphere in some way substantially affects radio-wave propagation. His discovery led to intensive study of the upper atmosphere. In about 1924, the existence of electrons in the upper atmosphere was established by experimental studies.

The electrons in the upper atmosphere result mainly from **photoionization**, which occurs when a molecule in the upper atmosphere absorbs solar radiation and the absorbed energy causes an electron to be ejected from the molecule. The molecule then becomes a positively charged ion. For photoionization to occur, therefore, a molecule must absorb a photon, and the photon must have enough energy to remove an electron. (Section 7.4) Notice that this is a very different process from photodissociation.

Four important photoionization processes occurring in the atmosphere above about 90 km are shown in Table 18.3. Photons of any wavelength shorter than the maximum lengths given in the table have enough energy to cause photoionization. A look back at Figure 18.3 shows you that virtually all of these high-energy photons are filtered out of the radiation reaching Earth because they are absorbed by the upper atmosphere.

#### Give It Some Thought

Does photoionization lead to the formation of a cation or an anion? Does photoionization lead to bond breaking?

**TABLE 18.3 Photoionization Reactions for Four Components of the Atmosphere**

| Process  | Ionization Energy (kJ/mol) | $\lambda_{\text{max}}$ (nm) |
|--|----------------------------|-----------------------------|
| $\text{N}_2 + h\nu \longrightarrow \text{N}_2^+ + e^-$ | 1495                       | 80.1                        |
| $\text{O}_2 + h\nu \longrightarrow \text{O}_2^+ + e^-$ | 1205                       | 99.3                        |
| $\text{O} + h\nu \longrightarrow \text{O}^+ + e^-$     | 1313                       | 91.2                        |
| $\text{NO} + h\nu \longrightarrow \text{NO}^+ + e^-$   | 890                        | 134.5                       |

## Ozone in the Stratosphere

Although  $\text{N}_2$ ,  $\text{O}_2$ , and atomic oxygen absorb photons having wavelengths shorter than 240 nm, ozone,  $\text{O}_3$ , is the key absorber of photons whose wavelengths range from 240 to 310 nm, in the ultraviolet region of the electromagnetic spectrum, as illustrated in **Figure 18.4**. Ozone in the upper atmosphere protects us from these harmful high-energy photons, which would otherwise penetrate to Earth's surface. Let's consider how ozone forms in the upper atmosphere and how it absorbs photons.

By the time radiation from the Sun reaches an altitude of 90 km above Earth's surface, most of the short-wavelength radiation capable of photoionization has been absorbed. Nevertheless, radiation capable of dissociating the  $\text{O}_2$  molecule is sufficiently intense for photodissociation of  $\text{O}_2$  (Equation 18.1) to remain important down to an altitude of 30 km. In the region between 30 and 90 km, the concentration of  $\text{O}_2$  is much greater than the concentration of atomic oxygen. Consequently, the oxygen atoms formed by photodissociation of  $\text{O}_2$  in this region frequently collide with  $\text{O}_2$  molecules and form ozone:

The asterisk on  $\text{O}_3^*$  denotes that the product contains an excess of energy, because the reaction is exothermic. The 105 kJ/mol that is released must be transferred away from the  $\text{O}_3^*$  molecule quickly or else the molecule will fly apart into  $\text{O}_2$  and atomic O—a decomposition that is the reverse of the reaction by which  $\text{O}_3^*$  is formed.

An energy-rich  $\text{O}_3^*$  molecule can release its excess energy by colliding with another atom or molecule and transferring some of the excess energy to it. Let's use M to represent the atom or molecule with which  $\text{O}_3^*$  collides. (Usually, M is  $\text{N}_2$  or  $\text{O}_2$  because these are the most abundant molecules in the atmosphere.) The formation of  $\text{O}_3^*$  and the transfer of excess energy to M are summarized by the equations

The rate at which the reactions of Equations 18.3 and 18.4 proceed depends on two factors that vary in opposite directions with increasing altitude. First, the formation of  $\text{O}_3^*$  (Equation 18.3) depends on the presence of O atoms. At low altitudes, most of the radiation energetic enough to dissociate  $\text{O}_2$  molecules into O atoms has been absorbed; thus, O atoms are not very plentiful at low altitudes. Second, Equations 18.3 and 18.4 both depend on molecular collisions.  $\infty$  (Section 14.5) The concentration of molecules is greater at low altitudes, and so the rates of both reactions are greater at lower altitudes. Because these two effects vary with altitude in opposite directions, the highest rate of  $\text{O}_3$  formation occurs in a band at an altitude of about 50 km, near the stratopause (Figure 18.1). Overall, roughly 90% of Earth's ozone is found in the stratosphere.

The photodissociation of ozone reverses the reaction that forms it. We thus have a cycle of ozone formation and decomposition, summarized on the next page:

## Go Figure

In what region of the electromagnetic spectrum does ozone most strongly absorb light: (a) IR, (b) visible, or (c) UV?

▲ **Figure 18.4** The absorption spectrum of ozone.

### Go Figure

Estimate the ozone concentration in moles per liter for the peak value in this graph.

▲ **Figure 18.5** Variation in ozone concentration in the atmosphere as a function of altitude.

The first and third processes are photochemical; they use a solar photon to initiate a chemical reaction. The second and fourth are exothermic chemical reactions. The net result of the four reactions is a cycle in which solar radiant energy is converted into thermal energy. The ozone cycle in the stratosphere is responsible for the rise in temperature that reaches its maximum at the strato-pause (Figure 18.1).

### Give It Some Thought

Based on its Lewis structure, which molecule will have stronger oxygen-oxygen bonds,  $\text{O}_2$  or  $\text{O}_3$ ?

The reactions of the ozone cycle account for some, but not all, of the facts about the ozone layer. Many chemical reactions occur that involve substances other than oxygen. We must also consider the effects of turbulence and winds that mix up the stratosphere. A complicated picture results. The overall result of ozone formation and removal reactions, coupled with atmospheric turbulence and other factors, is to produce the upper-atmosphere ozone profile shown in **Figure 18.5**, with a maximum ozone concentration occurring at an altitude of about 25 km. This band of relatively high ozone concentration is referred to as the “ozone layer” or the “ozone shield.”

Photons with wavelengths shorter than about 300 nm are energetic enough to break many kinds of single chemical bonds. Thus, the “ozone shield” is essential for our continued well-being. The ozone molecules that form this essential shield against high-energy radiation represent only a tiny fraction of the oxygen atoms present in the stratosphere, however, because these molecules are continually destroyed even as they are formed.

▲ **Figure 18.6** Mount Pinatubo erupts, June 1991.

## 18.2 | Human Activities and Earth's Atmosphere

Both natural and *anthropogenic* (human-caused) events can modify Earth's atmosphere. One impressive natural event was the eruption of Mount Pinatubo in June 1991 (**Figure 18.6**). The volcano ejected approximately  $10 \text{ km}^3$  of material into the stratosphere, causing a 10% drop in the amount of sunlight reaching Earth's surface during the next 2 years. That drop in sunlight led to a temporary  $0.5^\circ\text{C}$  drop in Earth's surface temperature. The volcanic particles that made it to the stratosphere remained there for approximately 3 years, *raising* the temperature of the stratosphere by several degrees due to light absorption. Measurements of the stratospheric ozone concentration showed significantly increased ozone decomposition in this 3-year period.

### The Ozone Layer and Its Depletion

The ozone layer protects Earth's surface from the damaging ultraviolet (UV) radiation. Therefore, if the concentration of ozone in the stratosphere decreases substantially, more UV radiation will reach Earth's surface, causing unwanted photochemical reactions, including reactions correlated with skin cancer. Satellite monitoring of ozone, which began in 1978, has revealed a depletion of ozone in the stratosphere that is particularly

severe over Antarctica, a phenomenon known as the *ozone hole* (Figure 18.7). The first scientific paper on this phenomenon appeared in 1985, and the National Aeronautics and Space Administration (NASA) maintains an “Ozone Hole Watch” website with daily updates and data from 1999 to the present.

In 1995, the Nobel Prize in Chemistry was awarded to F. Sherwood Rowland, Mario Molina, and Paul Crutzen for their studies of ozone depletion. In 1970, Crutzen showed that naturally occurring nitrogen oxides catalytically destroy ozone. Rowland and Molina recognized in 1974 that chlorine from **chlorofluorocarbons** (CFCs) may deplete the ozone layer. These substances, principally  $\text{CFCl}_3$  and  $\text{CF}_2\text{Cl}_2$ , do not occur in nature and have been widely used as propellants in spray cans, as refrigerant and air-conditioner gases, and as foaming agents for plastics. They are virtually unreactive in the lower atmosphere. Furthermore, they are relatively insoluble in water and are therefore not removed from the atmosphere by rainfall or by dissolution in the oceans. Unfortunately, the lack of reactivity that makes them commercially useful also allows them to survive in the atmosphere and to diffuse into the stratosphere. It is estimated that several million tons of chlorofluorocarbons are now present in the atmosphere.

As CFCs diffuse into the stratosphere, they are exposed to high-energy radiation, which can cause photodissociation. Because C—Cl bonds are considerably weaker than C—F bonds, free chlorine atoms are formed readily in the presence of light with wavelengths in the range from 190 to 225 nm, as shown in this typical reaction:

Calculations suggest that chlorine atom formation occurs at the greatest rate at an altitude of about 30 km, the altitude at which ozone is at its highest concentration.

Atomic chlorine reacts rapidly with ozone to form chlorine monoxide and molecular oxygen:

This reaction follows a second-order rate law with a very large rate constant:

$$\text{Rate} = k[\text{Cl}][\text{O}_3] \quad k = 7.2 \times 10^9 \text{ M}^{-1} \text{ s}^{-1} \text{ at } 298 \text{ K} \quad [18.8]$$

Under certain conditions, the ClO generated in Equation 18.7 can react to regenerate free Cl atoms. One way that this can happen is by photodissociation of ClO:

The Cl atoms generated in Equations 18.6 and 18.9 can react with more  $\text{O}_3$ , according to Equation 18.7. The result is a sequence of reactions that accomplishes the Cl-catalyzed decomposition of  $\text{O}_3$  to  $\text{O}_2$ :

The equation can be simplified by eliminating like species from each side to give

Because the rate of Equation 18.7 increases linearly with  $[\text{Cl}]$ , the rate at which ozone is destroyed increases as the quantity of Cl atoms increases. Thus, the higher the concentration of CFCs in the stratosphere, the faster the destruction of the ozone layer. Even though troposphere-to-stratosphere diffusion rates are slow, a substantial thinning of the ozone layer over the South Pole has been observed, particularly during September and October (Figure 18.7).

▲ **Figure 18.7** Ozone present in the Southern Hemisphere, September 24, 2006. The data were taken from an orbiting satellite. This day had the lowest stratospheric ozone concentration yet recorded. One “Dobson unit” corresponds to  $2.69 \times 10^{16}$  ozone molecules in a  $1 \text{ cm}^2$  column of atmosphere.

### Give It Some Thought

Since the rate of ozone destruction depends on  $[\text{Cl}]$ , can Cl be considered a catalyst for the reaction of Equation 18.10?

Because of the environmental problems associated with CFCs, steps have been taken to limit their manufacture and use. A major step was the signing in 1987 of the Montreal Protocol on Substances That Deplete the Ozone Layer, in which participating nations agreed to reduce CFC production. More stringent limits were set in 1992, when representatives of approximately 100 nations agreed to ban the production and use of CFCs by 1996, with some exceptions for “essential uses.” Since then, the production of CFCs has indeed dropped precipitously. Images such as that shown in Figure 18.7 taken annually reveal that the depth and size of the ozone hole has begun to slowly decline. Nevertheless, because CFCs are unreactive and because they diffuse so slowly into the stratosphere, scientists estimate that it will take many decades for ozone concentrations in the stratosphere to return to pre-1980 levels. What substances have replaced CFCs? At this time, the main alternatives are hydrofluorocarbons (HFCs), compounds in which C—H bonds replace the C—Cl bonds of CFCs. One such compound in current use is  $\text{CH}_2\text{FCF}_3$ , known as HFC-134a. While the HFCs are a big improvement over the CFCs because they contain no C—Cl bonds, it turns out that they are potent greenhouse warming gases, with which we will deal shortly.

There are no naturally occurring CFCs, but some natural sources contribute chlorine and bromine to the atmosphere, and, just like halogens from CFCs, these naturally occurring Cl and Br atoms can participate in ozone-depleting reactions. The principal natural sources are methyl bromide and methyl chloride, which are emitted from the oceans. It is estimated that these molecules contribute less than a third of the total Cl and Br in the atmosphere; the remaining two-thirds is a result of human activities.

Volcanoes are a source of HCl, but generally the HCl they release reacts with water in the troposphere and does not make it to the upper atmosphere.

## Sulfur Compounds and Acid Rain

Sulfur-containing compounds are present to some extent in the natural, unpolluted atmosphere. They originate in the bacterial decay of organic matter, in volcanic gases, and from other sources listed in Table 18.2. The amount of these compounds released into the atmosphere worldwide from natural sources is about  $24 \times 10^{12}$  g per year, less than the amount from human activities, about  $80 \times 10^{12}$  g per year (principally related to combustion of fuels).

Sulfur compounds, chiefly sulfur dioxide,  $\text{SO}_2$ , are among the most unpleasant and harmful of the common pollutant gases. Table 18.4 shows the concentrations of several pollutant gases in a *typical* urban environment (where by *typical* we mean one that is not particularly affected by smog). According to these data, the level of sulfur dioxide is 0.08 ppm or higher about half the time. This concentration is considerably lower than that of other pollutants, notably carbon monoxide. Nevertheless,  $\text{SO}_2$  is regarded as the most serious health hazard among the pollutants shown, especially for people with respiratory difficulties.

Combustion of coal accounts for about 65% of the  $\text{SO}_2$  released annually in the United States, and combustion of oil accounts for another 20%. The majority of this amount is from coal-burning electrical power plants, which generate about 50% of our electricity. The extent to which  $\text{SO}_2$  emissions are a problem when coal is burned depends on the amount of sulfur in the coal. Because of concern about  $\text{SO}_2$  pollution, low-sulfur coal is in greater demand and is thus more expensive. Much of the coal from east of the Mississippi is relatively high in sulfur content, up to 6% by mass. Much of the coal from the western states has a lower sulfur content, but also a lower heat content per unit mass, so the difference in sulfur content per unit of heat produced is not as large as is often assumed.

In 2010, the U.S. Environmental Protection Agency set new standards to reduce  $\text{SO}_2$  emissions. The old standard of 140 parts per billion, measured over 24 h, has been replaced by a standard of 75 parts per billion, measured over 1 h. The impact of  $\text{SO}_2$  emissions is not restricted to the United States, however. China, which generates about 70% of its energy from coal, is the world’s largest generator of  $\text{SO}_2$ , producing about

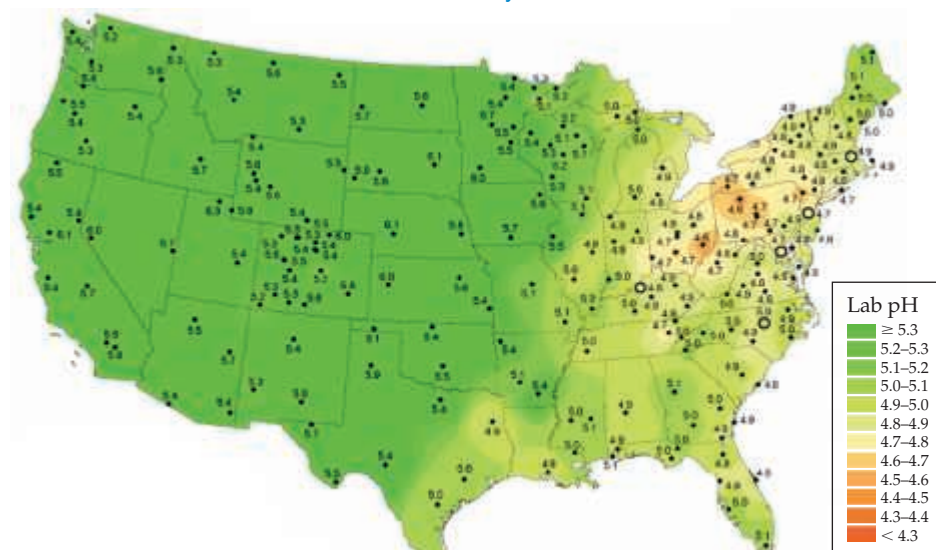

**TABLE 18.4 Median Concentrations of Atmospheric Pollutants in a Typical Urban Atmosphere**

| Pollutant                         | Concentration (ppm) |
|-----------------------------------|---------------------|
| Carbon monoxide                   | 10                  |
| Hydrocarbons                      | 3                   |
| Sulfur dioxide                    | 0.08                |

## Go Figure

Why is the pH found in freshwater sources in the Eastern half of the United States dramatically lower than that found in the western half?

▲ **Figure 18.8** Water pH values from freshwater sites across the United States, 2008. The numbered dots indicate the locations of monitoring stations.

$30 \times 10^{12}$  g annually from coal and other sources. As a result, that nation has a major problem with  $\text{SO}_2$  pollution and has set targets to reduce emissions with some success. While China leads the world in  $\text{SO}_2$  emissions, India, where coal is a major source of energy, is rapidly catching up. Whereas levels of  $\text{SO}_2$  emissions in China peaked in 2007, India saw atmospheric  $\text{SO}_2$  levels double between 2005 and 2014. Nations will need to work together to address what has truly become a global issue.

Sulfur dioxide is harmful to both human health and property; furthermore, atmospheric  $\text{SO}_2$  can be oxidized to  $\text{SO}_3$  by several pathways (such as reaction with  $\text{O}_2$  or  $\text{O}_3$ ). When  $\text{SO}_3$  dissolves in water, it produces sulfuric acid:

Many of the environmental effects ascribed to  $\text{SO}_2$  are actually due to  $\text{H}_2\text{SO}_4$ .

The presence of  $\text{SO}_2$  in the atmosphere and the sulfuric acid it produces result in the phenomenon of **acid rain**. (Nitrogen oxides, which form nitric acid, are also major contributors to acid rain.) Uncontaminated rainwater generally has a pH value of about 5.6. The primary source of this natural acidity is  $\text{CO}_2$ , which reacts with water to form carbonic acid,  $\text{H}_2\text{CO}_3$ . Acid rain typically has a pH value of about 4. This shift toward greater acidity has affected many lakes in northern Europe, the northern United States, and Canada, reducing fish populations and affecting other parts of the ecological network in the lakes and surrounding forests.

The pH of most natural waters containing living organisms is between 6.5 and 8.5, but as **Figure 18.8** shows, freshwater pH values are far below 6.5 in many parts of the continental United States. At pH levels below 4.0, all vertebrates, most invertebrates, and many microorganisms are destroyed. The lakes most susceptible to damage are those with low concentrations of basic ions, such as  $\text{HCO}_3^-$ , that would act as a buffer to minimize changes in pH. Some of these lakes are recovering as sulfur emissions from fossil fuel combustion decrease, in part because of the Clean Air Act. In the period 1980–2014 the average ambient air concentration of  $\text{SO}_2$  nationwide has declined by 80%.

Because acids react with metals and with carbonates, acid rain is corrosive both to metals and to stone building materials. Marble and limestone, for example, whose major constituent is  $\text{CaCO}_3$ , are readily attacked by acid rain (**Figure 18.9**). Billions of dollars each year are lost because of corrosion due to  $\text{SO}_2$  pollution.

► **Figure 18.9** Damage from acid rain. The right photograph, recently taken, shows how the statue has lost detail in its carvings.

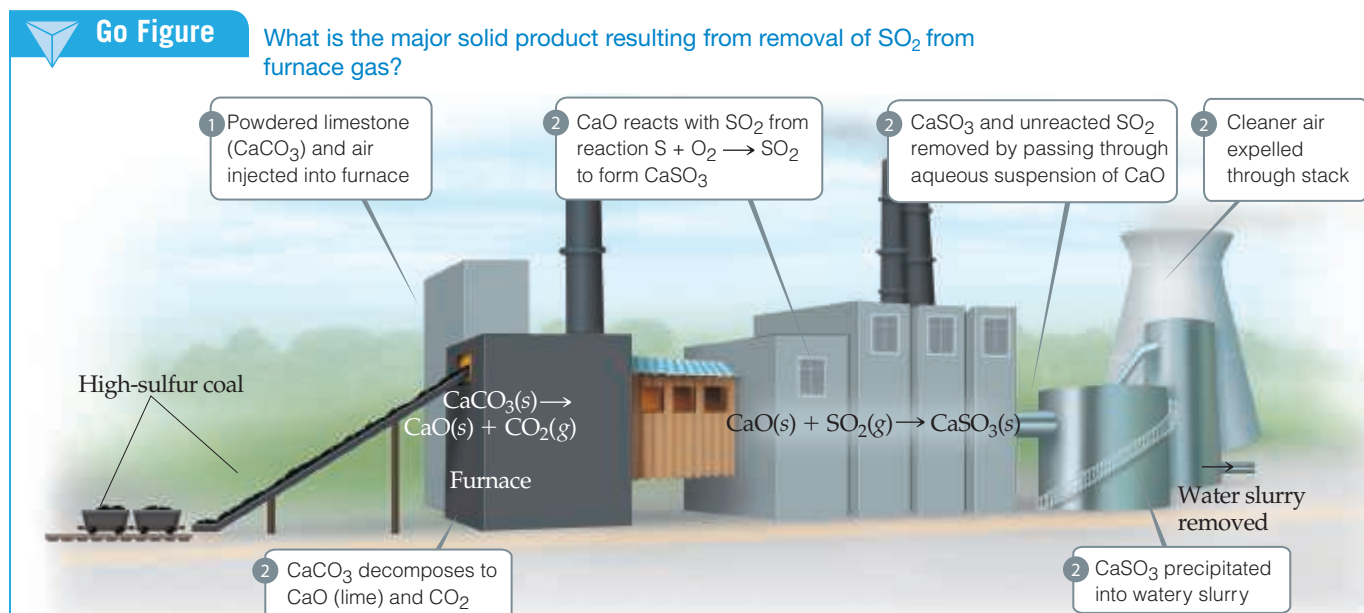

One way to reduce the quantity of  $\text{SO}_2$  released into the environment is to remove sulfur from coal and oil before these fuels are burned. Although difficult and expensive, several methods have been developed. Powdered limestone ( $\text{CaCO}_3$ ), for example, can be injected into the furnace of a power plant, where it decomposes into lime ( $\text{CaO}$ ) and carbon dioxide:

The  $\text{CaO}$  then reacts with  $\text{SO}_2$  to form calcium sulfite:

The solid particles of  $\text{CaSO}_3$ , as well as much of the unreacted  $\text{SO}_2$ , can be removed from the furnace gas by passing it through an aqueous suspension of  $\text{CaO}$  (**Figure 18.10**). Not all the  $\text{SO}_2$  is removed, however, and given the enormous quantities of coal and oil burned worldwide, pollution by  $\text{SO}_2$  will probably remain a problem for some time.

▲ **Figure 18.10** One method for removing  $\text{SO}_2$  from combusted fuel.

### Give It Some Thought

What sulfur-containing molecule forms sulfuric acid when it reacts with  $\text{H}_2\text{O}$ ?

## Nitrogen Oxides and Photochemical Smog

Nitrogen oxides are primary components of smog, a phenomenon with which city dwellers are all too familiar. The term *smog* refers to the pollution condition that occurs in certain urban environments when weather conditions produce a relatively stagnant air mass. The smog made famous by Los Angeles, but now common in many other urban areas as well, is more accurately described as **photochemical smog** because photochemical processes play a major role in its formation (Figure 18.11).

The majority of nitrogen oxide emissions (about 50%) comes from cars, buses, and other forms of transportation. Nitric oxide,  $\text{NO}$ , forms in small quantities in the cylinders of internal combustion engines in the reaction

As noted in the Chemistry Put to Work box in Section 15.7, the equilibrium constant for this reaction increases from about  $10^{-15}$  at 300 K to about 0.05 at 2400 K (approximate temperature in the cylinder of an engine during combustion). Thus, the reaction is more favorable at higher temperatures. In fact, some  $\text{NO}$  is formed in any high-temperature combustion process. As a result, electrical power plants are also major contributors to nitrogen oxide pollution.

Before the installation of pollution-control devices on automobiles, typical emission levels of  $\text{NO}_x$  were 4 g/mi. (The  $x$  is either 1 or 2 because both  $\text{NO}$  and  $\text{NO}_2$  are formed, although  $\text{NO}$  predominates.) Starting in 2004, the auto emission standards for  $\text{NO}_x$  called for a phased-in reduction to 0.07 g/mi by 2009, which was achieved.

In air, nitric oxide is rapidly oxidized to nitrogen dioxide:

The equilibrium constant for this reaction decreases from about  $10^{12}$  at 300 K to about  $10^{-5}$  at 2400 K.

The photodissociation of  $\text{NO}_2$  initiates the reactions associated with photochemical smog. Dissociation of  $\text{NO}_2$  requires 304 kJ/mol, which corresponds to a photon wavelength of 393 nm. In sunlight, therefore,  $\text{NO}_2$  dissociates to  $\text{NO}$  and  $\text{O}$ :

The atomic oxygen formed undergoes several reactions, one of which gives ozone, as described earlier:

Although it is essential to screen out harmful UV radiation in the upper atmosphere, ozone is an undesirable pollutant in the troposphere. It is extremely reactive and toxic, and breathing air that contains appreciable amounts of ozone can be especially dangerous for asthma sufferers, exercisers, and the elderly. We therefore have two ozone problems: excessive amounts in many urban environments, where it is harmful, and depletion in the stratosphere, where its presence is vital.

In addition to nitrogen oxides and carbon monoxide, an automobile engine also emits unburned *hydrocarbons* as pollutants. These organic compounds are the principal components of gasoline and of many compounds we use as fuel (propane,  $\text{C}_3\text{H}_8$ , and butane,  $\text{C}_4\text{H}_{10}$ ; for example), but are major ingredients of smog. A typical engine without effective emission controls emits about 10 to 15 g of hydrocarbons per mile. Current standards require that hydrocarbon emissions be less than 0.075 g/mi. Hydrocarbons are also emitted naturally from living organisms (see A Closer Look box later in this section).

Reduction or elimination of smog requires that the ingredients essential to its formation be removed from automobile exhaust. Catalytic converters reduce the levels of  $\text{NO}_x$  and hydrocarbons, two of the major ingredients of smog. (See the Chemistry Put to Work: Catalytic Converters in Section 14.7.)

▲ **Figure 18.11** Photochemical smog is produced largely by the action of sunlight on vehicle exhaust gases, as illustrated in this photo of Beijing, China.

### Give It Some Thought

What photochemical reaction involving nitrogen oxides initiates the formation of photochemical smog?

## Greenhouse Gases: Water Vapor, Carbon Dioxide, and Climate

In addition to screening out harmful short-wavelength radiation, the atmosphere is essential in maintaining a reasonably uniform and moderate temperature on Earth's surface. Earth is in overall thermal balance with its surroundings. This means that the planet radiates energy into space at a rate equal to the rate at which it absorbs energy from the Sun. **Figure 18.12** shows the flow of energy into and out of Earth, and

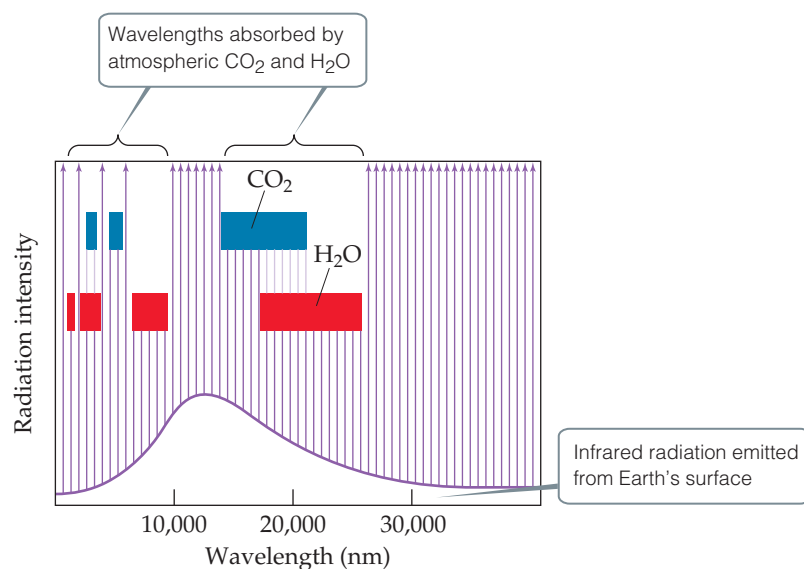

### Go Figure

What is the total amount of energy absorbed by the surface? What fraction of that energy is emitted upward as infrared radiation?

▲ **Figure 18.12** Earth's thermal balance. The amount of radiation reaching the surface of the planet is equal to the amount radiated back into space.

▲ **Figure 18.13** Portions of the infrared radiation emitted by Earth's surface that are absorbed by atmospheric  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

**Figure 18.13** shows the fraction of infrared radiation leaving the surface that is absorbed by atmospheric water vapor and carbon dioxide. In absorbing this radiation, these two atmospheric gases help maintain a livable uniform temperature at the surface by holding in, as it were, the infrared radiation, which we feel as heat.

The influence of  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , and certain other atmospheric gases on Earth's temperature is called the *greenhouse effect* because in trapping infrared radiation these gases act much like the glass of a greenhouse. The gases themselves are called **greenhouse gases**.

Water vapor makes the largest contribution to the greenhouse effect. The partial pressure of water vapor in the atmosphere varies greatly from place to place and time to time but is generally highest near Earth's surface and drops off with increasing elevation. Because water vapor absorbs infrared radiation so strongly, it plays the major role in maintaining the atmospheric temperature at night, when the surface is emitting radiation into space and not receiving energy from the Sun. In very dry desert climates, where the water-vapor concentration is low, it may be extremely hot during the day but very cold at night. In the absence of a layer of water vapor to absorb and then radiate part of the infrared radiation back to Earth, the surface loses this radiation into space and cools off very rapidly.

Carbon dioxide plays a secondary but very important role in maintaining the surface temperature. The worldwide combustion of fossil fuels, principally coal and oil, on a prodigious scale in the modern era has sharply increased carbon dioxide levels in the atmosphere. To get a sense of the amount of  $\text{CO}_2$  produced—for example, by the combustion of hydrocarbons and other carbon-containing substances, which are the components of fossil fuels—consider the combustion of butane,  $\text{C}_4\text{H}_{10}$ . Combustion of 1.00 g of  $\text{C}_4\text{H}_{10}$  produces 3.03 g of  $\text{CO}_2$ . ∞ (Section 3.6). Combustion of fossil fuels releases about  $2.2 \times 10^{16}$  g (24 billion tons) of  $\text{CO}_2$  into the atmosphere annually, with the largest quantity coming from transportation vehicles.

### Sample Exercise 18.3

#### Estimating the Quantity of $\text{CO}_2$ Released from Combustion of Gasoline

What mass of carbon dioxide is produced when 1.0 gallon of gasoline is combusted? The approximate density and composition of gasoline are 0.70 g/mL and  $\text{C}_8\text{H}_{18}$ , respectively.

*Continued*

## SOLUTION

**Analyze** We are asked to calculate the mass of  $\text{CO}_2$  produced when 1.0 gallon of  $\text{C}_8\text{H}_{18}$  reacts with oxygen to form carbon dioxide and water.

**Plan** We first must determine the mass in grams of  $\text{C}_8\text{H}_{18}$  in 1.0 gallon of gasoline. We then write a balanced chemical equation for the combustion of  $\text{C}_8\text{H}_{18}$  and use it to determine the theoretical yield of  $\text{CO}_2$ .

## Solve

First, convert the volume from gallons to mL.

$$(1.0 \text{ gallon}) \left( \frac{3.785 \text{ L}}{1 \text{ gallon}} \right) \left( \frac{1000 \text{ mL}}{1 \text{ L}} \right) = 3.79 \times 10^3 \text{ mL}$$

Next, use the density of gasoline to calculate its mass in grams.

$$(3.79 \times 10^3 \text{ mL}) \left( \frac{0.70 \text{ g}}{\text{mL}} \right) = 2.65 \times 10^3 \text{ g}$$

To calculate the theoretical yield of carbon dioxide, we must write a balanced chemical equation for the combustion of  $\text{C}_8\text{H}_{18}$  (octane):

Using the balanced equation and the mass of  $\text{C}_8\text{H}_{18}$ , we can calculate the theoretical yield of  $\text{CO}_2$ .

$$(2.65 \times 10^3 \text{ g C}_8\text{H}_{18}) \left( \frac{1 \text{ mol C}_8\text{H}_{18}}{114.2 \text{ g C}_8\text{H}_{18}} \right) \left( \frac{16 \text{ mol CO}_2}{2 \text{ mol C}_8\text{H}_{18}} \right) \left( \frac{44 \text{ g CO}_2}{1 \text{ mol CO}_2} \right) = 8.2 \times 10^3 \text{ g CO}_2$$

So we see that for every gallon of gasoline burned 8.2 kg of  $\text{CO}_2$  are produced.

## Practice Exercise 1

Many cars can run on a mixture of gasoline and ethanol,  $\text{C}_2\text{H}_5\text{OH}$  (density = 0.789 g/mL). What mass of  $\text{CO}_2$  is produced by combustion of 1.0 gallon of ethanol?

(a) 2.9 kg (b) 5.7 kg (c) 6.0 kg (d) 8.6 kg (e) 9.2 kg

## Practice Exercise 2

A typical propane,  $\text{C}_3\text{H}_8$ , tank for an outdoor grill contains 15 pounds of propane. What mass of  $\text{CO}_2$  is produced by combusting the propane in such a tank?

Much  $\text{CO}_2$  is absorbed into oceans or used by plants. Nevertheless, we are now generating  $\text{CO}_2$  much faster than it is being absorbed or used. Analysis of air trapped in ice cores taken from Antarctica and Greenland makes it possible to determine the atmospheric levels of  $\text{CO}_2$  during the past 160,000 years. These measurements reveal that the level of  $\text{CO}_2$  remained fairly constant from the last Ice Age, some 10,000 years ago, until roughly the beginning of the Industrial Revolution, about 300 years ago. Since that time, the concentration of  $\text{CO}_2$  has increased by about 30% to a current high of about 400 ppm (Figure 18.14). Climate scientists believe that the  $\text{CO}_2$  level has not been this high since 3 to 5 million years ago.

## Go Figure

What is the source of the steady increase in slope of this curve over time?

▲ **Figure 18.14** Rising  $\text{CO}_2$  levels. The sawtooth shape of the graph is due to regular seasonal variations in  $\text{CO}_2$  concentration for each year.

The consensus among climate scientists is that the increase in atmospheric  $\text{CO}_2$  is perturbing Earth's climate and is very likely playing a role in the observed increase in the average global air temperature of  $0.3\text{--}0.6^\circ\text{C}$  over the past century. Scientists often use the term *climate change* instead of *global warming* to refer to this effect because as the Earth's temperature increases, winds and ocean currents are affected in ways that cool some areas and warm others.

On the basis of present and expected future rates of fossil-fuel use, the atmospheric  $\text{CO}_2$  level is expected to double from its present level sometime between 2050 and 2100. Computer models predict that this increase will result in an average global temperature increase of  $1^\circ\text{C}$  to  $3^\circ\text{C}$ . Because so many factors go into determining climate, we cannot predict with certainty what changes will occur because of this warming. Clearly, however, atmospheric concentrations of  $\text{CO}_2$  and other heat-trapping gases are rising as a result of human activity. The effects of these changes on the climate are already being felt, and if left unchecked they have the potential to substantially alter the climate of the planet.

The climate change threat posed by atmospheric  $\text{CO}_2$  has sparked considerable research into ways of capturing the gas at its largest combustion sources and storing it under ground or under the seafloor. There is also much interest in developing new ways to use  $\text{CO}_2$  as a chemical feedstock. However, the approximately 115 million tons of  $\text{CO}_2$  used annually by the global chemical industry is but a small fraction of the approximately 24 billion tons of annual  $\text{CO}_2$  emissions. The use of  $\text{CO}_2$  as a raw material will probably never be great enough to significantly reduce its atmospheric concentration.

### Give It Some Thought

Explain why nighttime temperatures remain higher in locations where there is higher humidity.

## A CLOSER LOOK Other Greenhouse Gases

Although  $\text{CO}_2$  receives most of the attention, other gases contribute to the greenhouse effect, including methane,  $\text{CH}_4$ , hydrofluorocarbons (HFCs), and chlorofluorocarbons (CFCs).

HFCs have replaced CFCs in a host of applications, including refrigerants and air-conditioner gases. Although they do not contribute to the depletion of the ozone layer, HFCs are nevertheless potent greenhouse gases. For example, one of the by-product molecules from production of HFCs that are used in commerce is  $\text{HCF}_3$ , which is estimated to have a global warming potential, gram for gram, more than 14,000 times that of  $\text{CO}_2$ . The total concentration of HFCs in the atmosphere has been increasing about 10% per year. Thus, these substances are becoming increasingly important contributors to the greenhouse effect. Methane already makes a significant contribution to the greenhouse effect. Studies of atmospheric gas trapped long ago in the Greenland and Antarctic ice sheets show that the atmospheric methane concentration has increased from preindustrial values of 0.3 to 0.7 ppm to the present value of about 1.8 ppm. The major sources of methane are associated with agriculture and fossil-fuel use.

Methane is formed in biological processes that occur in low-oxygen environments. Anaerobic bacteria, which flourish in swamps and landfills, near the roots of rice plants, and in the digestive systems of cows and other ruminant animals, produce methane (Figure 18.15). It also leaks into the atmosphere during natural-gas extraction and transport. It is estimated that about two-thirds of present-day methane emissions, which are increasing by about 1% per year, are related to human activities.

Methane has a half-life in the atmosphere of about 10 years, whereas  $\text{CO}_2$  is much longer-lived. This might seem a good thing, but there are indirect effects to consider. Methane is oxidized in the stratosphere, producing water vapor, a powerful greenhouse gas that

▲ **Figure 18.15** Methane production. Ruminant animals, such as cows and sheep, produce methane in their digestive systems.

is otherwise virtually absent from the stratosphere. In the troposphere, methane is attacked by reactive species such as OH radicals or nitrogen oxides, eventually producing other greenhouse gases, such as  $\text{O}_3$ . It has been estimated that on a per-molecule level, the global warming potential of  $\text{CH}_4$  is about 21 times that of  $\text{CO}_2$ . Given this large contribution, important reductions of the greenhouse effect could be achieved by reducing methane emissions or capturing the emissions for use as a fuel.

**Related Exercises:** 18.65, 18.67

## 18.3 | Earth's Water

Water covers 72% of Earth's surface and is essential to life. Our bodies are about 65% water by mass. Because of extensive hydrogen bonding, water has unusually high melting and boiling points and a high heat capacity. ∞ (Section 11.2) Water's highly polar character is responsible for its exceptional ability to dissolve a wide range of ionic and polar-covalent substances. Many reactions occur in water, including reactions in which  $\text{H}_2\text{O}$  itself is a reactant. Recall, for example, that  $\text{H}_2\text{O}$  can participate in acid-base reactions as either a proton donor or a proton acceptor. ∞ (Section 16.3) All these properties play a role in our environment.

### The Global Water Cycle

All the water on Earth is connected in a global water cycle (Figure 18.16). Most of the processes depicted here rely on the phase changes of water. For instance, warmed by the Sun, liquid water in the oceans evaporates into the atmosphere as water vapor and condenses into liquid water droplets that we see as clouds. Water droplets in the clouds can crystallize to ice, which can precipitate as hail or snow. Once on the ground, the hail or snow melts to liquid water, which soaks into the ground. If conditions are right, it is also possible for ice on the ground to sublime to water vapor in the atmosphere. Because the processes occurring on the surface (evaporation, sublimation) are endothermic and those occurring in the atmosphere (condensation, crystallization) are exothermic they act to transfer heat absorbed by the surface into the atmosphere.

#### Give It Some Thought

Consider the phase diagram for water shown in Figure 11.28 (page 457). In what pressure range and in what temperature range must  $\text{H}_2\text{O}$  exist in order for  $\text{H}_2\text{O}(s)$  to sublime to  $\text{H}_2\text{O}(g)$ ?

#### Go Figure

Which processes shown in this figure involve the phase transition  $\text{H}_2\text{O}(l) \rightarrow \text{H}_2\text{O}(g)$ ?

▲ Figure 18.16 The global water cycle.

## Salt Water: Earth's Oceans and Seas

The vast layer of salty water that covers so much of the planet is in actuality one large connected body and is generally constant in composition. For this reason, oceanographers speak of a *world ocean* rather than of the separate oceans we learn about in geography books.

The world ocean is huge, having a volume of  $1.35 \times 10^9 \text{ km}^3$  and containing 97.2% of all the water on Earth. Of the remaining 2.8%, 2.1% is in the form of ice caps and glaciers. All the freshwater—in lakes, in rivers, and in the ground—amounts to only 0.6%. Most of the remaining 0.1% is in brackish (salty) water, such as that in the Great Salt Lake in Utah.

Seawater is often referred to as saline water. The **salinity** of seawater is the mass in grams of dry salts present in 1 kg of seawater. In the world ocean, salinity averages about 35. To put it another way, seawater contains about 3.5% dissolved salts by mass. The list of elements present in seawater is very long. Most, however, are present only in very low concentrations. **Table 18.5** lists the 11 ionic species most abundant in seawater.

Seawater temperature varies as a function of depth (**Figure 18.17**), as does salinity and density. Sunlight penetrates well only 200 m into the water; the region between 200 m and 1000 m deep is the “twilight zone,” where visible light is faint. Below 1000 m, the ocean is pitch-black and cold, about 4 °C. The transport of heat, salt, and other chemicals throughout the ocean is influenced by these changes in the physical properties of seawater, and in turn the changes in the way heat and substances are transported affects ocean currents and the global climate.

The sea is so vast that if the concentration of a substance in seawater is 1 part per billion ( $1 \times 10^{-6} \text{ g/kg}$  of water), there is  $1 \times 10^{12} \text{ kg}$  of the substance in the world ocean. Nevertheless, because of high extracting costs, only three substances are obtained from seawater in commercially important amounts: sodium chloride, bromine (from bromide salts), and magnesium (from its salts).

Absorption of  $\text{CO}_2$  by the ocean plays a large role in global climate. Because carbon dioxide and water form carbonic acid, the  $\text{H}_2\text{CO}_3$  concentration in the ocean increases as the water absorbs atmospheric  $\text{CO}_2$ . Most of the carbon in the ocean, however, is in the form of  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$  ions, which form a buffer system that maintains the ocean's pH between 8.0 and 8.3. The pH of the ocean is predicted to decrease as the concentration of  $\text{CO}_2$  in the atmosphere increases, as discussed in the “Chemistry and Life” box on ocean acidification on page 792.

**TABLE 18.5 Ionic Constituents of Seawater Present in Concentrations Greater than 0.001 g/kg (1 ppm)**

| Ionic Constituent                   | Salinity | Concentration (M)    |
|-------------------------------------|----------|----------------------|
| Chloride, $\text{Cl}^-$             | 19.35    | 0.55                 |
| Sodium, $\text{Na}^+$               | 10.76    | 0.47                 |
| Sulfate, $\text{SO}_4^{2-}$         | 2.71     | 0.028                |
| Magnesium, $\text{Mg}^{2+}$         | 1.29     | 0.054                |
| Calcium, $\text{Ca}^{2+}$           | 0.412    | 0.010                |
| Potassium, $\text{K}^+$             | 0.40     | 0.010                |
| Carbon dioxide*                     | 0.106    | $2.3 \times 10^{-3}$ |
| Bromide, $\text{Br}^-$              | 0.067    | $8.3 \times 10^{-4}$ |
| Boric acid, $\text{H}_3\text{BO}_3$ | 0.027    | $4.3 \times 10^{-4}$ |
| Strontium, $\text{Sr}^{2+}$         | 0.0079   | $9.1 \times 10^{-5}$ |
| Fluoride, $\text{F}^-$              | 0.0013   | $7.0 \times 10^{-5}$ |

\* $\text{CO}_2$  is present in seawater as  $\text{HCO}_3^-$  and  $\text{CO}_3^{2-}$ .

## Go Figure

Based on the temperature variation here would you expect the density of seawater to increase or decrease as the depth increases?

▲ Figure 18.17 Typical average temperature of mid-latitude seawater as a function of depth.

## Freshwater and Groundwater

*Freshwater* is the term used to denote natural waters that have low concentrations (less than 500 ppm) of dissolved salts and solids. Freshwater includes the waters of lakes, rivers, ponds, and streams. The United States is fortunate in its abundance of freshwater— $1.7 \times 10^{15}$  L (660 trillion gallons) is the estimated reserve, which is renewed by rainfall. An estimated  $9 \times 10^{11}$  L of freshwater is used every day in the United States. Most of this is used for agriculture (41%) and hydroelectric power (39%), with small amounts for industry (6%), household needs (6%), and drinking water (1%). An adult drinks about 2 L of water per day. In the United States, our daily use of water per person far exceeds this subsistence level, amounting to an average of about 300 L/day for personal consumption and hygiene. We use about 8 L/person for cooking and drinking, about 120 L/person for cleaning (bathing, laundering, and housecleaning), 80 L/person for flushing toilets, and 80 L/person for watering lawns.

The total amount of freshwater on Earth is not a very large fraction of the total water present. Indeed, freshwater is one of our most precious resources. It forms by evaporation from the oceans and the land. The water vapor that accumulates in the atmosphere is transported by global atmospheric circulation, eventually returning to Earth as rain, snow, and other forms of precipitation (Figure 18.16).

As water runs off the land on its way to the oceans, it dissolves a variety of cations (mainly  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{Fe}^{2+}$ ), anions (mainly  $\text{Cl}^-$ ,  $\text{SO}_4^{2-}$ , and  $\text{HCO}_3^-$ ), and gases (principally  $\text{O}_2$ ,  $\text{N}_2$ , and  $\text{CO}_2$ ). As we use water, it becomes laden with additional dissolved material, including the wastes of human society. As our population and output of environmental pollutants increase, ever-increasing amounts of money and resources must be spent to guarantee a supply of freshwater.

The availability and cost of fresh water that is clean enough to sustain daily life varies greatly among nations. To illustrate, daily fresh water use in the United States approaches 600 L/person, whereas in the relatively underdeveloped nations of sub-Saharan Africa it is only about 30 L. To make matters worse, for many people, water is not only scarce, it is so contaminated that it is a continuing source of diseases.

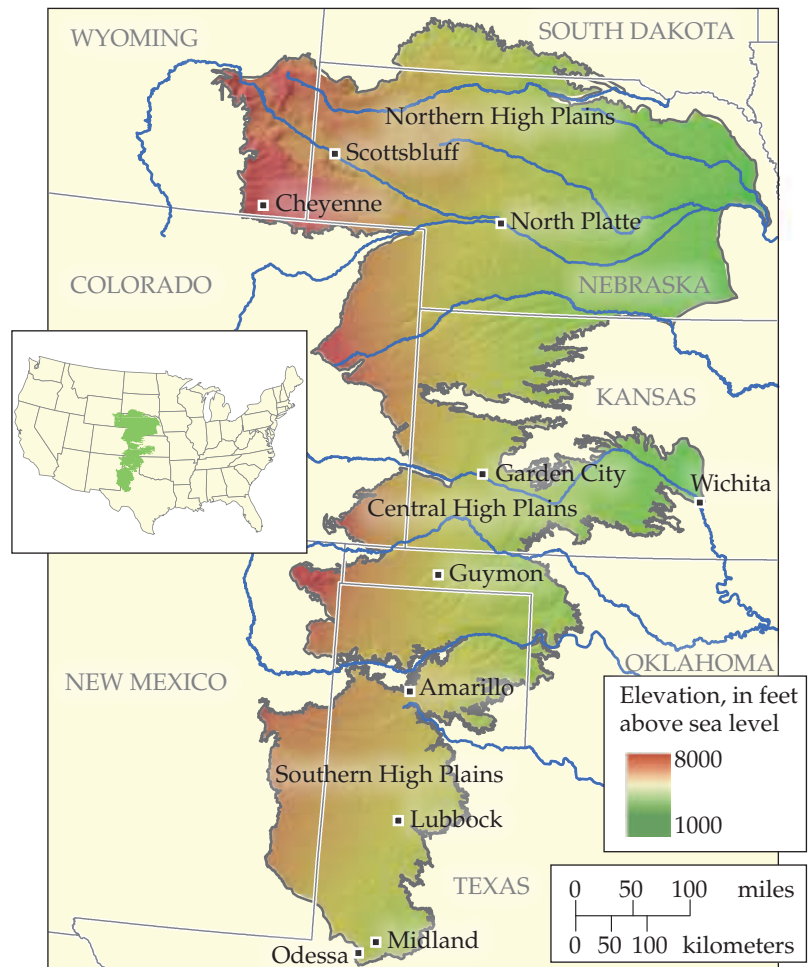

Approximately 20% of the world's freshwater is under the soil, in the form of *groundwater*. Groundwater resides in *aquifers*, which are layers of porous rock that hold water. The water in aquifers can be very pure, and accessible for human consumption if near the surface. Dense underground formations that do not allow water to readily penetrate can hold groundwater for years or even millennia. When their water is removed by drilling and pumping, such aquifers are slow to recharge via the diffusion of surface water.

## A CLOSER LOOK The Ogallala Aquifer—A Shrinking Resource

The Ogallala Aquifer, also referred to as the High Plains Aquifer, is an enormous underground body of water lying beneath the Great Plains of the United States. One of the world's largest aquifers, it covers an area of approximately 450,000 km<sup>2</sup> (170,000 mi<sup>2</sup>) encompassing portions of eight states: South Dakota, Nebraska, Wyoming, Colorado, Kansas, Oklahoma, New Mexico, and Texas. (Figure 18.18). The water-saturated depth of the underground aquifer ranges from as little as 1 m to more than 300 m. The total volume of water stored in the aquifer is more than that of Lake Huron.

Anyone who has flown over the Great Plains is familiar with the view of huge circles made by the center pivot irrigators nearly covering the land. The center pivot irrigation system, developed in the post-World War II era, permitted application of water onto large areas. As a result, the Great Plains became one of the most productive agricultural areas in the world. Unfortunately, the premise that the aquifer is an inexhaustible source of fresh water proved false. Recharge of the aquifer from surface water is slow, taking hundreds, perhaps thousands of years. Water levels in parts of the southern half of the aquifer have fallen by more than 50 m over the past seven decades, making the costs of bringing water to the surface prohibitive. As aquifer levels continue to drop, less water will be available for the needs of cities, residences, and businesses.

**Related Exercise: 18.44**

▲ **Figure 18.18** A map showing the extent of the Ogallala (High Plains) aquifer. Note that the elevation of the land varies greatly. The aquifer follows the topography of the formations that underlie the area.

The nature of the rock that contains the groundwater has a large influence on the water's chemical composition. If minerals in the rock are water soluble to some extent, ions can leach out of the rock and remain dissolved in the groundwater. Arsenic in the form of  $\text{HAsO}_4^{2-}$ ,  $\text{H}_2\text{AsO}_4^-$ , and  $\text{H}_3\text{AsO}_3$  is found in many groundwater sources across the world, most infamously in Bangladesh, at concentrations poisonous to humans.

## 18.4 | Human Activities and Water Quality

All life on Earth depends on the availability of suitable water. Many human activities entail waste disposal into natural waters without any treatment. These practices result in contaminated water that is detrimental to both plant and animal aquatic life. Unfortunately people in many parts of the world do not have access to water that has been treated to remove harmful contaminants, including disease-bearing bacteria.

## Dissolved Oxygen and Water Quality

The amount of  $O_2$  dissolved in water is an important indicator of water quality. Water fully saturated with air at 1 atm and  $20^\circ C$  contains about 9 ppm of  $O_2$ . Oxygen is necessary for fish and most other aquatic life. Cold-water fish require water containing at least 5 ppm of dissolved oxygen for survival. Aerobic bacteria consume dissolved oxygen to oxidize organic materials for energy. The organic material the bacteria are able to oxidize is said to be **biodegradable**.

Excessive quantities of biodegradable organic materials in water are detrimental because they remove the oxygen necessary to sustain normal animal life. Typical sources of these biodegradable materials, which are called *oxygen-demanding wastes*, include sewage, industrial wastes from food-processing plants and paper mills, and liquid waste from meatpacking plants.

In the presence of oxygen, the carbon, hydrogen, nitrogen, sulfur, and phosphorus in biodegradable material end up mainly as  $CO_2$ ,  $HCO_3^-$ ,  $H_2O$ ,  $NO_3^-$ ,  $SO_4^{2-}$ , and phosphates. The formation of these oxidation products sometimes reduces the amount of dissolved oxygen to the point where aerobic bacteria can no longer survive. Anaerobic bacteria then take over the decomposition process, forming  $CH_4$ ,  $NH_3$ ,  $H_2S$ ,  $PH_3$ , and other products, several of which contribute to the offensive odors of some polluted waters.

Plant nutrients, particularly nitrogen and phosphorus, contribute to water pollution by stimulating excessive growth of aquatic plants. The most visible results of excessive plant growth are floating algae and murky water. What is more significant, however, is that as plant growth becomes excessive, the amount of dead and decaying plant matter increases rapidly, a process called *eutrophication* (Figure 18.19). The processes by which plants decay consume  $O_2$ , and without sufficient oxygen, the water cannot sustain animal life.

The most significant sources of nitrogen and phosphorus compounds in water are domestic sewage (phosphate-containing detergents and nitrogen-containing body wastes), runoff from agricultural land (fertilizers contain both nitrogen and phosphorus), and runoff from livestock areas (animal wastes contain nitrogen).

▲ **Figure 18.19 Eutrophication.** This rapid accumulation of dead and decaying plant matter in a body of water uses up the water's oxygen supply, making the water unsuitable for aquatic animals.

### Give It Some Thought

Which two elements are largely responsible for fresh water eutrophication?

## Water Purification: Desalination

Because of its high salt content, seawater is unfit for human consumption and for most of the uses to which we put water. In the United States, the salt content of municipal water supplies is restricted by health codes to no more than about 0.05% by mass. This amount is much lower than the 3.5% dissolved salts present in seawater and the 0.5% or so present in brackish water found underground in some regions. The removal of salts from seawater or brackish water to make the water usable is called **desalination**.

Water can be separated from dissolved salts by *distillation* because water is a volatile substance and the salts are nonvolatile. ∞ (Section 1.3, "Separation of Mixtures") The principle of distillation is simple enough, but carrying out the process on a large scale presents many problems. As water is distilled from seawater, for example, the salts become more and more concentrated and eventually precipitate out. Distillation is also an energy-intensive process.

Seawater can also be desalinated using **reverse osmosis**. Recall that osmosis is the net movement of solvent molecules, but not solute molecules, through a semipermeable membrane. ∞ (Section 13.5) In osmosis, the solvent passes from the more dilute solution into the more concentrated one. However, if sufficient external pressure is applied, osmosis can be stopped and, at still higher pressures, reversed. When

reverse osmosis occurs, solvent passes from the more concentrated into the more dilute solution. In a modern reverse-osmosis facility, hollow fibers are used as the semipermeable membrane (Figure 18.20). Saline water (water containing significant salts) is introduced under pressure into the fibers, and desalinated water is recovered.

The world's largest desalination plant, in Jubail, Saudi Arabia, provides 50% of that country's drinking water by using reverse osmosis to desalinate seawater from the Persian Gulf. An even larger plant, which will produce 600 million L/day (160 million gallons) of drinking water, is scheduled for completion in Saudi Arabia in 2018. Such plants are becoming increasingly common in the United States. The largest, which opened in late 2015 near Carlsbad, California, is capable of producing 50 million gallons of drinking water per day. To operate at full capacity it uses approximately 38 MW of electricity, enough to power 38,500 homes. Two gallons of seawater are needed to produce one gallon of freshwater.

## Water Purification: Municipal Treatment

The water needed for domestic, agricultural, and industrial use is taken either from lakes, rivers, and underground sources or from reservoirs. Much of the water that finds its way into municipal water systems is "used" water, meaning it has already passed through one or more sewage systems or industrial plants. Consequently, this water must be treated before it is distributed to our faucets.

Municipal water treatment usually involves five steps (Figure 18.21).

1. After coarse filtration through a screen, the water is allowed to stand in large sedimentation tanks where sand and other minute particles settle out. To aid in removing very small particles, the water may first be made slightly basic with  $\text{CaO}$ .
2. Then  $\text{Al}_2(\text{SO}_4)_3$  is added and reacts with  $\text{OH}^-$  ions to form a spongy, gelatinous precipitate of  $\text{Al}(\text{OH})_3$  ( $K_{sp} = 1.3 \times 10^{-33}$ ). This precipitate settles slowly, carrying suspended particles down with it, thereby removing nearly all finely divided matter and most bacteria.
3. The water is then filtered through a sand bed.
4. Following filtration, the water may be sprayed into the air (aeration) to hasten oxidation of dissolved inorganic ions of iron and manganese, reduce concentrations of any  $\text{H}_2\text{S}$  or  $\text{NH}_3$  that may be present, and reduce bacterial concentrations.

▲ Figure 18.20 Reverse osmosis.

### Go Figure

What is the primary function of the aeration step in water treatment?

▲ Figure 18.21 Common steps in treating water for a public water system.

▲ **Figure 18.22** A LifeStraw purifies water as it is drunk.

- The final step normally involves treating the water with a chemical agent to ensure the destruction of bacteria. Ozone is more effective, but chlorine is less expensive. Liquefied  $\text{Cl}_2$  is dispensed from tanks through a metering device directly into the water supply. The amount used depends on the presence of other substances with which the chlorine might react and on the concentrations of bacteria and viruses to be removed.

The sterilizing action of chlorine is not due to  $\text{Cl}_2$  itself but to hypochlorous acid, which forms when chlorine reacts with water:

It is estimated that about 800 million people worldwide lack access to clean water. According to the United Nations, 95% of the world's cities still dump raw sewage into their water supplies. Thus, it should come as no surprise that 80% of all the health maladies in developing countries can be traced to waterborne diseases associated with unsanitary water.

One promising development is a device called the LifeStraw (Figure 18.22). When a person sucks water through the straw, the water first encounters a textile filter with a mesh opening of  $100\ \mu\text{m}$  followed by a second textile filter with a mesh opening of  $15\ \mu\text{m}$ . These filters remove debris and even clusters of bacteria. The water next encounters a chamber of iodine-impregnated beads, where bacteria, viruses, and parasites are killed. Finally, the water passes through granulated active carbon, which removes the smell of iodine as well as the parasites that have not been taken by the filters or killed by the iodine. At present the Lifestraw is too costly to permit widespread use in underdeveloped countries, but there is hope that its cost can be greatly reduced.

Water disinfection is one of the greatest public health innovations in human history. It has dramatically decreased the incidences of waterborne bacterial diseases such as cholera and typhus. However, this great benefit comes at a price. In 1974 scientists in Europe and the United States discovered that chlorination of water produces a group of by-products previously undetected. These by-products are called *trihalomethanes* (THMs) because all have a single carbon atom and three halogen atoms:  $\text{CHCl}_3$ ,  $\text{CHCl}_2\text{Br}$ ,  $\text{CHClBr}_2$ , and  $\text{CHBr}_3$ . These and many other chlorine- and bromine-containing organic substances are produced by the reaction of dissolved chlorine with the organic materials present in nearly all natural waters, as well as with substances that are by-products of human activity. Recall that chlorine dissolves in water to form the oxidizing agent  $\text{HClO}$  as shown in Equation 18.15.

## A CLOSER LOOK Fracking and Water Quality

In recent years **fracking**, short for *hydraulic fracturing*, has become widely used to greatly increase the availability of petroleum reserves. In fracking, a large volume of water, typically two million gallons or more, mixed with various additives, is injected at high pressure into wellbores extended horizontally into rock formations (Figure 18.23). The water is laden with sand, ceramic materials, and other additives, including gels, foams, and compressed gases, that serve to increase the yield in the process. The high-pressure fluid finds its way into tiny faults in geological formations, releasing petroleum and natural gas. Fracking has greatly increased petroleum reserves, particularly of natural gas, in many parts of the world.

Unfortunately, the potential for environmental damage from fracking is significant. The large volume of fracking fluid required to create a well must be returned to the surface. Without purification the fluid is rendered unfit for other uses, and becomes a large-scale environmental problem. Often the waste water is allowed to sit in open waste water pits. The 2005 Energy Policy act and other federal legislation exempts hydraulic fracturing operations from certain provisions of the Safe Drinking Water act and other regulations. Some

areas of the country that are already facing water shortages thus have one more large demand for a limited supply. Because fracturing of rock formations increases the pathways for flows of petroleum and various gases, bodies of underground water that have been serving as municipal water supplies or wells for individual homes in some locales have become contaminated with petroleum, hydrogen sulfide and other toxic substances. The escape of a variety of gases, including methane and other hydrocarbons, from the wellheads contributes to air pollution. In a study published in 2013, methane emissions to the atmosphere during hydraulic fracturing operations in Utah were estimated to be in the range of 6–12% of the amount of methane produced. As related in the Closer Look box on page 783, methane is a potent greenhouse gas.

The many environmental issues surrounding the practice of fracking have generated widespread concern and adverse public reaction. Fracking represents yet one more instance of the conflict between those who advocate the availability of low cost energy and those who are more focused on sustaining long term the quality of the environment.

▲ **Figure 18.23** A schematic of a well site employing fracking. The yellow arrows indicate the avenues through which contaminants enter the environment.

The  $\text{HClO}$  in turn reacts with organic substances to form THMs. Bromine enters the reaction sequence through the reaction of  $\text{HClO}$  with dissolved bromide ion:

Then both  $\text{HBrO}(aq)$  and  $\text{HClO}(aq)$  can halogenate organic substances to form the THMs.

Some THMs and other halogenated organic substances are suspected carcinogens; others interfere with the body's endocrine system. As a result, the World Health Organization and the U.S. Environmental Protection Agency have placed concentration limits of  $80 \mu\text{g/L}$  (80 ppb) on the total quantity of THMs in drinking water. The goal is to reduce the levels of THMs and other disinfection by-products in the drinking water supply while preserving the antibacterial effectiveness of the water treatment. In some cases, lowering the concentration of chlorine may provide adequate disinfection while reducing the concentrations of THMs formed. Alternative oxidizing agents, such as ozone or chlorine dioxide, produce less of the halogenated substances but have their own disadvantages. For example, each is capable of oxidizing dissolved bromide, as shown here for ozone:

Bromate ion,  $\text{BrO}_3^-$ , has been shown to cause cancer in animal tests.

At present, there seem to be no completely satisfactory alternatives to chlorination or ozonation, and we are faced with a consideration of benefit versus risk. In this case, the risks of cancer from THMs and related substances in municipal water are very low relative to the risks of cholera, typhus, and gastrointestinal disorders from untreated water. When the water supply is cleaner to begin with, less disinfectant is needed and thus the risk of THMs is lowered. Once THMs form, their concentrations in the water supply can be reduced by aeration because the THMs are more volatile than water. Alternatively, they can be removed by adsorption onto activated charcoal or other adsorbents.

## CHEMISTRY AND LIFE Ocean Acidification

Seawater is a weakly basic solution, with pH values typically between 8.0 and 8.3. This pH range is maintained through a carbonic acid buffer system similar to the one in blood (see Equation 17.10). Because the pH of seawater is higher than that of blood (7.35–7.45), the second dissociation of carbonic acid cannot be neglected and  $\text{CO}_3^{2-}$  becomes an important aqueous species.

The availability of carbonate ions plays an important role in shell formation for a number of marine organisms, including stony corals (Figure 18.24). These organisms, which are referred to as marine *calcifiers* and play an important role in the food chains of nearly all oceanic ecosystems, depend on dissolved  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  ions to form their shells and exoskeletons. The relatively low solubility-product constant of  $\text{CaCO}_3$ ,

and the fact that the ocean contains saturated concentrations of  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  mean that  $\text{CaCO}_3$  is usually quite stable once formed. In fact, calcium carbonate skeletons of creatures that died millions of years ago are not uncommon in the fossil record.

The concentration of dissolved  $\text{CO}_2$  in the ocean is sensitive to changes in atmospheric  $\text{CO}_2$  levels. As discussed in Section 18.2, the atmospheric  $\text{CO}_2$  concentration has risen by approximately 30% over the past three centuries to the present level of 400 ppm. Human activity has played a prominent role in this increase. Scientists estimate that one-third to one-half of the  $\text{CO}_2$  emissions resulting from human activity have been absorbed by Earth's oceans. While this absorption helps mitigate the greenhouse gas effects of  $\text{CO}_2$ , the extra  $\text{CO}_2$  in the ocean produces carbonic acid, which lowers the pH. Because  $\text{CO}_3^{2-}$  is the conjugate base of the weak acid  $\text{HCO}_3^-$ , the carbonate ion readily combines with the hydrogen ion:

This consumption of carbonate ion shifts the  $\text{CaCO}_3$  dissolution equilibrium to the right, increasing the solubility of  $\text{CaCO}_3$ , which can lead to partial dissolution of calcium carbonate shells and exoskeletons. If the amount of atmospheric  $\text{CO}_2$  continues to increase at the present rate, scientists estimate that seawater pH will fall to 7.9 sometime over the next 50 years. While this change might sound small, it has dramatic ramifications for oceanic ecosystems.

**Related Exercises:** 18.7, 18.10, 18.71

▲ **Figure 18.24** Marine calcifiers. Many sea-dwelling organisms use  $\text{CaCO}_3$  for their shells and exoskeletons. Examples include stony coral, crustaceans, some phytoplankton, and echinoderms, such as sea urchins and starfish.

## 18.5 | Green Chemistry

The planet on which we live is, to a large extent, a *closed system*, one that exchanges energy but not matter with its surroundings. If humankind is to thrive in the future, all the processes we carry out should be in balance with Earth's natural processes and physical resources. This goal requires that no toxic materials be released to the environment, that our needs be met with renewable resources, and that we consume the least possible amount of energy. Although the chemical industry is but a small part of human activity, chemical processes are involved in nearly all aspects of modern life. Chemistry is therefore at the heart of efforts to accomplish these goals.

**Green chemistry** is an initiative that promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. Green chemistry rests on a set of 12 principles:

- 1. Prevention** It is better to prevent waste than to clean it up after it has been created.
- 2. Atom Economy** Methods to make chemical compounds should be designed to maximize the incorporation of all starting atoms into the final product.
- 3. Less Hazardous Chemical Syntheses** Wherever practical, synthetic methods should be designed to use and generate substances that possess little or no toxicity to human health and the environment.
- 4. Design of Safer Chemicals** Chemical products should be designed to minimize toxicity and yet maintain their desired function.

- 5. Safer Solvents and Auxiliaries** Auxiliary substances (for example, solvents, separation agents, etc.) should be used as little as possible. Those that are used should be as nontoxic as possible.
- 6. Design for Energy Efficiency** Energy requirements of chemical processes should be recognized for their environmental and economic impacts and should be minimized. If possible, chemical reactions should be conducted at room temperature and pressure.
- 7. Use of Renewable Feedstocks** A raw material or feedstock should be renewable whenever technically and economically practical.
- 8. Reduction of Derivatives** Unnecessary derivatization (intermediate compound formation, temporary modification of physical/chemical processes) should be minimized or avoided if possible because such steps require additional reagents and can generate waste.
- 9. Catalysis** Catalytic reagents (as selective as possible) improve product yields within a given time and with a lower energy cost compared to noncatalytic processes and are, therefore, preferred to noncatalytic alternatives.
- 10. Design for Degradation** The end products of chemical processing should break down at the end of their useful lives into innocuous degradation products that do not persist in the environment.
- 11. Real-Time Analysis for Pollution Prevention** Analytical methods need to be developed that allow for real-time, in-process monitoring and control prior to the formation of hazardous substances.
- 12. Inherently Safer Chemistry for Accident Prevention** Reagents and solvents used in a chemical process should be chosen to minimize the potential for chemical accidents, including releases, explosions, and fires.\*

### Give It Some Thought

Explain how a chemical reaction that uses a catalyst can be “greener” than the same reaction run without a catalyst.

To illustrate how green chemistry works, consider the manufacture of styrene, an important building block for many polymers, including the expanded polystyrene packages used to pack eggs and restaurant takeout food. The global demand for styrene is more than 25 billion kg per year. For many years, styrene has been produced in a two-step process: Benzene and ethylene react to form ethyl benzene, followed by the ethyl benzene being mixed with high-temperature steam and passed over an iron oxide catalyst to form styrene:

This process has several shortcomings. One is that both benzene, which is formed from crude oil, and ethylene, formed from natural gas, are high-priced starting materials for a product that should be a low-priced commodity. Another is that benzene is a known

\*Adapted from P. T. Anastas and J. C. Warner, *Green Chemistry: Theory and Practice*. New York: Oxford University Press 1998, p. 30. See also Mike Lancaster, *Green Chemistry: An Introductory Text*. Cambridge, UK: RSC Publishing, 2010, Second Edition, Chapter 1.

carcinogen. In a recently developed process that bypasses some of these shortcomings, the two-step process is replaced by a one-step process in which toluene is reacted with methanol at 425 °C over a special catalyst:

The one-step process saves money both because toluene and methanol are less expensive than benzene and ethylene, and because the reaction requires less energy input. Additional benefits are that the methanol could be produced from biomass and that benzene is replaced by less toxic toluene. The hydrogen formed in the reaction can be recycled as a source of energy. This example demonstrates how finding the right catalyst is often key in discovering a new process.

Let's consider some other examples in which green chemistry can operate to improve environmental quality.

## Supercritical Solvents

A major area of concern in chemical processes is the use of volatile organic compounds as solvents. Generally, the solvent in which a reaction is run is not consumed in the reaction, and there are unavoidable releases of solvent into the atmosphere even in the most carefully controlled processes. Further, the solvent may be toxic or may decompose to some extent during the reaction, thus creating waste products.

The use of supercritical fluids represents a way to replace conventional solvents. Recall that a supercritical fluid is an unusual state of matter that has properties of both a gas and a liquid. [∞ \(Section 11.4\)](#) Water and carbon dioxide are the two most popular choices as supercritical fluid solvents. One recently developed industrial process, for example, replaces chlorofluorocarbon solvents with liquid or supercritical CO<sub>2</sub> in the production of polytetrafluoroethylene ([CF<sub>2</sub>CF<sub>2</sub>]<sub>n</sub>, sold as Teflon®). Though CO<sub>2</sub> is a greenhouse gas, no new CO<sub>2</sub> need be manufactured for use as a supercritical fluid solvent.

As a further example, *para*-xylene is oxidized to form terephthalic acid, which is used to make polyethylene terephthalate (PET) plastic and polyester fiber [∞ \(Section 12.8, Table 12.5\)](#):

This commercial process requires pressurization and a relatively high temperature. Oxygen is the oxidizing agent, and acetic acid (CH<sub>3</sub>COOH) is the solvent. An alternative route employs supercritical water as the solvent and hydrogen peroxide as the oxidant. This alternative process has several potential advantages, most particularly the elimination of acetic acid as solvent.

## Greener Reagents and Processes

Let us examine two more examples of green chemistry in action.

Hydroquinone, HO—C<sub>6</sub>H<sub>4</sub>—OH, is a common intermediate used to make polymers. The standard industrial route to hydroquinone, used until recently, yields many by-products that are treated as waste:

Using the principles of green chemistry, researchers have improved this process. The new process for hydroquinone production uses a new starting material. Two of the by-products of the new reaction (shown in green) can be isolated and used to make the new starting material.

The new process is an example of “atom economy,” a phrase that means that a high percentage of the atoms from the starting materials end up in the product.

### Give It Some Thought

Assuming the by-products shown in green (phenol and acetone) are recycled, what atoms, if any, used in the new process for making hydroquinone do not end up in the final products?

Another example of atom economy is a reaction in which, at room temperature and in the presence of a copper(I) catalyst, an organic *azide* and an *alkyne* form one product molecule:

This reaction is informally called a *click reaction*. The yield—actual, not just theoretical—is close to 100%, and there are no by-products. Depending on the type of azide and type of alkyne we start with, this very efficient click reaction can be used to create any number of valuable product molecules.

### Give It Some Thought

What are the hybridizations of the two alkyne C atoms before and after the click reaction?

## Sample Integrative Exercise

### Putting Concepts Together

(a) Acid rain is no threat to lakes in areas where the rock is limestone (calcium carbonate), which can neutralize the acid. Where the rock is granite, however, no neutralization occurs. How does limestone neutralize acid? (b) Acidic water can be treated with basic substances to increase the pH, although such a procedure is usually only a temporary cure. Calculate the minimum mass of lime, CaO, needed to adjust the pH of a small lake ( $V = 4 \times 10^9 \text{ L}$ ) from 5.0 to 6.5. Why might more lime be needed?

### SOLUTION

**Analyze** We need to remember what a neutralization reaction is and calculate the amount of a substance needed to effect a certain change in pH.

**Plan** For (a), we need to think about how acid can react with calcium carbonate, a reaction that evidently does not happen with acid and granite. For (b), we need to think about what reaction between an acid and CaO is possible and do stoichiometric calculations. From the proposed change in pH, we can calculate the change in proton concentration needed and then figure out how much CaO is needed.

### Solve

(a) The carbonate ion, which is the anion of a weak acid, is basic (Sections 16.2 and 16.7) and so reacts with  $\text{H}^+(aq)$ . If the concentration of  $\text{H}^+(aq)$  is low, the major product is the bicarbonate ion,  $\text{HCO}_3^-$ . If the concentration of  $\text{H}^+(aq)$  is high,  $\text{H}_2\text{CO}_3$  forms and decomposes to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . (Section 4.3)

(b) The initial and final concentrations of  $\text{H}^+(aq)$  in the lake are obtained from their pH values:

$$[\text{H}^+]_{\text{initial}} = 10^{-5.0} = 1 \times 10^{-5} \text{ M}$$

$$[\text{H}^+]_{\text{final}} = 10^{-6.5} = 3 \times 10^{-7} \text{ M}$$

Using the lake volume, we can calculate the number of moles of  $\text{H}^+(aq)$  at both pH values:

$$(1 \times 10^{-5} \text{ mol/L})(4.0 \times 10^9 \text{ L}) = 4 \times 10^4 \text{ mol}$$

$$(3 \times 10^{-7} \text{ mol/L})(4.0 \times 10^9 \text{ L}) = 1 \times 10^3 \text{ mol}$$

Hence, the change in the amount of  $\text{H}^+(aq)$  is  $4 \times 10^4 \text{ mol} - 1 \times 10^3 \text{ mol} \approx 4 \times 10^4 \text{ mol}$ .

Let's assume that all the acid in the lake is completely ionized, so that only the free  $\text{H}^+(aq)$  contributing to the pH needs to be neutralized. We need to neutralize at least that much acid, although there may be a great deal more than that amount in the lake.

The oxide ion of CaO is very basic. (Section 16.5) In the neutralization reaction, 1 mol of CaO reacts with 2 mol of  $\text{H}^+$  to form  $\text{H}_2\text{O}$  and  $\text{Ca}^{2+}$  ions. Thus,  $4 \times 10^4 \text{ mol}$  of  $\text{H}^+$  requires

$$(4 \times 10^4 \text{ mol H}^+) \left( \frac{1 \text{ mol CaO}}{2 \text{ mol H}^+} \right) \left( \frac{56.1 \text{ g CaO}}{1 \text{ mol CaO}} \right) = 1 \times 10^6 \text{ g CaO}$$

This is slightly more than a ton of CaO. That would not be very costly because CaO is inexpensive, selling for less than \$100 per ton when purchased in large quantities. This amount of CaO is the minimum amount needed, however, because there are likely to be weak acids in the water that must also be neutralized.

This liming procedure has been used to bring the pH of some small lakes into the range necessary for fish to live. The lake in our example would be about a half mile long and a half mile wide and have an average depth of 20 ft.

## Chapter Summary and Key Terms

**EARTH'S ATMOSPHERE (SECTION 18.1)** In this section we examined the physical and chemical properties of Earth's atmosphere. The complex temperature variations in the atmosphere give rise to four regions, each with characteristic properties. The lowest of these regions, the **troposphere**, extends from Earth's surface up to an altitude of about 12 km. Above the troposphere, in order of increasing altitude, are the **stratosphere**, mesosphere, and thermosphere. In the upper reaches of the atmosphere, only the simplest chemical species can survive the bombardment of highly energetic particles and radiation from the Sun. The average molecular weight of the atmosphere at high elevations is lower than that at Earth's surface because the lightest atoms and molecules diffuse upward and also because of **photodissociation**, which is the breaking of bonds in molecules because of the absorption of light. Absorption of radiation may also lead to the formation of ions via **photoionization**.

### HUMAN ACTIVITIES AND EARTH'S ATMOSPHERE (SECTION 18.2)

Ozone is produced in the upper atmosphere from the reaction of atomic oxygen with  $O_2$ . Ozone is itself decomposed by absorption of a photon or by reaction with an active species such as Cl. **Chlorofluorocarbons** can undergo photodissociation in the stratosphere, introducing atomic chlorine, which is capable of catalytically destroying ozone. A marked reduction in the ozone level in the upper atmosphere would have serious adverse consequences because the ozone layer filters out certain wavelengths of harmful ultraviolet light that are not removed by any other atmospheric component. In the troposphere the chemistry of trace atmospheric components is of major importance. Many of these minor components are pollutants. Sulfur dioxide is one of the more noxious and prevalent examples. It is oxidized in air to form sulfur trioxide, which, upon dissolving in water, forms sulfuric acid. The oxides of sulfur are major contributors to **acid rain**. One method of preventing the escape of  $SO_2$  from industrial operations is to react it with CaO to form calcium sulfite  $CaSO_3$ .

**Photochemical smog** is a complex mixture in which both nitrogen oxides and ozone play important roles. Smog components are generated mainly in automobile engines, and smog control consists largely of controlling auto emissions.

Carbon dioxide and water vapor are the major components of the atmosphere that strongly absorb infrared radiation.  $CO_2$  and  $H_2O$  are therefore critical in maintaining Earth's surface temperature. The concentrations of  $CO_2$  and other so-called

**greenhouse gases** in the atmosphere are thus important in determining global climate. Because of the extensive combustion of fossil fuels (coal, oil, and natural gas), the concentration of carbon dioxide in the atmosphere is steadily increasing, which in turn appears to be contributing to an increase in the average temperature of the Earth.

**EARTH'S WATER (SECTION 18.3)** Earth's water is largely in the oceans and seas; only a small fraction is freshwater. Seawater contains about 3.5% by mass of dissolved salts and is described as having a **salinity** (grams of dry salts per 1 kg seawater) of 35. Seawater's density and salinity vary with depth. Because most of the world's water is in the oceans, humans may eventually need to recover freshwater from seawater. The global water cycle involves continuous phase changes of water.

### HUMAN ACTIVITIES AND WATER QUALITY (SECTION 18.4)

Freshwater contains many dissolved substances including dissolved oxygen, which is necessary for fish and other aquatic life. Substances that are decomposed by bacteria are said to be **biodegradable**. Because the oxidation of biodegradable substances by aerobic bacteria consumes dissolved oxygen, these substances are called oxygen-demanding wastes. The presence of an excess amount of oxygen-demanding wastes in water can sufficiently deplete the dissolved oxygen to kill fish and produce offensive odors. Plant nutrients can contribute to the problem by stimulating the growth of plants that become oxygen-demanding wastes when they die. **Desalination** is the removal of dissolved salts from seawater or brackish water to make it fit for human consumption. Desalination may be accomplished by distillation or by **reverse osmosis**.

The water available from freshwater sources may require treatment before it can be used domestically. The several steps generally used in municipal water treatment include coarse filtration, sedimentation, sand filtration, aeration, and sterilization.

**GREEN CHEMISTRY (SECTION 18.5)** The **green chemistry** initiative promotes the design and application of chemical products and processes that are compatible with human health and that preserve the environment. The areas in which the principles of green chemistry can operate to improve environmental quality include choices of solvents and reagents for chemical reactions, development of alternative processes, and improvements in existing systems and practices.

## Learning Outcomes After studying this chapter, you should be able to:

- Describe the regions of Earth's atmosphere in terms of how temperature varies with altitude. (Section 18.1)  
*Related exercises 18.11, 18.12*
- Describe the composition of the atmosphere in terms of the major components in dry air at sea level. (Section 18.1)  
*Related exercises 18.14, 18.16*
- Calculate concentrations of gases in parts per million (ppm). (Section 18.1) *Related exercises 18.13, 18.15*
- Describe the processes of photodissociation and photoionization and their role in the upper atmosphere. (Section 18.1)  
*Related exercises 18.19, 18.20*
- Calculate the minimum frequency or maximum wavelength needed to cause photodissociation or photoionization. (Section 18.1) *Related exercises 18.17, 18.18, 18.21*
- Explain how ozone in the upper atmosphere functions to filter short wavelength solar radiation, and how chlorofluorocarbons (CFCs) cause depletion of the ozone layer. (Sections 18.1 and 18.2) *Related exercises 18.22, 18.25, 18.27, 18.28*
- Describe the origins and behavior of sulfur oxides and nitrogen oxides as air pollutants, including the generation of acid rain and photochemical smog. (Section 18.2)  
*Related exercises 18.29, 18.30, 18.33, 18.34*
- Describe how water and carbon dioxide cause an increase in atmospheric temperature near Earth's surface. (Section 18.2)  
*Related exercises 18.35, 18.36*
- Describe the global water cycle. (Section 18.3)  
*Related exercises 18.39, 18.40*

- Explain what is meant by the salinity of water and describe the process of reverse osmosis as a means of desalination. (Section 18.4) *Related Exercises 18.45, 18.46*
- List the major cations, anions, and gases present in natural waters and describe the relationship between dissolved oxygen and water quality. (Section 18.4) *Related exercises 18.43, 18.48–18.50*
- List the main steps involved in treating water for domestic uses. (Section 18.4) *Related exercises 18.51–18.54*
- Describe the main goals of green chemistry. (Section 18.5) *Related exercises 18.55, 18.56*
- Compare reactions and decide which reaction is greener. (Section 18.5) *Related exercises 18.58–18.60*

## Exercises

### Visualizing Concepts

- 18.1** At 273 K and 1 atm pressure, 1 mol of an ideal gas occupies 22.4 L. (Section 10.4) **(a)** Looking at Figure 18.1, predict whether a 1 mol sample of the atmosphere in the middle of the stratosphere would occupy a greater or smaller volume than 22.4 L **(b)** Looking at Figure 18.1, we see that the temperature is lower at 85 km altitude than at 50 km. Does this mean that one mole of an ideal gas would occupy less volume at 85 km than at 50 km? Explain. **(c)** In which parts of the atmosphere would you expect gases to behave most ideally (ignoring any photochemical reactions)? [Section 18.1]
- 18.2** Molecules in the upper atmosphere tend to contain double and triple bonds rather than single bonds. Suggest an explanation. [Section 18.1]
- 18.3** The figure shows the three lowest regions of Earth's atmosphere. **(a)** Name each and indicate the approximate elevations at which the boundaries occur. **(b)** In which region is ozone a pollutant? In which region does it filter UV solar radiation? **(c)** In which region is infrared radiation from Earth's surface most strongly reflected back? **(d)** An aurora borealis is due to excitation of atoms and molecules in the atmosphere 55–95 km above Earth's surface. Which regions in the figure are involved in an aurora borealis? **(e)** Compare the changes in relative concentrations of water vapor and carbon dioxide with increasing elevation in these three regions [Section 18.1].

- 18.4** You are working with an artist who has been commissioned to make a sculpture for a big city in the eastern United States. The artist is wondering what material to use to make her sculpture because she has heard that acid rain in the eastern United States might destroy it over time. You take samples of granite, marble, bronze, and other materials, and place them outdoors for a long time in the big city. You periodically examine the appearance and measure the

mass of the samples. **(a)** What observations would lead you to conclude that one or more of the materials are well-suited for the sculpture? **(b)** What chemical process (or processes) is (are) the most likely responsible for any observed changes in the materials? [Section 18.2]

- 18.5** Where does the energy come from to evaporate the estimated 425,000 km<sup>3</sup> of water that annually leaves the oceans, as illustrated here? [Section 18.3]

- 18.6** The Earth's oceans have a salinity of 35. What is the concentration of dissolved salts in seawater when expressed in ppm? What percentage of salts must be removed from seawater before it can be considered freshwater (dissolved salts < 500 ppm)? [Section 18.3]
- 18.7** Describe what changes occur when atmospheric CO<sub>2</sub> interacts with the world ocean as illustrated here. [Section 18.3]

- 18.8** The first stage of treatment at the reverse osmosis plant in Carlsbad, California, is to flow the water through rock, sand, and gravel as shown here. Would this step remove

particulate matter? Would this step remove dissolved salts? [Section 18.4]

- 18.9** From study of Figure 18.23 describe the various ways in which operation of a fracking well site could lead to environmental contamination.
- 18.10** One mystery in environmental science is the imbalance in the “carbon dioxide budget.” Considering only human activities, scientists have estimated that 1.6 billion metric tons of  $\text{CO}_2$  is added to the atmosphere every year because of deforestation (plants use  $\text{CO}_2$ , and fewer plants will leave more  $\text{CO}_2$  in the atmosphere). Another 5.5 billion tons per year is put into the atmosphere because of burning

fossil fuels. It is further estimated (again, considering only human activities) that the atmosphere actually takes up about 3.3 billion tons of this  $\text{CO}_2$  per year, while the oceans take up 2 billion tons per year, leaving about 1.8 billion tons of  $\text{CO}_2$  per year unaccounted for. Describe a mechanism by which  $\text{CO}_2$  is removed from the atmosphere and ultimately ends up below the surface (*Hint*: What is the source of the fossil fuels?). [Sections 18.1–18.3]

## Earth's Atmosphere (Section 18.1)

- 18.11** (a) What is the primary basis for the division of the atmosphere into different regions? (b) Name the regions of the atmosphere, indicating the altitude interval for each one.
- 18.12** (a) How are the boundaries between the regions of the atmosphere determined? (b) Explain why the stratosphere, which is about 35 km thick, has a smaller total mass than the troposphere, which is about 12 km thick.
- 18.13** Air pollution in the Mexico City metropolitan area is among the worst in the world. The concentration of ozone in Mexico City has been measured at 441 ppb (0.441 ppm). Mexico City sits at an altitude of 7400 feet, which means its atmospheric pressure is only 0.67 atm. (a) Calculate the partial pressure of ozone at 441 ppb if the atmospheric pressure is 0.67 atm. (b) How many ozone molecules are in 1.0 L of air in Mexico City? Assume  $T = 25^\circ\text{C}$ .
- 18.14** From the data in Table 18.1, calculate the partial pressures of carbon dioxide and argon when the total atmospheric pressure is 1.05 bar.
- 18.15** The average concentration of carbon monoxide in air in an Ohio city in 2006 was 3.5 ppm. Calculate the number of CO molecules in 1.0 L of this air at a pressure of 759 torr and a temperature of  $22^\circ\text{C}$ .
- 18.16** (a) From the data in Table 18.1, what is the concentration of neon in the atmosphere in ppm? (b) What is the concentration of neon in the atmosphere in molecules per liter, assuming an atmospheric pressure of 730 torr and a temperature of 296 K?
- 18.17** The dissociation energy of a carbon–bromine bond is typically about 276 kJ/mol. (a) What is the maximum wavelength of photons that can cause C—Br bond dissociation? (b) Which kind of electromagnetic radiation—ultraviolet, visible, or infrared—does the wavelength you calculated in part (a) correspond to?
- 18.18** In  $\text{CF}_3\text{Cl}$  the C—Cl bond-dissociation energy is 339 kJ/mol. In  $\text{CCl}_4$  the C—Cl bond-dissociation energy is 293 kJ/mol. What is the range of wavelengths of photons that can cause C—Cl bond rupture in one molecule but not in the other?
- 18.19** (a) Distinguish between *photodissociation* and *photoionization*. (b) Use the energy requirements of these two processes to explain why photodissociation of oxygen is more important than photoionization of oxygen at altitudes below about 90 km.
- 18.20** Why is the photodissociation of  $\text{N}_2$  in the atmosphere relatively unimportant compared with the photodissociation of  $\text{O}_2$ ?
- 18.21** The wavelength at which the  $\text{O}_2$  molecule most strongly absorbs light is approximately 145 nm. (a) In which region of the electromagnetic spectrum does this light fall? (b) Would a photon whose wavelength is 145 nm have enough energy to photodissociate  $\text{O}_2$  whose bond energy is 495 kJ/mol? Would it have enough energy to photoionize  $\text{O}_2$ ?
- 18.22** The ultraviolet spectrum can be divided into three regions based on wavelength: UV-A (315–400 nm), UV-B (280–315 nm), and UV-C (100–280 nm). (a) Photons from which region have the highest energy and therefore are the most harmful to living tissue? (b) In the absence of ozone, which of these three regions, if any, are absorbed by the atmosphere? (c) When appropriate concentrations of ozone are present in the stratosphere, is all of the UV light absorbed before reaching the Earth's surface? If not, which region or regions are not filtered out?

## Human Activities and Earth's Atmosphere (Section 18.2)

- 18.23** Do the reactions involved in ozone depletion involve changes in oxidation state of the O atoms? Explain.
- 18.24** Which of the following reactions in the stratosphere cause an increase in temperature there?
- (a)  $\text{O}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow \text{O}_3^*(\text{g})$   
 (b)  $\text{O}_3^*(\text{g}) + \text{M}(\text{g}) \longrightarrow \text{O}_3(\text{g}) + \text{M}^*(\text{g})$   
 (c)  $\text{O}_2(\text{g}) + h\nu \longrightarrow 2\text{O}(\text{g})$   
 (d)  $\text{O}(\text{g}) + \text{N}_2(\text{g}) \longrightarrow \text{NO}(\text{g}) + \text{N}(\text{g})$   
 (e) All of the above
- 18.25** (a) What is the difference between chlorofluorocarbons and hydrofluorocarbons? (b) Why are hydrofluorocarbons potentially less harmful to the ozone layer than CFCs?
- 18.26** Draw the Lewis structure for the chlorofluorocarbon CFC-11,  $\text{CFCl}_3$ . What chemical characteristics of this substance allow it to effectively deplete stratospheric ozone?
- 18.27** The average bond enthalpies of the C—F and C—Cl bonds are 485 kJ/mol and 328 kJ/mol, respectively. (a) What is the maximum wavelength that a photon can possess and still have sufficient energy to break the C—F and C—Cl bonds, respectively? (b) Given the fact that  $\text{O}_2$ ,  $\text{N}_2$ , and O in the upper atmosphere absorb most of the light with wavelengths shorter than 240 nm, would you expect the photodissociation of C—F bonds to be significant in the lower atmosphere?
- 18.28** (a) When chlorine atoms react with atmospheric ozone, what are the products of the reaction? (b) Based on average bond enthalpies, would you expect a photon capable of dissociating a C—Cl bond to have sufficient energy to dissociate a C—Br bond? (c) Would you expect the substance  $\text{CFBr}_3$  to accelerate depletion of the ozone layer?
- 18.29** Nitrogen oxides like  $\text{NO}_2$  and NO are a significant source of acid rain. For each of these molecules write an equation that shows how an acid is formed from the reaction with water.
- 18.30** Why is rainwater naturally acidic, even in the absence of polluting gases such as  $\text{SO}_2$ ?
- 18.31** (a) Write a chemical equation that describes the attack of acid rain on limestone,  $\text{CaCO}_3$ . (b) If a limestone sculpture were treated to form a surface layer of calcium sulfate, would this help to slow down the effects of acid rain? Explain.
- 18.32** The first stage in corrosion of iron upon exposure to air is oxidation to  $\text{Fe}^{2+}$ . (a) Write a balanced chemical equation to show the reaction of iron with oxygen and protons from acid rain. (b) Would you expect the same sort of reaction to occur with a silver surface? Explain.
- 18.33** Alcohol-based fuels for automobiles lead to the production of formaldehyde ( $\text{CH}_2\text{O}$ ) in exhaust gases. Formaldehyde undergoes photodissociation, which contributes to photochemical smog:

The maximum wavelength of light that can cause this reaction is 335 nm. (a) In what part of the electromagnetic spectrum is light with this wavelength found? (b) What is the maximum strength of a bond, in kJ/mol, that can be broken by absorption of a photon of 335-nm light? (c) Compare your answer from part (b) to the appropriate value from Table 8.3. What do you conclude about C—H bond energy

in formaldehyde? **(d)** Write out the formaldehyde photodissociation reaction, showing Lewis-dot structures.

- 18.34** An important reaction in the formation of photochemical smog is the photodissociation of  $\text{NO}_2$ :

The maximum wavelength of light that can cause this reaction is 420 nm. **(a)** In what part of the electromagnetic spectrum is light with this wavelength found? **(b)** What is the maximum strength of a bond, in kJ/mol, that can be broken by absorption of a photon of 420-nm light? **(c)** Write out the photodissociation reaction showing Lewis-dot structures.

- 18.35** Consider the Earth's energy balance shown in Figure 18.12. **(a)** How many different sources transfer energy to the atmosphere? Which makes the largest contribution? What is the total amount of energy transferred into the atmosphere in  $\text{W/m}^2$ ? **(b)** To maintain a balance the atmosphere must lose an equal amount of energy by emitting radiation, either into space or back toward the surface. What fraction is radiated back to the surface?
- 18.36** The atmosphere of Mars is 96%  $\text{CO}_2$ , with a pressure of approximately  $6 \times 10^{-3}$  atm at the surface. Based on measurements taken over a period of several years by the Rover Environmental Monitoring Station (REMS), the average daytime temperature at the REMS location on Mars is  $-5.7^\circ\text{C}$  ( $22^\circ\text{F}$ ), while the average nighttime temperature is  $-79^\circ\text{C}$  ( $-109^\circ\text{F}$ ). This daily variation in temperature is much larger than what we experience on Earth. What factor plays the largest role in this wide temperature variation, the composition or the density of the atmosphere?

### Earth's Water (Section 18.3)

- 18.37** What is the molarity of  $\text{Na}^+$  in a solution of  $\text{NaCl}$  whose salinity is 5.6 if the solution has a density of 1.03 g/mL?
- 18.38** Phosphorus is present in seawater to the extent of 0.07 ppm by mass. Assuming that the phosphorus is present as dihydrogenphosphate,  $\text{H}_2\text{PO}_4^-$ , calculate the corresponding molar concentration of  $\text{H}_2\text{PO}_4^-$  in seawater.
- 18.39** The enthalpy of evaporation of water is 40.67 kJ/mol. Sunlight striking Earth's surface supplies 168 W per square meter ( $1\text{ W} = 1\text{ watt} = 1\text{ J/s}$ ). **(a)** Assuming that evaporation of water is due only to energy input from the Sun, calculate how many grams of water could be evaporated from a 1.00 square meter patch of ocean over a 12-h day. **(b)** The specific heat capacity of liquid water is  $4.184\text{ J/g}^\circ\text{C}$ . If the initial surface temperature of a 1.00 square meter patch of ocean is  $26^\circ\text{C}$ , what is its final temperature after being in sunlight for 12 h, assuming no phase changes and assuming that sunlight penetrates uniformly to depth of 10.0 cm?
- [18.40]** The enthalpy of fusion of water is 6.01 kJ/mol. Sunlight striking Earth's surface supplies 168 W per square meter ( $1\text{ W} = 1\text{ watt} = 1\text{ J/s}$ ). **(a)** Assuming that melting of ice is due only to energy input from the Sun, calculate how many grams of ice could be melted from a 1.00 square meter patch of ice over a 12-h day. **(b)** The specific heat capacity of ice is  $2.032\text{ J/g}^\circ\text{C}$ . If the initial temperature of a 1.00 square meter patch of ice is  $-5.0^\circ\text{C}$ , what is its final temperature after being in sunlight for 12 h, assuming no phase changes and assuming that sunlight penetrates uniformly to a depth of 1.00 cm?
- 18.41** A first-stage recovery of magnesium from seawater is precipitation of  $\text{Mg}(\text{OH})_2$  with  $\text{CaO}$ :

What mass of  $\text{CaO}$ , in grams, is needed to precipitate 1000 lb of  $\text{Mg}(\text{OH})_2$ ?

- 18.42** Gold is found in seawater at very low levels, about 0.05 ppb by mass. Assuming that gold is worth about \$1300 per troy ounce, how many liters of seawater would you have to process to obtain \$1,000,000 worth of gold? Assume the density of seawater is 1.03 g/mL and that your gold recovery process is 50% efficient.
- 18.43** Although there are many ions in seawater, the overall charges of the dissolved cations and anions must maintain charge neutrality. Consider only the six most abundant ions in seawater, as listed in Table 18.5 ( $\text{Cl}^-$ ,  $\text{Na}^+$ ,  $\text{SO}_4^{2-}$ ,  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{K}^+$ ), calculate the total charge in Coulombs of the cations in 1.0 L of seawater. Calculate the total charge in Coulombs of the anions in 1.0 L of seawater. To how many significant figures are the two numbers equal?
- 18.44** The Ogallala aquifer described in the Closer Look box in Section 18.3, provides 82% of the drinking water for the people who live in the region, although more than 75% of the water that is pumped from it is for irrigation. Irrigation withdrawals are approximately 18 billion gallons per day. **(a)** Assuming that 2% of the rainfall that falls on an area of 600,000  $\text{km}^2$  recharges the aquifer, what average annual rainfall would be required to replace the water removed for irrigation? **(b)** What process or processes accounts for the presence of arsenic in well water?

### Human Activities and Water Quality (Section 18.4)

- 18.45** Suppose that one wishes to use reverse osmosis to reduce the salt content of brackish water containing 0.22 M total salt concentration to a value of 0.01 M, thus rendering it usable for human consumption. What is the minimum pressure that needs to be applied in the permeators (Figure 18.20) to achieve this goal, assuming that the operation occurs at 298 K? (*Hint:* Refer to Section 13.5.)
- 18.46** Assume that a portable reverse-osmosis apparatus operates on seawater, whose concentrations of constituent ions are listed in Table 18.5, and that the desalinated water output has an effective molarity of about 0.02 M. What minimum pressure must be applied by hand pumping at 297 K to cause reverse osmosis to occur? (*Hint:* Refer to Section 13.5.)
- 18.47** List the common products formed when an organic material containing the elements carbon, hydrogen, oxygen, sulfur, and nitrogen decomposes **(a)** under aerobic conditions, **(b)** under anaerobic conditions.
- 18.48** **(a)** Explain why the concentration of dissolved oxygen in freshwater is an important indicator of the quality of the water. **(b)** Find graphical data in the text that show variations of gas solubility with temperature, and estimate to two significant figures the percent solubility of  $\text{O}_2$  in water at  $30^\circ\text{C}$  as compared with  $20^\circ\text{C}$ . How do these data relate to the quality of natural waters?
- 18.49** The organic anion

is found in most detergents. Assume that the anion undergoes aerobic decomposition in the following manner:

What is the total mass of  $\text{O}_2$  required to biodegrade 10.0 g of this substance?

- 18.50** The average daily mass of  $\text{O}_2$  taken up by sewage discharged in the United States is 59 g per person. How many liters of water at 9 ppm  $\text{O}_2$  are 50% depleted of oxygen in 1 day by a population of 1,200,000 people?

- 18.51** Magnesium ions are removed in water treatment by the addition of slaked lime,  $\text{Ca}(\text{OH})_2$ . Write a balanced chemical equation to describe what occurs in this process.

- 18.52** In the lime soda process once used in large scale municipal water softening, calcium hydroxide prepared from lime and sodium carbonate are added to precipitate  $\text{Ca}^{2+}$  as  $\text{CaCO}_3(\text{s})$  and  $\text{Mg}^{2+}$  as  $\text{Mg}(\text{OH})_2(\text{s})$ :

How many moles of  $\text{Ca}(\text{OH})_2$  and  $\text{Na}_2\text{CO}_3$  should be added to soften (remove the  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ) 1200 L of water in which

$$[\text{Ca}^{2+}] = 5.0 \times 10^{-4} \text{ M} \quad \text{and}$$

$$[\text{Mg}^{2+}] = 7.0 \times 10^{-4} \text{ M}$$

- 18.53** (a) What are *trihalomethanes* (THMs)? (b) Draw the Lewis structures of two example THMs.

- 18.54** (a) Suppose that tests of a municipal water system reveal the presence of bromate ion,  $\text{BrO}_3^-$ . What are the likely origins of this ion? (b) Is bromate ion an oxidizing or reducing agent?

## Green Chemistry (Section 18.5)

- 18.55** One of the principles of green chemistry is that it is better to use as few steps as possible in making new chemicals. In what ways does following this rule advance the goals of green chemistry? How does this principle relate to energy efficiency?

- 18.56** Discuss how catalysts can make processes more energy efficient.

- 18.57** A reaction for converting ketones to lactones, called the Baeyer–Villiger reaction,

Ketone

3-Chloroperbenzoic acid

Lactone

3-Chlorobenzoic acid

is used in the manufacture of plastics and pharmaceuticals. 3-Chloroperbenzoic acid is shock-sensitive, however, and prone to explode. Also, 3-chlorobenzoic acid is a waste product. An alternative process being developed uses hydrogen peroxide and a catalyst consisting of tin deposited within a solid support. The catalyst is readily recovered from the reaction mixture. (a) What would you expect to be the other product of oxidation of the ketone to lactone by hydrogen peroxide? (b) What principles of green chemistry are addressed by use of the proposed process?

- 18.58** The hydrogenation reaction shown here was performed with an iridium catalyst, both in supercritical  $\text{CO}_2$  ( $\text{scCO}_2$ ) and in the chlorinated solvent  $\text{CH}_2\text{Cl}_2$ . The kinetic data for the reaction in both solvents are plotted in the graph. In what respects is the use of  $\text{scCO}_2$  a good example of a green chemical reaction?

- 18.59** In the following three instances, which choice is greener in each situation? Explain. (a) Benzene as a solvent or water as a solvent. (b) The reaction temperature is 500 K or 1000 K. (c) Sodium chloride as a by-product or chloroform ( $\text{CHCl}_3$ ) as a by-product.

- 18.60** In the following three instances, which choice is greener in a chemical process? Explain. (a) A reaction that can be run at 350 K for 12 h without a catalyst or one that can be run at 300 K for 1 h with a reusable catalyst. (b) A reagent for the reaction that can be obtained from corn husks or one that is obtained from petroleum. (c) A process that produces no by-products or one in which the by-products are recycled for another process.

## Additional Exercises

- 18.61** A friend of yours has seen each of the following items in newspaper articles and would like an explanation: **(a)** acid rain, **(b)** greenhouse gas, **(c)** photochemical smog, **(d)** ozone depletion. Give a brief explanation of each term and identify one or two of the chemicals associated with each.
- 18.62** Suppose that on another planet the atmosphere consists of 17% Kr, 38% CH<sub>4</sub>, and 45% O<sub>2</sub>. What is the average molar mass at the surface? What is the average molar mass at an altitude at which all the O<sub>2</sub> is photodissociated?
- 18.63** If an average O<sub>3</sub> molecule “lives” only 100–200 seconds in the stratosphere before undergoing dissociation, how can O<sub>3</sub> offer any protection from ultraviolet radiation?
- 18.64** Show how Equations 18.7 and 18.9 can be added to give Equation 18.10.
- 18.65** What properties of CFCs make them ideal for various commercial applications but also make them a long-term problem in the stratosphere?
- 18.66** Halons are fluorocarbons that contain bromine, such as CBrF<sub>3</sub>. They are used extensively as foaming agents for fighting fires. Like CFCs, halons are very unreactive and ultimately can diffuse into the stratosphere. **(a)** Based on the data in Table 8.3, would you expect photodissociation of Br atoms to occur in the stratosphere? **(b)** Propose a mechanism by which the presence of halons in the stratosphere could lead to the depletion of stratospheric ozone.
- 18.67** **(a)** What is the difference between a CFC and an HFC? **(b)** It is estimated that the lifetime for HFCs in the stratosphere is 2–7 years. Why is this number significant? **(c)** Why have HFCs been used to replace CFCs? **(d)** What is the major disadvantage of HFCs as replacements for CFCs?
- 18.68** Explain, using Le Châtelier’s principle, why the equilibrium constant for the formation of NO from N<sub>2</sub> and O<sub>2</sub> increases with increasing temperature, whereas the equilibrium constant for the formation of NO<sub>2</sub> from NO and O<sub>2</sub> decreases with increasing temperature.
- 18.69** Natural gas consists primarily of methane, CH<sub>4</sub>(g). **(a)** Write a balanced chemical equation for the complete combustion of methane to produce CO<sub>2</sub>(g) as the only carbon-containing product. **(b)** Write a balanced chemical equation for the incomplete combustion of methane to produce CO(g) as the only carbon-containing product. **(c)** At 25 °C and 1.0 atm pressure, what is the minimum quantity of dry air needed to combust 1.0 L of CH<sub>4</sub>(g) completely to CO<sub>2</sub>(g)?
- 18.70** It was estimated that the eruption of the Mount Pinatubo volcano resulted in the injection of 20 million metric tons of SO<sub>2</sub> into the atmosphere. Most of this SO<sub>2</sub> underwent oxidation to SO<sub>3</sub>, which reacts with atmospheric water to form an aerosol. **(a)** Write chemical equations for the processes leading to formation of the aerosol. **(b)** The aerosols caused a 0.5–0.6 °C drop in surface temperature in the northern hemisphere. What is the mechanism by which this occurs? **(c)** The sulfate aerosols, as they are called, also cause loss of ozone from the stratosphere. How might this occur?
- 18.71** One of the possible consequences of climate change is an increase in the temperature of ocean water. The oceans serve as a “sink” for CO<sub>2</sub> by dissolving large amounts of it. **(a)** The figure below shows the solubility of CO<sub>2</sub> in water as

a function of temperature. Does CO<sub>2</sub> behave more or less similarly to other gases in this respect?

**(b)** What are the implications of this figure for the problem of climate change?

- 18.72** The rate of solar energy striking Earth averages 168 watts per square meter. The rate of energy radiated from Earth’s surface averages 390 watts per square meter. Comparing these numbers, one might expect that the planet would cool quickly, yet it does not. Why not?
- 18.73** The solar power striking Earth every day averages 168 watts per square meter. The highest ever recorded electrical power usage in New York City was 13,200 MW. A record established in July of 2013. Considering that present technology for solar energy conversion is about 10% efficient, from how many square meters of land must sunlight be collected in order to provide this peak power? (For comparison, the total area of New York City is 830 km<sup>2</sup>.)
- 18.74** Write balanced chemical equations for each of the following reactions: **(a)** The nitric oxide molecule undergoes photodissociation in the upper atmosphere. **(b)** The nitric oxide molecule undergoes photoionization in the upper atmosphere. **(c)** Nitric oxide undergoes oxidation by ozone in the stratosphere. **(d)** Nitrogen dioxide dissolves in water to form nitric acid and nitric oxide.
- 18.75** **(a)** Explain why Mg(OH)<sub>2</sub> precipitates when CO<sub>3</sub><sup>2-</sup> ion is added to a solution containing Mg<sup>2+</sup>. **(b)** Will Mg(OH)<sub>2</sub> precipitate when 4.0 g of Na<sub>2</sub>CO<sub>3</sub> is added to 1.00 L of a solution containing 125 ppm of Mg<sup>2+</sup>?
- 18.76** **(a)** The EPA threshold for acceptable levels of lead ions in water is <15 ppb. What is the molarity of an aqueous solution with a concentration of 15 ppb? **(b)** Concentrations of lead in the bloodstream are often quoted in units of µg/dL. Averaged over the entire country, the mean concentration of lead in the blood was measured to be 1.6 µg/dL in 2008. Express this concentration in ppb.
- [18.77]** As of the writing of this text, EPA standards limit atmospheric ozone levels in urban environments to 84 ppb. How many moles of ozone would there be in the air above Los Angeles County (area about 4000 square miles; consider a height of 100 m above the ground) if ozone was at this concentration?

## Integrative Exercises

**18.78** The estimated average concentration of  $\text{NO}_2$  in air in the United States in 2006 was 0.016 ppm. (a) Calculate the partial pressure of the  $\text{NO}_2$  in a sample of this air when the atmospheric pressure is 755 torr (99.1 kPa). (b) How many molecules of  $\text{NO}_2$  are present under these conditions at  $20^\circ\text{C}$  in a room that measures  $15 \times 14 \times 8$  ft?

**[18.79]** In 1986 an electrical power plant in Taylorsville, Georgia, burned 8,376,726 tons of coal, a national record at that time. (a) Assuming that the coal was 83% carbon and 2.5% sulfur and that combustion was complete, calculate the number of tons of carbon dioxide and sulfur dioxide produced by the plant during the year. (b) If 55% of the  $\text{SO}_2$  could be removed by reaction with powdered  $\text{CaO}$  to form  $\text{CaSO}_3$ , how many tons of  $\text{CaSO}_3$  would be produced?

**18.80** The water supply for a midwestern city contains the following impurities: coarse sand, finely divided particulates, nitrate ions, trihalomethanes, dissolved phosphorus in the form of phosphates, potentially harmful bacterial strains, dissolved organic substances. Which of the following processes or agents, if any, is effective in removing each of these impurities: coarse sand filtration, activated carbon filtration, aeration, ozonization, precipitation with aluminum hydroxide?

**18.81** An impurity in water has an extinction coefficient of  $3.45 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$  at 280 nm, its absorption maximum (A Closer Look, p. 576). Below 50 ppb, the impurity is not a problem for human health. Given that most spectrometers cannot detect absorbances less than 0.0001 with good reliability, is measuring the absorbance of a water sample at 280 nm a good way to detect concentrations of the impurity above the 50-ppb threshold?

**18.82** The concentration of  $\text{H}_2\text{O}$  in the stratosphere is about 5 ppm. It undergoes photodissociation according to:

- Write out the Lewis-dot structures for both products and reactant.
- Using Table 8.3, calculate the wavelength required to cause this dissociation.
- The hydroxyl radical,  $\text{OH}$ , can react with ozone, giving the following reactions:

What overall reaction results from these two elementary reactions? What is the catalyst in the overall reaction? Explain.

**18.83** Bioremediation is the process by which bacteria repair their environment in response, for example, to an oil spill. The efficiency of bacteria for “eating” hydrocarbons depends on the amount of oxygen in the system, pH, temperature, and many other factors. In a certain oil spill, hydrocarbons from the oil disappeared with a first-order rate constant of  $2 \times 10^{-6} \text{ s}^{-1}$ . At that rate, how many days would it take for the hydrocarbons to decrease to 10% of their initial value?

**18.84** The standard enthalpies of formation of  $\text{ClO}$  and  $\text{ClO}_2$  are 101 and 102 kJ/mol, respectively. Using these data and the thermodynamic data in Appendix C, calculate the overall enthalpy change for each step in the following catalytic cycle:

What is the enthalpy change for the overall reaction that results from these two steps?

**18.85** The main reason that distillation is a costly method for purifying water is the high energy required to heat and vaporize water. (a) Using the density, specific heat, and heat of vaporization of water from Appendix B, calculate the amount of energy required to vaporize 1.00 gal of water beginning with water at  $20^\circ\text{C}$ . (b) If the energy is provided by electricity costing \$0.085/kWh, calculate its cost. (c) If distilled water sells in a grocery store for \$1.26 per gal, what percentage of the sales price is represented by the cost of the energy?

**[18.86]** A reaction that contributes to the depletion of ozone in the stratosphere is the direct reaction of oxygen atoms with ozone:

At 298 K the rate constant for this reaction is  $4.8 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ . (a) Based on the units of the rate constant, write the likely rate law for this reaction. (b) Would you expect this reaction to occur via a single elementary process? Explain why or why not. (c) Use  $\Delta H_f^\circ$  values from Appendix C to estimate the enthalpy change for this reaction. Would this reaction raise or lower the temperature of the stratosphere?

**18.87** The following data were collected for the destruction of  $\text{O}_3$  by  $\text{H}$  ( $\text{O}_3 + \text{H} \longrightarrow \text{O}_2 + \text{OH}$ ) at very low concentrations:

| Trial | $[\text{O}_3] (M)$     | $[\text{H}] (M)$       | Initial Rate ( $M/s$ ) |
|-------|------------------------|------------------------|------------------------|
| 1     | $5.17 \times 10^{-33}$ | $3.22 \times 10^{-26}$ | $1.88 \times 10^{-14}$ |
| 2     | $2.59 \times 10^{-33}$ | $3.25 \times 10^{-26}$ | $9.44 \times 10^{-15}$ |
| 3     | $5.19 \times 10^{-33}$ | $6.46 \times 10^{-26}$ | $3.77 \times 10^{-14}$ |

(a) Write the rate law for the reaction.

(b) Calculate the rate constant.

**18.88** The degradation of  $\text{CF}_3\text{CH}_2\text{F}$  (an HFC) by  $\text{OH}$  radicals in the troposphere is first order in each reactant and has a rate constant of  $k = 1.6 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$  at  $4^\circ\text{C}$ . If the tropospheric concentrations of  $\text{OH}$  and  $\text{CF}_3\text{CH}_2\text{F}$  are  $8.1 \times 10^5$  and  $6.3 \times 10^8$  molecules/ $\text{cm}^3$ , respectively, what is the rate of reaction at this temperature in  $M/s$ ?

**18.89** The Henry's law constant for  $\text{CO}_2$  in water at  $25^\circ\text{C}$  is  $3.1 \times 10^{-2} \text{ M atm}^{-1}$ . (a) What is the solubility of  $\text{CO}_2$  in water at this temperature if the solution is in contact with air at normal atmospheric pressure? (b) Assume that all of this  $\text{CO}_2$  is in the form of  $\text{H}_2\text{CO}_3$  produced by the reaction between  $\text{CO}_2$  and  $\text{H}_2\text{O}$ :

What is the pH of this solution?

**18.90** The precipitation of  $\text{Al}(\text{OH})_3$  ( $K_{sp} = 1.3 \times 10^{-33}$ ) is sometimes used to purify water. (a) Estimate the pH at which precipitation of  $\text{Al}(\text{OH})_3$  will begin if 5.0 lb of  $\text{Al}_2(\text{SO}_4)_3$  is added to 2000 gal of water. (b) Approximately how many pounds of  $\text{CaO}$  must be added to the water to achieve this pH?

**[18.91]** The valuable polymer polyurethane is made by a condensation reaction of alcohols ( $\text{ROH}$ ) with compounds that contain an isocyanate group ( $\text{RNCO}$ ). Two reactions that can generate a urethane monomer are shown here:

- (a) Which process, i or ii, is greener? Explain.  
 (b) What are the hybridization and geometry of the carbon atoms in each C-containing compound in each reaction?  
 (c) If you wanted to promote the formation of the isocyanate intermediate in each reaction, what could you do, using Le Châtelier's principle?

**18.92** The pH of a particular raindrop is 5.6. (a) Assuming the major species in the raindrop are  $\text{H}_2\text{CO}_3(aq)$ ,  $\text{HCO}_3^-(aq)$ , and  $\text{CO}_3^{2-}(aq)$ , calculate the concentrations of these species in the raindrop, assuming the total carbonate concentration is  $1.0 \times 10^{-5} M$ . The appropriate  $K_a$  values are given in Table 16.3. (b) What experiments could you do to test the hypothesis that the rain also contains sulfur-containing species that contribute to its pH? Assume you have a large sample of rain to test.

## Design an Experiment

Considerable fracking of petroleum/gas wells (see Closer Look box in Section 18.4) has occurred in recent years in a particular rural area. The residents have complained that the water in the residential wells serving their domestic water needs has become contaminated with chemicals associated with the fracking operations. The well operators respond that the chemicals about which complaints are lodged occur naturally, and are not the result of well-drilling activities.

Describe experiments that you could conduct on the waters from residential wells to help determine whether and to what extent well contaminants are due to fracking operations. Among the

chemicals that might be expected to be employed in fracking operations are hydrochloric acid, sodium chloride, ethylene glycol, borate salts, water-soluble gelling agents such as guar gum, citric acid, methanol, and other alcohols such as isopropanol, and methane. Assume that you have available the techniques to make measurements of the concentrations of these substances in the residential wells. What experiments would you conduct, and what analyses of the results would you carry out in an attempt to settle the question of whether fracking operations have led to contamination of the well water? Would simply measuring the concentrations of some or all of these substances in the well waters be sufficient to settle the issue?

19

# CHEMICAL THERMODYNAMICS

The amazing organization of living systems, from complex molecular structures such as those of nucleosomes, to cells, to tissues, and finally to whole plants and animals, is an unending source of wonder and delight to the scientists who study them. Energy must be spent, somehow, to form and maintain these organized systems. But how is that energy channeled to accomplish these tasks? We cannot merely take the requisite atoms, put them in a pot, add energy, and get something like a nucleosome.

Understanding natural processes, whether they be DNA replication, photosynthesis, or merely the rusting of a nail, relies on understanding the general laws that govern chemical reactions. There are two basic questions that chemists ask when studying reactions: “How fast is the reaction?” and “How far does it proceed?” The first question is addressed by chemical kinetics, which we discussed in Chapter 14. The second question relates to the equilibrium constant, the focus of Chapter 15.

The rate of any reaction is controlled largely by the activation energy of the reaction.  (Section 14.5) Chemical equilibrium is reached when a given reaction and its reverse reaction occur at the

◀ **THE NUCLEOSOME** Inside the nucleus of a living cell, DNA (the gray outer double-helical portion) surrounds eight protein molecules (the colored molecular models). This overall DNA/protein structure, called the nucleosome, is the basic unit of chromosomes in the nuclei of our cells. These structures are highly ordered, yet also must be unraveled for gene expression to take place. Both packaging and unpackaging of DNA in the nucleosome involve changes in the energy of the system.

## WHAT'S AHEAD

- 19.1** ▶ **Spontaneous Processes** Note that changes that occur in nature have a directional character. They move *spontaneously* in one direction but not in the reverse direction.
- 19.2** ▶ **Entropy and the Second Law of Thermodynamics** Learn that *entropy* is a thermodynamic state function important in determining whether a process is spontaneous. The *second law of thermodynamics* tells us that in any spontaneous process, the entropy of the universe (system plus surroundings) increases.
- 19.3** ▶ **The Molecular Interpretation of Entropy and the Third Law of Thermodynamics** On the molecular level, consider that the entropy of a system is related to the number of accessible *microstates*. The entropy of the system increases as the randomness of the system increases. The *third law of thermodynamics* states that, at 0 K, the entropy of a perfect crystalline solid is zero.
- 19.4** ▶ **Entropy Changes in Chemical Reactions** Calculate the standard entropy changes for systems undergoing reaction, using tabulated *standard molar entropies*.
- 19.5** ▶ **Gibbs Free Energy** Learn that another thermodynamic state function, *free energy* (or *Gibbs free energy*), is a measure of how far removed a system is from equilibrium. The change in free energy measures the maximum amount of useful work obtainable from a process and tells us the direction in which a chemical reaction is spontaneous.
- 19.6** ▶ **Free Energy and Temperature** Consider how the relationship among free-energy change, enthalpy change, and entropy change provides insight into how temperature affects the spontaneity of a process.
- 19.7** ▶ **Free Energy and the Equilibrium Constant** Examine how the standard free-energy change for a chemical reaction can be used to calculate the equilibrium constant for the reaction.

### Go Figure

Does the potential energy of the eggs change during this process?

Spontaneous

Not spontaneous

▲ Figure 19.1 A spontaneous process!

same rate. [∞ \(Section 15.1\)](#) Because reaction rates depend on activation energy, it is logical to expect that equilibrium also depends in some way on energy.

In this chapter, we explore the connection between energy and the extent of a reaction. Doing so requires a deeper look at *chemical thermodynamics*, the area of chemistry that deals with energy relationships. We first considered thermodynamics in Chapter 5, where we discussed the nature of energy, the first law of thermodynamics, and the concept of enthalpy. In this chapter, we discuss the second law of thermodynamics and the concept of *entropy*, a thermodynamic quantity that we encountered briefly in Chapter 13. [∞ \(Section 13.1\)](#)

## 19.1 | Spontaneous Processes

If you release a brick from your hand, it will fall. It never jumps back into your hand no matter how long you wait. Likewise, if you let a nail sit in the rain, it will eventually rust. The rusted nail will never convert to its original condition even when the sun shines and time passes. These are but two examples illustrating that there is directionality to events. We say that events like the falling brick and rusting nail occur spontaneously. A **spontaneous process** is one that occurs on its own without any outside assistance.

A spontaneous process occurs in one direction only, and the reverse of any spontaneous process is always *nonspontaneous*. Drop an egg above a hard surface, for example, and it breaks on impact ([Figure 19.1](#)). Now, imagine seeing a video clip in which a broken egg rises from the floor, reassembles itself, and ends up in someone's hand. You would conclude that the video is running in reverse because you know that broken eggs do not rise and reassemble themselves. An egg falling and breaking is a spontaneous process, whereas the egg rising and reassembling itself is a nonspontaneous process.

*Processes that are spontaneous in one direction are nonspontaneous in the opposite direction.*

Experimental conditions, such as temperature and pressure, are often important in determining whether a process is spontaneous. Consider, for example, the melting of ice. Ice melts spontaneously at atmospheric pressure when the temperature of the surroundings is above 0 °C. When the surroundings are below 0 °C, however, liquid water freezes spontaneously. The reverse process, melting, is then nonspontaneous as summarized in [Figure 19.2](#).

### Go Figure

In which direction is this process exothermic?

▲ Figure 19.2 Spontaneity can depend on temperature. At  $T > 0\text{ }^{\circ}\text{C}$ , ice melts spontaneously to liquid water. At  $T < 0\text{ }^{\circ}\text{C}$ , the reverse process, water freezing to ice, is spontaneous. At  $T = 0\text{ }^{\circ}\text{C}$  the two states are in equilibrium.

We must not confuse the *spontaneity* of a process with *speed*. Just because a process is spontaneous does not necessarily mean that it will occur at an observable rate. A spontaneous process can be fast, as in the case of acid–base neutralization, or slow, as in the rusting of iron. Thermodynamics tells us the *direction* and *extent* of reaction but nothing about the rate.

It is also important to understand that nonspontaneous does not mean impossible. For example, although the decomposition of table salt, NaCl, into sodium and chlorine is nonspontaneous under ordinary conditions, it is possible to decompose molten NaCl by supplying energy from an external source. A spontaneous process occurs without such outside intervention.

## Sample Exercise 19.1

### Identifying Spontaneous Processes

Predict whether each process is spontaneous as described, spontaneous in the reverse direction, or at equilibrium: (a) Water at 40 °C gets hotter when a piece of metal heated to 150 °C is added. (b) Water at room temperature decomposes into  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$ . (c) Benzene vapor,  $\text{C}_6\text{H}_6(\text{g})$ , at a pressure of 1 atm condenses to liquid benzene at the normal boiling point of benzene, 80.1 °C.

### SOLUTION

**Analyze** We are asked to judge whether each process is spontaneous in the direction indicated, in the reverse direction, or in neither direction.

**Plan** We need to think about whether each process is consistent with our experience about the natural direction of events or whether we expect the reverse process to occur.

### Solve

- (a) This process is spontaneous. Whenever two objects at different temperatures are brought into contact, heat is transferred from the hotter object to the colder one.  (Section 5.1) Thus, heat is transferred from the hot metal to the cooler water. The final temperature, after the metal and water achieve the same temperature (thermal equilibrium), will be somewhere between the initial temperatures of the metal and the water.
- (b) Experience tells us that this process is not spontaneous—we certainly have never seen hydrogen and oxygen gases spontaneously bubbling up out of water! Rather,

the *reverse* process—the reaction of  $\text{H}_2$  and  $\text{O}_2$  to form  $\text{H}_2\text{O}$ —is spontaneous.

- (c) The normal boiling point is the temperature at which a vapor at 1 atm is in equilibrium with its liquid. Thus, this is an equilibrium situation. If the temperature were below 80.1 °C, condensation would be spontaneous.

### Practice Exercise 1

The process of iron being oxidized to make iron(III) oxide (rust) is spontaneous. Which of these statements about this process is/are true? (a) The reduction of iron(III) oxide to iron is also spontaneous. (b) Because the process is spontaneous, the oxidation of iron must be fast. (c) The oxidation of iron is endothermic. (d) Equilibrium is achieved in a closed system when the rate of iron oxidation is equal to the rate of iron(III) oxide reduction. (e) The energy of the universe is decreased when iron is oxidized to rust.

### Practice Exercise 2

At 1 atm pressure,  $\text{CO}_2(\text{s})$  sublimates at  $-78^\circ\text{C}$ . Is this process spontaneous at  $-100^\circ\text{C}$  and 1 atm pressure?

## Seeking a Criterion for Spontaneity

A marble rolling down an incline or a brick falling from your hand loses potential energy. The loss of some form of energy is a common feature of spontaneous change in mechanical systems. In the 1870s, Marcellin Bertholet (1827–1907) suggested that the direction of spontaneous changes in chemical systems is determined by the loss of energy. He proposed that all spontaneous chemical and physical changes are exothermic. It takes only a few moments, however, to find exceptions to this generalization. For example, the melting of ice at room temperature is spontaneous and endothermic. Similarly, many spontaneous dissolution processes, such as the dissolving of  $\text{NH}_4\text{NO}_3$ , are endothermic, as we discovered in Section 13.1. We conclude that although the majority of spontaneous reactions are exothermic, there are spontaneous endothermic ones as well. Clearly, some other factor must be at work in determining the natural direction of processes.

To understand why certain processes are spontaneous, we need to consider more closely the ways in which the state of a system can change. Recall from Section 5.2 that quantities such as temperature, internal energy, and enthalpy are *state functions*, properties that define a state and do not depend on how we reach that state. The heat transferred between the system and its surroundings,  $q$ , and the work done on or by the

system,  $w$ , are *not* state functions—their values depend on the specific way in which the change occurs. That is, their values depend on the *path* taken between states. Understanding two kinds of paths, those that are *reversible* and those that are *irreversible*, is a key to understanding spontaneity.

## Reversible and Irreversible Processes

For any process, we can imagine a hypothetical, ideal path that can be reversed to restore both the system and its surroundings to exactly their original states. This means that after the process is reversed, both the system and surroundings are unchanged. Such an ideal process is said to be reversible.

- A **reversible process** is one for which we can restore the system to its original condition with no change to the surroundings.
- An **irreversible process** is one that leaves the surroundings somehow changed when the system is restored to its original state.

Sometimes these processes are referred to as being *thermodynamically reversible* or *thermodynamically irreversible* to add greater clarity to their meanings.

### Give It Some Thought

Suppose you have a system made up of water only, with the container and everything beyond being the surroundings. Consider a process in which the water is first evaporated and then condensed back into its original container. Is this two-step process necessarily reversible?

As an example, let's consider a process involving the transfer of heat. When two objects at different temperatures are in contact, heat flows spontaneously from the hotter object to the colder one. Because it is impossible to make the heat flow in the opposite direction, from colder to hotter, this is an irreversible process. Given this fact, can we imagine any hypothetical conditions under which the heat transfer could be reversible? The answer is yes, but only if we consider temperature changes that are infinitesimally small.

Imagine the system and its surroundings at essentially the same temperature, with just an infinitesimal temperature difference,  $\delta T$ , between them (Figure 19.3). If the

### Go Figure

If the flow of heat into or out of the system is to be reversible, what must be true of  $\delta T$ ?

▲ **Figure 19.3 Reversible flow of heat.** Heat can flow reversibly between a system and its surroundings only if the two have an infinitesimally small difference in temperature  $\delta T$ . (a) Increasing the temperature of the system by  $\delta T$  causes heat to flow from the hotter system to the colder surroundings. (b) Decreasing the temperature of the system by  $\delta T$  causes heat to flow from the hotter surroundings to the colder system.

▲ **Figure 19.4 An irreversible process.** Initially, an ideal gas is confined to the right half of a cylinder. When the partition is removed, the gas spontaneously expands to fill the whole cylinder. No work is done by the system during this expansion. Using the piston to compress the gas back to its original state requires the surroundings to do work on the system.

surroundings are at temperature  $T$  and the system is at an infinitesimally higher temperature  $T + \delta T$ , then an infinitesimal amount of heat flows from the system to surroundings. We can reverse the direction of heat flow by making an infinitesimal change of temperature in the opposite direction, lowering the system temperature to  $T - \delta T$ . Now the direction of heat flow is from surroundings to system. Thus, for the process to be reversible, the amounts of heat must be infinitesimally small and the transfer of heat must occur infinitely slowly.

*Reversible processes are those that reverse direction whenever an infinitesimal change is made in some property of the system.*

Now let's consider another example, the expansion of an ideal gas at constant temperature (referred to as an **isothermal** process). In the cylinder-piston arrangement of **Figure 19.4**, when the partition is removed, the gas expands spontaneously to fill the evacuated space. Can we determine whether this particular isothermal expansion is reversible or irreversible? Because the gas expands into a vacuum with no external pressure, it does no  $P$ - $V$  work on the surroundings. (Section 5.3) Thus, for the expansion,  $w = 0$ . We can use the piston to compress the gas back to its original state, but doing so requires that the surroundings do work on the system, meaning that  $w > 0$  for the compression. In other words, the path that restores the system to its original state requires a different value of  $w$  (and, by the first law, a different value of  $q$ ) than the path by which the system was first changed. The fact that the same path cannot be followed to restore the system to its original state indicates that the process is irreversible.

What might a *reversible* isothermal expansion of an ideal gas be? This process will occur only if initially, when the gas is confined to half the cylinder, the external pressure acting on the piston exactly balances the pressure exerted by the gas on the piston. If the external pressure is reduced infinitely slowly, the piston will move outward, allowing the pressure of the confined gas to readjust to maintain the pressure balance. This infinitely slow process in which the external pressure and internal pressure are always in equilibrium is reversible. If we reverse the process and compress the gas in the same infinitely slow manner, we can return the gas to its original volume. The complete cycle of expansion and compression in this hypothetical process, moreover, is accomplished without any net change to the surroundings.

From these and other examples we learn two important facts:

- Because real processes can at best only approximate the infinitesimal changes associated with reversible processes, *all real processes are irreversible*.
- Because spontaneous processes are real processes, *all spontaneous processes are irreversible*.

Thus, for any spontaneous change, returning the system to its original condition results in a net change in the surroundings. But what kind of change occurs?

Recall that the first law of thermodynamics states that energy is conserved. In mathematical terms,  $\Delta E = q + w$ ; that is, the change in internal energy of a system is equal to the heat absorbed (or released) by the system plus the work done on (or by) the system.  (Section 5.2) If we return a system to its original condition, no net change in energy takes place, but there is a change in the nature of the energy. Returning the system to its initial condition requires us to do work on the system. Doing work requires a focused, relatively concentrated application of energy. During the process, that focused, concentrated energy gets converted to a more diffuse form. Thus, the net change in the surroundings involves the nature of the energy—it becomes more dispersed and disordered and therefore less able to do work.

What we observe about energy changes is that *energy has a tendency to spread out*. Consider a hot cup of tea. As it cools, energy spreads (or disperses) from the smaller volume of the tea into the greater volume of its surroundings. On a molecular level, the random, chaotic motion of particles (thermal motion) transfers energy through molecular collisions from the higher temperature (greater average kinetic energy) to lower temperature (lesser average kinetic energy) until the tea and its surroundings reach the same temperature. This natural tendency for energy to spread from a more concentrated form to a less concentrated form renders some of the energy unavailable to do work. Interestingly, a reversible process produces the maximum amount of work that can be done by a system on its surroundings.

## 19.2 | Entropy and the Second Law of Thermodynamics

In order to apply what we have learned about irreversible processes to predict whether an unfamiliar process is spontaneous, we must examine the thermodynamic quantity called entropy.  (Section 13.1)

**Entropy** is a measure of the tendency for energy to spread or disperse, thereby reducing its ability to accomplish work. In a general sense, it reflects the degree of *randomness* or *disorder* associated with the particles that carry the energy.

In this section, we consider how entropy changes are related to heat transfer and temperature. Our analysis will bring us to a profound statement about entropy changes and spontaneity known as the second law of thermodynamics.

### The Relationship between Entropy and Heat

The entropy,  $S$ , of a system is a state function just like internal energy,  $E$ , and enthalpy,  $H$ . As with these other quantities, the value of  $S$  is a characteristic of the state of a system.  (Section 5.2) Thus, the change in entropy,  $\Delta S$ , in a system depends only on the initial and final states of the system and not on the path taken from one state to the other:

$$\Delta S = S_{\text{final}} - S_{\text{initial}} \quad [19.1]$$

For the special case of an isothermal process,  $\Delta S$  is equal to the heat that would be transferred if the process were reversible,  $q_{\text{rev}}$ , divided by the absolute temperature at which the process occurs:

$$\Delta S = \frac{q_{\text{rev}}}{T} \quad (\text{constant } T) \quad [19.2]$$

*Although many possible paths can take the system from one state to another, only one path is associated with a reversible process.* Thus, the value of  $q_{\text{rev}}$  is uniquely defined for any two states of the system. Because  $S$  is a state function, we can use Equation 19.2 to calculate  $\Delta S$  for *any* isothermal process between states, not just the reversible one.

#### Give It Some Thought

How can  $S$  be a state function when  $\Delta S$  depends on  $q$ , which is not a state function?

## $\Delta S$ for Phase Changes

The melting of a substance at its melting point and the vaporization of a substance at its boiling point are isothermal processes.  (Section 11.4) Consider the melting of ice. At 1 atm pressure, ice and liquid water are in equilibrium at 0°C. Imagine melting 1 mol of ice at 0°C, 1 atm to form 1 mol of liquid water at 0°C, 1 atm. We can achieve this change by adding heat to the system from the surroundings:  $q = \Delta H_{\text{fusion}}$ , where  $\Delta H_{\text{fusion}}$  is the heat of melting. Imagine adding the heat infinitely slowly, raising the temperature of the surroundings only infinitesimally above 0°C. When we make the change in this fashion, the process is reversible because we can reverse it by infinitely slowly removing the same amount of heat,  $\Delta H_{\text{fusion}}$ , from the system, using immediate surroundings that are infinitesimally below 0°C. Thus,  $q_{\text{rev}} = \Delta H_{\text{fusion}}$  for the melting of ice at  $T = 0^\circ\text{C} = 273\text{ K}$ .

The enthalpy of fusion for  $\text{H}_2\text{O}$  is  $\Delta H_{\text{fusion}} = 6.01\text{ kJ/mol}$  (a positive value because melting is an endothermic process). Thus, we can use Equation 19.2 to calculate  $\Delta S_{\text{fusion}}$  for melting 1 mol of ice at 273 K:

$$\Delta S_{\text{fusion}} = \frac{q_{\text{rev}}}{T} = \frac{\Delta H_{\text{fusion}}}{T} = \frac{(1\text{ mol})(6.01 \times 10^3\text{ J/mol})}{273\text{ K}} = 22.0\text{ J/K}$$

Notice that (1) we must use the absolute temperature in Equation 19.2, and (2) the units for  $\Delta S$ , J/K, are energy divided by absolute temperature, as we expect from Equation 19.2.

### Sample Exercise 19.2

#### Calculating $\Delta S$ for a Phase Change

Elemental mercury is a silver liquid at room temperature. Its normal freezing point is  $-38.9^\circ\text{C}$ , and its molar enthalpy of fusion is  $\Delta H_{\text{fusion}} = 2.29\text{ kJ/mol}$ . What is the entropy change of the system when 50.0 g of  $\text{Hg}(l)$  freezes at the normal freezing point?

#### SOLUTION

**Analyze** We first recognize that freezing is an *exothermic* process, which means heat is transferred from the system to the surroundings and  $q < 0$ . Because freezing is the reverse of melting, the enthalpy change that accompanies the freezing of 1 mol of Hg is  $-\Delta H_{\text{fusion}} = -2.29\text{ kJ/mol}$ .

**Plan** We can use  $-\Delta H_{\text{fusion}}$  and the atomic weight of Hg to calculate  $q$  for freezing 50.0 g of Hg. Then we use this value of  $q$  as  $q_{\text{rev}}$  in Equation 19.2 to determine  $\Delta S$  for the system.

#### Solve

For  $q$  we have:

$$q = (50.0\text{ g Hg})\left(\frac{1\text{ mol Hg}}{200.59\text{ g Hg}}\right)\left(\frac{-2.29\text{ kJ}}{1\text{ mol Hg}}\right)\left(\frac{1000\text{ J}}{1\text{ kJ}}\right) = -571\text{ J}$$

Before using Equation 19.2, we must first convert the given Celsius temperature to kelvins:

$$-38.9^\circ\text{C} = (-38.9 + 273.15)\text{ K} = 234.3\text{ K}$$

We can now calculate  $\Delta S_{\text{sys}}$ :

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{-571\text{ J}}{234.3\text{ K}} = -2.44\text{ J/K}$$

**Check** The entropy change is negative because our  $q_{\text{rev}}$  value is negative, which it must be because heat flows out of the system in this exothermic process.

**Comment** This procedure can be used to calculate  $\Delta S$  for other isothermal phase changes, such as the vaporization of a liquid at its boiling point.

#### Practice Exercise 1

Do all exothermic phase changes have a negative value for the entropy change of the system? **(a)** Yes, because the heat transferred from the system has a negative sign. **(b)** Yes,

because the temperature decreases during the phase transition. **(c)** No, because the entropy change depends on the sign of the heat transferred to or from the system. **(d)** No, because the heat transferred to the system has a positive sign. **(e)** More than one of the previous answers is correct.

#### Practice Exercise 2

The normal boiling point of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , is  $78.3^\circ\text{C}$ , and its molar enthalpy of vaporization is  $38.56\text{ kJ/mol}$ . What is the change in entropy in the system when 68.3 g of  $\text{C}_2\text{H}_5\text{OH}(g)$  at 1 atm condenses to liquid at the normal boiling point?

## A CLOSER LOOK The Entropy Change When a Gas Expands Isothermally

In general, the entropy of any system increases as the system becomes more random or more spread out. Thus, we expect the spontaneous expansion of a gas to result in an increase in entropy. To see how this entropy increase can be calculated, consider the expansion of an ideal gas that is initially constrained by a piston, as in the rightmost part of Figure 19.4. Imagine that we allow the gas to undergo a reversible isothermal expansion by infinitesimally decreasing the external pressure on the piston. The work done on the surroundings by the reversible expansion of the system against the piston can be calculated with the aid of calculus (we do not show the derivation):

$$w_{\text{rev}} = -nRT \ln \frac{V_2}{V_1}$$

In this equation,  $n$  is the number of moles of gas,  $R$  is the ideal-gas constant  $\infty$  (Section 10.4),  $T$  is the absolute temperature,  $V_1$  is the initial volume, and  $V_2$  is the final volume. Notice that if  $V_2 > V_1$ , as it must be in our expansion, then  $w_{\text{rev}} < 0$ , meaning that the expanding gas does work on the surroundings.

One characteristic of an ideal gas is that its internal energy depends only on temperature, not on pressure. Thus, when an ideal gas expands isothermally,  $\Delta E = 0$ . Because  $\Delta E = q_{\text{rev}} + w_{\text{rev}} = 0$ , we see that  $q_{\text{rev}} = -w_{\text{rev}} = nRT \ln(V_2/V_1)$ . Then, using Equation 19.2, we can calculate the entropy change in the system:

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{nRT \ln \frac{V_2}{V_1}}{T} = nR \ln \frac{V_2}{V_1} \quad [19.3]$$

Let's calculate the entropy change for 1.00 L of an ideal gas at 1.00 atm pressure, 0 °C temperature, expanding to 2.00 L. From the ideal-gas equation, we can calculate the number of moles in 1.00 L of an ideal gas at 1.00 atm and 0 °C as we did in Chapter 10:

$$n = \frac{PV}{RT} = \frac{(1.00 \text{ atm})(1.00 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(273 \text{ K})} = 4.46 \times 10^{-2} \text{ mol}$$

The gas constant,  $R$ , can also be expressed as 8.314 J/mol·K (Table 10.2), and this is the value we must use in Equation 19.3 because we want our answer to be expressed in terms of J rather than in L·atm. Thus, for the expansion of the gas from 1.00 L to 2.00 L, we have

$$\begin{aligned} \Delta S_{\text{sys}} &= (4.46 \times 10^{-2} \text{ mol}) \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) \left( \ln \frac{2.00 \text{ L}}{1.00 \text{ L}} \right) \\ &= 0.26 \text{ J/K} \end{aligned}$$

In Section 19.3 we will see that this increase in entropy is a measure of the increased randomness of the molecules due to the expansion.

**Related Exercises: 19.27, 19.28**

## The Second Law of Thermodynamics

The key idea of the first law of thermodynamics is that energy is conserved in any process.  $\infty$  (Section 5.2) Is entropy also conserved in a spontaneous process in the same way that energy is conserved?

Let's try to answer this question by calculating the entropy change of a system and the entropy change of its surroundings when our system is 1 mol of ice (a piece roughly the size of an ice cube) melting in the palm of your hand, which is part of the surroundings. The process is not reversible because the system and surroundings are at different temperatures. Nevertheless, because  $\Delta S$  is a state function, its value is the same regardless of whether the process is reversible or irreversible. Earlier (just before Sample Exercise 19.2) we calculated the entropy change of this system:

$$\Delta S_{\text{sys}} = \frac{q_{\text{rev}}}{T} = \frac{(1 \text{ mol})(6.01 \times 10^3 \text{ J/mol})}{273 \text{ K}} = 22.0 \text{ J/K}$$

The portion of the surroundings immediately in contact with the ice is your palm, which we assume is at body temperature, 37 °C = 310 K. We will use this as the temperature of the surroundings. The quantity of heat lost by your palm is  $-6.01 \times 10^3 \text{ J/mol}$ , which is equal in magnitude to the quantity of heat gained by the ice but has the opposite sign. Hence, the entropy change of the surroundings is

$$\Delta S_{\text{surr}} = \frac{q_{\text{rev}}}{T} = \frac{(1 \text{ mol})(-6.01 \times 10^3 \text{ J/mol})}{310 \text{ K}} = -19.4 \text{ J/K}$$

We can consider that everything in the universe consists of the system of interest and its surroundings. Therefore,  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$ . Thus, the overall entropy change of the universe is positive in our example:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = (22.0 \text{ J/K}) + (-19.4 \text{ J/K}) = 2.6 \text{ J/K}$$

If the temperature of the surroundings were not 310 K but rather some temperature infinitesimally above 273 K, the melting would be reversible instead of irreversible. In that case, the entropy change of the surroundings would equal  $-22.0 \text{ J/K}$  and  $\Delta S_{\text{univ}}$  would be zero.

In general, any irreversible process results in an increase in the entropy of the universe, whereas any reversible process results in no change in the entropy of the universe:

$$\begin{aligned} \text{Reversible Process:} \quad & \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0 \\ \text{Irreversible Process:} \quad & \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \end{aligned} \quad [19.4]$$

These equations summarize the **second law of thermodynamics**. Because spontaneous processes are irreversible, we can also state the second law this way:

*The entropy of the universe increases for any spontaneous process.*

### Give It Some Thought

The rusting of iron is spontaneous and is accompanied by a decrease in the entropy of the system (the iron and oxygen). What can we conclude about the entropy change of the surroundings?

The second law of thermodynamics tells us the essential character of any spontaneous change—it is always accompanied by an increase in the entropy of the universe. We can use this law as a criterion to predict whether or not a given process is spontaneous. Before seeing how this is done, however, we will find it useful to explore entropy from a molecular perspective.

A word on notation before we proceed: Throughout most of the remainder of this chapter, we will focus on systems rather than surroundings. To simplify the notation, we will usually refer to the entropy change of the system as  $\Delta S$  rather than explicitly indicating  $\Delta S_{\text{sys}}$ .

## 19.3 | The Molecular Interpretation of Entropy and the Third Law of Thermodynamics

As chemists, we are interested in molecules. What does entropy have to do with them and with their transformations? What molecular property does entropy reflect? Ludwig Boltzmann (1844–1906) gave another conceptual meaning to the notion of entropy, and to understand his contribution, we need to examine the ways in which we can interpret entropy at the molecular level.

### Expansion of a Gas at the Molecular Level

Consider a simple spontaneous process—the expansion of a gas into a vacuum as shown in **Figure 19.5**. Though we now understand that the entropy of the universe increases during the expansion, how can we explain the spontaneity of this process at the molecular level? We can get a sense of what makes this expansion spontaneous by envisioning the gas as a collection of particles in constant motion, as we did in discussing the kinetic-molecular theory of gases. (Section 10.7) When the stopcock in **Figure 19.5** is opened, we can view the expansion of the gas as the ultimate result of the gas molecules moving randomly throughout the larger volume.

Let's look at this idea more closely by tracking two of the gas molecules as they move around. Before the stopcock is opened, both molecules are confined to the left flask, as shown in **Figure 19.6(a)**. After the stopcock is opened, the molecules travel randomly throughout the entire apparatus. As **Figure 19.6(b)** shows, there are four

The two molecules are colored red and blue to keep track of them.

Four possible arrangements (microstates) once the stopcock is opened.

### Go Figure

If flask B were smaller than flask A, would the final pressure after the stopcock is opened be greater than, equal to, or less than 0.5 atm?

When stopcock opens, gas expands to occupy both flasks.

This process is spontaneous

All gas molecules move back into flask A.

This process is not spontaneous

▲ **Figure 19.5** Expansion of a gas into an evacuated space is a spontaneous process. The reverse process—gas molecules initially distributed evenly in two flasks all moving into one flask—is not spontaneous.

◀ **Figure 19.6** Possible arrangements of two gas molecules in two flasks. (a) Before the stopcock is opened, both molecules are in the left flask. (b) After the stopcock is opened, there are four possible arrangements of the two molecules.

possible arrangements for the two molecules once both flasks are available to them. Because the molecular motion is random, all four arrangements are equally likely. Note that now only one arrangement corresponds to the situation before the stopcock was opened: both molecules in the left flask.

Figure 19.6(b) shows that with both flasks available to the molecules, the probability of the red molecule being in the left flask is two in four (top right and bottom left arrangements), and the probability of the blue molecule being in the left flask is the same (top left and bottom left arrangements). Because the probability is  $2/4 = 1/2$  that each molecule is in the left flask, the probability that *both* are there is  $(1/2)^2 = 1/4$ . If we apply the same analysis to *three* gas molecules, we find that the probability that all three are in the left flask at the same time is  $(1/2)^3 = 1/8$ .

Now let's consider a *mole* of gas. The probability that all the molecules are in the left flask at the same time is  $(1/2)^N$ , where  $N = 6.02 \times 10^{23}$ . This is a vanishingly small number! Thus, there is essentially zero likelihood that all the gas molecules will be in the left flask at the same time. This analysis of the microscopic behavior of the gas molecules leads to the expected macroscopic behavior: The gas spontaneously expands to fill both the left and right flasks, and it does not spontaneously all go back in the left flask.

This molecular view of gas expansion shows the tendency of the molecules to “spread out” among the different arrangements they can take. Before the stopcock is opened, there is only one possible arrangement: all molecules in the left flask. When the stopcock is opened, the arrangement in which all the molecules are in the left flask is but one of an extremely large number of possible arrangements. The most probable arrangements by far are those in which there are essentially equal numbers of molecules in the two flasks. When the gas spreads throughout the apparatus, any given molecule can be in either flask rather than confined to the left flask. We say that with the stopcock opened, the arrangement of gas molecules is more dispersed than when the molecules are all confined in the left flask.

We will see that this notion of increasing dispersion helps us understand entropy at the molecular level.

## Boltzmann's Equation and Microstates

The science of thermodynamics developed as a means of describing the properties of matter in our macroscopic world without regard to microscopic structure. In fact, thermodynamics was a well-developed field before the modern view of atomic and molecular structure was even known. The thermodynamic properties of water, for example, addressed the behavior of bulk water (or ice or water vapor) as a substance without considering any specific properties of individual  $\text{H}_2\text{O}$  molecules.

To connect the microscopic and macroscopic descriptions of matter, scientists have developed the field of *statistical thermodynamics*, which uses the tools of statistics and probability to link the microscopic and macroscopic worlds. Here we show how entropy, which is a property of bulk matter, can be connected to the behavior of atoms and molecules. Because the mathematics of statistical thermodynamics is complex, our discussion will be largely conceptual.

In our discussion of two gas molecules in the two-flask system in Figure 19.6, we saw that the number of possible arrangements helped explain why the gas expands.

Suppose we now consider one mole of an ideal gas in a particular thermodynamic state, which we can define by specifying the temperature,  $T$ , and volume,  $V$ , of the gas. What is happening to this gas at the microscopic level, and how does what is going on at the microscopic level relate to the entropy of the gas?

Imagine taking a snapshot of the positions and speeds of all the molecules at a given instant. The speed of each molecule relates to its kinetic energy. That particular set of  $6 \times 10^{23}$  positions and kinetic energies of the individual gas molecules is what we call a *microstate* of the system. A **microstate** is a single possible arrangement of the positions and kinetic energies of the molecules when the molecules are in a specific thermodynamic state. We could envision continuing to take snapshots of our system to see other possible microstates.

As you no doubt see, there would be such a staggeringly large number of microstates that taking individual snapshots of all of them is not feasible. Because we are examining such a large number of particles, however, we can use the tools of statistics and probability to determine the total number of microstates for the thermodynamic state. (That is where the *statistical* part of the name *statistical thermodynamics* comes in.) Each thermodynamic state has a characteristic number of microstates associated with it, and we will use the symbol  $W$  for that number.

Students sometimes have difficulty distinguishing between the state of a system and the microstates associated with the state.

- A *state* describes the macroscopic view of the system as characterized, for example, by the pressure and temperature of a sample of gas.
- A *microstate* is a particular microscopic arrangement of the atoms or molecules of the system that corresponds to the given state of the system.

Each of the snapshots we described is a microstate—the positions and kinetic energies of individual gas molecules will change from snapshot to snapshot, but each one is a possible arrangement of the collection of molecules corresponding to a single state. For macroscopically sized systems, such as a mole of gas, there is a very large number of microstates for each state—that is,  $W$  is generally an extremely large number.

The connection between the number of microstates of a system,  $W$ , and the entropy of the system,  $S$ , is expressed in a beautifully simple equation developed by Boltzmann and engraved on his tombstone (Figure 19.7):

$$S = k \ln W \quad [19.5]$$

In this equation,  $k$  is the Boltzmann constant,  $1.38 \times 10^{-23} \text{ J/K}$ . We see from the equation that:

*Entropy is a measure of how many microstates are associated with a particular macroscopic state.*

### Give It Some Thought

What is the entropy of a system that has only a single microstate?

From Equation 19.5, we see that the entropy change accompanying any process is

$$\Delta S = k \ln W_{\text{final}} - k \ln W_{\text{initial}} = k \ln \frac{W_{\text{final}}}{W_{\text{initial}}} \quad [19.6]$$

Any change in the system that leads to an increase in the number of microstates ( $W_{\text{final}} > W_{\text{initial}}$ ) leads to a positive value of  $\Delta S$ :

*Entropy increases with the number of microstates of the system.*

Let's consider two modifications to our ideal-gas sample and see how the entropy changes in each case. First, suppose we increase the volume of the system, which is analogous to allowing the gas to expand isothermally. A greater volume means a greater number of positions available to the gas atoms and therefore a greater number of microstates. The entropy therefore increases as the volume increases, as we saw in the “A Closer Look” box in Section 19.2.

▲ **Figure 19.7** Ludwig Boltzmann's gravestone. Boltzmann's gravestone in Vienna is inscribed with his famous relationship between the entropy of a state,  $S$ , and the number of available microstates,  $W$ . (In Boltzmann's time, “log” was used to represent the natural logarithm.)

Second, suppose we keep the volume fixed but increase the temperature. How does this change affect the entropy of the system? Recall the distribution of molecular speeds presented in Figure 10.13(a). An increase in temperature increases the most probable speed of the molecules and also broadens the distribution of speeds. Hence, the molecules have a greater number of possible kinetic energies, and the number of microstates increases. Thus, the entropy of the system increases with increasing temperature.

## Molecular Motions and Energy

When a substance is heated, the motion of its molecules increases. In Section 10.7, we found that the average kinetic energy of the molecules of an ideal gas is directly proportional to the absolute temperature of the gas. That means the higher the temperature, the faster the molecules move and the more kinetic energy they possess. Moreover, hotter systems have a *broader distribution* of molecular speeds, as Figure 10.12(a) shows.

The particles of an ideal gas are idealized points with no volume and no bonds, however—points that we visualize as flitting around through space. Any real molecule can undergo three kinds of more complex motion. The entire molecule can move in one direction, which is the simple motion we visualize for an ideal particle and see in a macroscopic object, such as a thrown baseball. We call such movement **translational motion**. The molecules in a gas have more freedom of translational motion than those in a liquid, which have more freedom of translational motion than the molecules of a solid.

A real molecule can also undergo **vibrational motion**, in which the atoms in the molecule move periodically toward and away from one another, and **rotational motion**, in which the molecule spins about an axis. Figure 19.8 shows the vibrational motions and one of the rotational motions possible for the water molecule. These different forms of motion are ways in which a molecule can store energy.

### Give It Some Thought

Can an argon atom undergo vibrational motion?

The vibrational and rotational motions possible in real molecules lead to arrangements that a single atom cannot have. A collection of real molecules therefore has a greater number of possible microstates than does the same number of ideal-gas particles. In general, *the number of microstates possible for a system increases with an increase in volume, an increase in temperature, or an increase in the number of molecules because any of these changes increases the possible positions and kinetic energies of the molecules making up the system.* We will also see that the number of microstates increases as the complexity of the molecule increases because there are more vibrational motions available.

### Go Figure

Describe another possible rotational motion for this molecule.

▲ Figure 19.8 Vibrational and rotational motions in a water molecule.

Chemists have several ways of describing an increase in the number of microstates possible for a system and therefore an increase in the entropy for the system. Each way seeks to capture a sense of the increased freedom of motion that causes molecules to spread out when not restrained by physical barriers or chemical bonds.

The most common way of describing an increase in entropy is the increase in the *randomness*, or *disorder*, of the system. Another way likens an entropy increase to an increased *dispersion (spreading out) of energy* because there is an increase in the number of ways the positions and energies of the molecules can be distributed throughout the system. Each description (randomness or energy dispersal) is conceptually helpful if applied correctly.

## Making Qualitative Predictions about $\Delta S$

It is usually not difficult to estimate qualitatively how the entropy of a system changes during a simple process. As noted earlier, an increase in either the temperature or the volume of a system leads to an increase in the number of microstates, and hence an increase in the entropy. One more factor that correlates with number of microstates is the number of independently moving particles.

We can usually make qualitative predictions about entropy changes by focusing on these factors. For example, when water vaporizes, the molecules spread out into a larger volume. Because they occupy a larger volume, there is an increase in their freedom of motion, giving rise to a greater number of possible microstates, and hence an increase in entropy.

Now consider the phases of water. In ice, hydrogen bonding leads to the rigid structure shown in Figure 19.9. Each molecule in the ice is free to vibrate, but its translational and rotational motions are much more restricted than in liquid water. Although there are hydrogen bonds in liquid water, the molecules can more readily move about relative to one another (translation) and tumble around (rotation). During melting, therefore, the number of possible microstates increases, and so does the entropy. In water vapor, the molecules are essentially independent of one another and have their

▲ **Figure 19.9** Entropy and the phases of water. The larger the number of possible microstates, the higher the entropy of the system.

▲ **Figure 19.10** Entropy changes when an ionic solid dissolves in water. The ions become more spread out and disordered, but the water molecules that hydrate the ions become less disordered.

### Go Figure

What major factor leads to a decrease in entropy as this reaction takes place?

▲ **Figure 19.11** Entropy decreases when  $\text{NO}(g)$  is oxidized by  $\text{O}_2(g)$  to  $\text{NO}_2(g)$ . A decrease in the number of gaseous molecules leads to a decrease in the entropy of the system.

full range of translational, vibrational, and rotational motions. Thus, water vapor has an even greater number of possible microstates and therefore a higher entropy than liquid water or ice.

When an ionic solid dissolves in water, a mixture of water and ions replaces the pure solid and pure water, as shown for KCl in **Figure 19.10**. The ions in the liquid move in a volume that is larger than the volume in which they were able to move in the crystal lattice and so undergo more motion. This increased motion might lead us to conclude that the entropy of the system has increased. We have to be careful, however, because some of the water molecules have lost some freedom of motion because they are now held around the ions as water of hydration. [∞ \(Section 13.1\)](#) These water molecules are in a *more* ordered state than before because they are now confined to the immediate environment of the ions. Therefore, the dissolving of a salt involves both a disordering process (the ions become less confined) and an ordering process (some water molecules become more confined). The disordering processes are usually dominant, and so the overall effect is an increase in the randomness of the system when most salts dissolve in water.

Now, imagine arranging biomolecules into a highly organized biochemical system, such as the nucleosome in the chapter-opening figure. We might expect that the creation of this well-ordered structure would lead to a decrease in the entropy of the system. But this is frequently not the case. Waters of hydration and counterions can be expelled from the interface as two large biomolecules interact, and so the entropy of the system can actually increase—if you consider the water and counterions to be part of the system.

The same ideas apply to chemical reactions. Consider the reaction between nitric oxide gas and oxygen gas to form nitrogen dioxide gas:

which results in a decrease in the number of molecules—three molecules of gaseous reactants form two molecules of gaseous products (**Figure 19.11**). The formation of new N—O bonds reduces the motions of the atoms in the system. The formation of new bonds decreases the *number of degrees of freedom*, or forms of motion, available to the atoms. That is, the atoms are less free to move in random fashion because of the formation of new bonds. The decrease in the number of molecules and the resultant decrease in motion result in fewer possible microstates and therefore a decrease in the entropy of the system.

In summary, we generally expect the entropy of a system to increase for processes in which

1. Gases form from either solids or liquids.
2. Liquids or solutions form from solids.
3. The number of gas molecules increases during a chemical reaction.

## Sample Exercise 19.3

### Predicting the Sign of $\Delta S$

Predict whether  $\Delta S$  is positive or negative for each process, assuming each occurs at constant temperature:

- (a)  $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g)$
- (b)  $\text{Ag}^+(aq) + \text{Cl}^-(aq) \longrightarrow \text{AgCl}(s)$
- (c)  $4 \text{Fe}(s) + 3 \text{O}_2(g) \longrightarrow 2 \text{Fe}_2\text{O}_3(s)$
- (d)  $\text{N}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{NO}(g)$

### SOLUTION

**Analyze** We are given four reactions and asked to predict the sign of  $\Delta S$  for each.

**Plan** We expect  $\Delta S$  to be positive if there is an increase in temperature, increase in volume, or increase in number of gas particles. The question states that the temperature is constant, and so we

need to concern ourselves only with volume and number of particles.

### Solve

- (a) Evaporation involves a large increase in volume as liquid changes to gas. One mole of water (18 g) occupies about 18 mL as a liquid, and if it could exist as a gas at STP it would occupy 22.4 L. Because the molecules are distributed throughout a much larger volume in the gaseous state, an increase in motional freedom accompanies vaporization and  $\Delta S$  is positive.
- (b) In this process, ions, which are free to move throughout the volume of the solution, form a solid, in which they are confined to a smaller volume and restricted to more highly constrained positions. Thus,  $\Delta S$  is negative.
- (c) The particles of a solid are confined to specific locations and have fewer ways to move (fewer microstates) than do the molecules of a gas. Because  $O_2$  gas is converted into part of the solid product  $Fe_2O_3$ ,  $\Delta S$  is negative.

- (d) The number of moles of reactant gases is the same as the number of moles of product gases, and so the entropy change is expected to be small. The sign of  $\Delta S$  is impossible to predict based on our discussions thus far, but we can predict that  $\Delta S$  will be close to zero.

### Practice Exercise 1

Indicate whether each process produces an increase or decrease in the entropy of the system:

- (a)  $CO_2(s) \longrightarrow CO_2(g)$   
 (b)  $CaO(s) + CO_2(g) \longrightarrow CaCO_3(s)$   
 (c)  $HCl(g) + NH_3(g) \longrightarrow NH_4Cl(s)$   
 (d)  $2 SO_2(g) + O_2(g) \longrightarrow 2 SO_3(g)$

### Practice Exercise 2

Since the entropy of the universe increases for spontaneous processes, does it mean that the entropy of the universe decreases for nonspontaneous processes?

## Sample Exercise 19.4

### Predicting Relative Entropies

In each pair, choose the system that has greater entropy and explain your choice: (a) 1 mol of  $NaCl(s)$  or 1 mol of  $HCl(g)$  at  $25^\circ C$ , (b) 2 mol of  $HCl(g)$  or 1 mol of  $HCl(g)$  at  $25^\circ C$ , (c) 1 mol of  $HCl(g)$  or 1 mol of  $Ar(g)$  at 298 K.

### SOLUTION

**Analyze** We need to select the system in each pair that has the greater entropy.

**Plan** We examine the state of each system and the complexity of the molecules it contains.

**Solve** (a)  $HCl(g)$  has the higher entropy because the particles in gases are more disordered and have more freedom of motion than the particles in solids. (b) When these two systems are at the same pressure, the sample containing 2 mol of  $HCl$  has twice the number of molecules as the sample containing 1 mol. Thus, the 2-mol sample has twice the number of microstates and twice the entropy. (c) The  $HCl$  system has the higher entropy

because the number of ways in which an  $HCl$  molecule can store energy is greater than the number of ways in which an  $Ar$  atom can store energy. (Molecules can rotate and vibrate; atoms cannot.)

### Practice Exercise 1

Which system has the greatest entropy? (a) 1 mol of  $H_2(g)$  at STP (b) 1 mol of  $H_2(g)$  at  $100^\circ C$  and 0.5 atm (c) 1 mol of  $H_2O(s)$  at  $0^\circ C$  (d) 1 mol of  $H_2O(l)$  at  $25^\circ C$

### Practice Exercise 2

Choose the system with the greater entropy in each case: (a) 1 mol of  $H_2(g)$  at STP or 1 mol of  $SO_2(g)$  at STP, (b) 1 mol of  $N_2O_4(g)$  at STP or 2 mol of  $NO_2(g)$  at STP.

## The Third Law of Thermodynamics

If we decrease the thermal energy of a system by lowering the temperature, the energy stored in translational, vibrational, and rotational motion decreases. As less energy is stored, the entropy of the system decreases because it has fewer and fewer microstates available. If we keep lowering the temperature, do we reach a state in which these motions are essentially shut down, a point described by a single microstate? This question is addressed by the **third law of thermodynamics**:

*The entropy of a pure, perfect crystalline substance at absolute zero is zero:  $S(0 K) = 0$ .*

Consider a pure, perfect crystalline solid. At absolute zero, the individual atoms or molecules in the lattice would be perfectly ordered in position. Because none of them would have thermal motion, there is only one possible microstate. As a result, Equation 19.5 becomes  $S = k \ln W = k \ln 1 = 0$ . As the temperature is increased from absolute zero, the atoms or molecules in the crystal gain energy in the form of vibrational motion about their lattice positions. This means that the degrees of freedom and the entropy both increase. What happens to the entropy, however, as we continue to heat the crystal? We consider this important question in the next section.

## CHEMISTRY AND LIFE Entropy and Human Society

Any living organism is a complex, highly organized, well-ordered system, even at the molecular level like the nucleosome we saw at the beginning of this chapter. Our entropy content is much lower than it would be if we were completely decomposed into carbon dioxide, water, and several other simple chemicals. Does this mean that life is a violation of the second law? No, because the thousands of chemical reactions necessary to produce and maintain life have caused a large increase in the entropy of the rest of the universe. Thus, as the second law requires, the overall entropy change during the lifetime of a human, or any other living system, is positive.

The second law of thermodynamics applies also to the way we humans order our surroundings. In addition to being complex living systems ourselves, we are masters of producing order in the world around us. We manipulate and order matter at the nanoscale level in order to produce the technological breakthroughs that have become

so commonplace in the twenty-first century. We use tremendous quantities of raw materials to produce highly ordered materials. In so doing, we expend a great deal of energy to, in essence, “fight” the second law of thermodynamics.

For every bit of order we produce, however, we produce an even greater amount of disorder. Petroleum, coal, and natural gas are burned to provide the energy necessary for us to achieve highly ordered structures, but their combustion increases the entropy of the universe by releasing  $\text{CO}_2(g)$ ,  $\text{H}_2\text{O}(g)$ , and heat. Thus, even as we strive to create more impressive discoveries and greater order in our society, we drive the entropy of the universe higher, as the second law says we must.

We humans are, in effect, using up our storehouse of energy-rich materials to create order and advance technology. As noted in Chapter 5, we must learn to harness new energy sources, such as solar energy and thereby reduce our dependence on nonrenewable sources.

## 19.4 | Entropy Changes in Chemical Reactions

In Section 5.5 we discussed how calorimetry can be used to measure  $\Delta H$  for chemical reactions. No comparable method exists for measuring  $\Delta S$  for a reaction. However, because the third law establishes a zero point for entropy, we can use experimental measurements to determine the *absolute value of the entropy*,  $S$ . To see schematically how this is done, let's review in greater detail the variation in the entropy of a substance with temperature.

### Temperature Variation of Entropy

We know that the entropy of a pure, perfect crystalline solid at 0 K is zero and that the entropy increases as the temperature of the crystal is increased. **Figure 19.12** shows that the entropy of the solid increases steadily with increasing temperature up to the melting point of the solid. When the solid melts, the atoms or molecules are free to move about the entire volume of the sample. The added degrees of freedom increase the randomness of the substance, thereby increasing its entropy. We therefore see a sharp increase in the entropy at the melting point. After all the solid has melted, the temperature again increases and with it, the entropy.

#### Go Figure

Why does the plot show vertical jumps at the melting and boiling points?

▲ **Figure 19.12** Entropy increases with increasing temperature.

At the boiling point of the liquid, another abrupt increase in entropy occurs. We can understand this increase as resulting from the increased volume available to the atoms or molecules as they enter the gaseous state. When the gas is heated further, the entropy increases steadily as more energy is stored in the translational motion of the gas atoms or molecules.

Another change occurring at higher temperatures is the skewing of molecular speeds toward higher values (Figure 10.13(a)). The expansion of the range of speeds leads to increased kinetic energy and increased disorder and, hence, increased entropy. The conclusions we reach in examining Figure 10.13 are consistent with what we noted earlier: Entropy generally increases with increasing temperature because the increased motional energy leads to a greater number of possible microstates.

Entropy versus temperature graphs such as Figure 19.12 can be obtained by carefully measuring how the heat capacity of a substance  $\infty$  (Section 5.5) varies with temperature, and we can use the data to obtain the absolute entropies at different temperatures. (The theory and methods used for these measurements and calculations are beyond the scope of this text.) Entropies are usually tabulated as molar quantities, in units of joules per mole-kelvin (J/mol-K).

## Standard Molar Entropies

Molar entropies for substances in their standard states are known as **standard molar entropies** and denoted  $S^\circ$ . The standard state for any substance is defined as the pure substance at 1 atm pressure.\* Table 19.1 lists the values of  $S^\circ$  for a number of substances at 298 K; Appendix C gives a more extensive list.

We can make several observations about the  $S^\circ$  values in Table 19.1:

1. Unlike enthalpies of formation, standard molar entropies of elements at the reference temperature of 298 K are *not* zero.
2. The standard molar entropies of gases are greater than those of liquids and solids, consistent with our interpretation of experimental observations, as represented in Figure 19.12.
3. Standard molar entropies generally increase with increasing molar mass.
4. Standard molar entropies generally increase with an increasing number of atoms in the formula of a substance.

Point 4 is related to the molecular motion discussed in Section 19.3. In general, as the number of atoms increases, the number of possible microstates also increases. Figure 19.13 compares the standard molar entropies of three hydrocarbons in the gas phase. Notice how the entropy increases as the number of atoms in the molecule increases.

**TABLE 19.1** Standard Molar Entropies of Selected Substances at 298 K

| Substance                        | $S^\circ$ (J/mol-K) |
|----------------------------------|---------------------|
| $\text{H}_2(\text{g})$           | 130.6               |
| $\text{N}_2(\text{g})$           | 191.5               |
| $\text{O}_2(\text{g})$           | 205.0               |
| $\text{H}_2\text{O}(\text{g})$   | 188.8               |
| $\text{NH}_3(\text{g})$          | 192.5               |
| $\text{CH}_3\text{OH}(\text{g})$ | 237.6               |
| $\text{C}_6\text{H}_6(\text{g})$ | 269.2               |
| $\text{H}_2\text{O}(\text{l})$   | 69.9                |
| $\text{CH}_3\text{OH}(\text{l})$ | 126.8               |
| $\text{C}_6\text{H}_6(\text{l})$ | 172.8               |
| $\text{Li}(\text{s})$            | 29.1                |
| $\text{Na}(\text{s})$            | 51.4                |
| $\text{K}(\text{s})$             | 64.7                |
| $\text{Fe}(\text{s})$            | 27.23               |
| $\text{FeCl}_3(\text{s})$        | 142.3               |
| $\text{NaCl}(\text{s})$          | 72.3                |

### Go Figure

What might you expect for the value of  $S^\circ$  for butane,  $\text{C}_4\text{H}_{10}$ ?

Methane,  $\text{CH}_4$   
 $S^\circ = 186.3 \text{ J/mol-K}$

Ethane,  $\text{C}_2\text{H}_6$   
 $S^\circ = 229.6 \text{ J/mol-K}$

Propane,  $\text{C}_3\text{H}_8$   
 $S^\circ = 270.3 \text{ J/mol-K}$

**▲ Figure 19.13** Entropy increases with increasing molecular complexity.

\* The standard pressure used in thermodynamics is no longer 1 atm but rather is based on the SI unit for pressure, the pascal (Pa). The standard pressure is  $10^5 \text{ Pa}$ , a quantity known as a *bar*:  $1 \text{ bar} = 10^5 \text{ Pa} = 0.987 \text{ atm}$ . Because 1 bar differs from 1 atm by only 1.3%, we will continue to refer to the standard pressure as 1 atm.

## Calculating the Standard Entropy Change for a Reaction

The entropy change in a chemical reaction equals the sum of the entropies of the products minus the sum of the entropies of the reactants:

$$\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants}) \quad [19.8]$$

As in Equation 5.31, the coefficients  $n$  and  $m$  are the coefficients in the balanced chemical equation for the reaction.

### Sample Exercise 19.5

#### Calculating $\Delta S^\circ$ from Tabulated Entropies

Calculate the change in the standard entropy of the system,  $\Delta S^\circ$ , for the synthesis of ammonia from  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$  at 298 K:

#### SOLUTION

**Analyze** We are asked to calculate the standard entropy change for the synthesis of  $\text{NH}_3(\text{g})$  from its constituent elements.

**Plan** We can make this calculation using Equation 19.8 and the standard molar entropy values in Table 19.1 and Appendix C.

#### Solve

Using Equation 19.8, we have:

$$\Delta S^\circ = 2 S^\circ(\text{NH}_3) - [S^\circ(\text{N}_2) + 3 S^\circ(\text{H}_2)]$$

Substituting the appropriate  $S^\circ$  values from Table 19.1 yields:

$$\begin{aligned} \Delta S^\circ &= (2 \text{ mol})(192.5 \text{ J/mol}\cdot\text{K}) - [(1 \text{ mol})(191.5 \text{ J/mol}\cdot\text{K}) \\ &\quad + (3 \text{ mol})(130.6 \text{ J/mol}\cdot\text{K})] \\ &= -198.3 \text{ J/K} \end{aligned}$$

**Check:** The value for  $\Delta S^\circ$  is negative, in agreement with our qualitative prediction based on the decrease in the number of molecules of gas during the reaction.

#### Practice Exercise 1

Using the standard molar entropies in Appendix C, calculate the standard entropy change,  $\Delta S^\circ$ , for the “water-splitting” reaction at 298 K:

- (a) 326.3 J/K   (b) 265.7 J/K   (c) 163.2 J/K   (d) 88.5 J/K  
(e) -326.3 J/K

#### Practice Exercise 2

Using the standard molar entropies in Appendix C, calculate the standard entropy change,  $\Delta S^\circ$ , for the following reaction at 298 K:

## Entropy Changes in the Surroundings

We can use tabulated absolute entropy values to calculate the standard entropy change in a system, such as a chemical reaction, as just described. But what about the entropy change in the surroundings? We encountered this situation in Section 19.2, but it is good to revisit it now that we are examining chemical reactions.

We should recognize that the surroundings for any system serve essentially as a large, constant-temperature heat source (or heat sink if the heat flows from the system to the surroundings). The change in entropy of the surroundings depends on how much heat is absorbed or given off by the system.

For an isothermal process, the entropy change of the surroundings is given by

$$\Delta S_{\text{surr}} = \frac{q_{\text{surr}}}{T} = \frac{-q_{\text{sys}}}{T}$$

Because in a constant-pressure process,  $q_{\text{sys}}$  is simply the enthalpy change for the reaction,  $\Delta H$ , we can write

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T} \quad [\text{at constant P}] \quad [19.9]$$

For the ammonia synthesis reaction in Sample Exercise 19.5,  $q_{\text{sys}}$  is the enthalpy change for the reaction under standard conditions,  $\Delta H^\circ$ , so the changes in entropy will be standard entropy changes,  $\Delta S^\circ$ . Therefore, using the procedures described in Section 5.7, we have

$$\begin{aligned}\Delta H_{\text{rxn}}^\circ &= 2 \Delta H_f^\circ[\text{NH}_3(\text{g})] - 3 \Delta H_f^\circ[\text{H}_2(\text{g})] - \Delta H_f^\circ[\text{N}_2(\text{g})] \\ &= 2(-46.19 \text{ kJ}) - 3(0 \text{ kJ}) - (0 \text{ kJ}) = -92.38 \text{ kJ}\end{aligned}$$

The negative value tells us that at 298 K the formation of ammonia from  $\text{H}_2(\text{g})$  and  $\text{N}_2(\text{g})$  is exothermic. The surroundings absorb the heat given off by the system, which means an increase in the entropy of the surroundings:

$$\Delta S_{\text{surr}}^\circ = \frac{92.38 \text{ kJ}}{298 \text{ K}} = 0.310 \text{ kJ/K} = 310 \text{ J/K}$$

Notice that the magnitude of the entropy gained by the surroundings is greater than that lost by the system, calculated as  $-198.3 \text{ J/K}$  in Sample Exercise 19.5.

The overall entropy change for the reaction is

$$\Delta S_{\text{univ}}^\circ = \Delta S_{\text{sys}}^\circ + \Delta S_{\text{surr}}^\circ = -198.3 \text{ J/K} + 310 \text{ J/K} = 112 \text{ J/K}$$

Because  $\Delta S_{\text{univ}}^\circ$  is positive for any spontaneous reaction, this calculation indicates that when  $\text{NH}_3(\text{g})$ ,  $\text{H}_2(\text{g})$ , and  $\text{N}_2(\text{g})$  are together at 298 K in their standard states (each at 1 atm pressure), the reaction moves spontaneously toward formation of  $\text{NH}_3(\text{g})$ .

Keep in mind that while the thermodynamic calculations indicate that formation of ammonia is spontaneous, they do not tell us anything about the rate at which ammonia is formed. Establishing equilibrium in this system within a reasonable period requires a catalyst, as discussed in Section 15.7.

### Give It Some Thought

If a process is exothermic, does the entropy of the surroundings (a) always increase, (b) always decrease, or (c) sometimes increase and sometimes decrease, depending on the process?

## 19.5 | Gibbs Free Energy

We have seen examples of endothermic processes that are spontaneous, such as the dissolution of ammonium nitrate in water. [∞ \(Section 13.1\)](#) We learned in our discussion of the solution process that a spontaneous process that is endothermic must be accompanied by an increase in the entropy of the system. However, we have also encountered processes that are spontaneous and yet proceed with a *decrease* in the entropy of the system, such as the highly exothermic formation of sodium chloride from its constituent elements. [∞ \(Section 8.2\)](#) Spontaneous processes that result in a decrease in the system's entropy are always exothermic. Thus, the spontaneity of a reaction seems to involve two thermodynamic concepts, enthalpy and entropy.

How can we use  $\Delta H$  and  $\Delta S$  to predict whether a given reaction occurring at constant temperature and pressure will be spontaneous? The means for doing so was first developed by the American mathematician J. Willard Gibbs (1839–1903). Gibbs proposed a new state function, now called the **Gibbs free energy** (or just **free energy**),  $G$ , and defined as

$$G = H - TS \quad [19.10]$$

where  $T$  is the absolute temperature. For an isothermal process, the change in the free energy of the system,  $\Delta G$ , is

$$\Delta G = \Delta H - T\Delta S \quad [19.11]$$

### Go Figure

Are the processes that move a system toward equilibrium spontaneous or nonspontaneous?

▲ **Figure 19.14 Potential energy and free energy.** An analogy is shown between the gravitational potential-energy change of a boulder rolling down a hill and the free-energy change in a spontaneous reaction. Free energy always decreases in a spontaneous process when pressure and temperature are held constant.

Under standard conditions, this equation becomes

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ \quad [19.12]$$

To see how the state function  $G$  relates to reaction spontaneity, recall that for a reaction occurring at constant temperature and pressure

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = \Delta S_{\text{sys}} + \left( \frac{-\Delta H_{\text{sys}}}{T} \right)$$

where Equation 19.9 substitutes for  $\Delta S_{\text{surr}}$ . Multiplying both sides by  $-T$  gives

$$-T\Delta S_{\text{univ}} = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} \quad [19.13]$$

Comparing Equations 19.11 and 19.13, we see that in a process occurring at constant temperature and pressure, the free-energy change,  $\Delta G$ , is equal to  $-T\Delta S_{\text{univ}}$ . We know that for spontaneous processes,  $\Delta S_{\text{univ}}$  is always positive and, therefore,  $-T\Delta S_{\text{univ}}$  is always negative. Thus, the sign of  $\Delta G$  provides us with extremely valuable information about the spontaneity of processes that occur at constant temperature and pressure. If both  $T$  and  $P$  are constant, the relationship between the sign of  $\Delta G$  and the spontaneity of a reaction is:

- If  $\Delta G < 0$ , the reaction is spontaneous in the forward direction.
- If  $\Delta G = 0$ , the reaction is at equilibrium.
- If  $\Delta G > 0$ , the reaction in the forward direction is nonspontaneous (work must be done to make it occur) but the reverse reaction is spontaneous.

It is more convenient to use  $\Delta G$  as a criterion for spontaneity than to use  $\Delta S_{\text{univ}}$  because  $\Delta G$  relates to the system alone and avoids the complication of having to examine the surroundings.

An analogy is often drawn between the free-energy change during a spontaneous reaction and the potential-energy change when a boulder rolls down a hill (Figure 19.14). Potential energy in a gravitational field “drives” the boulder until it reaches a state of minimum potential energy in the valley. Similarly, the free energy of a chemical system decreases until it reaches a minimum value. When this minimum is reached, a state of equilibrium exists. *In any spontaneous process carried out at constant temperature and pressure, the free energy always decreases.*

To illustrate these ideas, let’s return to the Haber process for the synthesis of ammonia from nitrogen and hydrogen, which we discussed extensively in Chapter 15:

Imagine that we have a reaction vessel that allows us to maintain a constant temperature and pressure and that we have a catalyst that allows the reaction to proceed at a reasonable rate. What happens when we load the vessel with a certain number of moles of  $\text{N}_2$  and three times that number of moles of  $\text{H}_2$ ? As we saw in Figure 15.4, the  $\text{N}_2$  and  $\text{H}_2$  react spontaneously to form  $\text{NH}_3$  until equilibrium is achieved. Similarly, Figure 15.4 shows that if we load the vessel with pure  $\text{NH}_3$ , it decomposes spontaneously to  $\text{N}_2$  and  $\text{H}_2$  until equilibrium is reached. In each case, the free energy of the system gets progressively lower and lower as the reaction moves toward equilibrium, which represents a minimum in the free energy. We illustrate these cases in Figure 19.15.

### Give It Some Thought

- What are the criteria for spontaneity
- in terms of entropy and
  - in terms of free energy?

This is a good time to remind ourselves of the significance of the reaction quotient,  $Q$ , for a system that is not at equilibrium. ∞ (Section 15.6) Recall that when  $Q < K$ , there is an excess of reactants relative to products, and the reaction proceeds spontaneously in the forward direction to reach equilibrium, as noted in Figure 19.15. When  $Q > K$ , the reaction proceeds spontaneously in the reverse direction. At equilibrium  $Q = K$ .

## Go Figure

Why are the spontaneous processes shown sometimes said to be “downhill” in free energy?

▲ **Figure 19.15** Free energy and approaching equilibrium. In the reaction  $\text{N}_2(g) + 3 \text{H}_2(g) \rightleftharpoons 2 \text{NH}_3(g)$ , if the reaction mixture has too much  $\text{N}_2$  and  $\text{H}_2$  relative to  $\text{NH}_3$  (left),  $Q < K$  and  $\text{NH}_3$  forms spontaneously. If there is more  $\text{NH}_3$  in the mixture relative to the reactants  $\text{N}_2$  and  $\text{H}_2$  (right),  $Q > K$  and the  $\text{NH}_3$  decomposes spontaneously into  $\text{N}_2$  and  $\text{H}_2$ .

## Sample Exercise 19.6

Calculating Free-Energy Change from  $\Delta H^\circ$ ,  $T$ , and  $\Delta S^\circ$ 

Calculate the standard free-energy change for the formation of  $\text{NO}(g)$  from  $\text{N}_2(g)$  and  $\text{O}_2(g)$  at 298 K:

given that  $\Delta H^\circ = 180.7 \text{ kJ}$  and  $\Delta S^\circ = 24.7 \text{ J/K}$ . Is the reaction spontaneous under these conditions?

## SOLUTION

**Analyze** We are asked to calculate  $\Delta G^\circ$  for the indicated reaction (given  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $T$ ) and to predict whether the reaction is spontaneous under standard conditions at 298 K.

**Plan** To calculate  $\Delta G^\circ$ , we use Equation 19.12,  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ . To determine whether the reaction is spontaneous under standard conditions, we look at the sign of  $\Delta G^\circ$ .

## Solve

$$\begin{aligned} \Delta G^\circ &= \Delta H^\circ - T\Delta S^\circ \\ &= 180.7 \text{ kJ} - (298 \text{ K})(24.7 \text{ J/K})\left(\frac{1 \text{ kJ}}{10^3 \text{ J}}\right) \\ &= 180.7 \text{ kJ} - 7.4 \text{ kJ} \\ &= 173.3 \text{ kJ} \end{aligned}$$

Because  $\Delta G^\circ$  is positive, the reaction is not spontaneous under standard conditions at 298 K.

**Comment** Notice that we converted the units of the  $T\Delta S^\circ$  term to kJ so that they could be added to the  $\Delta H^\circ$  term, whose units are kJ.

## ► Practice Exercise 1

Which of these statements is true? (a) All spontaneous reactions have a negative enthalpy change (b) All spontaneous reactions have a positive entropy change (c) All spontaneous reactions have a positive free-energy change (d) All spontaneous reactions have a negative free-energy change (e) All spontaneous reactions have a negative entropy change

## ► Practice Exercise 2

Calculate  $\Delta G^\circ$  for a reaction for which  $\Delta H^\circ = 24.6 \text{ kJ}$  and  $\Delta S^\circ = 132 \text{ J/K}$  at 298 K. Is the reaction spontaneous under these conditions?

**TABLE 19.2** Conventions Used in Establishing Standard Free Energies

| State of Matter | Standard State                                       |
|-----------------|--|
| Solid           | Pure solid   |
| Liquid          | Pure liquid  |
| Gas             | 1 atm pressure                                       |
| Solution        | 1 M concentration                                    |
| Element         | $\Delta G_f^\circ = 0$ for element in standard state |

## Standard Free Energy of Formation

Recall that we defined *standard enthalpies of formation*,  $\Delta H_f^\circ$ , as the enthalpy change when a substance is formed from its elements under defined standard conditions. [∞ \(Section 5.7\)](#) We can define **standard free energies of formation**,  $\Delta G_f^\circ$ , in a similar way:  $\Delta G_f^\circ$  for a substance is the free-energy change for its formation from its elements under standard conditions. As is summarized in [Table 19.2](#), standard state means 1 atm pressure for gases, the pure solid for solids, and the pure liquid for liquids. For substances in solution, the standard state is normally a concentration of 1 M. (In very accurate work it may be necessary to make certain corrections, but we need not worry about these.)

The temperature usually chosen for purposes of tabulating data is 25 °C, but we will calculate  $\Delta G$  at other temperatures as well. Just as for the standard heats of formation, the free energies of elements in their standard states are set to zero. This arbitrary choice of a reference point has no effect on the quantity in which we are interested, which is the *difference* in free energy between reactants and products.

A listing of standard free energies of formation is given in Appendix C.

### Give It Some Thought

What does the superscript ° indicate when associated with a thermodynamic quantity, as in  $\Delta H^\circ$ ,  $\Delta S^\circ$ , or  $\Delta G^\circ$ ?

Standard free energies of formation are useful in calculating the *standard free-energy change* for chemical processes. The procedure is analogous to the calculation of  $\Delta H^\circ$  (Equation 5.31) and  $\Delta S^\circ$  (Equation 19.8):

$$\Delta G^\circ = \sum n \Delta G_f^\circ(\text{products}) - \sum m \Delta G_f^\circ(\text{reactants}) \quad [19.14]$$

## Sample Exercise 19.7

### Calculating Standard Free-Energy Change from Free Energies of Formation

(a) Use data from Appendix C to calculate the standard free-energy change for the reaction  $\text{P}_4(\text{g}) + 6 \text{Cl}_2(\text{g}) \longrightarrow 4 \text{PCl}_3(\text{g})$  at 298 K. (b) What is  $\Delta G^\circ$  for the reverse of this reaction?

### SOLUTION

**Analyze** We are asked to calculate the free-energy change for a reaction and then to determine the free-energy change for the reverse reaction.

**Plan** We look up the free-energy values for the products and reactants and use Equation 19.14. We multiply the molar quantities by the coefficients in the balanced equation and subtract the total for the reactants from that for the products.

### Solve

(a)  $\text{Cl}_2(\text{g})$  is in its standard state, so  $\Delta G_f^\circ$  is zero for this reactant.  $\text{P}_4(\text{g})$ , however, is not in its standard state, so  $\Delta G_f^\circ$  is not zero for this reactant. From the balanced equation and values from Appendix C, we have

$$\begin{aligned} \Delta G_{\text{rxn}}^\circ &= 4 \Delta G_f^\circ[\text{PCl}_3(\text{g})] - \Delta G_f^\circ[\text{P}_4(\text{g})] - 6 \Delta G_f^\circ[\text{Cl}_2(\text{g})] \\ &= (4 \text{ mol})(-269.6 \text{ kJ/mol}) - (1 \text{ mol})(24.4 \text{ kJ/mol}) - 0 \\ &= -1102.8 \text{ kJ} \end{aligned}$$

That  $\Delta G^\circ$  is negative tells us that a mixture of  $\text{P}_4(\text{g})$ ,  $\text{Cl}_2(\text{g})$ , and  $\text{PCl}_3(\text{g})$  at 25 °C, each present at a partial pressure of 1 atm, would react spontaneously in the forward direction to form

more  $\text{PCl}_3$ . Remember, however, that the value of  $\Delta G^\circ$  tells us nothing about the rate at which the reaction occurs.

(b) When we reverse the reaction, we reverse the roles of the reactants and products. Thus, reversing the reaction changes the sign of  $\Delta G$  in Equation 19.14, just as reversing the reaction changes the sign of  $\Delta H$ . [∞ \(Section 5.4\)](#) Hence, using the result from part (a), we have

### Practice Exercise 1

The following chemical equations describe the same chemical reaction. How do the free energies of these two chemical equations compare?

### Practice Exercise 2

Use data from Appendix C to calculate  $\Delta G^\circ$  at 298 K for the combustion of methane:

## Sample Exercise 19.8

### Predicting and Calculating $\Delta G^\circ$

In Section 5.7 we used Hess's law to calculate  $\Delta H^\circ$  for the combustion of propane gas at 298 K:

- (a) Without using data from Appendix C, predict whether  $\Delta G^\circ$  for this reaction is more negative or less negative than  $\Delta H^\circ$ .  
 (b) Use data from Appendix C to calculate  $\Delta G^\circ$  for the reaction at 298 K. Is your prediction from part (a) correct?

### SOLUTION

**Analyze** In part (a) we must predict the value for  $\Delta G^\circ$  relative to that for  $\Delta H^\circ$  on the basis of the balanced equation for the reaction. In part (b) we must calculate the value for  $\Delta G^\circ$  and compare this value with our qualitative prediction.

**Plan** The free-energy change incorporates both the change in enthalpy and the change in entropy for the reaction (Equation 19.11), so under standard conditions

$$\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$$

To determine whether  $\Delta G^\circ$  is more negative or less negative than  $\Delta H^\circ$ , we need to determine the sign of the term  $T\Delta S^\circ$ . Because  $T$  is the absolute temperature, 298 K, it is always a positive number. We can predict the sign of  $\Delta S^\circ$  by looking at the reaction.

#### Solve

- (a) The reactants are six molecules of gas, and the products are three molecules of gas and four molecules of liquid. Thus, the number of molecules of gas has decreased significantly during the reaction. By using the general rules discussed in Section 19.3, we expect a decrease in the number of gas molecules to lead to a decrease in the entropy of the system—the products have fewer possible microstates than the reactants. We therefore expect  $\Delta S^\circ$  and  $T\Delta S^\circ$  to be negative. Because we are subtracting  $T\Delta S^\circ$ , which is a negative number, we predict that  $\Delta G^\circ$  is *less negative* than  $\Delta H^\circ$ .

- (b) Using Equation 19.14 and values from Appendix C, we have

$$\begin{aligned} \Delta G^\circ &= 3 \Delta G_f^\circ[\text{CO}_2(g)] + 4 \Delta G_f^\circ[\text{H}_2\text{O}(l)] \\ &\quad - \Delta G_f^\circ[\text{C}_3\text{H}_8(g)] - 5 \Delta G_f^\circ[\text{O}_2(g)] \\ &= 3 \text{ mol}(-394.4 \text{ kJ/mol}) + 4 \text{ mol}(-237.13 \text{ kJ/mol}) - \\ &\quad 1 \text{ mol}(-23.47 \text{ kJ/mol}) - 5 \text{ mol}(0 \text{ kJ/mol}) = -2108 \text{ kJ} \end{aligned}$$

Notice that we have been careful to use the value of  $\Delta G_f^\circ$  for  $\text{H}_2\text{O}(l)$ . As in calculating  $\Delta H$  values, the phases of the reactants and products are important. As we predicted,  $\Delta G^\circ$  is less negative than  $\Delta H^\circ$  because of the decrease in entropy during the reaction.

#### Practice Exercise 1

If a reaction is exothermic and its entropy change is positive, which statement is true? (a) The reaction is spontaneous at all temperatures (b) The reaction is nonspontaneous at all temperatures (c) The reaction is spontaneous only at higher temperatures (d) The reaction is spontaneous only at lower temperatures

#### Practice Exercise 2

For the combustion of butane at 298 K,  
 $2 \text{C}_4\text{H}_{10}(g) + 13 \text{O}_2(g) \longrightarrow 8 \text{CO}_2(g) + 10 \text{H}_2\text{O}(g)$ , do you expect  $\Delta G^\circ$  to be more negative or less negative than  $\Delta H^\circ$ ?

## A CLOSER LOOK What's "Free" About Free Energy?

The Gibbs free energy is a remarkable thermodynamic quantity. Because so many chemical reactions are carried out under conditions of near-constant pressure and temperature, chemists, biochemists, and engineers consider the sign and magnitude of  $\Delta G$  as exceptionally useful tools in the design of chemical and biochemical reactions. We will see examples of the usefulness of  $\Delta G$  throughout the remainder of this chapter and this text.

When first learning about  $\Delta G$ , two common questions often arise: Why is the sign of  $\Delta G$  an indicator of the spontaneity of reactions? And what is "free" about free energy?

In Section 19.2, we saw that the second law of thermodynamics governs the spontaneity of processes. In order to apply the second law (Equation 19.4), however, we must determine  $\Delta S_{\text{univ}}$ , which is often difficult to evaluate. When  $T$  and  $P$  are constant, however, we can relate  $\Delta S_{\text{univ}}$  to the changes in entropy and enthalpy of just the *system* by substituting the Equation 19.9 expression for  $\Delta S_{\text{surr}}$  in Equation 19.4:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = \Delta S_{\text{sys}} + \left( \frac{-\Delta H_{\text{sys}}}{T} \right) \quad (\text{constant } T, P) \quad [19.15]$$

Thus, at constant temperature and pressure, the second law becomes

$$\begin{aligned} \text{Reversible process: } \Delta S_{\text{univ}} &= \Delta S_{\text{sys}} - \frac{\Delta H_{\text{sys}}}{T} = 0 \\ \text{Irreversible process: } \Delta S_{\text{univ}} &= \Delta S_{\text{sys}} - \frac{\Delta H_{\text{sys}}}{T} > 0 \end{aligned} \quad [19.16] \quad (\text{constant } T, P)$$

Now we can see the relationship between  $\Delta G_{\text{sys}}$  (which we call simply  $\Delta G$ ) and the second law. From Equation 19.11 we know that  $\Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}}$ . If we multiply Equations 19.16 by  $-T$  and rearrange, we reach the following conclusion:

$$\begin{aligned} \text{Reversible process: } \Delta G &= \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} = 0 \\ \text{Irreversible process: } \Delta G &= \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} < 0 \end{aligned} \quad [19.17] \quad (\text{constant } T, P)$$

Equations 19.17 allow us to use the sign of  $\Delta G$  to conclude whether a reaction is spontaneous, nonspontaneous, or at equilibrium. When  $\Delta G < 0$ , a process is irreversible and, therefore, spontaneous. When  $\Delta G = 0$ , the process is reversible and, therefore, at equilibrium. If a process has  $\Delta G > 0$ , then the reverse process will have  $\Delta G < 0$ ; thus,

*Continued*

the process as written is nonspontaneous, but its reverse reaction will be irreversible and spontaneous.

The magnitude of  $\Delta G$  is also significant. A reaction for which  $\Delta G$  is large and negative, such as the burning of gasoline, is much more capable of doing work on the surroundings than is a reaction for which  $\Delta G$  is small and negative, such as ice melting at room temperature. In fact, thermodynamics tells us that *the change in free energy for a process,  $\Delta G$ , equals the maximum useful work that can be done by the system on its surroundings in a spontaneous process occurring at constant temperature and pressure:*

$$\Delta G = -w_{\max} \quad [19.18]$$

(Remember our sign convention from Table 5.1: Work done *by* a system is negative.) In other words,  $\Delta G$  gives the theoretical limit to how much work can be done by a process.

The relationship in Equation 19.18 explains why  $\Delta G$  is called the *free energy change*—it is the portion of the energy change of a spontaneous reaction that is free to do useful work. The remainder of the energy enters the environment as heat. For example, the theoretical maximum work obtained for the combustion of gasoline is given by the value of  $\Delta G$  for the combustion reaction. On average, standard internal combustion engines are inefficient in utilizing this potential work—more than 60% of the potential work is lost (primarily as heat) in converting the chemical energy of the gasoline to mechanical energy to move the vehicle. When other losses are considered—idling time, braking, aerodynamic drag, and so forth—only about 15% of the potential work from the gasoline is used to move the car. Advances in automobile design—such as hybrid technology, and new lightweight materials—have the potential to increase the percentage of useful work obtained from the gasoline.

## 19.6 | Free Energy and Temperature

Tabulations of  $\Delta G_f^\circ$ , such as those in Appendix C, make it possible to calculate  $\Delta G^\circ$  for reactions at the standard temperature of 25 °C, but we are often interested in examining reactions at other temperatures. To see how  $\Delta G$  is affected by temperature, let's look again at Equation 19.11:

$$\Delta G = \Delta H - T\Delta S = \underset{\substack{\text{Enthalpy} \\ \text{term}}}{\Delta H} + \underset{\substack{\text{Entropy} \\ \text{term}}}{(-T\Delta S)}$$

Notice that we have written the expression for  $\Delta G$  as a sum of two contributions, an enthalpy term,  $\Delta H$ , and an entropy term,  $-T\Delta S$ . Because the value of  $-T\Delta S$  depends directly on the absolute temperature  $T$ ,  $\Delta G$  varies with temperature. We know that the enthalpy term,  $\Delta H$ , can be either positive or negative and that  $T$  is positive at all temperatures other than absolute zero. The entropy term,  $-T\Delta S$ , can also be positive or negative. When  $\Delta S$  is positive, which means the final state has greater randomness (a greater number of microstates) than the initial state, the term  $-T\Delta S$  is negative. When  $\Delta S$  is negative,  $-T\Delta S$  is positive.

The sign of  $\Delta G$ , which tells us whether a process is spontaneous, depends on the signs and magnitudes of  $\Delta H$  and  $-T\Delta S$ . The various combinations of  $\Delta H$  and  $-T\Delta S$  signs are given in Table 19.3.

Note in Table 19.3 that when  $\Delta H$  and  $-T\Delta S$  have opposite signs, the sign of  $\Delta G$  depends on the magnitudes of these two terms. In these instances, temperature is an important consideration. Generally,  $\Delta H$  and  $\Delta S$  change very little with temperature. However, the value of  $T$  directly affects the magnitude of  $-T\Delta S$ . As the temperature increases, the magnitude of  $-T\Delta S$  increases, and this term becomes relatively more important in determining the sign and magnitude of  $\Delta G$ .

As an example, let's consider once more the melting of ice to liquid water at 1 atm:

This process is endothermic, which means that  $\Delta H$  is positive. Because the entropy increases during the process,  $\Delta S$  is positive, which makes  $-T\Delta S$  negative. At temperatures below 0 °C (273 K), the magnitude of  $\Delta H$  is greater than that of  $-T\Delta S$ . Hence, the

**TABLE 19.3** How Signs of  $\Delta H$  and  $\Delta S$  Affect Reaction Spontaneity

| $\Delta H$ | $\Delta S$ | $-T\Delta S$ | $\Delta G = \Delta H - T\Delta S$ | Reaction Characteristics                            | Example   |
|------------|------------|--------------|-----------------------------------|---|---|
| –          | +          | –            | –                                 | Spontaneous at all temperatures                     | $2 \text{O}_3(g) \longrightarrow 3 \text{O}_2(g)$             |
| +          | –          | +            | +                                 | Nonspontaneous at all temperatures                  | $3 \text{O}_2(g) \longrightarrow 2 \text{O}_3(g)$             |
| –          | –          | +            | + or –                            | Spontaneous at low $T$ ; nonspontaneous at high $T$ | $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(s)$ |
| +          | +          | –            | + or –                            | Spontaneous at high $T$ ; nonspontaneous at low $T$ | $\text{H}_2\text{O}(s) \longrightarrow \text{H}_2\text{O}(l)$ |

positive enthalpy term dominates, and  $\Delta G$  is positive. This positive value of  $\Delta G$  means that ice melting is not spontaneous at  $T < 0^\circ\text{C}$ , just as our everyday experience tells us; rather, the reverse process, the freezing of liquid water into ice, is spontaneous at these temperatures.

What happens at temperatures greater than  $0^\circ\text{C}$ ? As  $T$  increases, so does the magnitude of  $-T\Delta S$ . When  $T > 0^\circ\text{C}$ , the magnitude of  $-T\Delta S$  is greater than the magnitude of  $\Delta H$ , which means that the  $-T\Delta S$  term dominates and  $\Delta G$  is negative. The negative value of  $\Delta G$  tells us that ice melting is spontaneous at  $T > 0^\circ\text{C}$ .

At the normal melting point of water,  $T = 0^\circ\text{C}$ , the two phases are in equilibrium. Recall that  $\Delta G = 0$  at equilibrium; at  $T = 0^\circ\text{C}$ ,  $\Delta H$  and  $-T\Delta S$  are equal in magnitude and opposite in sign, so they cancel and give  $\Delta G = 0$ .

### Give It Some Thought

The normal boiling point of benzene is  $80^\circ\text{C}$ . At  $100^\circ\text{C}$  and 1 atm, which term is greater in magnitude for the vaporization of benzene,  $\Delta H$  or  $-T\Delta S$ ?

Our discussion of the temperature dependence of  $\Delta G$  is also relevant to standard free-energy changes. We can calculate the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  at 298 K from the data in Appendix C. If we assume that these values do not change with temperature, we can then use Equation 19.12 to estimate  $\Delta G$  at temperatures other than 298 K.

## Sample Exercise 19.9

### Determining the Effect of Temperature on Spontaneity

The Haber process for the production of ammonia involves the equilibrium

For this reaction,  $\Delta H^\circ = -92.38 \text{ kJ}$  and  $\Delta S^\circ = -198.3 \text{ J/K}$ . Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  for this reaction do not change with temperature. (a) Predict the direction in which  $\Delta G$  for the reaction changes with increasing temperature. (b) Calculate  $\Delta G$  at  $25^\circ\text{C}$  and at  $500^\circ\text{C}$ .

### SOLUTION

**Analyze** In part (a) we are asked to predict the direction in which  $\Delta G$  changes as temperature increases. In part (b) we need to determine  $\Delta G$  for the reaction at two temperatures.

**Plan** We can answer part (a) by determining the sign of  $\Delta S$  for the reaction and then using that information to analyze Equation 19.12. In part (b) we use the given  $\Delta H^\circ$  and  $\Delta S^\circ$  values for the reaction together with Equation 19.12 to calculate  $\Delta G$ .

### Solve

(a) The temperature dependence of  $\Delta G$  comes from the entropy term in Equation 19.12,  $\Delta G = \Delta H - T\Delta S$ . We expect  $\Delta S$  for this reaction to be negative because the number of molecules of gas is smaller in the products. Because  $\Delta S$  is negative,  $-T\Delta S$  is positive and increases with increasing temperature. As a result,  $\Delta G$  becomes less negative (or more positive) with increasing temperature. Thus, the driving force for the production of  $\text{NH}_3$  becomes smaller with increasing temperature.

(b) If we assume that the values for  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature, we can calculate  $\Delta G$  at any temperature by using Equation 19.12. At  $T = 25^\circ\text{C} = 298 \text{ K}$ , we have

$$\begin{aligned}\Delta G^\circ &= -92.38 \text{ kJ} - (298 \text{ K})(-198.3 \text{ J/K})\left(\frac{1 \text{ kJ}}{1000 \text{ J}}\right) \\ &= -92.38 \text{ kJ} + 59.1 \text{ kJ} = -33.3 \text{ kJ}\end{aligned}$$

At  $T = 500^\circ\text{C} = 773 \text{ K}$ , we have

$$\begin{aligned}\Delta G &= -92.38 \text{ kJ} - (773 \text{ K})(-198.3 \text{ J/K})\left(\frac{1 \text{ kJ}}{1000 \text{ J}}\right) \\ &= -92.38 \text{ kJ} + 153 \text{ kJ} = 61 \text{ kJ}\end{aligned}$$

Notice that we had to convert the units of  $-T\Delta S^\circ$  to kJ in both calculations so that this term can be added to the  $\Delta H^\circ$  term, which has units of kJ.

**Comment** Increasing the temperature from 298 K to 773 K changes  $\Delta G$  from  $-33.3 \text{ kJ}$  to  $+61 \text{ kJ}$ . Of course, the result at 773 K assumes that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature. Although these values do change slightly with temperature, the result at 773 K should be a reasonable approximation.

The positive increase in  $\Delta G$  with increasing  $T$  agrees with our prediction in part (a). Our result indicates that in a mixture of  $\text{N}_2(\text{g})$ ,  $\text{H}_2(\text{g})$ , and  $\text{NH}_3(\text{g})$ , each present at a partial pressure of 1 atm, the  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$  react spontaneously at 298 K to form more  $\text{NH}_3(\text{g})$ . At 773 K, the positive value of  $\Delta G$  tells us that the reverse reaction is spontaneous. Thus, when the mixture of these gases, each at a partial pressure of 1 atm, is heated to 773 K, some of the  $\text{NH}_3(\text{g})$  spontaneously decomposes into  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$ .

*Continued*

**► Practice Exercise 1**

What is the temperature above which the Haber ammonia process becomes nonspontaneous?

- (a) 25 °C (b) 47 °C (c) 61 °C (d) 193 °C (e) 500 °C

**► Practice Exercise 2**

(a) Using standard enthalpies of formation and standard entropies in Appendix C, calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  at 298 K for the reaction  $2\text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2\text{SO}_3(g)$ . (b) Use your values from part (a) to estimate  $\Delta G$  at 400 K.

## 19.7 | Free Energy and the Equilibrium Constant

In Section 19.5 we saw a special relationship between  $\Delta G$  and equilibrium: For a system at equilibrium,  $\Delta G = 0$ . We have also seen how to use tabulated thermodynamic data to calculate values of the standard free-energy change,  $\Delta G^\circ$ . In this final section, we learn two more ways in which we can use free energy to analyze chemical reactions: using  $\Delta G^\circ$  to calculate  $\Delta G$  under *nonstandard* conditions and relating the values of  $\Delta G^\circ$  and  $K$  for a reaction.

### Free Energy under Nonstandard Conditions

The set of standard conditions for which  $\Delta G^\circ$  values pertain is given in Table 19.2. Most chemical reactions occur under nonstandard conditions. For any chemical process, the relationship between the free-energy change under standard conditions,  $\Delta G^\circ$ , and the free-energy change under any other conditions,  $\Delta G$ , is given by

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [19.19]$$

In this equation  $R$  is the ideal-gas constant, 8.314 J/mol·K;  $T$  is the absolute temperature; and  $Q$  is the reaction quotient for the reaction mixture of interest. [∞ \(Section 15.6\)](#) Recall that the reaction quotient  $Q$  is calculated like an equilibrium constant, except that you use the concentrations at any point of interest in the reaction; if  $Q = K$ , then the reaction is at equilibrium. Under standard conditions, the concentrations of all the reactants and products are equal to 1 M. Thus, under standard conditions  $Q = 1$ ,  $\ln Q = 0$ , and Equation 19.19 reduces to  $\Delta G = \Delta G^\circ$  under standard conditions, as it should.

### Sample Exercise 19.10

#### Relating $\Delta G$ to a Phase Change at Equilibrium

(a) Write the chemical equation that defines the normal boiling point of liquid carbon tetrachloride,  $\text{CCl}_4(l)$ . (b) What is the value of  $\Delta G^\circ$  for the equilibrium in part (a)? (c) Use data from Appendix C and Equation 19.12 to estimate the normal boiling point of  $\text{CCl}_4$ .

#### SOLUTION

**Analyze** (a) We must write a chemical equation that describes the physical equilibrium between liquid and gaseous  $\text{CCl}_4$  at the normal boiling point. (b) We must determine the value of  $\Delta G^\circ$  for  $\text{CCl}_4$ , in equilibrium with its vapor at the normal boiling point. (c) We must estimate the normal boiling point of  $\text{CCl}_4$ , based on available thermodynamic data.

**Plan** (a) The chemical equation is the change of state from liquid to gas. For (b), we need to analyze Equation 19.19 at equilibrium ( $\Delta G = 0$ ), and for (c) we can use Equation 19.12 to calculate  $T$  when  $\Delta G = 0$ .

#### Solve

(a) The normal boiling point is the temperature at which a pure liquid is in equilibrium with its vapor at a pressure of 1 atm:

(b) At equilibrium,  $\Delta G = 0$ . In any normal boiling-point equilibrium, both liquid and vapor are in their standard state of pure liquid and vapor at 1 atm (Table 19.2). Consequently,  $Q = 1$ ,  $\ln Q = 0$ , and  $\Delta G = \Delta G^\circ$  for this process. We conclude that  $\Delta G^\circ = 0$  for the equilibrium representing the normal boiling point of any liquid. (We would also find that  $\Delta G^\circ = 0$  for the equilibria relevant to normal melting points and normal sublimation points.)

$$\Delta G^\circ = 0$$

- (c) Combining Equation 19.12 with the result from part (b), we see that the equality at the normal boiling point,  $T_b$ , of  $\text{CCl}_4(l)$  (or any other pure liquid) is:

$$\Delta G^\circ = \Delta H^\circ - T_b \Delta S^\circ = 0$$

Solving the equation for  $T_b$ , we obtain:

$$T_b = \Delta H^\circ / \Delta S^\circ$$

Strictly speaking, we need the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  for the  $\text{CCl}_4(l)/\text{CCl}_4(g)$  equilibrium at the normal boiling point to do this calculation. However, we can *estimate* the boiling point by using the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  for the phases of  $\text{CCl}_4$  at 298 K, which we obtain from Appendix C and Equations 5.31 and 19.8:

$$\Delta H^\circ = (1 \text{ mol})(-106.7 \text{ kJ/mol}) - (1 \text{ mol})(-139.3 \text{ kJ/mol}) = +32.6 \text{ kJ}$$

$$\Delta S^\circ = (1 \text{ mol})(309.4 \text{ J/mol}\cdot\text{K}) - (1 \text{ mol})(214.4 \text{ J/mol}\cdot\text{K}) = +95.0 \text{ J/K}$$

As expected, the process is endothermic ( $\Delta H > 0$ ) and produces a gas, thus increasing the entropy ( $\Delta S > 0$ ). We now use these values to estimate  $T_b$  for  $\text{CCl}_4(l)$ :

$$T_b = \frac{\Delta H^\circ}{\Delta S^\circ} = \left( \frac{32.6 \text{ kJ}}{95.0 \text{ J/K}} \right) \left( \frac{1000 \text{ J}}{1 \text{ kJ}} \right) = 343 \text{ K} = 70^\circ \text{C}$$

Note that we have used the conversion factor between joules and kilojoules to make the units of  $\Delta H^\circ$  and  $\Delta S^\circ$  match.

**Check** The experimental normal boiling point of  $\text{CCl}_4(l)$  is  $76.5^\circ \text{C}$ . The small deviation of our estimate from the experimental value is due to the assumption that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature.

#### ► Practice Exercise 1

If the normal boiling point of a liquid is  $67^\circ \text{C}$ , and the standard molar entropy change for the boiling process is

+100 J/K, estimate the standard molar enthalpy change for the boiling process.

(a) +6700 J (b) -6700 J (c) +34,000 J (d) -34,000 J

#### ► Practice Exercise 2

Use data in Appendix C to estimate the normal boiling point, in K, for elemental bromine,  $\text{Br}_2(l)$ . (The experimental value is given in Figure 11.5.)

When the concentrations of reactants and products are nonstandard, we must calculate  $Q$  in order to determine  $\Delta G$ . We illustrate how this is done in Sample Exercise 19.11. At this stage in our discussion, therefore, it becomes important to note the units used to calculate  $Q$  when using Equation 19.19. The convention used for standard states is used when applying this equation: In determining the value of  $Q$ , the concentrations of gases are always expressed as partial pressures in atmospheres and solutes are expressed as their concentrations in molarities.

## Sample Exercise 19.11

### Calculating the Free-Energy Change under Nonstandard Conditions

Calculate  $\Delta G$  at 298 K for a mixture of 1.0 atm  $\text{N}_2$ , 3.0 atm  $\text{H}_2$ , and 0.50 atm  $\text{NH}_3$  being used in the Haber process:

#### SOLUTION

**Analyze** We are asked to calculate  $\Delta G$  under nonstandard conditions.

**Plan** We can use Equation 19.19 to calculate  $\Delta G$ . Doing so requires that we calculate the value of the reaction quotient  $Q$

for the specified partial pressures, for which we use the partial-pressures form of Equation 15.24 (the equilibrium constant expression). We then use a table of standard free energies of formation to evaluate  $\Delta G^\circ$ .

#### Solve

The partial-pressures form of Equation 15.24 gives:

$$Q = \frac{P_{\text{NH}_3}^2}{P_{\text{N}_2} P_{\text{H}_2}^3} = \frac{(0.50)^2}{(1.0)(3.0)^3} = 9.3 \times 10^{-3}$$

In Sample Exercise 19.9 we calculated  $\Delta G^\circ = -33.3 \text{ kJ}$  for this reaction. We will have to change the units of this quantity in applying Equation 19.19, however. For the units in Equation 19.19 to work out, we will use kJ/mol as our units for  $\Delta G^\circ$ , where “per mole” means “per mole of the reaction as written.” Thus,  $\Delta G^\circ = -33.3 \text{ kJ/mol}$  implies per 1 mol of  $\text{N}_2$ , per 3 mol of  $\text{H}_2$ , and per 2 mol of  $\text{NH}_3$ .

We now use Equation 19.19 to calculate  $\Delta G$  for these nonstandard conditions:

$$\begin{aligned} \Delta G &= \Delta G^\circ + RT \ln Q \\ &= (-33.3 \text{ kJ/mol}) \\ &\quad + (8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})(1 \text{ kJ}/1000 \text{ J}) \ln(9.3 \times 10^{-3}) \\ &= (-33.3 \text{ kJ/mol}) + (-11.6 \text{ kJ/mol}) = -44.9 \text{ kJ/mol} \end{aligned}$$

*Continued*

**Comment** We see that  $\Delta G$  becomes more negative as the pressures of  $\text{N}_2$ ,  $\text{H}_2$ , and  $\text{NH}_3$  are changed from 1.0 atm (standard conditions,  $\Delta G^\circ$ ) to 1.0 atm, 3.0 atm, and 0.50 atm, respectively. The larger negative value for  $\Delta G$  indicates a larger “driving force” to produce  $\text{NH}_3$ .

We would make the same prediction based on Le Châtelier’s principle. [∞ \(Section 15.7\)](#) Relative to standard conditions, we have increased the pressure of a reactant ( $\text{H}_2$ ) and decreased the pressure of the product ( $\text{NH}_3$ ). Le Châtelier’s principle predicts that both changes shift the reaction to the product side, thereby forming more  $\text{NH}_3$ .

### Practice Exercise 1

Which of the following statements is true? **(a)** The larger the  $Q$ , the larger the  $\Delta G^\circ$ . **(b)** If  $Q = 0$ , the system is at equilibrium. **(c)** If a reaction is spontaneous under standard conditions, it is spontaneous under all conditions. **(d)** The free-energy change for a reaction is independent of temperature. **(e)** If  $Q > 1$ ,  $\Delta G > \Delta G^\circ$ .

### Practice Exercise 2

Calculate  $\Delta G$  at 298 K for the Haber reaction if the reaction mixture consists of 0.50 atm  $\text{N}_2$ , 0.75 atm  $\text{H}_2$ , and 2.0 atm  $\text{NH}_3$ .

## Relationship between $\Delta G^\circ$ and $K$

We can now use Equation 19.19 to derive the relationship between  $\Delta G^\circ$  and the equilibrium constant,  $K$ . At equilibrium,  $\Delta G = 0$  and  $Q = K$ . Thus, at equilibrium, Equation 19.19 transforms as follows:

$$\begin{aligned}\Delta G &= \Delta G^\circ + RT \ln Q \\ 0 &= \Delta G^\circ + RT \ln K \\ \Delta G^\circ &= -RT \ln K\end{aligned}\quad [19.20]$$

Equation 19.20 is a very important one, with broad significance in chemistry. By relating  $K$  to  $\Delta G^\circ$ , we can also relate  $K$  to entropy and enthalpy changes for a reaction.

We can also solve Equation 19.20 for  $K$ , to yield an expression that allows us to calculate  $K$  if we know the value of  $\Delta G^\circ$ :

$$\begin{aligned}\ln K &= \frac{\Delta G^\circ}{-RT} \\ K &= e^{-\Delta G^\circ/RT}\end{aligned}\quad [19.21]$$

As usual, we must be careful in our choice of units. In Equations 19.20 and 19.21 we again express  $\Delta G^\circ$  in kJ/mol. In the equilibrium-constant expression, we use atmospheres for gas pressures, molarities for solutions; and solids, liquids, and solvents do not appear in the expression. [∞ \(Section 15.4\)](#) Thus, the equilibrium constant is  $K_p$  for gas-phase reactions and  $K_c$  for reactions in solution. [∞ \(Section 15.2\)](#)

From Equation 19.20 we see that if  $\Delta G^\circ$  is negative,  $\ln K$  must be positive, which means  $K > 1$ . Therefore, the more negative  $\Delta G^\circ$  is, the larger  $K$  is. Conversely, if  $\Delta G^\circ$  is positive,  $\ln K$  is negative, which means  $K < 1$ . Finally, if  $\Delta G^\circ$  is zero,  $K = 1$ .

### Give It Some Thought

Can  $K = 0$ ?

## Sample Exercise 19.12

### Calculating an Equilibrium Constant from $\Delta G^\circ$

The standard free-energy change for the Haber process at 25 °C was obtained in Sample Exercise 19.9 for the Haber reaction:

Use this value of  $\Delta G^\circ$  to calculate the equilibrium constant for the process at 25 °C.

### SOLUTION

**Analyze** We are asked to calculate  $K$  for a reaction, given  $\Delta G^\circ$ .

**Plan** We can use Equation 19.21 to calculate  $K$ .

**Solve** Remembering to use the absolute temperature for  $T$  in Equation 19.21 and the form of  $R$  that matches our units, we have

$$K = e^{-\Delta G^\circ/RT} = e^{-(-33,300 \text{ J/mol})/(8.314 \text{ J/mol}\cdot\text{K})(298 \text{ K})} = e^{13.4} = 7 \times 10^5$$

**Comment** This is a large equilibrium constant, which indicates that the product,  $\text{NH}_3$ , is greatly favored in the equilibrium mixture at 25 °C. The equilibrium constants for the Haber reaction at temperatures in the range 300 °C to 600 °C, given in Table 15.2, are much smaller than the value at 25 °C. Clearly, a low-temperature equilibrium favors the production of ammonia more than a high-temperature one. Nevertheless, the Haber process is carried out at high

temperatures because the reaction is extremely slow at room temperature.

**Remember** Thermodynamics can tell us the direction and extent of a reaction but tells us nothing about the rate at which it will occur. If a catalyst were found that would permit the reaction to proceed at a rapid rate at room temperature, high pressures would not be needed to force the equilibrium toward  $\text{NH}_3$ .

### Practice Exercise 1

The  $K_{\text{sp}}$  for a very insoluble salt is  $4.2 \times 10^{-47}$  at 298 K. What is  $\Delta G^\circ$  for the dissolution of the salt in water?

- (a)  $-265 \text{ kJ/mol}$  (b)  $-115 \text{ kJ/mol}$  (c)  $-2.61 \text{ kJ/mol}$   
(d)  $+115 \text{ kJ/mol}$  (e)  $+265 \text{ kJ/mol}$

### Practice Exercise 2

Use data from Appendix C to calculate  $\Delta G^\circ$  and  $K$  at 298 K for the reaction  $\text{H}_2(\text{g}) + \text{Br}_2(\text{l}) \rightleftharpoons 2 \text{HBr}(\text{g})$ .

## CHEMISTRY AND LIFE Driving Nonspontaneous Reactions: Coupling Reactions

Many desirable chemical reactions, including a large number that are central to living systems, are nonspontaneous as written. For example, consider the extraction of copper metal from the mineral *chalcocite*, which contains  $\text{Cu}_2\text{S}$ . The decomposition of  $\text{Cu}_2\text{S}$  to its elements is nonspontaneous:

Because  $\Delta G^\circ$  is very positive, we cannot obtain  $\text{Cu}(\text{s})$  directly via this reaction. Instead, we must find some way to “do work” on the reaction to force it to occur as we wish. We can do this by coupling the reaction to another one so that the overall reaction is spontaneous. For example, we can envision the  $\text{S}(\text{s})$  reacting with  $\text{O}_2(\text{g})$  to form  $\text{SO}_2(\text{g})$ :

By coupling (adding together) these reactions, we can extract much of the copper metal via a spontaneous reaction:

In essence, we have used the spontaneous reaction of  $\text{S}(\text{s})$  with  $\text{O}_2(\text{g})$  to provide the free energy needed to extract the copper metal from the mineral.

Biological systems employ the same principle of using spontaneous reactions to drive nonspontaneous ones. Many of the biochemical reactions that are essential for the formation and maintenance

of highly ordered biological structures are not spontaneous. These necessary reactions are made to occur by coupling them with spontaneous reactions that release energy. The metabolism of food is the usual source of the free energy needed to do the work of maintaining biological systems. For example, complete oxidation of the sugar glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ , to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  yields substantial free energy:

This energy can be used to drive nonspontaneous reactions in the body. However, a means is necessary to transport the energy released by glucose metabolism to the reactions that require energy. One way, shown in **Figure 19.16**, involves the interconversion of adenosine triphosphate (ATP) and adenosine diphosphate (ADP), molecules that are related to the building blocks of nucleic acids. The conversion of ATP to ADP releases free energy ( $\Delta G^\circ = -30.5 \text{ kJ}$ ) that can be used to drive other reactions.

In the human body, the metabolism of glucose occurs via a complex series of reactions, most of which release free energy. The free energy released during these steps is used in part to reconvert lower-energy ADP back to higher-energy ATP. Thus, the ATP-ADP interconversions are used to store energy during metabolism and to release it as needed to drive nonspontaneous reactions in the body. If you take a course in general biology or biochemistry, you will have the opportunity to learn more about the remarkable sequence of reactions used to transport free energy throughout the human body.

**Related Exercises: 19.100, 19.101**

**Figure 19.16** Schematic representation of free-energy changes during cell metabolism. The oxidation of glucose to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  produces free energy that is then used to convert ADP into the more energetic ATP. The ATP is then used, as needed, as an energy source to drive nonspontaneous reactions, such as the conversion of simple molecules into more complex cell constituents.

## Sample Integrative Exercise

## Putting Concepts Together

Consider the simple salts NaCl(s) and AgCl(s). We will examine the equilibria in which these salts dissolve in water to form aqueous solutions of ions:

(a) Calculate the value of  $\Delta G^\circ$  at 298 K for each of the preceding reactions. (b) The two values from part (a) are very different. Is this difference primarily due to the enthalpy term or the entropy term of the standard free-energy change? (c) Use the values of  $\Delta G^\circ$  to calculate the  $K_{sp}$  values for the two salts at 298 K. (d) Sodium chloride is considered a soluble salt, whereas silver chloride is considered insoluble. Are these descriptions consistent with the answers to part (c)? (e) How will  $\Delta G^\circ$  for the solution process of these salts change with increasing  $T$ ? What effect should this change have on the solubility of the salts?

## SOLUTION

(a) We will use Equation 19.14 along with  $\Delta G_f^\circ$  values from Appendix C to calculate the  $\Delta G_{\text{soln}}^\circ$  values for each equilibrium. (As we did in Section 13.1, we use the subscript “soln” to indicate that these are thermodynamic quantities for the formation of a solution.) We find

$$\begin{aligned}\Delta G_{\text{soln}}^\circ(\text{NaCl}) &= (-261.9 \text{ kJ/mol}) + (-131.2 \text{ kJ/mol}) \\ &\quad - (-384.0 \text{ kJ/mol}) \\ &= -9.1 \text{ kJ/mol}\end{aligned}$$

$$\begin{aligned}\Delta G_{\text{soln}}^\circ(\text{AgCl}) &= (+77.11 \text{ kJ/mol}) + (-131.2 \text{ kJ/mol}) \\ &\quad - (-109.70 \text{ kJ/mol}) \\ &= +55.6 \text{ kJ/mol}\end{aligned}$$

(b) We can write  $\Delta G_{\text{soln}}^\circ$  as the sum of an enthalpy term,  $\Delta H_{\text{soln}}^\circ$ , and an entropy term,  $-T\Delta S_{\text{soln}}^\circ$ :  $\Delta G_{\text{soln}}^\circ = \Delta H_{\text{soln}}^\circ + (-T\Delta S_{\text{soln}}^\circ)$ . We can calculate the values of  $\Delta H_{\text{soln}}^\circ$  and  $\Delta S_{\text{soln}}^\circ$  by using Equations 5.31 and 19.8. We can then calculate  $-T\Delta S_{\text{soln}}^\circ$  at  $T = 298 \text{ K}$ . The results are summarized in the following table:

| Salt | $\Delta H_{\text{soln}}^\circ$ | $\Delta S_{\text{soln}}^\circ$ | $-T\Delta S_{\text{soln}}^\circ$ |
|------|--------------------------------|--------------------------------|----------------------------------|
| NaCl | +3.6 kJ/mol                    | +43.2 J/mol-K                  | -12.9 kJ/mol                     |
| AgCl | +65.7 kJ/mol                   | +34.3 J/mol-K                  | -10.2 kJ/mol                     |

The entropy terms for the solution of the two salts are very similar. That seems sensible because each solution process should lead to a similar increase in randomness as the salt dissolves, forming hydrated ions. (Section 13.1) In contrast, we see a very large difference in the enthalpy term for the solution of the two salts. The difference in the values of  $\Delta G_{\text{soln}}^\circ$  is dominated by the difference in the values of  $\Delta H_{\text{soln}}^\circ$ .

(c) The solubility product,  $K_{sp}$ , is the equilibrium constant for the solution process. (Section 17.4) As such, we can relate  $K_{sp}$  directly to  $\Delta G_{\text{soln}}^\circ$  by using Equation 19.21:

$$K_{sp} = e^{-\Delta G_{\text{soln}}^\circ/RT}$$

We can calculate the  $K_{sp}$  values in the same way we applied Equation 19.21 in Sample Exercise 19.12. We use the  $\Delta G_{\text{soln}}^\circ$  values we obtained in part (a), remembering to convert them from kJ/mol to J/mol:

$$\begin{aligned}\text{NaCl: } K_{sp} &= [\text{Na}^+][\text{Cl}^-] = e^{-(-9100)/(8.314)(298)} \\ &= e^{+3.7} = 40\end{aligned}$$

$$\begin{aligned}\text{AgCl: } K_{sp} &= [\text{Ag}^+][\text{Cl}^-] = e^{-(+55,600)/(8.314)(298)} \\ &= e^{-22.4} \\ &= 1.9 \times 10^{-10}\end{aligned}$$

The value calculated for the  $K_{sp}$  of AgCl is very close to that listed in Appendix D.

(d) A soluble salt is one that dissolves appreciably in water. (Section 4.2) The  $K_{sp}$  value for NaCl is greater than 1, indicating that NaCl dissolves to a great extent. The  $K_{sp}$  value for AgCl is very small, indicating that very little dissolves in water. Silver chloride should indeed be considered an insoluble salt.

(e) As we expect, the solution process has a positive value of  $\Delta S$  for both salts (see the table in part b). As such, the entropy term of the free-energy change,  $-T\Delta S_{\text{soln}}^\circ$ , is negative. If we assume that  $\Delta H_{\text{soln}}^\circ$  and  $\Delta S_{\text{soln}}^\circ$  do not change much with temperature, then an increase in  $T$  will serve to make  $\Delta G_{\text{soln}}^\circ$  more negative. Thus, the driving force for dissolution of the salts will increase with increasing  $T$ , and we therefore expect the solubility of the salts to increase with increasing  $T$ . In Figure 13.18, we see that the solubility of NaCl (and that of nearly any other salt) increases with increasing temperature. (Section 13.3)

## Chapter Summary and Key Terms

**SPONTANEOUS PROCESSES (SECTION 19.1)** Most reactions and chemical processes have an inherent directionality: They are **spontaneous** in one direction and nonspontaneous in the reverse direction. The spontaneity of a process is related to the thermodynamic path the system takes from the initial state to the final state. In a **reversible process**, both the system and its surroundings can be restored to their original state by exactly reversing the change. In an **irreversible process**, the system cannot return to its original state without a permanent change in the surroundings. Any spontaneous process is

irreversible. A process that occurs at a constant temperature is said to be **isothermal**.

**ENTROPY AND THE SECOND LAW OF THERMODYNAMICS (SECTION 19.2)** The spontaneous nature of processes is related to a thermodynamic state function called **entropy**, denoted  $S$ . For a process that occurs at constant temperature, the entropy change of the system is given by the heat absorbed by the system along a reversible path, divided by the temperature:  $\Delta S = q_{\text{rev}}/T$ . For any process, the entropy

change of the universe equals the entropy change of the system plus the entropy change of the surroundings:  $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$ . The way entropy controls the spontaneity of processes is given by the **second law of thermodynamics**, which states that in an irreversible (spontaneous) process  $\Delta S_{\text{univ}} > 0$ . Entropy values are usually expressed in units of joules per kelvin, J/K.

**THE MOLECULAR INTERPRETATION OF ENTROPY AND THE THIRD LAW OF THERMODYNAMICS (SECTION 19.3)** A particular combination of motions and locations of the atoms and molecules of a system at a particular instant is called a **microstate**. The entropy of a system is a measure of its randomness or disorder. The entropy is related to the number of microstates,  $W$ , corresponding to the state of the system:  $S = k \ln W$ . Molecules can undergo three kinds of motion: In **translational motion** the entire molecule moves in space. Molecules can also undergo **vibrational motion**, in which the atoms of the molecule move toward and away from one another in periodic fashion, and **rotational motion**, in which the entire molecule spins like a top. The number of available microstates, and therefore the entropy, increases with an increase in volume, temperature, or motion of molecules because any of these changes increases the possible motions and locations of the molecules. As a result, entropy generally increases when liquids or solutions are formed from solids, gases are formed from either solids or liquids, or the number of molecules of gas increases during a chemical reaction. The **third law of thermodynamics** states that the entropy of a pure crystalline solid at 0 K is zero.

#### ENTROPY CHANGES IN CHEMICAL REACTIONS (SECTION 19.4)

The third law allows us to assign entropy values for substances at different temperatures. Under standard conditions, the entropy of a mole of a substance is called its **standard molar entropy**, denoted  $S^\circ$ . From tabulated values of  $S^\circ$ , we can calculate the entropy change for any process under standard conditions. For an isothermal process, the entropy change in the surroundings is equal to  $-\Delta H/T$ .

**GIBBS FREE ENERGY (SECTION 19.5)** The **Gibbs free energy** (or just **free energy**),  $G$ , is a thermodynamic state function that combines the two state functions enthalpy and entropy:  $G = H - TS$ . For processes that occur at constant temperature,  $\Delta G = \Delta H - T\Delta S$ . For a process occurring at constant temperature and pressure, the sign of  $\Delta G$  relates to the spontaneity of the process. When  $\Delta G$  is negative, the process is spontaneous. When  $\Delta G$  is positive, the process is nonspontaneous, but the reverse process is spontaneous. At equilibrium the process is reversible and  $\Delta G$  is zero. The free energy is also a measure of the maximum useful work that can be performed by a system in a spontaneous process. The standard free-energy change,  $\Delta G^\circ$ , for any process can be calculated from tabulations of **standard free energies of formation**,  $\Delta G_f^\circ$ , which are defined in a fashion analogous to standard enthalpies of formation,  $\Delta H_f^\circ$ . The value of  $\Delta G_f^\circ$  for a pure element in its standard state is defined to be zero.

#### FREE ENERGY, TEMPERATURE, AND THE EQUILIBRIUM CONSTANT (SECTIONS 19.6 AND 19.7)

The values of  $\Delta H$  and  $\Delta S$  for a chemical process generally do not vary much with temperature. Therefore, the dependence of  $\Delta G$  with temperature is governed mainly by the value of  $T$  in the expression  $\Delta G = \Delta H - T\Delta S$ . The entropy term  $-T\Delta S$  has the greater effect on the temperature dependence of  $\Delta G$  and, hence, on the spontaneity of the process. For example, a process for which  $\Delta H > 0$  and  $\Delta S > 0$ , such as the melting of ice, can be nonspontaneous ( $\Delta G > 0$ ) at low temperatures and spontaneous ( $\Delta G < 0$ ) at higher temperatures. Under nonstandard conditions,  $\Delta G$  is related to  $\Delta G^\circ$  and the value of the reaction quotient,  $Q$ :  $\Delta G = \Delta G^\circ + RT \ln Q$ . At equilibrium ( $\Delta G = 0$ ,  $Q = K$ ),  $\Delta G^\circ = -RT \ln K$ . Thus, the standard free-energy change is directly related to the equilibrium constant for the reaction. This relationship expresses the temperature dependence of equilibrium constants.

## Learning Outcomes After studying this chapter, you should be able to:

- Explain and apply the terms spontaneous process, reversible process, irreversible process, and isothermal process. (Section 19.1) *Related Exercises: 19.11–19.14*
- Define entropy and state the second law of thermodynamics. (Section 19.2) *Related Exercises: 19.21, 19.22*
- Calculate  $\Delta S$  for a phase change. (Section 19.2) *Related Exercises: 19.23, 19.24*
- Explain how the entropy of a system is related to the number of possible microstates. (Section 19.3) *Related Exercises: 19.30, 19.31*
- Describe the kinds of molecular motion that a molecule can possess. (Section 19.3) *Related Exercise: 19.37*
- Predict the sign of  $\Delta S$  for physical and chemical processes. (Section 19.3) *Related Exercises: 19.35, 19.36, 19.41, 19.42*
- State the third law of thermodynamics. (Section 19.3) *Related Exercise: 19.37*
- Compare the values of standard molar entropies. (Section 19.4) *Related Exercises: 19.45–19.48*
- Calculate standard entropy changes for a system from standard molar entropies. (Section 19.4) *Related Exercises: 19.53, 19.54*
- Calculate the Gibbs free energy from the enthalpy change and entropy change at a given temperature. (Section 19.5) *Related Exercises: 19.55–19.58*
- Use free-energy changes to predict whether reactions are spontaneous. (Section 19.5) *Related Exercises: 19.55, 19.56*
- Calculate standard free-energy changes using standard free energies of formation. (Section 19.5) *Related Exercises: 19.59, 19.60*
- Predict the effect of temperature on spontaneity given  $\Delta H$  and  $\Delta S$ . (Section 19.6) *Related Exercises: 19.63, 19.64, 19.69, 19.70*
- Calculate  $\Delta G$  under nonstandard conditions. (Section 19.7) *Related Exercises: 19.77, 19.78*
- Relate  $\Delta G^\circ$  and equilibrium constant. (Section 19.7) *Related Exercises: 19.79–19.82*

## Key Equations

- $\Delta S = \frac{q_{\text{rev}}}{T}$  (constant  $T$ ) [19.2]
- $\left. \begin{array}{l} \text{Reversible process: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0 \\ \text{Irreversible process: } \Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} > 0 \end{array} \right\}$  [19.4]

Relating entropy change to the heat absorbed or released in a reversible process

The second law of thermodynamics

- $S = k \ln W$  [19.5] Relating entropy to the number of microstates
- $\Delta S^\circ = \sum nS^\circ(\text{products}) - \sum mS^\circ(\text{reactants})$  [19.8] Calculating the standard entropy change from standard molar entropies
- $\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T}$  [19.9] The entropy change of the surroundings for a process at constant temperature and pressure
- $\Delta G = \Delta H - T\Delta S$  [19.11] Calculating the Gibbs free-energy change from enthalpy and entropy changes at constant temperature
- $\Delta G^\circ = \sum n\Delta G_f^\circ(\text{products}) - \sum m\Delta G_f^\circ(\text{reactants})$  [19.14] Calculating the standard free-energy change from standard free energies of formation
- $\left. \begin{array}{l} \text{Reversible process: } \Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} = 0 \\ \text{Irreversible process: } \Delta G = \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} < 0 \end{array} \right\}$  [19.17] Relating the free-energy change to the reversibility of a process at constant temperature and pressure
- $\Delta G = -w_{\text{max}}$  [19.18] Relating the free-energy change to the maximum work a system can perform
- $\Delta G = \Delta G^\circ + RT \ln Q$  [19.19] Calculating the free-energy change under nonstandard conditions
- $\Delta G^\circ = -RT \ln K$  [19.20] Relating the standard free-energy change and the equilibrium constant

## Exercises

### Visualizing Concepts

- 19.1** Two different gases occupy the two bulbs shown here. Consider the process that occurs when the stopcock is opened, assuming the gases behave ideally. **(a)** Draw the final (equilibrium) state. **(b)** Predict the signs of  $\Delta H$  and  $\Delta S$  for the process. **(c)** Is the process that occurs when the stopcock is opened a reversible one? **(d)** How does the process affect the entropy of the surroundings? [Sections 19.1 and 19.2]

- 19.2** As shown here, one type of computer keyboard cleaner contains liquefied 1,1-difluoroethane ( $\text{C}_2\text{H}_4\text{F}_2$ ), which is a gas at atmospheric pressure. When the nozzle is squeezed, the 1,1-difluoroethane vaporizes out of the nozzle at high pressure, blowing dust out of objects. **(a)** Based on your experience, is the vaporization a spontaneous process at room temperature? **(b)** Defining the 1,1-difluoroethane as the system, do you expect  $q_{\text{sys}}$  for the process to be positive or negative? **(c)** Predict whether  $\Delta S$  is positive or negative for this process. **(d)** Given your answers to (a), (b), and (c), do you think the operation of this product depends more on enthalpy or entropy? [Sections 19.1 and 19.2]

- 19.3** **(a)** What are the signs of  $\Delta S$  and  $\Delta H$  for the process depicted here? **(b)** If energy can flow in and out of the system to maintain a constant temperature during the process, what can you say about the entropy change of the surroundings as a result of this process? [Sections 19.2 and 19.5]

- 19.4** Predict the signs of  $\Delta H$  and  $\Delta S$  for this reaction. Explain your choice. [Section 19.3]

- 19.5** The accompanying diagram shows how entropy varies with temperature for a substance that is a gas at the highest temperature shown. (a) What processes correspond to the entropy increases along the vertical lines labeled 1 and 2? (b) Why is the entropy change for 2 larger than that for 1? (c) If this substance is a perfect crystal at  $T = 0$  K, what is the value of  $S$  at this temperature? [Section 19.3]

- 19.6** Isomers are molecules that have the same chemical formula but different arrangements of atoms, as shown here for two isomers of pentane,  $C_5H_{12}$ . (a) Do you expect a significant difference in the enthalpy of combustion of the two isomers? Explain. (b) Which isomer do you expect to have the higher standard molar entropy? Explain. [Section 19.4]

- 19.7** The accompanying diagram shows how  $\Delta H$  (red line) and  $T\Delta S$  (blue line) change with temperature for a hypothetical reaction. (a) What is the significance of the point at 300 K, where  $\Delta H$  and  $T\Delta S$  are equal? (b) In what temperature range is this reaction spontaneous? [Section 19.6]

- 19.8** The accompanying diagram shows how  $\Delta G$  for a hypothetical reaction changes as temperature changes. (a) At what temperature is the system at equilibrium? (b) In what temperature range is the reaction spontaneous? (c) Is  $\Delta H$  positive or negative? (d) Is  $\Delta S$  positive or negative? [Sections 19.5 and 19.6]

- 19.9** Consider a reaction  $A_2(g) + B_2(g) \rightleftharpoons 2AB(g)$ , with atoms of A shown in red in the diagram and atoms of B shown in blue. (a) If  $K_c = 1$ , which box represents the system at equilibrium? (b) If  $K_c = 1$ , which box represents the system at  $Q < K_c$ ? (c) Rank the boxes in order of increasing magnitude of  $\Delta G$  for the reaction. [Sections 19.5 and 19.7]

- 19.10** The accompanying diagram shows how the free energy,  $G$ , changes during a hypothetical reaction  $A(g) + B(g) \rightarrow C(g)$ . On the left are pure reactants A

and B, each at 1 atm, and on the right is the pure product, C, also at 1 atm. Indicate whether each of the following statements is true or false. (a) The minimum of the graph corresponds to the equilibrium mixture of reactants and products for this reaction. (b) At equilibrium, all of A and B have reacted to give pure C. (c) The entropy change for this reaction is positive. (d) The “ $x$ ” on the graph corresponds to  $\Delta G$  for the reaction. (e)  $\Delta G$  for the reaction corresponds to the difference between the top left of the curve and the bottom of the curve. [Section 19.7]

### Spontaneous Processes (Section 19.1)

- 19.11** Which of the following processes are spontaneous and which are nonspontaneous: (a) the ripening of a banana, (b) dissolution of sugar in a cup of hot coffee, (c) the reaction of nitrogen atoms to form  $N_2$  molecules at  $25^\circ\text{C}$  and 1 atm, (d) lightning, (e) formation of  $\text{CH}_4$  and  $\text{O}_2$  molecules from  $\text{CO}_2$  and  $\text{H}_2\text{O}$  at room temperature and 1 atm of pressure?
- 19.12** Which of the following processes are spontaneous: (a) the melting of ice cubes at  $-10^\circ\text{C}$  and 1 atm pressure; (b) separating a mixture of  $N_2$  and  $\text{O}_2$  into two separate samples, one that is pure  $N_2$  and one that is pure  $\text{O}_2$ ; (c) alignment of iron filings in a magnetic field; (d) the reaction of hydrogen gas with oxygen gas to form water vapor at room temperature; (e) the dissolution of  $\text{HCl(g)}$  in water to form concentrated hydrochloric acid?
- 19.13** Indicate whether each statement is true or false. (a) A reaction that is spontaneous in one direction will be nonspontaneous in the reverse direction under the same reaction conditions. (b) All spontaneous processes are fast. (c) Most spontaneous processes are reversible. (d) An isothermal process is one in which the system loses no heat. (e) The maximum amount of work can be accomplished by an irreversible process rather than a reversible one.
- 19.14** (a) Can endothermic chemical reactions be spontaneous? (b) Can a process be spontaneous at one temperature and nonspontaneous at a different temperature? (c) Water can be decomposed to form hydrogen and oxygen, and the hydrogen and oxygen can be recombined to form water. Does this mean that the processes are thermodynamically reversible? (d) Does the amount of work that a system can do on its surroundings depend on the path of the process?
- 19.15** Consider the vaporization of liquid water to steam at a pressure of 1 atm. (a) Is this process endothermic or exothermic? (b) In what temperature range is it a spontaneous process? (c) In what temperature range is it a nonspontaneous process? (d) At what temperature are the two phases in equilibrium?
- 19.16** The normal freezing point of  $n$ -octane ( $\text{C}_8\text{H}_{18}$ ) is  $-57^\circ\text{C}$ . (a) Is the freezing of  $n$ -octane an endothermic or exothermic process? (b) In what temperature range is the freezing of  $n$ -octane a spontaneous process? (c) In what temperature range is it a nonspontaneous process? (d) Is there any temperature at which liquid  $n$ -octane and solid  $n$ -octane are in equilibrium? Explain.
- 19.17** Consider a process in which an ideal gas changes from state 1 to state 2 in such a way that its temperature changes from 300 K to 200 K. (a) Does the temperature change depend on whether the process is reversible or irreversible? (b) Is this process isothermal? (c) Does the change in the internal energy,  $\Delta E$ , depend on the particular pathway taken to carry out this change of state?
- 19.18** A system goes from state 1 to state 2 and back to state 1. (a) Is  $\Delta E$  the same in magnitude for both the forward and reverse processes? (b) Without further information, can you conclude that the amount of heat transferred to the system as it goes from state 1 to state 2 is the same or different as compared to that upon going from state 2 back to state 1? (c) Suppose the changes in state are reversible processes. Is the work done by the system upon going from state 1 to state 2 the same or different as compared to that upon going from state 2 back to state 1?
- 19.19** Consider a system consisting of an ice cube. (a) Under what conditions can the ice cube melt reversibly? (b) If the ice cube melts reversibly, is  $\Delta H$  zero for the process?
- 19.20** Consider what happens when a sample of the explosive TNT is detonated under atmospheric pressure. (a) Is the detonation a reversible process? (b) What is the sign of  $q$  for this process? (c) Is  $w$  positive, negative, or zero for the process?

### Entropy and the Second Law of Thermodynamics (Section 19.2)

- 19.21** Indicate whether each statement is true or false. (a)  $\Delta S$  is a state function. (b) If a system undergoes a reversible change, the entropy of the universe increases. (c) If a system undergoes a reversible process, the change in entropy of the system is exactly matched by an equal and opposite change in the entropy of the surroundings. (d) If a system undergoes a reversible process, the entropy change of the system must be zero.
- 19.22** Indicate whether each statement is true or false. (a) The entropy of the universe increases for any spontaneous process. (b) The entropy change of the system is equal and opposite that of the surroundings for any irreversible process. (c) The entropy of the system must increase in any spontaneous process. (d) The entropy change for an isothermal process depends on both the absolute temperature and the amount of heat reversibly transferred.
- 19.23** The normal boiling point of  $\text{Br}_2(l)$  is  $58.8^\circ\text{C}$ , and its molar enthalpy of vaporization is  $\Delta H_{\text{vap}} = 29.6 \text{ kJ/mol}$ . (a) When  $\text{Br}_2(l)$  boils at its normal boiling point, does its entropy increase or decrease? (b) Calculate the value of  $\Delta S$  when 1.00 mol of  $\text{Br}_2(l)$  is vaporized at  $58.8^\circ\text{C}$ .
- 19.24** The element gallium (Ga) freezes at  $29.8^\circ\text{C}$ , and its molar enthalpy of fusion is  $\Delta H_{\text{fus}} = 5.59 \text{ kJ/mol}$ . (a) When molten gallium solidifies to Ga(s) at its normal melting point, is  $\Delta S$  positive or negative? (b) Calculate the value of  $\Delta S$  when 60.0 g of Ga(l) solidifies at  $29.8^\circ\text{C}$ .

- 19.25** Indicate whether each statement is true or false. (a) The second law of thermodynamics says that entropy is conserved. (b) If the entropy of the system increases during a reversible process, the entropy change of the surroundings must decrease by the same amount. (c) In a certain spontaneous process the system undergoes an entropy change of  $4.2\text{ J/K}$ ; therefore, the entropy change of the surroundings must be  $-4.2\text{ J/K}$ .
- 19.26** (a) Does the entropy of the surroundings increase for spontaneous processes? (b) In a particular spontaneous process the entropy of the system decreases. What can you conclude about the sign and magnitude of  $\Delta S_{\text{surr}}$ ? (c) During a certain reversible process, the surroundings undergo an entropy change,  $\Delta S_{\text{surr}} = -78\text{ J/K}$ . What is the entropy change of the system for this process?
- 19.27** (a) What sign for  $\Delta S$  do you expect when the volume of  $0.200\text{ mol}$  of an ideal gas at  $27^\circ\text{C}$  is increased isothermally from an initial volume of  $10.0\text{ L}$ ? (b) If the final volume is  $18.5\text{ L}$ , calculate the entropy change for the process. (c) Do you need to specify the temperature to calculate the entropy change?
- 19.28** (a) What sign for  $\Delta S$  do you expect when the pressure on  $0.600\text{ mol}$  of an ideal gas at  $350\text{ K}$  is increased isothermally from an initial pressure of  $0.750\text{ atm}$ ? (b) If the final pressure on the gas is  $1.20\text{ atm}$ , calculate the entropy change for the process. (c) Do you need to specify the temperature to calculate the entropy change?

### The Molecular Interpretation of Entropy and the Third Law of Thermodynamics (Section 19.3)

- 19.29** For the isothermal expansion of a gas into a vacuum,  $\Delta E = 0$ ,  $q = 0$ , and  $w = 0$ . (a) Is this a spontaneous process? (b) Explain why no work is done by the system during this process. (c) What is the “driving force” for the expansion of the gas: enthalpy or entropy?
- 19.30** (a) What is the difference between a *state* and a *microstate* of a system? (b) As a system goes from state A to state B, its entropy decreases. What can you say about the number of microstates corresponding to each state? (c) In a particular spontaneous process, the number of microstates available to the system decreases. What can you conclude about the sign of  $\Delta S_{\text{surr}}$ ?
- 19.31** Would each of the following changes increase, decrease, or have no effect on the number of microstates available to a system: (a) increase in temperature, (b) decrease in volume, (c) change of state from liquid to gas?
- 19.32** (a) Using the heat of vaporization in Appendix B, calculate the entropy change for the vaporization of water at  $25^\circ\text{C}$  and at  $100^\circ\text{C}$ . (b) From your knowledge of microstates and the structure of liquid water, explain the difference in these two values.
- 19.33** (a) What do you expect for the sign of  $\Delta S$  in a chemical reaction in which  $2\text{ mol}$  of gaseous reactants are converted to  $3\text{ mol}$  of gaseous products? (b) For which of the processes in Exercise 19.11 does the entropy of the system increase?
- 19.34** (a) In a chemical reaction, two gases combine to form a solid. What do you expect for the sign of  $\Delta S$ ? (b) How does the entropy of the system change in the processes described in Exercise 19.12?
- 19.35** Does the entropy of the system increase, decrease, or stay the same when (a) a solid melts, (b) a gas liquefies, (c) a solid sublimates?

- 19.36** Does the entropy of the system increase, decrease, or stay the same when (a) the temperature of the system increases, (b) the volume of a gas increases, (c) equal volumes of ethanol and water are mixed to form a solution?

- 19.37** Indicate whether each statement is true or false. (a) The third law of thermodynamics says that the entropy of a perfect, pure crystal at absolute zero increases with the mass of the crystal. (b) “Translational motion” of molecules refers to their change in spatial location as a function of time. (c) “Rotational” and “vibrational” motions contribute to the entropy in atomic gases like He and Xe. (d) The larger the number of atoms in a molecule, the more degrees of freedom of rotational and vibrational motion it likely has.

- 19.38** Indicate whether each statement is true or false. (a) Unlike enthalpy, where we can only ever know changes in  $H$ , we can know absolute values of  $S$ . (b) If you heat a gas such as  $\text{CO}_2$ , you will increase its degrees of translational, rotational and vibrational motions. (c)  $\text{CO}_2(\text{g})$  and  $\text{Ar}(\text{g})$  have nearly the same molar mass. At a given temperature, they will have the same number of microstates.

- 19.39** For each of the following pairs, predict which substance has the higher entropy per mole at a given temperature: (a)  $\text{Ar}(\text{l})$  or  $\text{Ar}(\text{g})$ , (b)  $\text{He}(\text{g})$  at  $3\text{ atm}$  pressure or  $\text{He}(\text{g})$  at  $1.5\text{ atm}$  pressure, (c)  $1\text{ mol}$  of  $\text{Ne}(\text{g})$  in  $15.0\text{ L}$  or  $1\text{ mol}$  of  $\text{Ne}(\text{g})$  in  $1.50\text{ L}$ , (d)  $\text{CO}_2(\text{g})$  or  $\text{CO}_2(\text{s})$ .

- 19.40** For each of the following pairs, predict which substance possesses the larger entropy per mole: (a)  $1\text{ mol}$  of  $\text{O}_2(\text{g})$  at  $300^\circ\text{C}$ ,  $0.01\text{ atm}$ , or  $1\text{ mol}$  of  $\text{O}_3(\text{g})$  at  $300^\circ\text{C}$ ,  $0.01\text{ atm}$ ; (b)  $1\text{ mol}$  of  $\text{H}_2\text{O}(\text{g})$  at  $100^\circ\text{C}$ ,  $1\text{ atm}$ , or  $1\text{ mol}$  of  $\text{H}_2\text{O}(\text{l})$  at  $100^\circ\text{C}$ ,  $1\text{ atm}$ ; (c)  $0.5\text{ mol}$  of  $\text{N}_2(\text{g})$  at  $298\text{ K}$ ,  $20\text{-L volume}$ , or  $0.5\text{ mol}$   $\text{CH}_4(\text{g})$  at  $298\text{ K}$ ,  $20\text{-L volume}$ ; (d)  $100\text{ g}$   $\text{Na}_2\text{SO}_4(\text{s})$  at  $30^\circ\text{C}$  or  $100\text{ g}$   $\text{Na}_2\text{SO}_4(\text{aq})$  at  $30^\circ\text{C}$ .

- 19.41** Predict the sign of the entropy change of the system for each of the following reactions:

- 19.42** Predict the sign of  $\Delta S_{\text{sys}}$  for each of the following processes: (a) Molten gold solidifies. (b) Gaseous  $\text{Cl}_2$  dissociates in the stratosphere to form gaseous  $\text{Cl}$  atoms. (c) Gaseous  $\text{CO}$  reacts with gaseous  $\text{H}_2$  to form liquid methanol,  $\text{CH}_3\text{OH}$ . (d) Calcium phosphate precipitates upon mixing  $\text{Ca}(\text{NO}_3)_2(\text{aq})$  and  $(\text{NH}_4)_3\text{PO}_4(\text{aq})$ .

### Entropy Changes in Chemical Reactions (Section 19.4)

- 19.43** (a) Using Figure 19.12 as a model, sketch how the entropy of water changes as it is heated from  $-50^\circ\text{C}$  to  $110^\circ\text{C}$  at sea level. Show the temperatures at which there are vertical increases in entropy. (b) Which process has the larger entropy change: melting ice or boiling water? Explain.
- 19.44** Propanol ( $\text{C}_3\text{H}_7\text{OH}$ ) melts at  $-126.5^\circ\text{C}$  and boils at  $97.4^\circ\text{C}$ . Sketch how the entropy changes as propanol is heated from  $-150^\circ\text{C}$  to  $150^\circ\text{C}$  at  $1\text{ atm}$ . (Use Figure 19.12 as a model.)
- 19.45** In each of the following pairs, which compound would you expect to have the higher standard molar entropy: (a)  $\text{C}_2\text{H}_2(\text{g})$  or  $\text{C}_2\text{H}_6(\text{g})$ , (b)  $\text{CO}_2(\text{g})$  or  $\text{CO}(\text{g})$ ?

- 19.46** Cyclopropane and propylene are isomers that both have the formula  $C_3H_6$ . Based on the molecular structures shown, which of these isomers would you expect to have the higher standard molar entropy at 25 °C?

- 19.47** Predict which member of each of the following pairs has the greater standard entropy at 25 °C: (a)  $Sc(s)$  or  $Sc(g)$ , (b)  $NH_3(g)$  or  $NH_3(aq)$ , (c)  $O_2(g)$  or  $O_3(g)$ , (d)  $C(\text{graphite})$  or  $C(\text{diamond})$ . Use Appendix C to find the standard entropy of each substance.
- 19.48** Predict which member of each of the following pairs has the greater standard entropy at 25 °C: (a)  $C_6H_6(l)$  or  $C_6H_6(g)$ , (b)  $CO(g)$  or  $CO_2(g)$ , (c) 1 mol  $N_2O_4(g)$  or 2 mol  $NO_2(g)$ , (d)  $HCl(g)$  or  $HCl(aq)$ . Use Appendix C to find the standard entropy of each substance.
- [19.49]** The standard entropies at 298 K for certain group 4A elements are:  $C(s, \text{diamond}) = 2.43 \text{ J/mol}\cdot\text{K}$ ,  $Si(s) = 18.81 \text{ J/mol}\cdot\text{K}$ ,  $Ge(s) = 31.09 \text{ J/mol}\cdot\text{K}$ , and  $Sn(s) = 51.818 \text{ J/mol}\cdot\text{K}$ . All but Sn have the same (diamond) structure. How do you account for the trend in the  $S^\circ$  values?
- [19.50]** Three of the forms of elemental carbon are graphite, diamond, and buckminsterfullerene. The entropies at 298 K for graphite and diamond are listed in Appendix C. (a) Account for the difference in the  $S^\circ$  values of graphite and diamond in light of their structures (Figure 12.29, p. 495). (b) What would you expect for the  $S^\circ$  value of buckminsterfullerene (Figure 12.49, p. 509) relative to the values for graphite and diamond? Explain.
- 19.51** Using  $S^\circ$  values from Appendix C, calculate  $\Delta S^\circ$  values for the following reactions. In each case, account for the sign of  $\Delta S^\circ$ .
- $C_2H_4(g) + H_2(g) \longrightarrow C_2H_6(g)$
  - $N_2O_4(g) \longrightarrow 2 NO_2(g)$
  - $Be(OH)_2(s) \longrightarrow BeO(s) + H_2O(g)$
  - $2 CH_3OH(g) + 3 O_2(g) \longrightarrow 2 CO_2(g) + 4 H_2O(g)$
- 19.52** Calculate  $\Delta S^\circ$  values for the following reactions by using tabulated  $S^\circ$  values from Appendix C. In each case, explain the sign of  $\Delta S^\circ$ .
- $HNO_3(g) + NH_3(g) \longrightarrow NH_4NO_3(s)$
  - $2 Fe_2O_3(s) \longrightarrow 4 Fe(s) + 3 O_2(g)$
  - $CaCO_3(s, \text{calcite}) + 2 HCl(g) \longrightarrow CaCl_2(s) + CO_2(g) + H_2O(l)$
  - $3 C_2H_6(g) \longrightarrow C_6H_6(l) + 6 H_2(g)$

### Gibbs Free Energy (Sections 19.5 and 19.6)

- 19.54** (a) Is the standard free-energy change,  $\Delta G^\circ$ , always larger than  $\Delta G$ ? (b) For any process that occurs at constant temperature and pressure, what is the significance of  $\Delta G = 0$ ? (c) For a certain process,  $\Delta G$  is large and negative. Does this mean that the process necessarily has a low activation barrier?
- 19.55** For a certain chemical reaction,  $\Delta H^\circ = -35.4 \text{ kJ}$  and  $\Delta S^\circ = -85.5 \text{ J/K}$ . (a) Is the reaction exothermic or endothermic? (b) Does the reaction lead to an increase or decrease in the randomness or disorder of the system? (c) Calculate  $\Delta G^\circ$  for the reaction at 298 K. (d) Is the reaction spontaneous at 298 K under standard conditions?
- 19.56** A certain reaction has  $\Delta H^\circ = +23.7 \text{ kJ}$  and  $\Delta S^\circ = +52.4 \text{ J/K}$ . (a) Is the reaction exothermic or endothermic? (b) Does the reaction lead to an increase or decrease in the randomness or disorder of the system? (c) Calculate  $\Delta G^\circ$  for the reaction at 298 K. (d) Is the reaction spontaneous at 298 K under standard conditions?
- 19.57** Using data in Appendix C, calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  at 298 K for each of the following reactions.
- $H_2(g) + F_2(g) \longrightarrow 2 HF(g)$
  - $C(s, \text{graphite}) + 2 Cl_2(g) \longrightarrow CCl_4(g)$
  - $2 PCl_3(g) + O_2(g) \longrightarrow 2 POCl_3(g)$
  - $2 CH_3OH(g) + H_2(g) \longrightarrow C_2H_6(g) + 2 H_2O(g)$
- 19.58** Use data in Appendix C to calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  at 25 °C for each of the following reactions.
- $4 Cr(s) + 3 O_2(g) \longrightarrow 2 Cr_2O_3(s)$
  - $BaCO_3(s) \longrightarrow BaO(s) + CO_2(g)$
  - $2 P(s) + 10 HF(g) \longrightarrow 2 PF_5(g) + 5 H_2(g)$
  - $K(s) + O_2(g) \longrightarrow KO_2(s)$
- 19.59** Using data from Appendix C, calculate  $\Delta G^\circ$  for the following reactions. Indicate whether each reaction is spontaneous at 298 K under standard conditions.
- $2 SO_2(g) + O_2(g) \longrightarrow 2 SO_3(g)$
  - $NO_2(g) + N_2O(g) \longrightarrow 3 NO(g)$
  - $6 Cl_2(g) + 2 Fe_2O_3(s) \longrightarrow 4 FeCl_3(s) + 3 O_2(g)$
  - $SO_2(g) + 2 H_2(g) \longrightarrow S(s) + 2 H_2O(g)$
- 19.60** Using data from Appendix C, calculate the change in Gibbs free energy for each of the following reactions. In each case, indicate whether the reaction is spontaneous at 298 K under standard conditions.
- $2 Ag(s) + Cl_2(g) \longrightarrow 2 AgCl(s)$
  - $P_4O_{10}(s) + 16 H_2(g) \longrightarrow 4 PH_3(g) + 10 H_2O(g)$
  - $CH_4(g) + 4 F_2(g) \longrightarrow CF_4(g) + 4 HF(g)$
  - $2 H_2O_2(l) \longrightarrow 2 H_2O(l) + O_2(g)$
- 19.61** Octane ( $C_8H_{18}$ ) is a liquid hydrocarbon at room temperature that is a constituent of gasoline. (a) Write a balanced equation for the combustion of  $C_8H_{18}(l)$  to form  $CO_2(g)$  and  $H_2O(l)$ . (b) Without using thermochemical data, predict whether  $\Delta G^\circ$  for this reaction is more negative or less negative than  $\Delta H^\circ$ .
- 19.62** Sulfur dioxide reacts with strontium oxide as follows:

- (a) Without using thermochemical data, predict whether  $\Delta G^\circ$  for this reaction is more negative or less negative than  $\Delta H^\circ$ . (b) If you had only standard enthalpy data for this reaction, how would you estimate the value of  $\Delta G^\circ$  at 298 K, using data from Appendix C on other substances.

- 19.53** (a) For a process that occurs at constant temperature, does the change in Gibbs free energy depend on changes in the enthalpy and entropy of the system? (b) For a certain process that occurs at constant  $T$  and  $P$ , the value of  $\Delta G$  is positive. Is the process spontaneous? (c) If  $\Delta G$  for a process is large, is the rate at which it occurs fast?

**19.63** Classify each of the following reactions as one of the four possible types summarized in Table 19.3: (i) spontaneous at all temperatures; (ii) not spontaneous at any temperature; (iii) spontaneous at low  $T$  but not spontaneous at high  $T$ ; (iv) spontaneous at high  $T$  but not spontaneous at low  $T$ .

**19.64** From the values given for  $\Delta H^\circ$  and  $\Delta S^\circ$ , calculate  $\Delta G^\circ$  for each of the following reactions at 298 K. If the reaction is not spontaneous under standard conditions at 298 K, at what temperature (if any) would the reaction become spontaneous?

**19.65** A particular constant-pressure reaction is barely spontaneous at 390 K. The enthalpy change for the reaction is +23.7 kJ. Estimate  $\Delta S$  for the reaction.

**19.66** A certain constant-pressure reaction is barely nonspontaneous at 45 °C. The entropy change for the reaction is 72 J/K. Estimate  $\Delta H$ .

**19.67** For a particular reaction,  $\Delta H = -32 \text{ kJ}$  and  $\Delta S = -98 \text{ J/K}$ . Assume that  $\Delta H$  and  $\Delta S$  do not vary with temperature. (a) At what temperature will the reaction have  $\Delta G = 0$ ? (b) If  $T$  is increased from that in part (a), will the reaction be spontaneous or nonspontaneous?

**19.68** Reactions in which a substance decomposes by losing CO are called *decarbonylation* reactions. The decarbonylation of acetic acid proceeds according to:

By using data from Appendix C, calculate the minimum temperature at which this process will be spontaneous under standard conditions. Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not vary with temperature.

**19.69** Consider the following reaction between oxides of nitrogen:

(a) Use data in Appendix C to predict how  $\Delta G$  for the reaction varies with increasing temperature. (b) Calculate  $\Delta G$  at 800 K, assuming that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change with temperature. Under standard conditions is the reaction spontaneous at 800 K? (c) Calculate  $\Delta G$  at 1000 K. Is the reaction spontaneous under standard conditions at this temperature?

**19.70** Methanol ( $\text{CH}_3\text{OH}$ ) can be made by the controlled oxidation of methane:

(a) Use data in Appendix C to calculate  $\Delta H^\circ$  and  $\Delta S^\circ$  for this reaction. (b) Will  $\Delta G$  for the reaction increase, decrease, or stay unchanged with increasing temperature? (c) Calculate  $\Delta G^\circ$  at 298 K. Under standard conditions, is the reaction spontaneous at this temperature? (d) Is

there a temperature at which the reaction would be at equilibrium under standard conditions and that is low enough so that the compounds involved are likely to be stable?

**19.71** (a) Use data in Appendix C to estimate the boiling point of benzene,  $\text{C}_6\text{H}_6(\text{l})$ . (b) Use a reference source, such as the *CRC Handbook of Chemistry and Physics*, to find the experimental boiling point of benzene.

**19.72** (a) Using data in Appendix C, estimate the temperature at which the free-energy change for the transformation from  $\text{I}_2(\text{s})$  to  $\text{I}_2(\text{g})$  is zero. (b) Use a reference source, such as Web Elements ([www.webelements.com](http://www.webelements.com)), to find the experimental melting and boiling points of  $\text{I}_2$ . (c) Which of the values in part (b) is closer to the value you obtained in part (a)?

**19.73** Acetylene gas,  $\text{C}_2\text{H}_2(\text{g})$ , is used in welding. (a) Write a balanced equation for the combustion of acetylene gas to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ . (b) How much heat is produced in burning 1 mol of  $\text{C}_2\text{H}_2$  under standard conditions if both reactants and products are brought to 298 K? (c) What is the maximum amount of useful work that can be accomplished under standard conditions by this reaction?

**19.74** The fuel in high-efficiency natural-gas vehicles consists primarily of methane ( $\text{CH}_4$ ). (a) How much heat is produced in burning 1 mol of  $\text{CH}_4(\text{g})$  under standard conditions if reactants and products are brought to 298 K and  $\text{H}_2\text{O}(\text{l})$  is formed? (b) What is the maximum amount of useful work that can be accomplished under standard conditions by this system?

## Free Energy and Equilibrium (Section 19.7)

**19.75** Indicate whether  $\Delta G$  increases, decreases, or stays the same for each of the following reactions as the partial pressure of  $\text{O}_2$  is increased:

**19.76** Indicate whether  $\Delta G$  increases, decreases, or does not change when the partial pressure of  $\text{H}_2$  is increased in each of the following reactions:

**19.77** Consider the reaction  $2 \text{NO}_2(\text{g}) \longrightarrow \text{N}_2\text{O}_4(\text{g})$ . (a) Using data from Appendix C, calculate  $\Delta G^\circ$  at 298 K. (b) Calculate  $\Delta G$  at 298 K if the partial pressures of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  are 0.40 atm and 1.60 atm, respectively.

**19.78** Consider the reaction  $3 \text{CH}_4(\text{g}) \longrightarrow \text{C}_3\text{H}_8(\text{g}) + 2 \text{H}_2(\text{g})$ . (a) Using data from Appendix C, calculate  $\Delta G^\circ$  at 298 K. (b) Calculate  $\Delta G$  at 298 K if the reaction mixture consists of 40.0 atm of  $\text{CH}_4$ , 0.0100 atm of  $\text{C}_3\text{H}_8(\text{g})$ , and 0.0180 atm of  $\text{H}_2$ .

**19.79** Use data from Appendix C to calculate the equilibrium constant,  $K$ , and  $\Delta G^\circ$  at 298 K for each of the following reactions:

**19.80** Using data from Appendix C, write the equilibrium-constant expression and calculate the value of the equilibrium

constant and the free-energy change for these reactions at 298 K:

**19.81** Consider the decomposition of barium carbonate:

Using data from Appendix C, calculate the equilibrium pressure of  $\text{CO}_2$  at (a) 298 K and (b) 1100 K.

**19.82** Consider the reaction

Using data in Appendix C, calculate the equilibrium pressure of  $\text{CO}_2$  in the system at (a) 400 °C and (b) 180 °C.

**19.83** The value of  $K_a$  for nitrous acid ( $\text{HNO}_2$ ) at 25 °C is given in Appendix D. (a) Write the chemical equation for the equilibrium that corresponds to  $K_a$ . (b) By using the value of  $K_a$ , calculate  $\Delta G^\circ$  for the dissociation of nitrous acid in aqueous solution. (c) What is the value of  $\Delta G$  at equilibrium? (d) What is the value of  $\Delta G$  when  $[\text{H}^+] = 5.0 \times 10^{-2} \text{ M}$ ,  $[\text{NO}_2^-] = 6.0 \times 10^{-4} \text{ M}$ , and  $[\text{HNO}_2] = 0.20 \text{ M}$ ?

**19.84** The  $K_b$  for methylamine ( $\text{CH}_3\text{NH}_2$ ) at 25 °C is given in Appendix D. (a) Write the chemical equation for the equilibrium that corresponds to  $K_b$ . (b) By using the value of  $K_b$ , calculate  $\Delta G^\circ$  for the equilibrium in part (a). (c) What is the value of  $\Delta G$  at equilibrium? (d) What is the value of  $\Delta G$  when  $[\text{H}^+] = 6.7 \times 10^{-9} \text{ M}$ ,  $[\text{CH}_3\text{NH}_3^+] = 2.4 \times 10^{-3} \text{ M}$ , and  $[\text{CH}_3\text{NH}_2] = 0.098 \text{ M}$ ?

## Additional Exercises

**19.85** (a) Which of the thermodynamic quantities  $T$ ,  $E$ ,  $q$ ,  $w$ , and  $S$  are state functions? (b) Which depend on the path taken from one state to another? (c) How many *reversible* paths are there between two states of a system? (d) For a reversible isothermal process, write an expression for  $\Delta E$  in terms of  $q$  and  $w$  and an expression for  $\Delta S$  in terms of  $q$  and  $T$ .

**19.86** The crystalline hydrate  $\text{Cd}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}(s)$  loses water when placed in a large, closed, dry vessel at room temperature:

This process is spontaneous and  $\Delta H^\circ$  is positive at room temperature. (a) What is the sign of  $\Delta S^\circ$  at room temperature? (b) If the hydrated compound is placed in a large, closed vessel that already contains a large amount of water vapor, does  $\Delta S^\circ$  change for this reaction at room temperature?

**19.87** Indicate whether each of the following statements is true or false. If it is false, correct it. (a) The feasibility of manufacturing  $\text{NH}_3$  from  $\text{N}_2$  and  $\text{H}_2$  depends entirely on the value of  $\Delta H$  for the process  $\text{N}_2(g) + 3\text{H}_2(g) \longrightarrow 2\text{NH}_3(g)$ . (b) The reaction of  $\text{Na}(s)$  with  $\text{Cl}_2(g)$  to form  $\text{NaCl}(s)$  is a spontaneous process. (c) A spontaneous process can in principle be conducted reversibly. (d) Spontaneous processes in general require that work be done to force them to proceed. (e) Spontaneous processes are those that are exothermic and that lead to a higher degree of order in the system.

**19.88** For each of the following processes, indicate whether the signs of  $\Delta S$  and  $\Delta H$  are expected to be positive, negative, or about zero. (a) A solid sublimates. (b) The temperature of a sample of  $\text{Co}(s)$  is lowered from 60 °C to 25 °C. (c) Ethyl alcohol evaporates from a beaker. (d) A diatomic molecule dissociates into atoms. (e) A piece of charcoal is combusted to form  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(g)$ .

**19.89** The reaction  $2\text{Mg}(s) + \text{O}_2(g) \longrightarrow 2\text{MgO}(s)$  is highly spontaneous. A classmate calculates the entropy change for this reaction and obtains a large negative value for  $\Delta S^\circ$ . Did your classmate make a mistake in the calculation? Explain.

**[19.90]** Consider a system that consists of two standard playing dice, with the state of the system defined by the sum of the values shown on the top faces. (a) The two arrangements of

top faces shown here can be viewed as two possible microstates of the system. Explain. (b) To which state does each microstate correspond? (c) How many possible states are there for the system? (d) Which state or states have the highest entropy? Explain. (e) Which state or states have the lowest entropy? Explain. (f) Calculate the absolute entropy of the two-dice system.

**19.91** Ammonium nitrate dissolves spontaneously and endothermally in water at room temperature. What can you deduce about the sign of  $\Delta S$  for this solution process?

**[19.92]** A standard air conditioner involves a *refrigerant* that is typically now a fluorinated hydrocarbon, such as  $\text{CH}_2\text{F}_2$ . An air-conditioner refrigerant has the property that it readily vaporizes at atmospheric pressure and is easily compressed to its liquid phase under increased pressure. The operation of an air conditioner can be thought of as a closed system made up of the refrigerant going through the two stages shown here (the air circulation is not shown in this diagram).

During *expansion*, the liquid refrigerant is released into an expansion chamber at low pressure, where it vaporizes. The vapor then undergoes *compression* at high pressure back to its liquid phase in a compression chamber. **(a)** What is the sign of  $q$  for the expansion? **(b)** What is the sign of  $q$  for the compression? **(c)** In a central air-conditioning system, one chamber is inside the home and the other is outside. Which chamber is where, and why? **(d)** Imagine that a sample of liquid refrigerant undergoes expansion followed by compression, so that it is back to its original state. Would you expect that to be a reversible process? **(e)** Suppose that a house and its exterior are both initially at 31 °C. Some time after the air conditioner is turned on, the house is cooled to 24 °C. Is this process spontaneous or nonspontaneous?

**[19.93]** Trouton's rule states that for many liquids at their normal boiling points, the standard molar entropy of vaporization is about 88 J/mol·K. **(a)** Estimate the normal boiling point of bromine, Br<sub>2</sub>, by determining  $\Delta H_{\text{vap}}^\circ$  for Br<sub>2</sub> using data from Appendix C. Assume that  $\Delta H_{\text{vap}}^\circ$  remains constant with temperature and that Trouton's rule holds. **(b)** Look up the normal boiling point of Br<sub>2</sub> in a chemistry handbook or at the WebElements website (www.webelements.com) and compare it to your calculation. What are the possible sources of error, or incorrect assumptions, in the calculation?

**[19.94]** **(a)** Write the chemical equations that correspond to  $\Delta G_f^\circ$  for NH<sub>3</sub>(g) and for CO(g). **(b)** For which of these formation reactions will the value of  $\Delta G_f^\circ$  be more positive (less negative) than  $\Delta H_f^\circ$ ? **(c)** In general, under which condition is  $\Delta G_f^\circ$  more positive (less negative) than  $\Delta H_f^\circ$ ? (i) When the temperature is high, (ii) when the reaction is reversible, (iii) when  $\Delta S_f^\circ$  is negative.

**19.95** Consider the following three reactions:

- (i)**  $\text{Ti}(s) + 2 \text{Cl}_2(g) \longrightarrow \text{TiCl}_4(g)$
- (ii)**  $\text{C}_2\text{H}_6(g) + 7 \text{Cl}_2(g) \longrightarrow 2 \text{CCl}_4(g) + 6 \text{HCl}(g)$
- (iii)**  $\text{BaO}(s) + \text{CO}_2(g) \longrightarrow \text{BaCO}_3(s)$

**(a)** For each of the reactions, use data in Appendix C to calculate  $\Delta H^\circ$ ,  $\Delta G^\circ$ ,  $K$ , and  $\Delta S^\circ$  at 25 °C. **(b)** Which of these reactions are spontaneous under standard conditions at 25 °C? **(c)** For each of the reactions, predict the manner in which the change in free energy varies with an increase in temperature.

**19.96** Using the data in Appendix C and given the pressures listed, calculate  $K_p$  and  $\Delta G$  for each of the following reactions:

- (a)**  $\text{N}_2(g) + 3 \text{H}_2(g) \longrightarrow 2 \text{NH}_3(g)$   
 $P_{\text{N}_2} = 2.6 \text{ atm}, P_{\text{H}_2} = 5.9 \text{ atm}, P_{\text{NH}_3} = 1.2 \text{ atm}$
- (b)**  $2 \text{N}_2\text{H}_4(g) + 2 \text{NO}_2(g) \longrightarrow 3 \text{N}_2(g) + 4 \text{H}_2\text{O}(g)$   
 $P_{\text{N}_2\text{H}_4} = P_{\text{NO}_2} = 5.0 \times 10^{-2} \text{ atm},$   
 $P_{\text{N}_2} = 0.5 \text{ atm}, P_{\text{H}_2\text{O}} = 0.3 \text{ atm}$
- (c)**  $\text{N}_2\text{H}_4(g) \longrightarrow \text{N}_2(g) + 2 \text{H}_2(g)$   
 $P_{\text{N}_2\text{H}_4} = 0.5 \text{ atm}, P_{\text{N}_2} = 1.5 \text{ atm}, P_{\text{H}_2} = 2.5 \text{ atm}$

**19.97** **(a)** For each of the following reactions, predict the sign of  $\Delta H^\circ$  and  $\Delta S^\circ$  without doing any calculations. **(b)** Based on your general chemical knowledge, predict which of these reactions will have  $K > 1$ . **(c)** In each case, indicate whether  $K$  should increase or decrease with increasing temperature.

- (i)**  $2 \text{Mg}(s) + \text{O}_2(g) \rightleftharpoons 2 \text{MgO}(s)$
- (ii)**  $2 \text{KI}(s) \rightleftharpoons 2 \text{K}(g) + \text{I}_2(g)$
- (iii)**  $\text{Na}_2(g) \rightleftharpoons 2 \text{Na}(g)$
- (iv)**  $2 \text{V}_2\text{O}_5(s) \rightleftharpoons 4 \text{V}(s) + 5 \text{O}_2(g)$

**19.98** Acetic acid can be manufactured by combining methanol with carbon monoxide, an example of a *carbonylation* reaction:

**(a)** Calculate the equilibrium constant for the reaction at 25 °C. **(b)** Industrially, this reaction is run at temperatures above 25 °C. Will an increase in temperature produce an increase or decrease in the mole fraction of acetic acid at equilibrium? Why are elevated temperatures used? **(c)** At what temperature will this reaction have an equilibrium constant equal to 1? (You may assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  are temperature independent, and you may ignore any phase changes that might occur.)

**19.99** The oxidation of glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) in body tissue produces CO<sub>2</sub> and H<sub>2</sub>O. In contrast, anaerobic decomposition, which occurs during fermentation, produces ethanol (C<sub>2</sub>H<sub>5</sub>OH) and CO<sub>2</sub>. **(a)** Using data given in Appendix C, compare the equilibrium constants for the following reactions:

**(b)** Compare the maximum work that can be obtained from these processes under standard conditions.

**[19.100]** The conversion of natural gas, which is mostly methane, into products that contain two or more carbon atoms, such as ethane (C<sub>2</sub>H<sub>6</sub>), is a very important industrial chemical process. In principle, methane can be converted into ethane and hydrogen:

In practice, this reaction is carried out in the presence of oxygen:

**(a)** Using the data in Appendix C, calculate  $K$  for these reactions at 25 °C and 500 °C. **(b)** Is the difference in  $\Delta G^\circ$  for the two reactions due primarily to the enthalpy term ( $\Delta H$ ) or the entropy term ( $-T\Delta S$ )? **(c)** Explain how the preceding reactions are an example of driving a nonspontaneous reaction, as discussed in the "Chemistry and Life" box in Section 19.7. **(d)** The reaction of CH<sub>4</sub> and O<sub>2</sub> to form C<sub>2</sub>H<sub>6</sub> and H<sub>2</sub>O must be carried out carefully to avoid a competing reaction. What is the most likely competing reaction?

**[19.101]** Cells use the hydrolysis of adenosine triphosphate (ATP) as a source of energy (Figure 19.16). The conversion of ATP to ADP has a standard free-energy change of -30.5 kJ/mol. If all the free energy from the metabolism of glucose,

goes into the conversion of ADP to ATP, how many moles of ATP can be produced for each mole of glucose?

**[19.102]** The potassium-ion concentration in blood plasma is about  $5.0 \times 10^{-3} \text{ M}$ , whereas the concentration in muscle-cell fluid is much greater (0.15 M). The plasma and intracellular fluid are separated by the cell membrane, which we assume is permeable only to K<sup>+</sup>. **(a)** What is  $\Delta G$  for the transfer of 1 mol of K<sup>+</sup> from blood plasma to the cellular fluid at body temperature 37 °C? **(b)** What is the minimum amount of work that must be used to transfer this K<sup>+</sup>?

## Integrative Exercises

**19.103** Most liquids follow Trouton's rule (see Exercise 19.93), which states that the molar entropy of vaporization is approximately  $88 \pm 5 \text{ J/mol}\cdot\text{K}$ . The normal boiling points and enthalpies of vaporization of several organic liquids are as follows:

| Substance                                 | Normal Boiling Point ( $^{\circ}\text{C}$ ) | $\Delta H_{\text{vap}}$ (kJ/mol) |
|---|---|----------------------------------|
| Acetone, $(\text{CH}_3)_2\text{CO}$       | 56.1  | 29.1                             |
| Dimethyl ether, $(\text{CH}_3)_2\text{O}$ | -24.8                                       | 21.5                             |
| Ethanol, $\text{C}_2\text{H}_5\text{OH}$  | 78.4  | 38.6                             |
| Octane, $\text{C}_8\text{H}_{18}$         | 125.6                                       | 34.4                             |
| Pyridine, $\text{C}_5\text{H}_5\text{N}$  | 115.3                                       | 35.1                             |

(a) Calculate  $\Delta S_{\text{vap}}$  for each of the liquids. Do all the liquids obey Trouton's rule? (b) With reference to intermolecular forces (Section 11.2), can you explain any exceptions to the rule? (c) Would you expect water to obey Trouton's rule? By using data in Appendix B, check the accuracy of your conclusion. (d) Chlorobenzene ( $\text{C}_6\text{H}_5\text{Cl}$ ) boils at  $131.8^{\circ}\text{C}$ . Use Trouton's rule to estimate  $\Delta H_{\text{vap}}$  for this substance.

**19.104** In chemical kinetics, the *entropy of activation* is the entropy change for the process in which the reactants reach the activated complex. Predict whether the entropy of activation for a bimolecular process is usually positive or negative.

**19.105** At what temperatures is the following reaction, the reduction of magnetite by graphite to elemental iron, spontaneous?

**19.106** The following processes were all discussed in Chapter 18, "Chemistry of the Environment." Estimate whether the entropy of the system increases or decreases during each process: (a) photodissociation of  $\text{O}_2(\text{g})$ , (b) formation of ozone from oxygen molecules and oxygen atoms, (c) diffusion of CFCs into the stratosphere, (d) desalination of water by reverse osmosis.

**[19.107]** An ice cube with a mass of 20 g at  $-20^{\circ}\text{C}$  (typical freezer temperature) is dropped into a cup that holds 500 mL of hot water, initially at  $83^{\circ}\text{C}$ . What is the final temperature in the cup? The density of liquid water is  $1.00 \text{ g/mL}$ ; the specific heat capacity of ice is  $2.03 \text{ J/g}\cdot\text{C}$ ; the specific heat capacity of liquid water is  $4.184 \text{ J/g}\cdot\text{C}$ ; the enthalpy of fusion of water is  $6.01 \text{ kJ/mol}$ .

**19.108** Carbon disulfide ( $\text{CS}_2$ ) is a toxic, highly flammable substance. The following thermodynamic data are available for  $\text{CS}_2(\text{l})$  and  $\text{CS}_2(\text{g})$  at 298 K:

|                         | $\Delta H_f^{\circ}$ (kJ/mol) | $\Delta G_f^{\circ}$ (kJ/mol) |
|-------------------------|-------------------------------|-------------------------------|
| $\text{CS}_2(\text{l})$ | 89.7                          | 65.3                          |
| $\text{CS}_2(\text{g})$ | 117.4                         | 67.2                          |

(a) Draw the Lewis structure of the molecule. What do you predict for the bond order of the C—S bonds? (b) Use the VSEPR method to predict the structure of the  $\text{CS}_2$  molecule. (c) Liquid  $\text{CS}_2$  burns in  $\text{O}_2$  with a blue flame, forming  $\text{CO}_2(\text{g})$  and  $\text{SO}_2(\text{g})$ . Write a balanced equation for this reaction. (d) Using the data in the preceding table and in Appendix C, calculate  $\Delta H^{\circ}$  and  $\Delta G^{\circ}$  for the reaction in part (c).

Is the reaction exothermic? Is it spontaneous at 298 K? (e) Use the data in the table to calculate  $\Delta S^{\circ}$  at 298 K for the vaporization of  $\text{CS}_2(\text{l})$ . Is the sign of  $\Delta S^{\circ}$  as you would expect for a vaporization? (f) Using data in the table and your answer to part (e), estimate the boiling point of  $\text{CS}_2(\text{l})$ . Do you predict that the substance will be a liquid or a gas at 298 K and 1 atm?

**[19.109]** The following data compare the standard enthalpies and free energies of formation of some crystalline ionic substances and aqueous solutions of the substances:

| Substance                  | $\Delta H_f^{\circ}$ (kJ/mol) | $\Delta G_f^{\circ}$ (kJ/mol) |
|----------------------------|-------------------------------|-------------------------------|
| $\text{AgNO}_3(\text{s})$  | -124.4                        | -33.4                         |
| $\text{AgNO}_3(\text{aq})$ | -101.7                        | -34.2                         |
| $\text{MgSO}_4(\text{s})$  | -1283.7                       | -1169.6                       |
| $\text{MgSO}_4(\text{aq})$ | -1374.8                       | -1198.4                       |

Write the formation reaction for  $\text{AgNO}_3(\text{s})$ . Based on this reaction, do you expect the entropy of the system to increase or decrease upon the formation of  $\text{AgNO}_3(\text{s})$ ? (b) Use  $\Delta H_f^{\circ}$  and  $\Delta G_f^{\circ}$  of  $\text{AgNO}_3(\text{s})$  to determine the entropy change upon formation of the substance. Is your answer consistent with your reasoning in part (a)? (c) Is dissolving  $\text{AgNO}_3$  in water an exothermic or endothermic process? What about dissolving  $\text{MgSO}_4$  in water? (d) For both  $\text{AgNO}_3$  and  $\text{MgSO}_4$ , use the data to calculate the entropy change when the solid is dissolved in water. (e) Discuss the results from part (d) with reference to material presented in this chapter and in the "A Closer Look" box on page 814.

**[19.110]** Consider the following equilibrium:

Thermodynamic data on these gases are given in Appendix C. You may assume that  $\Delta H^{\circ}$  and  $\Delta S^{\circ}$  do not vary with temperature. (a) At what temperature will an equilibrium mixture contain equal amounts of the two gases? (b) At what temperature will an equilibrium mixture of 1 atm total pressure contain twice as much  $\text{NO}_2$  as  $\text{N}_2\text{O}_4$ ? (c) At what temperature will an equilibrium mixture of 10 atm total pressure contain twice as much  $\text{NO}_2$  as  $\text{N}_2\text{O}_4$ ?

**[19.111]** The reaction

is the basis of a suggested method for removal of  $\text{SO}_2$  from power-plant stack gases. The standard free energy of each substance is given in Appendix C. (a) What is the equilibrium constant for the reaction at 298 K? (b) In principle, is this reaction a feasible method of removing  $\text{SO}_2$ ? (c) If  $P_{\text{SO}_2} = P_{\text{H}_2\text{S}}$  and the vapor pressure of water is 25 torr, calculate the equilibrium  $\text{SO}_2$  pressure in the system at 298 K. (d) Would you expect the process to be more or less effective at higher temperatures?

**19.112** When most elastomeric polymers (e.g., a rubber band) are stretched, the molecules become more ordered, as illustrated here:

Suppose you stretch a rubber band. **(a)** Do you expect the entropy of the system to increase or decrease? **(b)** If the rubber band were stretched isothermally, would heat need to be absorbed or emitted to maintain constant temperature? **(c)** Try this experiment: Stretch a rubber band and

wait a moment. Then place the stretched rubber band on your upper lip, and let it return suddenly to its unstretched state (remember to keep holding on!). What do you observe? Are your observations consistent with your answer to part (b)?

## Design an Experiment

You are measuring the equilibrium constant for a drug candidate binding to its DNA target over a series of different temperatures. You chose your drug candidate based on computer-aided molecular modeling, which indicates that the drug molecule likely would make many hydrogen bonds and favorable dipole–dipole interactions with the DNA site. You perform a set of experiments in buffer solution for the drug–DNA complex and generate a table of  $K$ 's at different  $T$ 's. **(a)** Derive an equation that relates equilibrium constant to standard enthalpy and entropy changes. (*Hint: equilibrium constant, enthalpy and entropy are all related to free energy*). **(b)** Show how you

can graph your  $K$  and  $T$  data to calculate the standard entropy and enthalpy changes for the drug candidate + DNA binding interaction. **(c)** You are surprised to learn that the enthalpy change for the binding reaction is close to zero, and the entropy change is large and positive. Suggest an explanation and design an experiment to test it. (*Hint: Think about water and ions*). **(d)** You try another drug candidate with the DNA target and find that this drug candidate has a large negative enthalpy change upon DNA binding, and the entropy change is small and positive. Suggest an explanation, at the molecular level, and design an experiment to test your hypothesis.

20

# ELECTROCHEMISTRY

The electricity that powers much of modern society has many favorable characteristics, but it has a serious shortcoming: it cannot easily be stored. The electricity that flows into power lines is consumed as it is generated, but for many applications, stored electrical energy is needed. In such cases electrical energy is converted into chemical energy, which can be stored and is portable, and then converted back to electricity when needed.

Batteries are the most familiar devices for converting between electrical and chemical energies. Objects like laptop computers, cell phones, pace-makers, and countless other devices rely on batteries to provide the electricity needed for operation.

A considerable amount of effort is currently focused on research and development of new batteries, particularly for powering electric vehicles. New batteries are needed that are lighter, can charge faster, deliver more power, and have longer lifetimes. At the heart of such developments are the oxidation–reduction reactions that power batteries.

As discussed in Chapter 4, *oxidation* takes place when an atom loses electrons; the opposite process, gaining electrons, is called *reduction*.  (Section 4.4) Thus, oxidation–reduction (redox) reactions occur when electrons are transferred from an atom that is oxidized to an atom that is reduced. Redox reactions are involved not only in the operation of batteries but also in a wide variety of important natural processes, including the rusting of iron, the browning of foods, and the respiration of animals. **Electrochemistry** is the study of the relationships between electricity and chemical reactions. It includes the study of both spontaneous and nonspontaneous processes.

◀ **THE TESLA GIGAFACTORY**, under construction in Nevada, will be the largest lithium-ion battery production facility in the world once completed in 2017. These batteries will be used in a wide variety of applications, including Tesla's all-electric vehicles.

## WHAT'S AHEAD

- 20.2** ▶ **Balancing Redox Equations** Learn how to balance redox equations using the method of *half-reactions*.
- 20.3** ▶ **Voltaic Cells** Consider *voltaic cells*, which produce electricity from spontaneous redox reactions. Solid electrodes serve as the surfaces at which oxidation and reduction take place. The electrode where oxidation occurs is the *anode*, and the electrode where reduction occurs is the *cathode*.
- 20.4** ▶ **Cell Potentials under Standard Conditions** Learn about *cell potential*, which is the potential difference or voltage between the two electrodes of a voltaic cell. The cell potential can be calculated from the *standard reduction potentials* of the half-reactions occurring at each electrode.
- 20.5** ▶ **Free Energy and Redox Reactions** Relate the Gibbs free energy,  $\Delta G^\circ$ , to cell potential.
- 20.6** ▶ **Cell Potentials under Nonstandard Conditions** Calculate cell potentials under nonstandard conditions using standard cell potentials and the Nernst equation.
- 20.7** ▶ **Batteries and Fuel Cells** Learn about batteries and fuel cells, which are commercially important energy sources that use electrochemical reactions.
- 20.8** ▶ **Corrosion** Focus on corrosion, a spontaneous electrochemical process involving metals.
- 20.9** ▶ **Electrolysis** Examine *electrolytic cells*, which use electricity to drive chemical reactions that would otherwise be non-spontaneous.

## 20.1 | Oxidation States and Oxidation–Reduction Reactions

We determine whether a given chemical reaction is an oxidation–reduction reaction by keeping track of the *oxidation numbers* (*oxidation states*) of the elements involved in the reaction. ∞ (Section 4.4) This procedure identifies whether the oxidation number changes for any elements involved in the reaction. For example, consider the net reaction that occurs spontaneously when zinc metal is added to a strong acid (Figure 20.1):

Assigning oxidation numbers to all species in the reaction, we have

### Go Figure

Is this reaction exothermic or endothermic?

▲ Figure 20.1 Oxidation of zinc by hydrochloric acid.

The oxidation numbers below the equation show that the oxidation number of Zn changes from 0 to +2, while that of H changes from +1 to 0. Thus, this is an oxidation–reduction reaction. Electrons are transferred from zinc atoms to hydrogen ions; Zn is oxidized and  $\text{H}^+$  is reduced.

In a reaction such as Equation 20.2, a clear transfer of electrons occurs. In some reactions, however, the oxidation numbers change, but we cannot say that any substance literally gains or loses electrons. For example, in the combustion of hydrogen gas,

hydrogen is oxidized from the 0 to the +1 oxidation state and oxygen is reduced from the 0 to the –2 oxidation state, indicating that Equation 20.3 is an oxidation–reduction reaction. While keeping track of oxidation states offers a convenient form of “bookkeeping,” you should not generally equate the oxidation state of an atom with its actual charge in a chemical compound.  (Section 8.5, “Oxidation Numbers, Formal Charges, and Actual Partial Charges”)

### Give It Some Thought

What are the oxidation numbers of the elements in the nitrite ion,  $\text{NO}_2^-$ ?

In any redox reaction, both oxidation and reduction must occur. If one substance is oxidized, another must be reduced. The substance that oxidizes another substance is called either the **oxidizing agent** or the **oxidant**. The oxidizing agent acquires electrons from the other substance and so is itself reduced. A **reducing agent**, or **reductant**, is a substance that gives up electrons, thereby causing another substance to be reduced. The reducing agent is therefore oxidized in the process. In Equation 20.2,  $\text{H}^+(\text{aq})$ , the species that is reduced, is the oxidizing agent and  $\text{Zn}(\text{s})$ , the species that is oxidized, is the reducing agent.

### Sample Exercise 20.1

#### Identifying Oxidizing and Reducing Agents

The nickel–cadmium (nicad) battery uses the following redox reaction to generate electricity:

Identify the substances that are oxidized and reduced, and indicate which is the oxidizing agent and which is the reducing agent.

#### SOLUTION

**Analyze** We are given a redox equation and asked to identify the substance oxidized and the substance reduced and to label the oxidizing agent and the reducing agent.

**Plan** First, we use the rules outlined earlier  (Section 4.4) to assign oxidation states, or numbers, to all the atoms and determine which elements change oxidation state. Second, we apply the definitions of oxidation and reduction.

#### Solve

The oxidation state of Cd increases from 0 to +2, and that of Ni decreases from +4 to +2. Thus, the Cd atom is oxidized (loses electrons) and is the reducing agent. The oxidation state of

Ni decreases as  $\text{NiO}_2$  is converted into  $\text{Ni}(\text{OH})_2$ . Thus,  $\text{NiO}_2$  is reduced (gains electrons) and is the oxidizing agent.

**Comment** A common mnemonic for remembering oxidation and reduction is “LEO the lion says GER”: *losing* electrons is *oxidation*; *gaining* electrons is *reduction*.

#### Practice Exercise 1

What is the reducing agent in the following reaction?

(a)  $\text{Br}^-(\text{aq})$  (b)  $\text{H}_2\text{O}_2(\text{aq})$  (c)  $\text{H}^+(\text{aq})$  (d)  $\text{Br}_2(\text{aq})$

#### Practice Exercise 2

Identify the oxidizing and reducing agents in the reaction

## 20.2 | Balancing Redox Equations

Whenever we balance a chemical equation, we must obey the law of conservation of mass: The amount of each element must be the same on both sides of the equation. (Atoms are neither created nor destroyed in any chemical reaction.) As we balance oxidation–reduction reactions, there is an additional requirement: The gains and losses of electrons must be balanced. If a substance loses a certain number of electrons during a reaction, another substance must gain that same number of electrons. (Electrons are neither created nor destroyed in any chemical reaction.)

In many simple chemical equations, such as Equation 20.2, balancing the electrons is handled “automatically”—that is, we balance the equation without explicitly accounting for the transfer of electrons. Many redox equations are more complex than Equation 20.2, however, and cannot be balanced easily without taking into account the number of electrons lost and gained. In this section, we examine the *method of half-reactions*, a systematic procedure for balancing redox equations.

### Half-Reactions

Although oxidation and reduction must take place simultaneously, it is often convenient to consider them as separate processes. For example, the oxidation of  $\text{Sn}^{2+}$  by  $\text{Fe}^{3+}$ ,

can be considered as consisting of two processes: oxidation of  $\text{Sn}^{2+}$  and reduction of  $\text{Fe}^{3+}$ :

Notice that electrons are shown as products in the oxidation process and as reactants in the reduction process.

Equations that show either oxidation or reduction alone, such as Equations 20.4 and 20.5, are called **half-reactions**. In the overall redox reaction, the number of electrons lost in the oxidation half-reaction must equal the number of electrons gained in the reduction half-reaction. When this condition is met and each half-reaction is balanced, the electrons on the two sides cancel when the two half-reactions are added to give the balanced oxidation–reduction equation.

### Balancing Equations by the Method of Half-Reactions

In the half-reaction method, we usually begin with a “skeleton” ionic equation showing only the substances undergoing oxidation and reduction. In such cases, we assign oxidation numbers only when we are unsure whether the reaction involves oxidation–reduction. We will find that  $\text{H}^+$  (for acidic solutions),  $\text{OH}^-$  (for basic solutions), and  $\text{H}_2\text{O}$  are often involved as reactants or products in redox reactions. Unless  $\text{H}^+$ ,  $\text{OH}^-$ , or  $\text{H}_2\text{O}$  is being oxidized or reduced, these species do not appear in the skeleton equation. Their presence, however, can be deduced as we balance the equation.

#### How to Balance Redox Reactions in Acidic Aqueous Solution

1. Divide the equation into one oxidation half-reaction and one reduction half-reaction.
2. Balance each half-reaction.
  - (a) First, balance elements other than H and O.
  - (b) Next, balance O atoms by adding  $\text{H}_2\text{O}$  as needed.
  - (c) Then balance H atoms by adding  $\text{H}^+$  as needed.
  - (d) Finally, balance charge by adding  $\text{e}^-$  as needed.

This specific sequence (a)–(d) is important, and it is summarized in the diagram in the margin. At this point, you can check whether the number of electrons in each half-reaction corresponds to the changes in oxidation state.

3. Multiply half-reactions by integers as needed to make the number of electrons lost in the oxidation half-reaction equal the number of electrons gained in the reduction half-reaction.
4. Add half-reactions and, if possible, simplify by canceling species appearing on both sides of the combined equation.
5. Check to make sure that atoms and charges are balanced.

As an example, let's consider the reaction between permanganate ion ( $\text{MnO}_4^-$ ) and oxalate ion ( $\text{C}_2\text{O}_4^{2-}$ ) in acidic aqueous solution (Figure 20.2). When  $\text{MnO}_4^-$  is added to an acidified solution of  $\text{C}_2\text{O}_4^{2-}$ , the deep purple color of the  $\text{MnO}_4^-$  ion fades, bubbles of  $\text{CO}_2$  form, and the solution takes on the pale pink color of  $\text{Mn}^{2+}$ . We can write the skeleton equation as

Experiments show that  $\text{H}^+$  is consumed and  $\text{H}_2\text{O}$  is produced in the reaction. We will see that their involvement in the reaction is deduced in the course of balancing the equation.

To complete and balance Equation 20.6, we first write the two half-reactions (Step 1). One half-reaction must have Mn on both sides of the arrow, and the other must have C on both sides of the arrow:

We next complete and balance each half-reaction. First, we balance all the atoms except H and O (Step 2a). In the permanganate half-reaction, we have one manganese atom on each side of the equation and so need to do nothing. In the oxalate half-reaction, we add a coefficient 2 on the right to balance the two carbons on the left:

Next we balance O (Step 2b). The permanganate half-reaction has four oxygens on the left and none on the right; to balance these four oxygen atoms, we add four  $\text{H}_2\text{O}$  molecules on the right:

The eight hydrogen atoms now in the products must be balanced by adding 8  $\text{H}^+$  to the reactants (Step 2c):

### Go Figure

Which species is reduced in this reaction? Which species is the reducing agent?

▲ Figure 20.2 Titration of an acidic solution of  $\text{Na}_2\text{C}_2\text{O}_4$  with  $\text{KMnO}_4(aq)$ .

Now there are equal numbers of each type of atom on the two sides of the equation, but the charge still needs to be balanced. The charge of the reactants is  $8(1+) + 1(1-) = 7+$ , and that of the products is  $1(2+) + 4(0) = 2+$ . To balance the charge, we add five electrons to the reactant side (Step 2d):

We can use oxidation states to check our result. In this half-reaction, Mn goes from the +7 oxidation state in  $MnO_4^-$  to the +2 oxidation state of  $Mn^{2+}$ . Therefore, each Mn atom gains five electrons, in agreement with our balanced half-reaction.

In the oxalate half-reaction, we have C and O balanced (Step 2a). We balance the charge (Step 2d) by adding two electrons to the products:

We can check this result using oxidation states. Carbon goes from the +3 oxidation state in  $C_2O_4^{2-}$  to the +4 oxidation state in  $CO_2$ . Thus, each C atom loses one electron; therefore, the two C atoms in  $C_2O_4^{2-}$  lose two electrons, in agreement with our balanced half-reaction.

Now we multiply each half-reaction by an appropriate integer so that the number of electrons gained in one half-reaction equals the number of electrons lost in the other (Step 3). We multiply the  $MnO_4^-$  half-reaction by 2 and the  $C_2O_4^{2-}$  half-reaction by 5:

The balanced equation is the sum of the balanced half-reactions (Step 4). Note that the electrons on the reactant and product sides of the equation cancel each other.

We check the balanced equation by counting atoms and charges (Step 5). There are 16 H, 2 Mn, 28 O, 10 C, and a net charge of 4+ on each side of the equation, confirming that the equation is correctly balanced.

### Give It Some Thought

Do free electrons appear anywhere in the balanced equation for a redox reaction?

## Sample Exercise 20.2

### Balancing Redox Equations in Acidic Solution

Complete and balance this equation by the method of half-reactions:

### SOLUTION

**Analyze** We are given an incomplete, unbalanced (skeleton) equation for a redox reaction occurring in acidic solution and asked to complete and balance it.

**Plan** We use the half-reaction procedure we just learned.

#### Solve

**Step 1:** We divide the equation into two half-reactions:

**Step 2:** We balance each half-reaction. In the first half-reaction the presence of one  $Cr_2O_7^{2-}$  among the reactants requires two  $Cr^{3+}$  among the products. The seven oxygen atoms in  $Cr_2O_7^{2-}$  are balanced by adding seven  $H_2O$  to the products. The 14 hydrogen atoms in 7  $H_2O$  are then balanced by adding 14  $H^+$  to the reactants:

We then balance the charge by adding electrons to the left side of the equation so that the total charge is the same on the two sides:

We can check this result by looking at the oxidation state changes. Each chromium atom goes from +6 to +3, gaining three electrons; therefore, the two Cr atoms in  $Cr_2O_7^{2-}$  gain six electrons, in agreement with our half-reaction.

In the second half-reaction, two  $Cl^{-}$  are required to balance one  $Cl_2$ :

We add two electrons to the right side to attain charge balance:

This result agrees with the oxidation state changes. Each chlorine atom goes from  $-1$  to  $0$ , losing one electron; therefore, the two chlorine atoms lose two electrons.

**Step 3:** We equalize the number of electrons transferred in the two half-reactions. To do so, we multiply the Cl half-reaction by 3 so that the number of electrons gained in the Cr half-reaction (6) equals the number lost in the Cl half-reaction, allowing the electrons to cancel when the half-reactions are added:

**Step 4:** The equations are added to give the balanced equation:

**Step 5:** There are equal numbers of atoms of each kind on the two sides of the equation (14 H, 2 Cr, 7 O, 6 Cl). In addition, the charge is the same on the two sides ( $6+$ ). Thus, the equation is balanced.

### Practice Exercise 1

If you complete and balance the following equation in acidic solution

how many water molecules are there in the balanced equation (for the reaction balanced with the smallest whole-number coefficients)? (a) Four on the reactant side (b) Three on the

product side (c) One on the reactant side (d) Seven on the product side (e) Two on the product side

### Practice Exercise 2

Complete and balance the following equation in acidic solution using the method of half-reactions.

## Balancing Equations for Reactions Occurring in Basic Solution

If a redox reaction occurs in basic solution, the equation must be balanced by using  $OH^{-}$  and  $H_2O$  rather than  $H^{+}$  and  $H_2O$ . Because the water molecule and the hydroxide ion both contain hydrogen, this approach can take more moving back and forth from one side of the equation to the other to arrive at the appropriate half-reaction. There is an alternate approach.

### How to Balance Redox Reactions in Basic Aqueous Solution

1. Balance the half-reactions as if they occurred in acidic solution.
2. Count the number of  $H^{+}$  in each half-reaction, and then add the same number of  $OH^{-}$  to each side of the half-reaction.

Using this method, the reaction is mass-balanced because you are adding the same thing to both sides. In essence, what you are doing is “neutralizing” the protons to form water ( $H^{+} + OH^{-} \longrightarrow H_2O$ ) on the side containing  $H^{+}$ , and the other side ends up with the  $OH^{-}$ . The resulting water molecules can be canceled as needed.

### Sample Exercise 20.3

#### Balancing Redox Equations in Basic Solution

Complete and balance this equation for a redox reaction that takes place in basic solution:

#### SOLUTION

**Analyze** We are given an incomplete equation for a basic redox reaction and asked to balance it.

**Plan** We go through the first steps of our procedure as if the reaction were occurring in acidic solution. We then add the

appropriate number of  $\text{OH}^-$  to each side of the equation, combining  $\text{H}^+$  and  $\text{OH}^-$  to form  $\text{H}_2\text{O}$ . We complete the process by simplifying the equation.

#### Solve

**Step 1:** We write the incomplete, unbalanced half-reactions:

**Step 2:** We balance each half-reaction as if it took place in acidic solution:

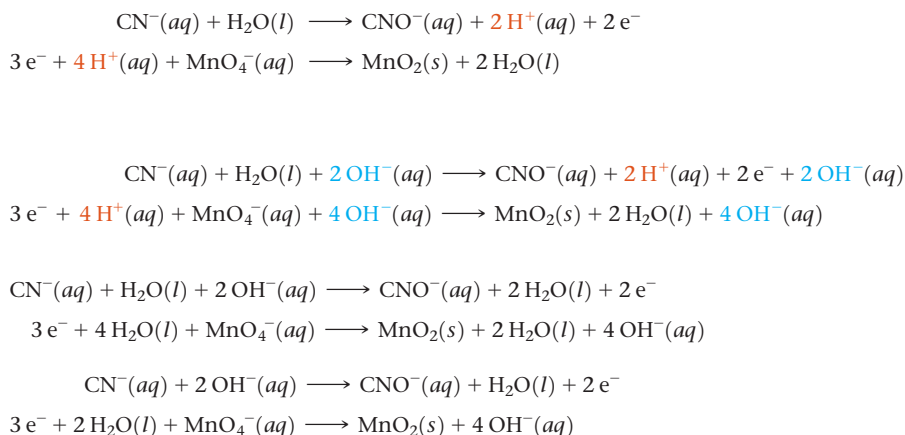

Now we must take into account that the reaction occurs in basic solution, adding  $\text{OH}^-$  to both sides of both half-reactions to neutralize  $\text{H}^+$ :

We “neutralize”  $\text{H}^+$  and  $\text{OH}^-$  by forming  $\text{H}_2\text{O}$  when they are on the same side of either half-reaction:

Next, we cancel water molecules that appear as both reactants and products:

Both half-reactions are now balanced. You can check the atoms and the overall charge.

**Step 3:** We multiply the cyanide half-reaction by 3, which gives six electrons on the product side, and multiply the permanganate half-reaction by 2, which gives six electrons on the reactant side:

**Step 4:** We add the two half-reactions together and simplify by canceling species that appear as both reactants and products:

**Step 5:** Check that the atoms and charges are balanced.

There are 3 C, 3 N, 2 H, 9 O, 2 Mn, and a charge of 5<sup>−</sup> on both sides of the equation.

**Comment** It is important to remember that this procedure does not imply that  $\text{H}^+$  ions are involved in the chemical reaction. Recall that in aqueous solutions at 25 °C,  $K_w = [\text{H}^+][\text{OH}^-] = 1.0 \times 10^{-14}$ . Thus,  $[\text{H}^+]$  is very small in this basic solution.  $\infty$  (Section 16.3)

#### Practice Exercise 1

If you complete and balance the following oxidation–reduction reaction in basic solution

how many hydroxide ions are there in the balanced equation (for the reaction balanced with the smallest whole-number coefficients)?

- (a) One on the reactant side (b) One on the product side  
(c) Four on the reactant side (d) Seven on the product side  
(e) None

#### Practice Exercise 2

Complete and balance the following oxidation–reduction reaction in basic solution:

## Go Figure

Why does the intensity of the blue solution color lessen as the reaction proceeds?

▲ Figure 20.3 A spontaneous oxidation–reduction reaction involving zinc and copper.

## 20.3 | Voltaic Cells

The energy released in a spontaneous redox reaction can be used to perform electrical work. This task is accomplished through a **voltaic** (or **galvanic**) **cell**, a device in which the transfer of electrons takes place through an external pathway rather than directly between reactants present in the same reaction vessel.

One such spontaneous reaction occurs when a strip of zinc is placed in contact with a solution containing  $\text{Cu}^{2+}(\text{aq})$ . As the reaction proceeds, the blue color of  $\text{Cu}^{2+}(\text{aq})$  ions fades and copper metal deposits on the zinc. At the same time, the zinc begins to dissolve. These transformations, shown in Figure 20.3, are summarized by the equation

Figure 20.4 shows a voltaic cell that uses the redox reaction given in Equation 20.7. Although the setup in Figure 20.4 is more complex than that in Figure 20.3, the reaction is the same in both cases. The significant difference is that in the voltaic cell the Zn metal and  $\text{Cu}^{2+}(\text{aq})$  are not in direct contact with each other. Instead, Zn metal is in contact with  $\text{Zn}^{2+}(\text{aq})$  in one compartment, and Cu metal is in contact with  $\text{Cu}^{2+}(\text{aq})$  in the other compartment. Consequently,  $\text{Cu}^{2+}(\text{aq})$  reduction can occur only by the flow of electrons through an external circuit, namely, a wire connecting the Zn and Cu strips. Electrons flowing through a wire and ions moving in solution both constitute an *electrical current*. This flow of electrical charge can be used to accomplish electrical work.

## Go Figure

Which metal, Cu or Zn, is oxidized in this voltaic cell?

▲ Figure 20.4 A Cu–Zn voltaic cell based on the reaction in Equation 20.7.

The two solid metals connected by the external circuit are called *electrodes*. By definition, the electrode at which oxidation occurs is the **anode** and the electrode at which reduction occurs is the **cathode**.\* The electrodes can be made of materials that participate in the reaction, as in the present example. Over the course of the reaction, the Zn electrode gradually disappears and the copper electrode gains mass. More typically, the electrodes are made of a conducting material, such as platinum or graphite, that does not gain or lose mass during the reaction but serves as a surface at which electrons are transferred.

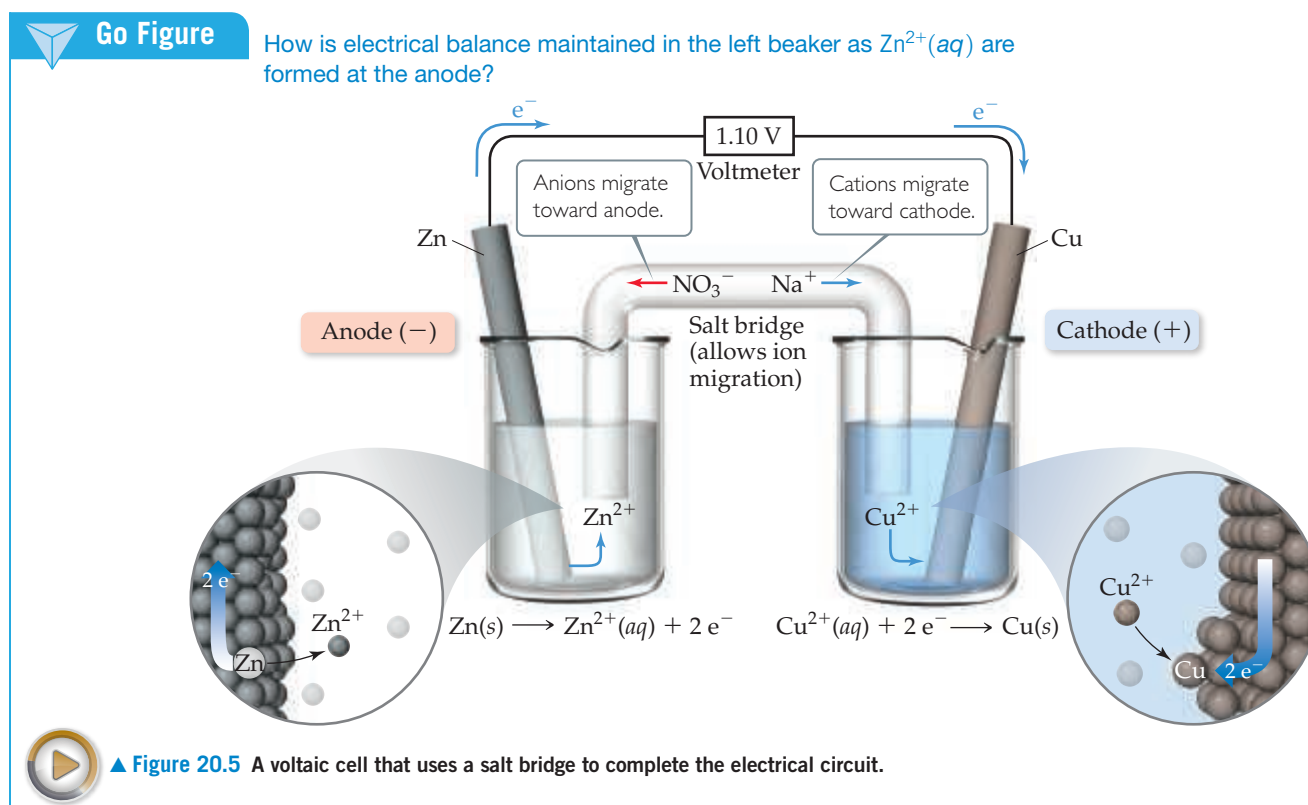

Each compartment of a voltaic cell is called a *half-cell*. One half-cell is the site of the oxidation half-reaction, and the other is the site of the reduction half-reaction. In our present example, Zn is oxidized and  $\text{Cu}^{2+}$  is reduced:

Electrons become available as zinc metal is oxidized at the anode. They flow through the external circuit to the cathode, where they are consumed as  $\text{Cu}^{2+}(\text{aq})$  is reduced. Because Zn(s) is oxidized in the cell, the zinc electrode loses mass, and the concentration of the  $\text{Zn}^{2+}(\text{aq})$  solution increases as the cell operates. At the same time, the Cu electrode gains mass, and the  $\text{Cu}^{2+}(\text{aq})$  solution becomes less concentrated as  $\text{Cu}^{2+}(\text{aq})$  is reduced to Cu(s).

For a voltaic cell to work, the solutions in the two half-cells must remain electrically neutral. As Zn is oxidized in the anode half-cell,  $\text{Zn}^{2+}(\text{aq})$  ions enter the solution, upsetting the initial  $\text{Zn}^{2+}/\text{SO}_4^{2-}$  charge balance. To keep the solution electrically neutral, there must be some means for  $\text{Zn}^{2+}(\text{aq})$  cations to migrate out of the anode half-cell and for anions to migrate in. Similarly, the reduction of  $\text{Cu}^{2+}(\text{aq})$  at the cathode removes these cations from the solution, leaving an excess of  $\text{SO}_4^{2-}$  anions in that half-cell. To maintain electrical neutrality, some of these anions must migrate out of the cathode half-cell, and positive ions must migrate in. In fact, no measurable electron flow occurs between electrodes unless a means is provided for ions to migrate through the solution from one half-cell to the other, thereby completing the circuit.

In Figure 20.4, a porous glass disc separating the two half-cells allows ions to migrate and maintain the electrical neutrality of the solutions. In Figure 20.5, a *salt bridge* serves

\*To help remember these definitions, note that *anode* and *oxidation* both begin with a vowel, and *cathode* and *reduction* both begin with a consonant.

this purpose. The salt bridge consists of a U-shaped tube containing an electrolyte solution, such as  $\text{NaNO}_3(aq)$ , whose ions will not react with other ions in the voltaic cell or with the electrodes. The electrolyte is often incorporated into a paste or gel so that the electrolyte solution does not pour out when the U-tube is inverted. As oxidation and reduction proceed at the electrodes, ions from the salt bridge migrate into the two half-cells—cations migrating to the cathode half-cell and anions migrating to the anode half-cell—to neutralize charge in the half-cell solutions. Whichever device is used to allow ions to migrate between half-cells, *anions always migrate toward the anode and cations toward the cathode*.

**Figure 20.6** summarizes the various relationships in a voltaic cell. Notice in particular that *electrons flow from the anode through the external circuit to the cathode*. Because of this directional flow, the anode in a voltaic cell is labeled with a negative sign and the cathode is labeled with a positive sign. We can envision the electrons as being attracted to the positive cathode from the negative anode through the external circuit.

**▲ Figure 20.6 Summary of reactions occurring in a voltaic cell.** The half-cells can be separated by either a porous glass disc (as in Figure 20.4) or by a salt bridge (as in Figure 20.5).

## Sample Exercise 20.4

### Describing a Voltaic Cell

The oxidation–reduction reaction

is spontaneous. A solution containing  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$  is poured into one beaker, and a solution of  $\text{KI}$  is poured into another. A salt bridge is used to join the beakers. A metallic conductor that will not react with either solution (such as platinum foil) is suspended in each solution, and the two conductors are connected with wires through a voltmeter or some other device to detect an electric current. The resulting voltaic cell generates an electric current. Indicate the reaction occurring at the anode, the reaction at the cathode, the direction of electron migration, the direction of ion migration, and the signs of the electrodes.

### SOLUTION

**Analyze** We are given the equation for a spontaneous reaction that takes place in a voltaic cell and a description of how the cell is constructed. We are asked to write the half-reactions occurring at the anode and at the cathode, as well as the directions of electron and ion movements and the signs assigned to the electrodes.

**Plan** Our first step is to divide the chemical equation into half-reactions so that we can identify the oxidation and the reduction processes. We then use the definitions of anode and cathode and the other terminologies summarized in Figure 20.6.

**Solve** In one half-reaction,  $\text{Cr}_2\text{O}_7^{2-}(aq)$  is converted into  $\text{Cr}^{3+}(aq)$ . Starting with these ions and then completing and balancing the half-reaction, we have

In the other half-reaction,  $\text{I}^-(aq)$  is converted to  $\text{I}_2(s)$ :

Now we can use the summary in Figure 20.6 to help us describe the voltaic cell. The first half-reaction is the reduction process (electrons on the reactant side of the equation). By definition, the reduction process occurs at the cathode. The second half-reaction is the oxidation process (electrons on the product side of the equation), which occurs at the anode.

The  $\text{I}^-$  ions are the source of electrons, and the  $\text{Cr}_2\text{O}_7^{2-}$  ions accept the electrons. Hence, the electrons flow through the external circuit from the electrode immersed in the  $\text{KI}$  solution (the anode) to the electrode immersed in the  $\text{K}_2\text{Cr}_2\text{O}_7\text{--H}_2\text{SO}_4$  solution (the cathode). The electrodes themselves do not react in any way; they merely provide a means of transferring electrons from or to the solutions. The cations move through the solutions toward the

cathode, and the anions move toward the anode. The anode (from which the electrons move) is the negative electrode, and the cathode (toward which the electrons move) is the positive electrode.

### Practice Exercise 1

The following two half-reactions occur in a voltaic cell:

Which one of the following descriptions most accurately describes what is occurring in the half-cell containing the  $\text{Cu}$  electrode and  $\text{Cu}^{2+}(aq)$  solution?

- The electrode is losing mass and cations from the salt bridge are flowing into the half-cell.
- The electrode is gaining mass and cations from the salt bridge are flowing into the half-cell.
- The electrode is losing mass and anions from the salt bridge are flowing into the half-cell.
- The electrode is gaining mass and anions from the salt bridge are flowing into the half-cell.

### Practice Exercise 2

The two half-reactions in a voltaic cell are

- Indicate which reaction occurs at the anode and which at the cathode. (b) Does the zinc electrode gain, lose, or retain the same mass as the reaction proceeds? (c) Does the platinum electrode gain, lose, or retain the same mass as the reaction proceeds? (d) Which electrode is positive?

## 20.4 | Cell Potentials under Standard Conditions

Why do electrons transfer spontaneously from a Zn atom to a  $\text{Cu}^{2+}$  ion, either directly as in Figure 20.3 or through an external circuit as in Figure 20.4? In a simple sense, we can compare the electron flow to the flow of water in a waterfall (Figure 20.7). Water flows spontaneously over a waterfall because of a difference in potential energy between the top of the falls and the bottom. [∞ \(Section 5.1\)](#) In a similar fashion, electrons flow spontaneously through an external circuit from the anode of a voltaic cell to the cathode because of a difference in potential energy. The potential energy of electrons is higher in the anode than in the cathode. Thus, electrons flow spontaneously toward the electrode with the more positive electrical potential.

The difference in potential energy per electrical charge (the *potential difference*) between two electrodes is measured in *volts*. One volt (V) is the potential difference required to impart 1 joule (J) of energy to a charge of 1 coulomb (C):

$$1 \text{ V} = 1 \frac{\text{J}}{\text{C}}$$

Recall that one electron has a charge of  $1.60 \times 10^{-19} \text{ C}$ . [∞ \(Section 2.2\)](#)

The potential difference between the two electrodes of a voltaic cell is called the **cell potential**, denoted  $E_{\text{cell}}$ . Because the potential difference provides the driving force that pushes electrons through the external circuit, we also call it the **electromotive** (“causing electron motion”) **force**, or **emf**. Because  $E_{\text{cell}}$  is measured in volts, it is also commonly called the *voltage* of the cell.

The cell potential of any voltaic cell is positive. The magnitude of the cell potential depends on the reactions that occur at the cathode and anode, the concentrations of reactants and products, and the temperature, which we will assume to be  $25^\circ\text{C}$  unless otherwise noted. In this section, we focus on cells that are operated at  $25^\circ\text{C}$  under *standard conditions*. Recall from Table 19.2 that standard conditions include 1 M concentration for reactants and products in solution and 1 atm pressure for gaseous reactants and products. The cell potential under standard conditions is called either the **standard cell potential** or **standard emf** and is denoted  $E_{\text{cell}}^\circ$ .

▲ **Figure 20.7** Water analogy for electron flow. Just as water spontaneously flows downhill, electrons flow spontaneously from the anode to the cathode in a voltaic cell.

For the Zn–Cu voltaic cell in Figure 20.5, for example, the standard cell potential at 25 °C is +1.10 V:

Recall that the superscript  $^{\circ}$  indicates standard-state conditions. [↔ \(Section 5.7\)](#)

### Give It Some Thought

If a standard cell potential is  $E_{\text{cell}}^{\circ} = +0.85 \text{ V}$  at 25 °C, is the redox reaction of the cell spontaneous?

## Standard Reduction Potentials

The standard cell potential of a voltaic cell,  $E_{\text{cell}}^{\circ}$ , depends on the particular cathode and anode half-cells. We could, in principle, tabulate the standard cell potentials for all possible cathode–anode combinations. However, it is not necessary to undertake this arduous task. Rather, we can assign a standard potential to each half-cell and then use these half-cell potentials to determine  $E_{\text{cell}}^{\circ}$ . The cell potential is the difference between two half-cell potentials. By convention, the potential associated with each electrode is chosen to be the potential for *reduction* at that electrode. Thus, standard half-cell potentials are tabulated for reduction reactions, which means they are **standard reduction potentials**, denoted  $E_{\text{red}}^{\circ}$ . The standard cell potential,  $E_{\text{cell}}^{\circ}$ , is the standard reduction potential of the cathode reaction,  $E_{\text{red}}^{\circ}$  (cathode), *minus* the standard reduction potential of the anode reaction,  $E_{\text{red}}^{\circ}$  (anode):

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) \quad [20.8]$$

It is not possible to measure the standard reduction potential of a half-reaction directly. If we assign a standard reduction potential to a certain reference half-reaction, however, we can then determine the standard reduction potentials of other half-reactions relative to that reference value. The reference half-reaction is the reduction of  $\text{H}^{+}(aq)$  to  $\text{H}_2(g)$  under standard conditions, which is assigned a standard reduction potential of exactly 0 V:

An electrode designed to produce this half-reaction is called a **standard hydrogen electrode (SHE)**. A SHE consists of a platinum wire connected to a piece of platinum foil covered with finely divided platinum that serves as an inert surface for the reaction (Figure 20.8). The SHE allows the platinum to be in contact with both  $1 M \text{H}^{+}(aq)$  and a

▲ **Figure 20.8** The standard hydrogen electrode (SHE) is used as a reference electrode.

stream of hydrogen gas at 1 atm. The SHE can operate as either the anode or cathode of a cell, depending on the nature of the other electrode.

**Figure 20.9** shows a voltaic cell using a SHE. The spontaneous reaction is the one shown in Figure 20.1, namely, oxidation of Zn and reduction of  $\text{H}^+$ :

When the cell is operated under standard conditions, the cell potential is +0.76 V. By using the standard cell potential ( $E_{\text{cell}}^\circ = 0.76\text{ V}$ ), the defined standard reduction potential of  $\text{H}^+$  ( $E_{\text{red}}^\circ = 0\text{ V}$ ) and Equation 20.8, we can determine the standard reduction potential for the  $\text{Zn}^{2+}/\text{Zn}$  half-reaction:

$$\begin{aligned} E_{\text{cell}}^\circ &= E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode}) \\ +0.76\text{ V} &= 0\text{ V} - E_{\text{red}}^\circ(\text{anode}) \\ E_{\text{red}}^\circ(\text{anode}) &= -0.76\text{ V} \end{aligned}$$

Thus, a standard reduction potential of  $-0.76\text{ V}$  can be assigned to the reduction of  $\text{Zn}^{2+}$  to Zn:

We write the reaction as a reduction even though the Zn reaction in Figure 20.9 is an oxidation. *Whenever we assign an electrical potential to a half-reaction, we write the reaction as a reduction.* Half-reactions, however, are reversible, being able to operate as either reductions or oxidations. Consequently, half-reactions are sometimes written using two arrows ( $\rightleftharpoons$ ) between reactants and products, as in equilibrium reactions.

The standard reduction potentials for other half-reactions can be determined in a fashion analogous to that used for the  $\text{Zn}^{2+}/\text{Zn}$  half-reaction. **Table 20.1** lists some standard reduction potentials; a more complete list is found in Appendix E. These standard reduction potentials, often called *half-cell potentials*, can be combined to calculate  $E_{\text{cell}}^\circ$  values for a large variety of voltaic cells.

### Give It Some Thought

For the half-reaction  $\text{Cl}_2(\text{g}) + 2\text{e}^- \longrightarrow 2\text{Cl}^-(\text{aq})$ , what are the standard conditions for the reactant and product?

TABLE 20.1 Standard Reduction Potentials in Water at 25°C

| $E^\circ_{\text{red}}(\text{V})$ | Reduction Half-Reaction  |
|----------------------------------|--|
| +2.87                            | $\text{F}_2(\text{g}) + 2 \text{e}^- \longrightarrow 2 \text{F}^-(\text{aq})$  |
| +1.51                            | $\text{MnO}_4^-(\text{aq}) + 8 \text{H}^+(\text{aq}) + 5 \text{e}^- \longrightarrow \text{Mn}^{2+}(\text{aq}) + 4 \text{H}_2\text{O}(\text{l})$                |
| +1.36                            | $\text{Cl}_2(\text{g}) + 2 \text{e}^- \longrightarrow 2 \text{Cl}^-(\text{aq})$  |
| +1.33                            | $\text{Cr}_2\text{O}_7^{2-}(\text{aq}) + 14 \text{H}^+(\text{aq}) + 6 \text{e}^- \longrightarrow 2 \text{Cr}^{3+}(\text{aq}) + 7 \text{H}_2\text{O}(\text{l})$ |
| +1.23                            | $\text{O}_2(\text{g}) + 4 \text{H}^+(\text{aq}) + 4 \text{e}^- \longrightarrow 2 \text{H}_2\text{O}(\text{l})$   |
| +1.06                            | $\text{Br}_2(\text{l}) + 2 \text{e}^- \longrightarrow 2 \text{Br}^-(\text{aq})$  |
| +0.96                            | $\text{NO}_3^-(\text{aq}) + 4 \text{H}^+(\text{aq}) + 3 \text{e}^- \longrightarrow \text{NO}(\text{g}) + 2 \text{H}_2\text{O}(\text{l})$                       |
| +0.80                            | $\text{Ag}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Ag}(\text{s})$  |
| +0.77                            | $\text{Fe}^{3+}(\text{aq}) + \text{e}^- \longrightarrow \text{Fe}^{2+}(\text{aq})$   |
| +0.68                            | $\text{O}_2(\text{g}) + 2 \text{H}^+(\text{aq}) + 2 \text{e}^- \longrightarrow \text{H}_2\text{O}_2(\text{aq})$  |
| +0.59                            | $\text{MnO}_4^-(\text{aq}) + 2 \text{H}_2\text{O}(\text{l}) + 3 \text{e}^- \longrightarrow \text{MnO}_2(\text{s}) + 4 \text{OH}^-(\text{aq})$                  |
| +0.54                            | $\text{I}_2(\text{s}) + 2 \text{e}^- \longrightarrow 2 \text{I}^-(\text{aq})$  |
| +0.40                            | $\text{O}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{l}) + 4 \text{e}^- \longrightarrow 4 \text{OH}^-(\text{aq})$  |
| +0.34                            | $\text{Cu}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Cu}(\text{s})$   |
| 0 [defined]                      | $2 \text{H}^+(\text{aq}) + 2 \text{e}^- \longrightarrow \text{H}_2(\text{g})$  |
| -0.28                            | $\text{Ni}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Ni}(\text{s})$   |
| -0.44                            | $\text{Fe}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Fe}(\text{s})$   |
| -0.76                            | $\text{Zn}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Zn}(\text{s})$   |
| -0.83                            | $2 \text{H}_2\text{O}(\text{l}) + 2 \text{e}^- \longrightarrow \text{H}_2(\text{g}) + 2 \text{OH}^-(\text{aq})$  |
| -1.66                            | $\text{Al}^{3+}(\text{aq}) + 3 \text{e}^- \longrightarrow \text{Al}(\text{s})$   |
| -2.71                            | $\text{Na}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Na}(\text{s})$  |
| -3.05                            | $\text{Li}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Li}(\text{s})$  |

Because electrical potential measures potential energy per electrical charge, standard reduction potentials are intensive properties.  (Section 1.3) In other words, if we increase the amount of substances in a redox reaction, we increase both the energy and the charges involved, but the ratio of energy (joules) to electrical charge (coulombs) remains constant ( $V = J/C$ ). Thus, *changing the stoichiometric coefficient in a half-reaction does not affect the value of the standard reduction potential*. For example,  $E^\circ_{\text{red}}$  for the reduction of 10 mol  $\text{Zn}^{2+}$  is the same as that for the reduction of 1 mol  $\text{Zn}^{2+}$ :

### Sample Exercise 20.5

#### Calculating $E^\circ_{\text{red}}$ from $E^\circ_{\text{cell}}$

For the Zn–Cu voltaic cell shown in Figure 20.5, we have

Given that the standard reduction potential of  $\text{Zn}^{2+}$  to  $\text{Zn}(\text{s})$  is  $-0.76 \text{V}$ , calculate the  $E^\circ_{\text{red}}$  for the reduction of  $\text{Cu}^{2+}$  to  $\text{Cu}$ :

#### SOLUTION

**Analyze** We are given  $E^\circ_{\text{cell}}$  and  $E^\circ_{\text{red}}$  for  $\text{Zn}^{2+}$  and asked to calculate  $E^\circ_{\text{red}}$  for  $\text{Cu}^{2+}$ .

**Plan** In the voltaic cell, Zn is oxidized and is therefore the anode. Thus, the given  $E^\circ_{\text{red}}$  for  $\text{Zn}^{2+}$  is  $E^\circ_{\text{red}}$  (anode). Because

$\text{Cu}^{2+}$  is reduced, it is in the cathode half-cell. Thus, the unknown reduction potential for  $\text{Cu}^{2+}$  is  $E^\circ_{\text{red}}$  (cathode). Knowing  $E^\circ_{\text{cell}}$  and  $E^\circ_{\text{red}}$  (anode), we can use Equation 20.8 to solve for  $E^\circ_{\text{red}}$  (cathode).

*Continued*

**Solve**

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$$

$$1.10 \text{ V} = E_{\text{red}}^{\circ}(\text{cathode}) - (-0.76 \text{ V})$$

$$E_{\text{red}}^{\circ}(\text{cathode}) = 1.10 \text{ V} - 0.76 \text{ V} = 0.34 \text{ V}$$

**Check** This standard reduction potential agrees with the one listed in Table 20.1.

**Comment** The standard reduction potential for  $\text{Cu}^{2+}$  can be represented as  $E_{\text{Cu}^{2+}}^{\circ} = 0.34 \text{ V}$  and that for  $\text{Zn}^{2+}$  as  $E_{\text{Zn}^{2+}}^{\circ} = -0.76 \text{ V}$ . The subscript identifies the ion that is reduced in the reduction half-reaction.

**Practice Exercise 1**

A voltaic cell based on the reaction  
 $2 \text{Eu}^{2+}(\text{aq}) + \text{Ni}^{2+}(\text{aq}) \longrightarrow 2 \text{Eu}^{3+}(\text{aq}) + \text{Ni}(\text{s})$  generates

$E_{\text{cell}}^{\circ} = 0.07 \text{ V}$ . Given the standard reduction potential of  $\text{Ni}^{2+}$  given in Table 20.1, what is the standard reduction potential for the reaction  $\text{Eu}^{3+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{Eu}^{2+}(\text{aq})$ ?  
**(a)**  $-0.35 \text{ V}$  **(b)**  $0.35 \text{ V}$  **(c)**  $-0.21 \text{ V}$  **(d)**  $0.21 \text{ V}$  **(e)**  $0.07 \text{ V}$

**Practice Exercise 2**

The standard cell potential is  $1.46 \text{ V}$  for a voltaic cell based on the following half-reactions:

Using Table 20.1, calculate  $E_{\text{red}}^{\circ}$  for the reduction of  $\text{In}^{3+}$  to  $\text{In}^{+}$ .

**Sample Exercise 20.6**

Calculating from

Use Table 20.1 to calculate  $E_{\text{cell}}^{\circ}$  for the voltaic cell described in Sample Exercise 20.4, which is based on the reaction

**SOLUTION**

**Analyze** We are given the equation for a redox reaction and asked to use data in Table 20.1 to calculate the standard cell potential for the associated voltaic cell.

**Plan** Our first step is to identify the half-reactions that occur at the cathode and anode, which we did in Sample Exercise 20.4. Then we use Table 20.1 and Equation 20.8 to calculate the standard cell potential.

**Solve**

The half-reactions are:

According to Table 20.1, the standard reduction potential for the reduction of  $\text{Cr}_2\text{O}_7^{2-}$  to  $\text{Cr}^{3+}$  is  $+1.33 \text{ V}$  and the standard reduction potential for the reduction of  $\text{I}_2$  to  $\text{I}^{-}$  (the reverse of the oxidation half-reaction) is  $+0.54 \text{ V}$ . We use these values in Equation 20.8:

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = 1.33 \text{ V} - 0.54 \text{ V} = 0.79 \text{ V}$$

Although we must multiply the iodide half-reaction by 3 to obtain a balanced equation, we do *not* multiply the  $E_{\text{red}}^{\circ}$  value by 3. As we have noted, the standard reduction potential is an intensive property and so is independent of the stoichiometric coefficients.

**Check** The cell potential,  $0.79 \text{ V}$ , is a positive number. As noted earlier, a voltaic cell must have a positive potential.

**Practice Exercise 1**

Using the data in Table 20.1, what value would you calculate for the standard emf ( $E_{\text{cell}}^{\circ}$ ) for a voltaic cell that employs the overall cell reaction  
 $2 \text{Ag}^{+}(\text{aq}) + \text{Ni}(\text{s}) \longrightarrow 2 \text{Ag}(\text{s}) + \text{Ni}^{2+}(\text{aq})$ ?  
**(a)**  $+0.52 \text{ V}$  **(b)**  $-0.52 \text{ V}$  **(c)**  $+1.08 \text{ V}$  **(d)**  $-1.08 \text{ V}$  **(e)**  $+0.80 \text{ V}$

**Practice Exercise 2**

Using data in Table 20.1, calculate the standard emf for a cell that employs the overall cell reaction  
 $2 \text{Al}(\text{s}) + 3 \text{I}_2(\text{s}) \longrightarrow 2 \text{Al}^{3+}(\text{aq}) + 6 \text{I}^{-}(\text{aq})$ .

For each half-cell in a voltaic cell, the standard reduction potential provides a measure of the tendency for reduction to occur: *The more positive the value of  $E_{\text{red}}^{\circ}$ , the greater the tendency for reduction under standard conditions.* In any voltaic cell operating under standard conditions, the  $E_{\text{red}}^{\circ}$  value for the reaction at the cathode is more positive than the  $E_{\text{red}}^{\circ}$  value for the reaction at the anode. Thus, electrons flow spontaneously through the external circuit from the electrode with the more negative value of  $E_{\text{red}}^{\circ}$  to the electrode with the more positive value of  $E_{\text{red}}^{\circ}$ . **Figure 20.10** graphically illustrates the relationship between the standard reduction potentials for the two half-reactions in the Zn–Cu voltaic cell of **Figure 20.5**.

▲ **Figure 20.10** Half-cell potentials and standard cell potential for the Zn–Cu voltaic cell.

### Give It Some Thought

The standard reduction potential of  $\text{Ni}^{2+}(\text{aq})$  is  $E_{\text{red}}^{\circ} = -0.28 \text{ V}$ , and that of  $\text{Fe}^{2+}(\text{aq})$  is  $E_{\text{red}}^{\circ} = -0.44 \text{ V}$ . In a Ni–Fe voltaic cell, which electrode is the cathode, Ni or Fe?

## Sample Exercise 20.7

### Determining Half-Reactions at Electrodes and Calculating Cell Potentials

A voltaic cell is based on the two standard half-reactions

Use data in Appendix E to determine (a) which half-reaction occurs at the cathode and which occurs at the anode and (b) the standard cell potential.

### SOLUTION

**Analyze** We have to look up  $E_{\text{red}}^{\circ}$  for two half-reactions. We then use these values first to determine the cathode and the anode and then to calculate the standard cell potential,  $E_{\text{cell}}^{\circ}$ .

**Plan** The cathode will have the reduction with the more positive  $E_{\text{red}}^{\circ}$  value, and the anode will have the less positive  $E_{\text{red}}^{\circ}$ . To write the half-reaction at the anode, we reverse the half-reaction written for the reduction, so that the half-reaction is written as an oxidation.

### Solve

- (a) According to Appendix E,  $E_{\text{red}}^{\circ}(\text{Cd}^{2+}/\text{Cd}) = -0.40 \text{ V}$  and  $E_{\text{red}}^{\circ}(\text{Sn}^{2+}/\text{Sn}) = -0.14 \text{ V}$ . The standard reduction potential for  $\text{Sn}^{2+}$  is more positive (less negative) than that for  $\text{Cd}^{2+}$ . Hence, the reduction of  $\text{Sn}^{2+}$  is the reaction that occurs at the cathode:

The anode reaction, therefore, is the loss of electrons by Cd:

- (b) The cell potential is given by the difference in the standard reduction potentials at the cathode and anode (Equation 20.8):

Notice that it is unimportant that the  $E_{\text{red}}^{\circ}$  values of both half-reactions are negative; the negative values merely indicate how these reductions compare to the reference reaction, the reduction of  $\text{H}^{+}(\text{aq})$ .

$$\begin{aligned} E_{\text{cell}}^{\circ} &= E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) \\ &= (-0.14 \text{ V}) - (-0.40 \text{ V}) = 0.26 \text{ V} \end{aligned}$$

Continued

**Check** The cell potential is positive, as it must be for a voltaic cell.

► **Practice Exercise 1**

Consider three voltaic cells, each similar to the one shown in Figure 20.5. In each voltaic cell, one half-cell contains a 1.0 M  $\text{Fe}(\text{NO}_3)_2(aq)$  solution with an Fe electrode. The contents of the other half-cells are as follows:

Cell 1: a 1.0 M  $\text{CuCl}_2(aq)$  solution with a Cu electrode

Cell 2: a 1.0 M  $\text{NiCl}_2(aq)$  solution with a Ni electrode

Cell 3: a 1.0 M  $\text{ZnCl}_2(aq)$  solution with a Zn electrode

In which voltaic cell(s) does iron act as the anode?

- (a) Cell 1
- (b) Cell 2
- (c) Cell 3
- (d) Cells 1 and 2
- (e) All three cells

► **Practice Exercise 2**

A voltaic cell is based on a  $\text{Co}^{2+}/\text{Co}$  half-cell and a  $\text{AgCl}/\text{Ag}$  half-cell. (a) What half-reaction occurs at the anode?

(b) What is the standard cell potential?

## Strengths of Oxidizing and Reducing Agents

Table 20.1 lists half-reactions in the order of decreasing tendency to undergo reduction. For example,  $\text{F}_2$  is located at the top of the table, having the most positive value for  $E_{\text{red}}^\circ$ . Thus,  $\text{F}_2$  is the most easily reduced species in Table 20.1 and therefore the strongest oxidizing agent listed.

Among the most frequently used oxidizing agents are the halogens,  $\text{O}_2$ , and oxyanions such as  $\text{MnO}_4^-$ ,  $\text{Cr}_2\text{O}_7^{2-}$ , and  $\text{NO}_3^-$ , whose central atoms have high positive oxidation states. As seen in Table 20.1, all these species have large positive values of  $E_{\text{red}}^\circ$  and therefore easily undergo reduction.

The lower the tendency for a half-reaction to occur in one direction, the greater the tendency for it to occur in the opposite direction. Thus, *the half-reaction with the most negative reduction potential in Table 20.1 is the one most easily reversed and run as an oxidation*. Being at the bottom of Table 20.1,  $\text{Li}^+(aq)$  is the most difficult species in the list to reduce and is therefore the poorest oxidizing agent listed. Although  $\text{Li}^+(aq)$  has little tendency to gain electrons, the reverse reaction, oxidation of  $\text{Li}(s)$  to  $\text{Li}^+(aq)$ , is highly favorable. Thus, Li is the strongest reducing agent among the substances listed in Table 20.1. (Note that, because Table 20.1 lists half-reactions as reductions, only the substances on the reactant side of these equations can serve as oxidizing agents; only those on the product side can serve as reducing agents.)

Commonly used reducing agents include  $\text{H}_2$  and the active metals, such as the alkali metals and the alkaline earth metals. Other metals whose cations have negative  $E_{\text{red}}^\circ$  values—Zn and Fe, for example—are also used as reducing agents. Solutions of reducing agents are difficult to store for extended periods because of the ubiquitous presence of  $\text{O}_2$ , a good oxidizing agent.

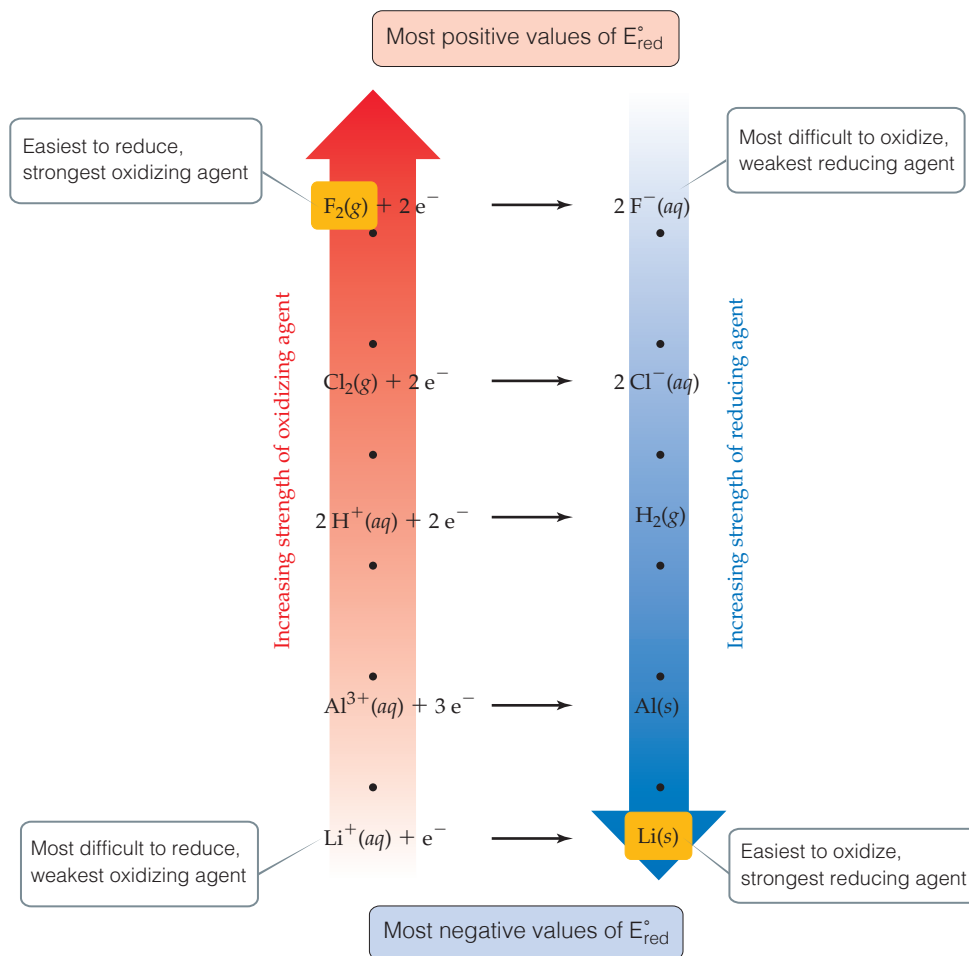

The information contained in Table 20.1 is summarized graphically in Figure 20.11. For the half-reactions at the top of Table 20.1 the substances on the reactant side of the equation are the most readily reduced species in the table and are therefore the strongest oxidizing agents. Substances on the product side of these reactions are the most difficult to oxidize and so are the weakest reducing agents in the table. Thus, Figure 20.11 shows  $\text{F}_2(g)$  as the strongest oxidizing agent and  $\text{F}^-(aq)$  as the weakest reducing agent. Conversely, the reactants in half-reactions at the bottom of Table 20.1, such as  $\text{Li}^+(aq)$  are the most difficult to reduce and so are the weakest oxidizing agents, while the products of these reactions, such as  $\text{Li}(s)$ , are the most readily oxidized species in the table and so are the strongest reducing agents.

This inverse relationship between oxidizing and reducing strength is similar to the inverse relationship between the strengths of conjugate acids and bases.  $\infty$  (Section 16.2 and Figure 16.3)

## Go Figure

Can an acidic solution oxidize a piece of aluminum?

▲ Figure 20.11 Relative strengths of oxidizing and reducing agents.

## Sample Exercise 20.8

## Determining Relative Strengths of Oxidizing Agents

Using Table 20.1, rank the following ions in the order of increasing strength as oxidizing agents:  $\text{NO}_3^-(aq)$ ,  $\text{Ag}^+(aq)$ ,  $\text{Cr}_2\text{O}_7^{2-}(aq)$ .

## SOLUTION

**Analyze** We are asked to rank the abilities of several ions to act as oxidizing agents.

**Plan** The more readily an ion is reduced (the more positive its  $E^\circ_{\text{red}}$  value), the stronger it is as an oxidizing agent.

## Solve

From Table 20.1, we have:

Because the standard reduction potential of  $\text{Cr}_2\text{O}_7^{2-}$  is the most positive,  $\text{Cr}_2\text{O}_7^{2-}$  is the strongest oxidizing agent of the three. The rank order is:

## ► Practice Exercise 1

Based on the data in Table 20.1, which of the following species would you expect to be the strongest oxidizing agent? (a)  $\text{Cl}^-(aq)$  (b)  $\text{Cl}_2(g)$  (c)  $\text{O}_2(g)$  (d)  $\text{H}^+(aq)$  (e)  $\text{Na}^+(aq)$

## ► Practice Exercise 2

Using Table 20.1, rank the following species from the strongest to the weakest reducing agent:  $\text{I}^-(aq)$ ,  $\text{Fe}(s)$ ,  $\text{Al}(s)$ .

## 20.5 | Free Energy and Redox Reactions

We have observed that voltaic cells use spontaneous redox reactions to produce a positive cell potential. Given half-cell potentials, we can determine whether a given redox reaction is spontaneous. In this endeavor, we can use a form of Equation 20.8 that describes redox reactions in general, not just reactions in voltaic cells:

$$E^\circ = E^\circ_{\text{red}} (\text{reduction process}) - E^\circ_{\text{red}} (\text{oxidation process}) \quad [20.10]$$

In writing the equation this way, we have dropped the subscript “cell” to indicate that the calculated emf does not necessarily refer to a voltaic cell. Also, we have generalized the standard reduction potentials by using the general terms *reduction* and *oxidation* rather than the terms specific to voltaic cells, *cathode* and *anode*. We can now make a general statement about the spontaneity of a reaction and its associated emf,  $E$ : *A positive value of  $E$  indicates a spontaneous process; a negative value of  $E$  indicates a nonspontaneous process.* We use  $E$  to represent the emf under nonstandard conditions and  $E^\circ$  to indicate the standard emf.

### Sample Exercise 20.9

#### Determining Spontaneity

Use Table 20.1 to determine whether the following reactions are spontaneous under standard conditions.

#### SOLUTION

**Analyze** We are given two reactions and must determine whether each is spontaneous.

**Plan** To determine whether a redox reaction is spontaneous under standard conditions, we first need to write its reduction and

oxidation half-reactions. We can then use the standard reduction potentials and Equation 20.10 to calculate the standard emf,  $E^\circ$ , for the reaction. If a reaction is spontaneous, its standard emf must be a positive number.

#### Solve

- (a) We first must identify the oxidation and reduction half-reactions that when combined give the overall reaction.

We look up standard reduction potentials for both half-reactions and use them to calculate  $E^\circ$  using Equation 20.10:

$$\begin{aligned} E^\circ &= E^\circ_{\text{red}} (\text{reduction process}) - E^\circ_{\text{red}} (\text{oxidation process}) \\ &= (0\text{ V}) - (0.34\text{ V}) = -0.34\text{ V} \end{aligned}$$

Because  $E^\circ$  is negative, the reaction is not spontaneous in the direction written. Copper metal does not react with acids as written in Equation (a). The reverse reaction, however, is spontaneous and has a positive  $E^\circ$  value:

Thus,  $\text{Cu}^{2+}$  can be reduced by  $\text{H}_2$ .

- (b) We follow a procedure analogous to that in (a):

In this case:

$$E^\circ = (1.36\text{ V}) - (0.54\text{ V}) = +0.82\text{ V}$$

Because the value of  $E^\circ$  is positive, this reaction is spontaneous and could be used to build a voltaic cell.

#### Practice Exercise 1

Which of the following elements is capable of oxidizing  $\text{Fe}^{2+}(aq)$  ions to  $\text{Fe}^{3+}(aq)$  ions: chlorine, bromine, iodine?  
(a)  $\text{I}_2$  (b)  $\text{Cl}_2$  (c)  $\text{Cl}_2$  and  $\text{I}_2$  (d)  $\text{Cl}_2$  and  $\text{Br}_2$  (e) all three elements

#### Practice Exercise 2

Using the standard reduction potentials listed in Appendix E, determine which of the following reactions are spontaneous under standard conditions:

We can use standard reduction potentials to understand the activity series of metals. [∞ \(Section 4.4\)](#) Recall that any metal in the activity series (Table 4.5) is oxidized by the ions of any metal below it. We can now recognize the origin of this rule based on standard reduction potentials. The activity series is based on the oxidation reactions of the metals, ordered from strongest reducing agent at the top to weakest reducing agent at the bottom. (Thus, the ordering is inverted relative to that in Table 20.1.) For example, nickel lies above silver in the activity series, making nickel the stronger reducing agent. Because a reducing agent is oxidized in any redox reaction, nickel is more easily oxidized than silver. In a mixture of nickel metal and silver cations, therefore, we expect a displacement reaction in which the silver ions are displaced in the solution by nickel ions:

In this reaction, Ni is oxidized and  $\text{Ag}^+$  is reduced. Therefore, the standard emf for the reaction is

$$\begin{aligned} E^\circ &= E^\circ_{\text{red}}(\text{Ag}^+/\text{Ag}) - E^\circ_{\text{red}}(\text{Ni}^{2+}/\text{Ni}) \\ &= (+0.80 \text{ V}) - (-0.28 \text{ V}) = +1.08 \text{ V} \end{aligned}$$

The positive value of  $E^\circ$  indicates that the displacement of silver by nickel resulting from oxidation of Ni metal and reduction of  $\text{Ag}^+$  is a spontaneous process. Remember that although we multiply the silver half-reaction by 2, the reduction potential is not multiplied.

### Give It Some Thought

Based on their relative positions in Table 4.5, which will have a more positive standard reduction potential,  $\text{Sn}^{2+}$  or  $\text{Ni}^{2+}$ ?

## Emf, Free Energy, and the Equilibrium Constant

The change in the Gibbs free energy,  $\Delta G$ , is a measure of the spontaneity of a process that occurs at constant temperature and pressure. [∞ \(Section 19.5\)](#) The emf,  $E$ , of a redox reaction also indicates whether the reaction is spontaneous. The relationship between emf and the free-energy change is

$$\Delta G = -nFE \quad [20.11]$$

In this equation,  $n$  is a positive number without units that represents the number of moles of electrons transferred according to the balanced equation for the reaction, and  $F$  is the **Faraday constant**, named after Michael Faraday ([Figure 20.12](#)):

$$F = 96,485 \text{ C/mol} = 96,485 \text{ J/V}\cdot\text{mol}$$

The Faraday constant is the quantity of electrical charge on 1 mol of electrons.

The units of  $\Delta G$  calculated with Equation 20.11 are J/mol. As in Equation 19.19, we use “per mole” to mean per mole of reaction as indicated by the coefficients in the balanced equation. [∞ \(Section 19.7\)](#)

Because both  $n$  and  $F$  are positive numbers, a positive value of  $E$  in Equation 20.11 leads to a negative value of  $\Delta G$ . Remember: *A positive value of  $E$  and a negative value of  $\Delta G$  both indicate a spontaneous reaction.* When the reactants and products are all in their standard states, Equation 20.11 can be modified to relate  $\Delta G^\circ$  and  $E^\circ$ .

$$\Delta G^\circ = -nFE^\circ \quad [20.12]$$

Because  $\Delta G^\circ$  is related to the equilibrium constant,  $K$ , for a reaction by the expression  $\Delta G^\circ = -RT \ln K$  (Equation 19.20), we can relate  $E^\circ$  to  $K$  by solving Equation 20.12 for  $E^\circ$  and then substituting the Equation 19.20 expression for  $\Delta G^\circ$ .

$$E^\circ = \frac{\Delta G^\circ}{-nF} = \frac{-RT \ln K}{-nF} = \frac{RT}{nF} \ln K \quad [20.13]$$

[Figure 20.13](#) summarizes the relationships among  $E^\circ$ ,  $\Delta G^\circ$ , and  $K$ .

**▲ Figure 20.12 Michael Faraday.** Faraday (1791–1867) was born in England, a child of a poor blacksmith. At the age of 14 he was apprenticed to a bookbinder who gave him time to read and to attend lectures. In 1812 he became an assistant in Humphry Davy’s laboratory at the Royal Institution. He succeeded Davy as the most famous and influential scientist in England, making an amazing number of important discoveries, including his formulation of the quantitative relationships between electrical current and the extent of chemical reaction in electrochemical cells.

## Go Figure

What does the variable  $n$  represent in the  $\Delta G^\circ$  and  $E^\circ$  equations?

▲ **Figure 20.13 Relationships of  $E^\circ$ ,  $\Delta G^\circ$ , and  $K$ .** Any one of these important parameters can be used to calculate the other two. The signs of  $E^\circ$  and  $\Delta G^\circ$  determine the direction in which the reaction proceeds under standard conditions. The magnitude of  $K$  determines the relative amounts of reactants and products in an equilibrium mixture.

## Sample Exercise 20.10

Using Standard Reduction Potentials to Calculate  $\Delta G^\circ$  and  $K$ 

- (a) Use the standard reduction potentials in Table 20.1 to calculate the standard free-energy change,  $\Delta G^\circ$ , and the equilibrium constant,  $K$ , at 298 K for the reaction

- (b) Suppose the reaction in part (a) is written

What are the values of  $E^\circ$ ,  $\Delta G^\circ$ , and  $K$  when the reaction is written in this way?

## SOLUTION

**Analyze** We are asked to determine  $\Delta G^\circ$  and  $K$  for a redox reaction, using standard reduction potentials.

**Plan** We use the data in Table 20.1 and Equation 20.10 to determine  $E^\circ$  for the reaction and then use  $E^\circ$  in Equation 20.12 to calculate  $\Delta G^\circ$ . We can then use either Equation 19.20 or Equation 20.13 to calculate  $K$ .

## Solve

- (a) We first calculate  $E^\circ$  by breaking the equation into two half-reactions and obtaining  $E^\circ_{\text{red}}$  values from Table 20.1 (or Appendix E):

Even though the second half-reaction has 4 Ag, we use the  $E^\circ_{\text{red}}$  value directly from Table 20.1 because emf is an intensive property.

Using Equation 20.10, we have:

$$E^\circ = (1.23 \text{ V}) - (0.80 \text{ V}) = 0.43 \text{ V}$$

The half-reactions show the transfer of four electrons. Thus, for this reaction  $n = 4$ . We now use Equation 20.12 to calculate  $\Delta G^\circ$ :

$$\begin{aligned} \Delta G^\circ &= -nFE^\circ \\ &= -(4)(96,485 \text{ J/V}\cdot\text{mol})(+0.43 \text{ V}) \\ &= -1.7 \times 10^5 \text{ J/mol} = -170 \text{ kJ/mol} \end{aligned}$$

Now we need to calculate the equilibrium constant,  $K$ , using  $\Delta G^\circ = RT \ln K$ . Because  $\Delta G^\circ$  is a large negative number, which means the reaction is thermodynamically very favorable, we expect  $K$  to be large.

$$\begin{aligned} \Delta G^\circ &= -RT \ln K \\ -1.7 \times 10^5 \text{ J/mol} &= -(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K}) \ln K \\ \ln K &= \frac{-1.7 \times 10^5 \text{ J/mol}}{-(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K})} \\ \ln K &= 69 \\ K &= 9 \times 10^{29} \end{aligned}$$

- (b) The overall equation is the same as that in part (a), multiplied by  $\frac{1}{2}$ . The half-reactions are:

The values of  $E^\circ_{\text{red}}$  are the same as they were in part (a); they are not changed by multiplying the half-reactions by  $\frac{1}{2}$ . Thus,  $E^\circ$  has the same value as in part (a):  $E^\circ = +0.43 \text{ V}$ . Notice, though, that the value of  $n$  has changed to  $n = 2$ , which is one-half the value in part (a). Thus,  $\Delta G^\circ$  is half as large as in part (a):

$$\Delta G^\circ = -(2)(96,485 \text{ J/V}\cdot\text{mol})(+0.43 \text{ V}) = -83 \text{ kJ/mol}$$

The value of  $\Delta G^\circ$  is half that in part (a) because the coefficients in the chemical equation are half those in (a).

Now we can calculate  $K$  as before:

$$\begin{aligned} -8.3 \times 10^4 \text{ J/mol} &= -(8.314 \text{ J/K}\cdot\text{mol})(298 \text{ K}) \ln K \\ K &= 4 \times 10^{14} \end{aligned}$$

**Comment**  $E^\circ$  is an *intensive* quantity, so multiplying a chemical equation by a certain factor will not affect the value of  $E^\circ$ . Multiplying an equation will change the value of  $n$ , however, and hence the value of  $\Delta G^\circ$ . The change in free energy, in units of J/mol of reaction as written, is an *extensive* quantity. The equilibrium constant is also an extensive quantity.

### Practice Exercise 1

For the reaction

$\Delta G^\circ = +87 \text{ kJ/mol}$ . Given the standard reduction potential of  $\text{Ni}^{2+}(\text{aq})$  in Table 20.1, what value do you calculate for the standard reduction potential of the half-reaction

### Practice Exercise 2

Consider the reaction

## A CLOSER LOOK Electrical Work

For any spontaneous process,  $\Delta G$  is a measure of the maximum useful work,  $w_{\text{max}}$ , that can be extracted from the process:  $\Delta G = w_{\text{max}}$ . (Section 19.5) Because  $\Delta G = -nFE$ , the maximum useful electrical work obtainable from a voltaic cell is

$$w_{\text{max}} = -nFE_{\text{cell}} \quad [20.14]$$

Because cell emf,  $E_{\text{cell}}$ , is always positive for a voltaic cell,  $w_{\text{max}}$  is negative, indicating that work is done *by* a system *on* its surroundings, as we expect for a voltaic cell. (Section 5.2)

As Equation 20.14 shows, the more charge a voltaic cell moves through a circuit (that is, the larger  $nF$  is) and the larger the emf pushing the electrons through the circuit (that is, the larger  $E_{\text{cell}}$  is), the more work the cell can accomplish. In Sample Exercise 20.10, we calculated  $\Delta G^\circ = -170 \text{ kJ/mol}$  for the reaction  $4 \text{ Ag}(\text{s}) + \text{O}_2(\text{g}) + 4 \text{ H}^+(\text{aq}) \longrightarrow 4 \text{ Ag}^+(\text{aq}) + 2 \text{ H}_2\text{O}(\text{l})$ . Thus, a voltaic cell utilizing this reaction could perform a maximum of 170 kJ of work in consuming 4 mol Ag, 1 mol  $\text{O}_2$ , and 4 mol  $\text{H}^+$ .

If a reaction is not spontaneous,  $\Delta G$  is positive and  $E$  is negative. To force a nonspontaneous reaction to occur in an electrochemical cell, we need to apply an external potential,  $E_{\text{ext}}$ , that exceeds  $|E_{\text{cell}}|$ . For example, if a nonspontaneous process has  $E = -0.9 \text{ V}$ , then the external potential  $E_{\text{ext}}$  must be greater than  $+0.9 \text{ V}$  in order for the process to occur. We will examine such nonspontaneous processes in Section 20.9.

Electrical work can be expressed in energy units of watts times time. The *watt* (W) is a unit of electrical power (that is, rate of energy expenditure):

$$1 \text{ W} = 1 \text{ J/s}$$

Thus, a watt-second is a joule. The unit employed by electric utilities is the kilowatt-hour (kWh), which equals  $3.6 \times 10^6 \text{ J}$ :

$$1 \text{ kWh} = (1000 \text{ W})(1 \text{ h}) \left( \frac{3600 \text{ s}}{1 \text{ h}} \right) \left( \frac{1 \text{ J/s}}{1 \text{ W}} \right) = 3.6 \times 10^6 \text{ J}$$

**Related Exercises:** 20.59, 20.60

## 20.6 | Cell Potentials under Nonstandard Conditions

We have seen how to calculate the emf of a cell when the reactants and products are under standard conditions. As a voltaic cell is discharged, however, reactants are consumed and products are generated, so concentrations change. The emf progressively drops until  $E = 0$ , at which point we say the cell is “dead.” In this section, we examine how the emf generated under nonstandard conditions can be calculated by using an equation first derived by Walther Nernst (1864–1941), a German chemist who established many of the theoretical foundations of electrochemistry.

## The Nernst Equation

The effect of concentration on cell emf can be obtained from the effect of concentration on free-energy change. [∞ \(Section 19.7\)](#) Recall that the free-energy change for any chemical reaction,  $\Delta G$ , is related to the standard free-energy change for the reaction,  $\Delta G^\circ$ :

$$\Delta G = \Delta G^\circ + RT \ln Q \quad [20.15]$$

The quantity  $Q$  is the reaction quotient, which has the form of the equilibrium-constant expression except that the concentrations are those that exist in the reaction mixture at a given moment. [∞ \(Section 15.6\)](#)

Substituting  $\Delta G = -nFE$  (Equation 20.11) into Equation 20.15 gives

$$-nFE = -nFE^\circ + RT \ln Q$$

Solving this equation for  $E$  gives the **Nernst equation**:

$$E = E^\circ - \frac{RT}{nF} \ln Q \quad [20.16]$$

This equation is customarily expressed in terms of the base-10 logarithm:

$$E = E^\circ - \frac{2.303 RT}{nF} \log Q \quad [20.17]$$

At  $T = 298 \text{ K}$ , the quantity  $2.303 RT/F$  equals  $0.0592$ , with units of volts, and so the Nernst equation simplifies to

$$E = E^\circ - \frac{0.0592 \text{ V}}{n} \log Q \quad (T = 298 \text{ K}) \quad [20.18]$$

We can use this equation to find the emf  $E$  produced by a cell under nonstandard conditions or to determine the concentration of a reactant or product by measuring  $E$  for the cell. For example, consider the following reaction:

In this case  $n = 2$  (two electrons are transferred from Zn to  $\text{Cu}^{2+}$ ), and the standard emf is  $+1.10 \text{ V}$ . [∞ \(Section 20.4\)](#) Thus, at  $298 \text{ K}$  the Nernst equation gives

$$E = 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \frac{[\text{Zn}^{2+}]}{[\text{Cu}^{2+}]} \quad [20.19]$$

Recall that pure solids are excluded from the expression for  $Q$ . [∞ \(Section 15.6\)](#) According to Equation 20.19, the emf increases as  $[\text{Cu}^{2+}]$  increases and as  $[\text{Zn}^{2+}]$  decreases. For example, when  $[\text{Cu}^{2+}]$  is  $5.0 \text{ M}$  and  $[\text{Zn}^{2+}]$  is  $0.050 \text{ M}$ , we have

$$\begin{aligned} E &= 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} \log \left( \frac{0.050}{5.0} \right) \\ &= 1.10 \text{ V} - \frac{0.0592 \text{ V}}{2} (-2.00) = 1.16 \text{ V} \end{aligned}$$

Thus, increasing the concentration of reactant  $\text{Cu}^{2+}$  and decreasing the concentration of product  $\text{Zn}^{2+}$  relative to standard conditions increases the emf of the cell relative to standard conditions ( $E^\circ = +1.10 \text{ V}$ ).

The Nernst equation helps us understand why the emf of a voltaic cell drops as the cell discharges. As reactants are converted to products, the value of  $Q$  increases, so the value of  $E$  decreases, eventually reaching  $E = 0$ . Because  $\Delta G = -nFE$  (Equation 20.11), it follows that  $\Delta G = 0$  when  $E = 0$ . Recall that a system is at equilibrium when  $\Delta G = 0$ . [∞ \(Section 19.7\)](#) Thus, when  $E = 0$ , the cell reaction has reached equilibrium, and no net reaction occurs.

In general, increasing the concentration of reactants or decreasing the concentration of products increases the driving force for the reaction, resulting in a higher emf. Conversely, decreasing the concentration of reactants or increasing the concentration of products causes the emf to decrease from its value under standard conditions.

## Sample Exercise 20.11

### Cell Potential under Nonstandard Conditions

Calculate the emf at 298 K generated by a voltaic cell in which the reaction is

when

$$[\text{Cr}_2\text{O}_7^{2-}] = 2.0 \text{ M}, [\text{H}^+] = 1.0 \text{ M}, [\text{I}^-] = 1.0 \text{ M}, \text{ and } [\text{Cr}^{3+}] = 1.0 \times 10^{-5} \text{ M}$$

### SOLUTION

**Analyze** We are given a chemical equation for a voltaic cell and the concentrations of reactants and products under which it operates. We are asked to calculate the emf of the cell under these nonstandard conditions.

#### Solve

We calculate  $E^\circ$  for the cell from standard reduction potentials (Table 20.1 or Appendix E). The standard emf for this reaction was calculated in Sample Exercise 20.6:  $E^\circ = 0.79 \text{ V}$ . As that exercise shows, six electrons are transferred from reducing agent to oxidizing agent, so  $n = 6$ . The reaction quotient,  $Q$ , is:

$$\begin{aligned} Q &= \frac{[\text{Cr}^{3+}]^2}{[\text{Cr}_2\text{O}_7^{2-}][\text{H}^+]^{14}[\text{I}^-]^6} \\ &= \frac{(1.0 \times 10^{-5})^2}{(2.0)(1.0)^{14}(1.0)^6} = 5.0 \times 10^{-11} \end{aligned}$$

Using Equation 20.18, we have:

$$\begin{aligned} E &= 0.79 \text{ V} - \left( \frac{0.0592 \text{ V}}{6} \right) \log(5.0 \times 10^{-11}) \\ &= 0.79 \text{ V} - \left( \frac{0.0592 \text{ V}}{6} \right) (-10.30) \\ &= 0.79 \text{ V} + 0.10 \text{ V} = 0.89 \text{ V} \end{aligned}$$

**Check** This result is qualitatively what we expect: Because the concentration of  $\text{Cr}_2\text{O}_7^{2-}$  (a reactant) is greater than 1 M and the concentration of  $\text{Cr}^{3+}$  (a product) is less than 1 M, the emf is greater than  $E^\circ$ . Because  $Q$  is about  $10^{-10}$ ,  $\log Q$  is about  $-10$ . Thus, the correction to  $E^\circ$  is about  $0.06 \times 10/6$ , which is 0.1, in agreement with the more detailed calculation.

#### Practice Exercise 1

Consider a voltaic cell whose overall reaction is  $\text{Pb}^{2+}(\text{aq}) + \text{Zn}(\text{s}) \longrightarrow \text{Pb}(\text{s}) + \text{Zn}^{2+}(\text{aq})$ . What is the emf

generated by this voltaic cell when the ion concentrations are  $[\text{Pb}^{2+}] = 1.5 \times 10^{-3} \text{ M}$  and  $[\text{Zn}^{2+}] = 0.55 \text{ M}$ ?  
(a) 0.71 V (b) 0.56 V (c) 0.49 V (d) 0.79 V (e) 0.64 V

#### Practice Exercise 2

For the Zn–Cu voltaic cell depicted in Figure 20.5, would the emf increase, decrease, or stay the same, if you increased the  $\text{Cu}^{2+}(\text{aq})$  concentration by adding  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  to the cathode compartment?

## Sample Exercise 20.12

### Calculating Concentrations in a Voltaic Cell

If the potential of a Zn– $\text{H}_2$  cell (like that in Figure 20.9) is 0.45 V at 25 °C when  $[\text{Zn}^{2+}] = 1.0 \text{ M}$  and  $P_{\text{H}_2} = 1.0 \text{ atm}$ , what is the pH of the cathode solution?

### SOLUTION

**Analyze** We are given a description of a voltaic cell, its emf, the concentration of  $\text{Zn}^{2+}$ , and the partial pressure of  $\text{H}_2$  (both products in the cell reaction). We are asked to calculate the pH of the cathode solution, which we can calculate from the concentration of  $\text{H}^+$ , a reactant.

**Plan** We write the equation for the cell reaction and use standard reduction potentials to calculate  $E^\circ$  for the reaction. After determining the value of  $n$  from our reaction equation, we solve the Nernst equation, Equation 20.18, for  $Q$ . We use the equation for the cell reaction to write an expression for  $Q$  that contains  $[\text{H}^+]$  to determine  $[\text{H}^+]$ . Finally, we use  $[\text{H}^+]$  to calculate pH.

#### Solve

The cell reaction is:

The standard emf is:

$$\begin{aligned} E^\circ &= E^\circ_{\text{red}}(\text{reduction}) - E^\circ_{\text{red}}(\text{oxidation}) \\ &= 0 \text{ V} - (-0.76 \text{ V}) = +0.76 \text{ V} \end{aligned}$$

Because each Zn atom loses two electrons,

$$n = 2$$

Continued

Using Equation 20.18, we can solve for  $Q$ :

$$0.45 \text{ V} = 0.76 \text{ V} - \frac{0.0592 \text{ V}}{2} \log Q$$

$$Q = 10^{10.5} = 3 \times 10^{10}$$

$Q$  has the form of the equilibrium constant for the reaction:

$$Q = \frac{[\text{Zn}^{2+}]P_{\text{H}_2}}{[\text{H}^+]^2} = \frac{(1.0)(1.0)}{[\text{H}^+]^2} = 3 \times 10^{10}$$

Solving for  $[\text{H}^+]$ , we have:

$$[\text{H}^+]^2 = \frac{1.0}{3 \times 10^{10}} = 3 \times 10^{-11}$$

$$[\text{H}^+] = \sqrt{3 \times 10^{-11}} = 6 \times 10^{-6} \text{ M}$$

Finally, we use  $[\text{H}^+]$  to calculate the pH of the cathode solution.

$$\text{pH} = \log [\text{H}^+] = -\log (6 \times 10^{-6}) = 5.2$$

**Comment** A voltaic cell whose cell reaction involves  $\text{H}^+$  can be used to measure  $[\text{H}^+]$  or pH. A pH meter is a specially designed voltaic cell with a voltmeter calibrated to read pH directly.  $\infty\infty$  (Section 16.4)

### ► Practice Exercise 1

Consider a voltaic cell where the anode half-reaction is  $\text{Zn}(s) \longrightarrow \text{Zn}^{2+}(aq) + 2e^-$  and the cathode half-reaction is  $\text{Sn}^{2+}(aq) + 2e^- \longrightarrow \text{Sn}(s)$ . What is the concentration of

$\text{Sn}^{2+}$  if  $\text{Zn}^{2+}$  is  $2.5 \times 10^{-3} \text{ M}$  and the cell emf is 0.660 V? Use the reduction potentials in Appendix E that are reported to three significant figures. (a)  $3.3 \times 10^{-2} \text{ M}$  (b)  $1.9 \times 10^{-4} \text{ M}$  (c)  $9.0 \times 10^{-3} \text{ M}$  (d)  $6.9 \times 10^{-4} \text{ M}$  (e)  $7.6 \times 10^{-3} \text{ M}$

### ► Practice Exercise 2

What is the pH of the solution in the cathode half-cell in Figure 20.9 when  $P_{\text{H}_2} = 1.0 \text{ atm}$ ,  $[\text{Zn}^{2+}]$  in the anode half-cell is 0.10 M, and the cell emf is 0.542 V?

## Concentration Cells

In the voltaic cells we have looked at thus far, the reactive species at the anode has been different from the reactive species at the cathode. Cell emf depends on concentration, however, so a voltaic cell can be constructed using the *same* species in both half-cells as long as the concentrations are different. A cell based solely on the emf generated because of a difference in a concentration is called a **concentration cell**.

An example of a concentration cell is diagrammed in **Figure 20.14(a)**. One half-cell consists of a strip of nickel metal immersed in a  $1.00 \times 10^{-3} \text{ M}$  solution of  $\text{Ni}^{2+}(aq)$ . The other half-cell also has an  $\text{Ni}(s)$  electrode, but it is immersed in a 1.00 M solution of  $\text{Ni}^{2+}(aq)$ . The two half-cells are connected by a salt bridge and by an

### Go Figure

Which electrode, if any, gains mass as the reaction proceeds?

▲ **Figure 20.14** Concentration cell based on  $\text{Ni}^{2+}$ – $\text{Ni}$  cell reaction. (a) Concentrations of  $\text{Ni}^{2+}(aq)$  in the two half-cells are unequal, and the cell generates an electrical current and a voltage. (b) The cell operates until  $[\text{Ni}^{2+}]$  is the same in the two half-cells, at which point the cell has reached equilibrium and the emf goes to zero.

external wire running through a voltmeter. The half-cell reactions are the reverse of each other:

Although the *standard* emf for this cell is zero,

$$E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode}) = (-0.28\text{ V}) - (-0.28\text{ V}) = 0\text{ V}$$

the cell operates under *nonstandard* conditions because the concentration of  $\text{Ni}^{2+}(\text{aq})$  is not 1 M in both half-cells. In fact, the cell operates until  $[\text{Ni}^{2+}]_{\text{anode}} = [\text{Ni}^{2+}]_{\text{cathode}}$ . Oxidation of  $\text{Ni(s)}$  occurs in the half-cell containing the more dilute solution, which means this is the anode of the cell. Reduction of  $\text{Ni}^{2+}(\text{aq})$  occurs in the half-cell containing the more concentrated solution, making it the cathode. The *overall* cell reaction is therefore

We can calculate the emf of a concentration cell by using the Nernst equation. For this particular cell, we see that  $n = 2$ . The expression for the reaction quotient for the overall reaction is  $Q = [\text{Ni}^{2+}]_{\text{dilute}}/[\text{Ni}^{2+}]_{\text{concentrated}}$ . Thus, the emf at 298 K is

$$\begin{aligned} E &= E^{\circ} - \frac{0.0592\text{ V}}{n} \log Q \\ &= 0 - \frac{0.0592\text{ V}}{2} \log \frac{[\text{Ni}^{2+}]_{\text{dilute}}}{[\text{Ni}^{2+}]_{\text{concentrated}}} = -\frac{0.0592\text{ V}}{2} \log \frac{1.00 \times 10^{-3}\text{ M}}{1.00\text{ M}} \\ &= +0.089\text{ V} \end{aligned}$$

This concentration cell generates an emf of nearly 0.09 V, even though  $E^{\circ} = 0$ . The difference in concentration provides the driving force for the cell. When the concentrations in the two half-cells become the same,  $Q = 1$  and  $E = 0$ .

The idea of generating a potential by a concentration difference is the basis for the operation of pH meters. It is also a critical aspect in biology. For example, nerve cells in the brain generate a potential across the cell membrane by having different concentrations of ions on the two sides of the membrane. Electric eels use cells called electrocytes that are based on a similar principle to generate short, but intense, pulses of electricity to stun prey and dissuade predators (Figure 20.15). The regulation of the heartbeat in mammals, as discussed in the following Chemistry and Life box, is another example of the importance of electrochemistry to living organisms.

◀ **Figure 20.15** An electric eel. Differences in ion concentrations, mainly  $\text{Na}^{+}$  and  $\text{K}^{+}$ , in special cells called electrocytes produce an emf on the order of 0.1 V. By connecting thousands of these cells in series, these South American fish are able to generate short electric pulses as high as 500 V.

## CHEMISTRY AND LIFE Heartbeats and Electrocardiography

The human heart is a marvel of efficiency and dependability. In a typical day, an adult's heart pumps more than 7000 L of blood through the circulatory system, usually with no maintenance required beyond a sensible diet and lifestyle. We generally think of the heart as a mechanical device, a muscle that circulates blood via regularly spaced muscular contractions. However, more than two centuries ago, two pioneers in electricity, Luigi Galvani (1729–1787) and Alessandro Volta (1745–1827), discovered that the contractions of the heart are controlled by electrical phenomena, as are nerve impulses throughout the body. The pulses of electricity that cause the heart to beat result from a remarkable combination of electrochemistry and the properties of semipermeable membranes.  $\infty$  (Section 13.5)

Cell walls are membranes with variable permeability with respect to a number of physiologically important ions (especially  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Ca}^{2+}$ ). The concentrations of these ions are different for the fluids inside the cells (the *intracellular fluid*, or ICF) and outside the cells (the *extracellular fluid*, or ECF). In cardiac muscle cells, for example, the concentrations of  $\text{K}^+$  in the ICF and ECF are typically about 135 millimolar (mM) and 4 mM, respectively. For  $\text{Na}^+$ , however, the concentration difference between the ICF and ECF is opposite to that for  $\text{K}^+$ ; typically,  $[\text{Na}^+]_{\text{ICF}} = 10 \text{ mM}$  and  $[\text{Na}^+]_{\text{ECF}} = 145 \text{ mM}$ .

The cell membrane is initially permeable to  $\text{K}^+$  ions but is much less so to  $\text{Na}^+$  and  $\text{Ca}^{2+}$ . The difference in concentration of  $\text{K}^+$  ions between the ICF and ECF generates a concentration cell. Even though the same ions are present on both sides of the membrane, there is a potential difference between the two fluids that we can calculate using the Nernst equation with  $E^\circ = 0$ . At physiological temperature ( $37^\circ\text{C}$ ) the potential in millivolts for moving  $\text{K}^+$  from the ECF to the ICF is

$$\begin{aligned} E &= E^\circ - \frac{2.30RT}{nF} \log \frac{[\text{K}^+]_{\text{ICF}}}{[\text{K}^+]_{\text{ECF}}} \\ &= 0 - (61.5 \text{ mV}) \log \left( \frac{135 \text{ mM}}{4 \text{ mM}} \right) = -94 \text{ mV} \end{aligned}$$

In essence, the interior of the cell and the ECF together serve as a voltaic cell. The negative sign for the potential indicates that work is required to move  $\text{K}^+$  into the ICF.

Changes in the relative concentrations of the ions in the ECF and ICF lead to changes in the emf of the voltaic cell. The cells of the heart that govern the rate of heart contraction are called the *pacemaker cells*. The membranes of the cells regulate the concentrations of ions in the ICF, allowing them to change in a systematic way. The concentration changes cause the emf to change in a cyclic fashion, as shown in Figure 20.16. The emf cycle determines the rate at which the heart beats. If the pacemaker cells malfunction because of disease or injury, an artificial pacemaker can be surgically implanted. The artificial pacemaker contains a small battery

▲ Figure 20.16 Changes in electrical potential in the human heart.

Variation of the electrical potential caused by changes of ion concentrations in the pacemaker cells of the heart.

that generates the electrical pulses needed to trigger the contractions of the heart.

During the late 1800s, scientists discovered that the electrical impulses that cause the contraction of the heart muscle are strong enough to be detected at the surface of the body. This observation formed the basis for *electrocardiography*, noninvasive monitoring of the heart by using a complex array of electrodes on the skin to measure voltage changes during heartbeats. A typical electrocardiogram is shown in Figure 20.17. It is quite striking that, although the heart's major function is the *mechanical* pumping of blood, it is most easily monitored by using the *electrical* impulses generated by tiny voltaic cells.

▲ Figure 20.17 A typical electrocardiogram. The printout records the electrical events monitored by electrodes attached to the body surface.

## Sample Exercise 20.13

## Determining pH Using a Concentration Cell

A voltaic cell is constructed with two hydrogen electrodes. Electrode 1 has  $P_{\text{H}_2} = 1.00 \text{ atm}$  and an unknown concentration of  $\text{H}^+(aq)$ . Electrode 2 is a standard hydrogen electrode ( $P_{\text{H}_2} = 1.00 \text{ atm}$ ,  $[\text{H}^+] = 1.00 \text{ M}$ ). At 298 K the measured cell potential is 0.211 V, and the electrical current is observed to flow from electrode 1 through the external circuit to electrode 2. What is the pH of the solution at electrode 1?

## SOLUTION

**Analyze** We are given the potential of a concentration cell and the direction in which the current flows. We also have the concentrations or partial pressures of all reactants and products except for  $[\text{H}^+]$  in half-cell 1, which is our unknown.

**Plan** We can use the Nernst equation to determine  $Q$  and then use  $Q$  to calculate the unknown concentration. Because this is a concentration cell,  $E^\circ_{\text{cell}} = 0 \text{ V}$ .

**Solve**

Using the Nernst equation, we have:

$$0.211 \text{ V} = 0 - \frac{0.0592 \text{ V}}{2} \log Q$$

$$\log Q = -(0.211 \text{ V}) \left( \frac{2}{0.0592 \text{ V}} \right) = -7.13$$

$$Q = 10^{-7.13} = 7.4 \times 10^{-8}$$

Because electrons flow from electrode 1 to electrode 2, electrode 1 is the anode of the cell and electrode 2 is the cathode. The electrode reactions are therefore as follows, with the concentration of  $\text{H}^+(aq)$  in electrode 1 represented with the unknown  $x$ :

Thus,

$$Q = \frac{[\text{H}^+(aq, x M)]^2}{[\text{H}^+(aq, 1.00 M)]^2}$$

$$= \frac{x^2}{(1.00)^2} = x^2 = 7.4 \times 10^{-8}$$

$$x = [\text{H}^+] = \sqrt{7.4 \times 10^{-8}} = 2.7 \times 10^{-4}$$

At electrode 1, therefore, the pH of the solution is:

$$\text{pH} = -\log[\text{H}^+] = -\log(2.7 \times 10^{-4}) = 3.57$$

**Comment** The concentration of  $\text{H}^+$  at electrode 1 is lower than that in electrode 2, which is why electrode 1 is the anode of the cell: The oxidation of  $\text{H}_2$  to  $\text{H}^+(aq)$  increases  $[\text{H}^+]$  at electrode 1.

► **Practice Exercise 1**

A concentration cell constructed from two hydrogen electrodes, both with  $P_{\text{H}_2} = 1.00$ . One electrode is immersed in pure  $\text{H}_2\text{O}$  and the other in  $6.0 M$  hydrochloric acid. What is the emf generated by the cell, and what is the identity of the electrode that is immersed in hydrochloric acid?

(a)  $-0.23 \text{ V}$ , cathode

(b)  $0.46 \text{ V}$ , anode

(c)  $0.023 \text{ V}$ , anode

(d)  $0.23 \text{ V}$ , cathode

(e)  $0.23 \text{ V}$ , anode

► **Practice Exercise 2**

A concentration cell is constructed with two  $\text{Zn}(s) - \text{Zn}^{2+}(aq)$  half-cells. In one half-cell  $[\text{Zn}^{2+}] = 1.35 M$ , and in the other  $[\text{Zn}^{2+}] = 3.75 \times 10^{-4} M$ . (a) Which half-cell is the anode? (b) What is the emf of the cell?

## 20.7 | Batteries and Fuel Cells

A **battery** is a portable, self-contained electrochemical power source that consists of one or more voltaic cells. For example, the  $1.5\text{-V}$  batteries used to power flashlights and many consumer electronic devices are single voltaic cells. Greater voltages can be achieved by using multiple cells, as in  $12\text{-V}$  automotive batteries. When cells are connected in series (which means the cathode of one attached to the anode of another), the battery produces a voltage that is the sum of the voltages of the individual cells. Higher voltages can also be achieved by using multiple batteries in series (Figure 20.18). Battery electrodes are marked following the convention of Figure 20.6—plus for cathode and minus for anode.

Although any spontaneous redox reaction can serve as the basis for a voltaic cell, making a commercial battery that has specific performance characteristics requires considerable ingenuity. The substances oxidized at the anode and reduced by the cathode determine the voltage, and the usable life of the battery depends on the quantities of these substances packaged in the battery. Usually, a barrier analogous to the porous barrier of Figure 20.6 separates the anode and cathode half-cells.

Different applications require batteries with different properties. The battery required to start a car, for example, must be capable of delivering a large electrical current for a short time period, whereas the battery that powers a heart pacemaker must be very small and capable of delivering a small but steady current over an extended time period. Some batteries are **primary cells**, meaning they cannot be recharged and must be either discarded or recycled after the voltage drops to zero. A **secondary cell** can be recharged from an external power source after its voltage has dropped.

▲ **Figure 20.18** Combining batteries. When batteries are connected in series, as in most flashlights, the total voltage is the sum of the individual voltages.

As we consider some common batteries, notice how the principles we have discussed so far help us understand these important sources of portable electrical energy.

## Lead–Acid Battery

A 12-V lead–acid automotive battery consists of six voltaic cells in series, each producing 2 V. The cathode of each cell is lead dioxide ( $\text{PbO}_2$ ) packed on a lead grid (Figure 20.19). The anode of each cell is lead. Both electrodes are immersed in sulfuric acid.

The reactions that occur during discharge are

The standard cell potential can be obtained from the standard reduction potentials in Appendix E:

$$E_{\text{cell}}^\circ = E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode}) = (+1.69 \text{ V}) - (-0.36 \text{ V}) = +2.05 \text{ V}$$

The reactants Pb and  $\text{PbO}_2$  are the electrodes. Because these reactants are solids, there is no need to separate the cell into half-cells; the Pb and  $\text{PbO}_2$  cannot come into contact with each other unless one electrode touches another. To keep the electrodes from touching, wood or glass-fiber spacers are placed between them (Figure 20.19). Using a reaction whose reactants and products are solids has another benefit. Because solids are excluded from the reaction quotient  $Q$ , the relative amounts of  $\text{Pb}(s)$ ,  $\text{PbO}_2(s)$ , and  $\text{PbSO}_4(s)$  have no effect on the voltage of the lead storage battery, helping the battery maintain a relatively constant voltage during discharge. The voltage does vary somewhat with use because the concentration of  $\text{H}_2\text{SO}_4$  varies with the extent of discharge. As Equation 20.20 indicates,  $\text{H}_2\text{SO}_4$  is consumed during the discharge.

A major advantage of the lead–acid battery is that it can be recharged. During recharging, an external source of energy is used to reverse the direction of the cell reaction, regenerating  $\text{Pb}(s)$  and  $\text{PbO}_2(s)$ :

In an automobile, the alternator provides the energy necessary for recharging the battery. Recharging is possible because  $\text{PbSO}_4$  formed during discharge adheres to the electrodes. As the external source forces electrons from one electrode to the other, the  $\text{PbSO}_4$  is converted to Pb at one electrode and to  $\text{PbO}_2$  at the other.

### Go Figure

What is the oxidation state of lead in the cathode of this battery?

### Go Figure

What substance is oxidized as the battery discharges?

**▲ Figure 20.20** Cutaway view of a miniature alkaline battery.

## Alkaline Battery

The most common primary (nonrechargeable) battery is the alkaline battery (Figure 20.20). The anode is powdered zinc metal immobilized in a gel in contact with a concentrated solution of KOH (hence, the name *alkaline* battery). The cathode is a mixture of  $\text{MnO}_2(s)$  and graphite, separated from the anode by a porous fabric. The battery is sealed in a steel can to reduce the risk of any of the concentrated KOH escaping.

The cell reactions are complex but can be approximately represented as follows:

## Nickel–Cadmium and Nickel–Metal Hydride Batteries

The tremendous growth in high-power-demand portable electronic devices in the last decade has increased the demand for lightweight, readily rechargeable batteries.

One relatively common rechargeable battery is the nickel–cadmium (nicad) battery. During discharge, cadmium metal is oxidized at the anode while nickel oxyhydroxide  $[\text{NiO}(\text{OH})(\text{s})]$  is reduced at the cathode:

As in the lead–acid battery, the solid reaction products adhere to the electrodes, which permits the electrode reactions to be reversed during charging. A single nicad voltaic cell has a voltage of 1.30 V. Nicad battery packs typically contain three or more cells in series to produce the higher voltages needed by most electronic devices.

Although nickel–cadmium batteries have a number of attractive characteristics, the use of cadmium as the anode introduces significant limitations. Because cadmium is toxic, these batteries must be recycled. The toxicity of cadmium has led to a decline in their popularity from a peak annual production level of approximately 1.5 billion batteries in the early 2000s. Cadmium also has a relatively high density, which increases battery weight, an undesirable characteristic for use in portable devices and electric vehicles. These shortcomings have fueled the development of the nickel–metal hydride (NiMH) battery. The cathode reaction is the same as that for nickel–cadmium batteries, but the anode reaction is very different. The anode consists of a metal alloy, typically with  $\text{AM}_5$  stoichiometry, where A is lanthanum (La) or a mixture of metals from the lanthanide series, and M is mostly nickel alloyed with smaller amounts of other transition metals. On charging, water is reduced at the anode to form hydroxide ions and hydrogen atoms that are absorbed into the  $\text{AM}_5$  alloy. When the battery is operating (discharging), the hydrogen atoms are oxidized and the resulting  $\text{H}^+$  ions react with  $\text{OH}^-$  ions to form  $\text{H}_2\text{O}$ .

## Lithium-Ion Batteries

Currently, most portable electronic devices, including cell phones and laptop computers, are powered by rechargeable lithium-ion (Li-ion) batteries. Because lithium is a very light element, Li-ion batteries achieve a greater *specific energy density*—the amount of energy stored per unit mass—than nickel-based batteries. Because  $\text{Li}^+$  has a very large negative standard reduction potential (Table 20.1), Li-ion batteries produce a higher voltage per cell than other batteries. A Li-ion battery produces a maximum voltage of 3.7 V per cell, nearly three times higher than the 1.3 V per cell that nickel–cadmium and nickel–metal hydride batteries generate. As a result, a Li-ion battery can deliver more power than other batteries of comparable size, which leads to a higher *volumetric energy density*—the amount of energy stored per unit volume.

The technology of Li-ion batteries is based on the ability of  $\text{Li}^+$  ions to be inserted into and removed from certain layered solids. In most commercial cells, the anode is made of graphite, which contains layers of  $sp^2$  bonded carbon atoms [Figure 12.29(b)]. The cathode is made of a transition metal oxide that also has a layered structure, typically lithium cobalt oxide ( $\text{LiCoO}_2$ ). The two electrodes are separated by an electrolyte, which functions like a salt bridge by allowing  $\text{Li}^+$  ions to pass through it. When the cell is being charged, cobalt ions are oxidized and  $\text{Li}^+$  ions migrate out of  $\text{LiCoO}_2$  and into the graphite. During discharge, when the battery is producing electricity for use, the  $\text{Li}^+$  ions spontaneously migrate from the graphite anode through the electrolyte to the cathode, enabling electrons to flow through the external circuit (Figure 20.21).

## Hydrogen Fuel Cells

The thermal energy released by burning fuels can be converted to electrical energy. The thermal energy may convert water to steam, for instance, which drives a turbine that in turn drives an electrical generator. Typically, a maximum of only 40% of the energy from combustion is converted to electricity in this manner; the remainder is lost as heat. The direct production of electricity from fuels by a voltaic cell could, in principle, yield

## Go Figure

When a Li-ion battery is fully discharged, the cathode has an empirical formula of  $\text{LiCoO}_2$ . What is the oxidation number of cobalt in this state? Does the oxidation number of the cobalt increase or decrease as the battery charges?

▲ **Figure 20.21 Schematic of a Li-ion battery.** When the battery is discharging (operating),  $\text{Li}^+$  ions move out of the anode and migrate through the electrolyte where they enter the spaces between the cobalt oxide layers, reducing the cobalt ions. To recharge the battery, electrical energy is used to drive the  $\text{Li}^+$  back to the anode, oxidizing the cobalt ions in the cathode.

## CHEMISTRY PUT TO WORK Batteries for Hybrid and Electric Vehicles

There has been a tremendous growth over the last two decades in the development of electric vehicles. This growth has been driven by a desire to reduce the use of fossil fuels and lower emissions. Today both hybrid electric vehicles and fully electric vehicles are commercially available. Hybrid electric vehicles can be powered either by electricity from batteries or by a conventional combustion engine, while fully electric vehicles are powered exclusively by the batteries (**Figure 20.22**). Hybrid electric vehicles can be further divided into plug-in hybrids, which require the owner to charge the battery by plugging it into a conventional outlet, or regular hybrids, which use regenerative braking and power from the combustion engine to charge the batteries.

Among the many technological advances needed to make electric vehicles practical, none is more important than advances in battery technology. Batteries for electric vehicles must have a high specific energy density, to reduce the weight of the car, as well as a high volumetric energy density, to minimize the space needed for the battery pack. A plot of energy densities for various types of rechargeable batteries is shown in **Figure 20.23**. The lead-acid batteries used in gasoline-powered automobiles are reliable and inexpensive, but their energy densities are far too low for

▲ **Figure 20.22 Electric car.** This Tesla electric automobile can go about 200 miles after 30 minutes of charging at this station.

▲ **Figure 20.23** Energy densities of various types of batteries. The higher the volumetric energy density, the smaller the amount of space needed for the batteries. The higher the specific energy density, the smaller the mass of the batteries. A Watt-hour (W-h) is equivalent to  $3.6 \times 10^3$  Joules.

practical use in an electric vehicle. Nickel–metal hydride batteries offer roughly three times higher energy density and until recently were the batteries of choice for commercial hybrid vehicles, such as the Toyota Prius.

Fully electric vehicles and plug-in hybrids use Li-ion batteries because they offer the highest energy density of all commercially available batteries. As Li-ion battery technology has advanced, these batteries have started to displace the nickel–metal hydride batteries used in hybrid electric cars. Concern over safety is one factor that has delayed implementation of Li-ion batteries in commercial automobiles. In rare cases overheating and/or overcharging can cause Li-ion batteries to combust (Section 7.3). Most electric vehicles now use Li-ion batteries where the  $\text{LiCoO}_2$  cathode has been replaced by a cathode made from lithium manganese spinel ( $\text{LiMn}_2\text{O}_4$ ). Batteries made with  $\text{LiMn}_2\text{O}_4$  cathodes have several advantages. They are not prone to thermal runaway events that can lead to combustion, they tend to have longer lifetimes, and manganese is less expensive and more environmentally friendly than cobalt. However, they do have one important shortcoming—the capacity of batteries made from  $\text{LiMn}_2\text{O}_4$  is only about two-thirds that of batteries with  $\text{LiCoO}_2$  cathodes. Scientists and engineers are intensively looking for new materials that will lead to further improvements in the energy density, cost, lifetime, and safety of batteries.

**Related Exercises:** 20.10, 20.79, 20.80

a higher rate of conversion of chemical energy to electrical energy. Voltaic cells that perform this conversion using conventional fuels, such as  $\text{H}_2$  and  $\text{CH}_4$ , are called **fuel cells**. Fuel cells are *not* batteries because they are not self-contained systems—the fuel must be continuously supplied to generate electricity.

The most common fuel-cell systems involve the reaction of  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$  to form  $\text{H}_2\text{O}(\text{l})$ . These cells can generate electricity twice as efficiently as the best internal combustion engine. Under acidic conditions, the reactions are

These cells employ hydrogen gas as the fuel and oxygen gas from air as the oxidant and generate about 1 V.

Fuel cells are often named for either the fuel or the electrolyte used. In the hydrogen-PEM fuel cell (the acronym PEM stands for either proton-exchange membrane or polymer-electrolyte membrane), the anode and cathode are separated by a membrane that is permeable to protons but not to electrons (Figure 20.24). The membrane therefore acts as the salt bridge. The electrodes are typically made from graphite.

The hydrogen-PEM cell operates at around  $80^\circ\text{C}$ . At this temperature, the electrochemical reactions would normally occur very slowly, and so small islands of platinum are deposited on each electrode to catalyze the reactions. The high cost and relative scarcity of platinum are two factors that limit wider use of hydrogen-PEM fuel cells.

In order to power a vehicle, multiple cells must be assembled into a fuel cell *stack*. The amount of power generated by a stack depends on the number and size of the fuel cells in the stack and on the surface area of the PEM.

Much fuel cell research today is directed toward improving electrolytes and catalysts and developing cells that use fuels such as hydrocarbons and alcohols, which are less difficult to handle and distribute than hydrogen gas.

## Go Figure

What half-reaction occurs at the cathode?

▲ **Figure 20.24** A hydrogen-PEM fuel cell. The proton-exchange membrane (PEM) allows  $\text{H}^+$  ions generated by  $\text{H}_2$  oxidation at the anode to migrate to the cathode, where  $\text{H}_2\text{O}$  is formed.

## 20.8 | Corrosion

In this section, we examine the undesirable redox reactions that lead to **corrosion** of metals. Corrosion reactions are spontaneous redox reactions in which a metal is attacked by some substance in its environment and converted to an unwanted compound.

For nearly all metals, oxidation is thermodynamically favorable in air at room temperature. When oxidation of a metal object is not inhibited, it can destroy the object. Oxidation can form an insulating protective oxide layer, however, that prevents further reaction of the underlying metal. Based on the standard reduction potential for  $\text{Al}^{3+}$ , for example, we expect aluminum metal to be readily oxidized. The many aluminum soft-drink and beer cans that litter the environment are ample evidence, however, that aluminum undergoes only very slow chemical corrosion. The exceptional stability of this active metal in air is due to the formation of a thin protective coat of oxide—a hydrated form of  $\text{Al}_2\text{O}_3$ —on the metal surface. The oxide coat is impermeable to  $\text{O}_2$  or  $\text{H}_2\text{O}$  and so protects the underlying metal from further corrosion.

Magnesium metal is similarly protected, and some metal alloys, such as stainless steel, likewise form protective impervious oxide coats.

### Corrosion of Iron (Rusting)

The rusting of iron is a familiar corrosion process that carries a significant economic impact. Up to 20% of the iron produced annually in the United States is used to replace iron objects that have been discarded because of rust damage.

Rusting of iron requires both oxygen and water, and the process can be accelerated by other factors such as pH, presence of salts, contact with metals more difficult to

oxidize than iron, and stress on the iron. The corrosion process involves oxidation and reduction, and the metal conducts electricity. Thus, electrons can move through the metal from a region where oxidation occurs to a region where reduction occurs, as in voltaic cells. Because the standard reduction potential for reduction of Fe<sup>2+</sup>(aq) is less positive than that for reduction of O<sub>2</sub>, Fe(s) can be oxidized by O<sub>2</sub>(g):

A portion of the iron, often associated with a dent or region of strain, can serve as an anode at which Fe is oxidized to Fe<sup>2+</sup> (Figure 20.25). The electrons produced in the oxidation migrate through the metal from this anodic region to another portion of the surface, which serves as the cathode where O<sub>2</sub> is reduced. The reduction of O<sub>2</sub> requires H<sup>+</sup>, so lowering the concentration of H<sup>+</sup> (increasing the pH) makes O<sub>2</sub> reduction less favorable. Iron in contact with a solution whose pH is greater than 9 does not corrode.

The Fe<sup>2+</sup> formed at the anode is eventually oxidized to Fe<sup>3+</sup>, which forms the hydrated iron(III) oxide known as rust:\*

Because the cathode is generally the area having the largest supply of O<sub>2</sub>, rust often deposits there. If you look closely at a shovel after it has stood outside in the moist air with wet dirt adhered to its blade, you may notice that pitting has occurred under the dirt but that rust has formed elsewhere, where O<sub>2</sub> is more readily available. The enhanced corrosion caused by the presence of salts is usually evident on autos in areas where roads are heavily salted during winter. Like a salt bridge in a voltaic cell, the ions of the salt provide the electrolyte necessary to complete the electrical circuit.

## Preventing Corrosion of Iron

Objects made of iron are often covered with a coat of paint or another metal to protect against corrosion. Covering the surface with paint prevents oxygen and water from

\*Frequently, metal compounds obtained from aqueous solution have water associated with them. For example, copper(II) sulfate crystallizes from water with 5 mol of water per mole of CuSO<sub>4</sub>. We represent this substance by the formula CuSO<sub>4</sub> · 5H<sub>2</sub>O. Such compounds are called hydrates. (Section 13.1) Rust is a hydrate of iron(III) oxide with a variable amount of water of hydration. We represent this variable water content by writing the formula Fe<sub>2</sub>O<sub>3</sub> · xH<sub>2</sub>O.

▲ **Figure 20.26** Cathodic protection of iron in contact with zinc. The standard reduction potentials are  $E_{\text{red}, \text{Fe}^{2+}}^{\circ} = -0.44\text{ V}$ ,  $E_{\text{red}, \text{Zn}^{2+}}^{\circ} = -0.76\text{ V}$ , making the zinc more readily oxidized.

reaching the iron surface. If the coating is broken, however, and the iron is exposed to oxygen and water, corrosion begins as the iron is oxidized.

With *galvanized iron*, which is iron coated with a thin layer of zinc, the iron is protected from corrosion even after the surface coat is broken. The standard reduction potentials are

Because  $E_{\text{red}}^{\circ}$  for  $\text{Fe}^{2+}$  is less negative (more positive) than  $E_{\text{red}}^{\circ}$  for  $\text{Zn}^{2+}$ ,  $\text{Zn}(\text{s})$  is more readily oxidized than  $\text{Fe}(\text{s})$ . Thus, even if the zinc coating is broken and the galvanized iron is exposed to oxygen and water, as in **Figure 20.26**, the zinc serves as the anode and is corroded (oxidized) instead of the iron. The iron serves as the cathode at which  $\text{O}_2$  is reduced.

Protecting a metal from corrosion by making it the cathode in an electrochemical cell is known as **cathodic protection**. The metal that is oxidized while protecting the cathode is called the *sacrificial anode*. Underground pipelines and storage tanks made of iron are often protected against corrosion by making the iron the cathode of a voltaic cell. For example, pieces of a metal that is more easily oxidized than iron, such as magnesium ( $E_{\text{red}}^{\circ} = -2.37\text{ V}$ ), are buried near the pipe or storage tank and connected to it by wire (**Figure 20.27**). In moist soil, where corrosion can occur, the sacrificial metal serves as the anode, and the pipe or tank experiences cathodic protection.

▲ **Figure 20.27** Cathodic protection of an iron pipe. A mixture of gypsum, sodium sulfate, and clay surrounds the sacrificial magnesium anode to promote conductivity of ions.

### Give It Some Thought

Based on the values in Table 20.1, which of these metals could provide cathodic protection to iron: Al, Cu, Ni, Zn?

## 20.9 | Electrolysis

Voltaic cells are based on spontaneous redox reactions. It is also possible for *nonspontaneous* redox reactions to occur, however, by using electrical energy to drive them. For example, electricity can be used to decompose molten sodium chloride into its

component elements Na and  $\text{Cl}_2$ . Such processes driven by an outside source of electrical energy are called **electrolysis reactions** and take place in **electrolytic cells**.

An electrolytic cell consists of two electrodes immersed either in a molten salt or in a solution. A battery or some other source of electrical energy acts as an electron pump, pushing electrons into one electrode and pulling them from the other. Just as in voltaic cells, the electrode at which reduction occurs is called the cathode, and the electrode at which oxidation occurs is called the anode.

In the electrolysis of molten NaCl,  $\text{Na}^+$  ions gain electrons and are reduced to Na at the cathode, **Figure 20.28**. As  $\text{Na}^+$  ions near the cathode are depleted, additional  $\text{Na}^+$  ions migrate in. Similarly, there is net movement of  $\text{Cl}^-$  ions to the anode where they are oxidized. The electrode reactions for the electrolysis are

Notice how the energy source is connected to the electrodes in **Figure 20.28**. The positive terminal is connected to the anode and the negative terminal is connected to the cathode, which forces electrons to move from the anode to the cathode.

Because of the high melting points of ionic substances, the electrolysis of molten salts requires very high temperatures. Do we obtain the same products if we electrolyze the aqueous solution of a salt instead of the molten salt? Frequently, the answer is no because water itself might be oxidized to form  $\text{O}_2$  or reduced to form  $\text{H}_2$  rather than the ions of the salt.

In our examples of the electrolysis of NaCl, the electrodes are *inert*; they do not react but merely serve as the surface where oxidation and reduction occur. Several practical applications of electrochemistry, however, are based on *active* electrodes—electrodes that participate in the electrolysis process. *Electroplating*, for example, uses electrolysis to deposit a thin layer of one metal on another metal to improve beauty or resistance to corrosion. Examples include electroplating nickel or chromium onto steel and electroplating a precious metal like silver onto a less expensive one.

**Figure 20.29** illustrates an electrolytic cell for electroplating nickel onto a piece of steel. The anode is a strip of nickel metal, and the cathode is the steel. The electrodes are immersed in a solution of  $\text{NiSO}_4(aq)$ . When an external voltage is applied, reduction occurs at the cathode. The standard reduction potential of  $\text{Ni}^{2+}$  ( $E^\circ_{\text{red}} = -0.28 \text{ V}$ ) is less negative than that of  $\text{H}_2\text{O}$  ( $E^\circ_{\text{red}} = -0.83 \text{ V}$ ), so  $\text{Ni}^{2+}$  is preferentially reduced, depositing a layer of nickel metal on the steel cathode.

**Figure 20.28** Electrolysis of molten sodium chloride. Pure NaCl melts at  $801^\circ\text{C}$ .

### Go Figure

What is  $E^\circ$  for this cell?

**Figure 20.29** Electrolytic cell with an active metal electrode. Nickel dissolves from the anode to form  $\text{Ni}^{2+}(aq)$ . At the cathode,  $\text{Ni}^{2+}(aq)$  is reduced and forms a nickel “plate” on the steel cathode.

At the anode, the nickel metal is oxidized. To explain this behavior, we need to compare the substances in contact with the anode,  $\text{H}_2\text{O}$  and  $\text{NiSO}_4(aq)$ , with the anode material, Ni. For the  $\text{NiSO}_4(aq)$  solution, neither  $\text{Ni}^{2+}$  nor  $\text{SO}_4^{2-}$  can be oxidized (because both already have their elements in their highest common oxidation state). Both the  $\text{H}_2\text{O}$  solvent and the Ni atoms in the anode, however, can undergo oxidation:

We saw in Section 20.4 that the half-reaction with the more negative  $E_{\text{red}}^\circ$  undergoes oxidation more readily. (Remember Figure 20.11: The strongest reducing agents, which are the substances oxidized most readily, have the most negative  $E_{\text{red}}^\circ$  values.) Thus, it is the  $\text{Ni}(s)$ , with its  $E_{\text{red}}^\circ = -0.28 \text{ V}$ , that is oxidized at the anode rather than the  $\text{H}_2\text{O}$ . If we look at the overall reaction, it appears as if nothing has been accomplished. However, this is not true because Ni atoms are transferred from the Ni anode to the steel cathode, plating the steel with a thin layer of nickel atoms.

The standard emf for the overall reaction is

$$E_{\text{cell}}^\circ = E_{\text{red}}^\circ(\text{cathode}) - E_{\text{red}}^\circ(\text{anode}) = (-0.28 \text{ V}) - (-0.28 \text{ V}) = 0$$

Because the standard emf is zero, only a small emf is needed to cause the transfer of nickel atoms from one electrode to the other.

## Quantitative Aspects of Electrolysis

The stoichiometry of a half-reaction shows how many electrons are needed to achieve an electrolytic process. For example, the reduction of  $\text{Na}^+$  to Na is a one-electron process:

Thus, 1 mol of electrons plates out 1 mol of Na metal, 2 mol of electrons plate out 2 mol of Na metal, and so forth. Similarly, 2 mol of electrons are required to produce 1 mol of Cu from  $\text{Cu}^{2+}$ , and 3 mol of electrons are required to produce 1 mol of Al from  $\text{Al}^{3+}$ :

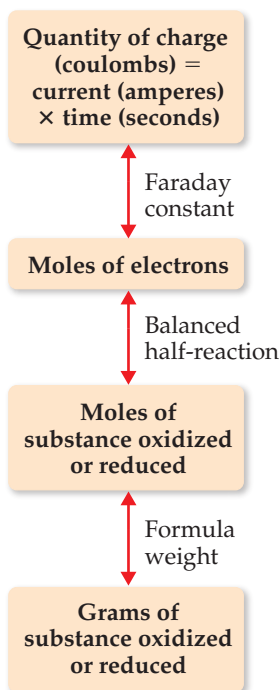

For any half-reaction, the amount of substance reduced or oxidized in an electrolytic cell is directly proportional to the number of electrons passed into the cell.

The quantity of charge passing through an electrical circuit, such as that in an electrolytic cell, is generally measured in *coulombs*. As noted in Section 20.5, the charge on 1 mol of electrons is 96,485 C. A coulomb is the quantity of charge passing a point in a circuit in 1 s when the current is 1 ampere (A). Therefore, the number of coulombs passing through a cell can be obtained by multiplying the current in amperes by the elapsed time in seconds.

$$\text{coulombs} = \text{amperes} \times \text{seconds} \quad [20.21]$$

Figure 20.30 shows how the quantities of substances produced or consumed in electrolysis are related to the quantity of electrical charge used. The same relationships can also be applied to voltaic cells. In other words, electrons can be thought of as “reagents” in electrolysis reactions.

▲ **Figure 20.30** Relationship between charge and amount of reactant and product in electrolysis reactions.

## Sample Exercise 20.14

### Relating Electrical Charge and Quantity of Electrolysis

Calculate the number of grams of aluminum produced in 1.00 h by the electrolysis of molten  $\text{AlCl}_3$  if the electrical current is 10.0 A.

### SOLUTION

**Analyze** We are told that  $\text{AlCl}_3$  is electrolyzed to form Al and asked to calculate the number of grams of Al produced in 1.00 h with 10.0 A.

**Plan** Figure 20.30 provides a roadmap for this problem. Using the current, time, a balanced half-reaction, and the atomic weight of aluminum we can calculate the mass of Al produced.

**Solve**

First, we calculate the coulombs of electrical charge passed into the electrolytic cell (note that  $10.0\text{ A} = 10.0\text{ C/s}$ ):

$$\text{Coulombs} = \text{amperes} \times \text{seconds} = (10.0\text{ C/s})(1.00\text{ h})\left(\frac{3600\text{ s}}{\text{h}}\right) = 3.60 \times 10^4\text{ C}$$

Second, we calculate the number of moles of electrons that pass into the cell:

$$\text{Moles } e^- = (3.60 \times 10^4\text{ C})\left(\frac{1\text{ mol } e^-}{96,485\text{ C}}\right) = 0.373\text{ mol } e^-$$

Third, we relate number of moles of electrons to number of moles of aluminum formed, using the half-reaction for the reduction of  $\text{Al}^{3+}$ :

Thus, 3 mol of electrons are required to form 1 mol of Al:

$$\text{Moles Al} = (0.373\text{ mol } e^-)\left(\frac{1\text{ mol Al}}{3\text{ mol } e^-}\right) = 0.124\text{ mol Al}$$

Finally, we convert moles to grams:

$$\text{Grams Al} = (0.124\text{ mol Al})\left(\frac{27.0\text{ g Al}}{1\text{ mol Al}}\right) = 3.36\text{ g Al}$$

Or, we could have combined all of the above steps:

$$\text{Grams Al} = (3.60 \times 10^4\text{ C})\left(\frac{1\text{ mol } e^-}{96,485\text{ C}}\right)\left(\frac{1\text{ mol Al}}{3\text{ mol } e^-}\right)\left(\frac{27.0\text{ g Al}}{1\text{ mol Al}}\right) = 3.36\text{ g Al}$$

**Practice Exercise 1**

How much time is needed to deposit 1.0 g of chromium metal from an aqueous solution of  $\text{CrCl}_3$  using a current of 1.5 A?

- (a)  $3.8 \times 10^{-2}\text{ s}$  (b) 21 min (c) 62 min (d) 139 min  
(e)  $3.2 \times 10^3\text{ min}$

**Practice Exercise 2**

(a) The half-reaction for formation of magnesium metal upon electrolysis of molten  $\text{MgCl}_2$  is  $\text{Mg}^{2+} + 2\text{e}^- \longrightarrow \text{Mg}$ . Calculate the mass of magnesium formed upon passage of a current of 60.0 A for a period of  $4.00 \times 10^3\text{ s}$ . (b) How many seconds would be required to produce 50.0 g of Mg from  $\text{MgCl}_2$  if the current is 100.0 A?

**CHEMISTRY PUT TO WORK Electrometallurgy of Aluminum**

Many processes used to produce or refine metals are based on electrolysis. Collectively, these processes are referred to as *electrometallurgy*. Electrometallurgical procedures can be broadly differentiated according to whether they involve electrolysis of a molten salt or of an aqueous solution.

Electrolytic methods using molten salts are important for obtaining the more active metals, such as sodium, magnesium, and aluminum. These metals cannot be obtained from aqueous solution because water is more easily reduced than the metal ions. The standard reduction potentials of water under both acidic ( $E^\circ_{\text{red}} = 0.00\text{ V}$ ) and basic ( $E^\circ_{\text{red}} = -0.83\text{ V}$ ) conditions are more positive than those of  $\text{Na}^+$  ( $E^\circ_{\text{red}} = -2.71\text{ V}$ ),  $\text{Mg}^{2+}$  ( $E^\circ_{\text{red}} = -2.37\text{ V}$ ), and  $\text{Al}^{3+}$  ( $E^\circ_{\text{red}} = -1.66\text{ V}$ ).

Historically, obtaining aluminum metal has been a challenge. It is obtained from bauxite ore, which is chemically treated to concentrate aluminum oxide ( $\text{Al}_2\text{O}_3$ ). The melting point of aluminum oxide is above  $2000^\circ\text{C}$ , which is too high to permit its use as a molten medium for electrolysis.

The electrolytic process used commercially to produce aluminum is the *Hall-Héroult process*, named after its inventors, Charles M. Hall and Paul Héroult. Hall (1863–1914) (Figure 20.31) began working on the problem of reducing aluminum in about 1885 after he had learned from a professor of the difficulty of reducing ores of very active metals. Before the development of an electrolytic process, aluminum was obtained by a chemical reduction using sodium or potassium as the reducing agent, a costly procedure that made aluminum metal expensive. As late as 1852, the cost of aluminum was \$545 per pound, far greater than the cost of gold. During the Paris

**▲ Figure 20.31** Charles M. Hall as a young man.

Exposition in 1855, aluminum was exhibited as a rare metal, even though it is the third most abundant element in Earth's crust.

Hall, who was 21 years old when he began his research, utilized handmade and borrowed equipment in his studies and used a woodshed near his Ohio home as his laboratory. In about a year's time, he developed an electrolytic procedure using an ionic compound that melts to form a conducting medium that dissolves  $\text{Al}_2\text{O}_3$  but does not interfere with the electrolysis reactions. The ionic compound he selected was the relatively rare mineral cryolite ( $\text{Na}_3\text{AlF}_6$ ). Héroult, who was the same age as Hall, independently made the same

*Continued*

discovery in France at about the same time. Because of the research of these two unknown young scientists, large-scale production of aluminum became commercially feasible, and aluminum became a common and familiar metal. Indeed, the factory that Hall subsequently built to produce aluminum evolved into Alcoa Corporation.

In the Hall-Héroult process,  $\text{Al}_2\text{O}_3$  is dissolved in molten cryolite, which melts at  $1012^\circ\text{C}$  and is an effective electrical conductor (Figure 20.32). Graphite rods are employed as anodes and are consumed in the electrolysis:

A large amount of electrical energy is needed in the Hall-Héroult process, with the result that the aluminum industry consumes about 2% of the electrical energy generated in the United States. Because recycled aluminum requires only 5% of the energy needed to produce “new” aluminum, considerable energy savings can be realized by increasing the amount of aluminum recycled. Approximately 65% of aluminum beverage containers are recycled in the United States.

▲ **Figure 20.32** The Hall-Héroult process. Because molten aluminum is denser than the mixture of cryolite ( $\text{Na}_3\text{AlF}_6$ ) and  $\text{Al}_2\text{O}_3$ , the metal collects at the bottom of the cell.

## Sample Integrative Exercise

### Putting Concepts Together

The  $K_{sp}$  at 298 K for iron(II) fluoride is  $2.4 \times 10^{-6}$ . (a) Write a half-reaction that gives the likely products of the two-electron reduction of  $\text{FeF}_2(s)$  in water. (b) Use the  $K_{sp}$  value and the standard reduction potential of  $\text{Fe}^{2+}(aq)$  to calculate the standard reduction potential for the half-reaction in part (a). (c) Rationalize the difference between the reduction potential in part (a) and the reduction potential for  $\text{Fe}^{2+}(aq)$ .

### SOLUTION

**Analyze** We are going to combine what we know about equilibrium constants and electrochemistry to obtain reduction potentials.

**Plan** For (a) we need to determine which ion,  $\text{Fe}^{2+}$  or  $\text{F}^-$ , is more likely to be reduced by two electrons and complete the overall

reaction  $\text{FeF}_2 + 2 e^- \longrightarrow ?$ . For (b) we need to write the chemical equation associated with the  $K_{sp}$  and see how it relates to  $E^\circ$  for the reduction half-reaction in (a). For (c) we need to compare  $E^\circ$  from (b) with the value for the reduction of  $\text{Fe}^{2+}$ .

### Solve

(a) Iron(II) fluoride is an ionic substance that consists of  $\text{Fe}^{2+}$  and  $\text{F}^-$  ions. We are asked to predict where two electrons could be added to  $\text{FeF}_2$ . We cannot envision adding the electrons to the  $\text{F}^-$  ions to form  $\text{F}^{2-}$ , so it seems likely that we could reduce the  $\text{Fe}^{2+}$  ions to  $\text{Fe}(s)$ . We therefore predict the half-reaction:

(b) The  $K_{sp}$  for  $\text{FeF}_2$  refers to the following equilibrium:  $\infty$  (Section 17.4)

We were also asked to use the standard reduction potential of  $\text{Fe}^{2+}$ , whose half-reaction and standard reduction potentials are listed in Appendix E:

According to Hess's law, if we can add chemical equations to get a desired equation, then we can add their associated thermodynamic state functions, like  $\Delta H$  or  $\Delta G$ , to determine the thermodynamic quantity for the desired reaction.  $\infty$  (Section 5.6) So we need to consider whether the three equations we are working with can be combined in a similar fashion. Notice that if we add the  $K_{sp}$  reaction to the standard reduction half-reaction for  $\text{Fe}^{2+}$ , we get the half-reaction we want:

Reaction 3 is still a half-reaction, so we do see the free electrons.

Overall:

1.  $\text{FeF}_2(s) \longrightarrow \text{Fe}^{2+}(aq) + 2 \text{F}^-(aq)$
2.  $\text{Fe}^{2+}(aq) + 2 e^- \longrightarrow \text{Fe}(s)$
3.  $\text{FeF}_2(s) + 2 e^- \longrightarrow \text{Fe}(s) + 2 \text{F}^-(aq)$

If we knew  $\Delta G^\circ$  for reactions 1 and 2, we could add them to get  $\Delta G^\circ$  for reaction 3. We can relate  $\Delta G^\circ$  to  $E^\circ$  by  $\Delta G^\circ = -nFE^\circ$  (Equation 20.12) and to  $K$  by  $\Delta G^\circ = -RT \ln K$  (Equation 19.20; see also Figure 20.13). Furthermore, we know that  $K$  for reaction 1 is the  $K_{sp}$  of  $\text{FeF}_2$ , and we know  $E^\circ$  for reaction 2. Therefore, we can calculate  $\Delta G^\circ$  for reactions 1 and 2:  
(Recall that 1 volt is 1 joule per coulomb.)

Reaction 1:

$$\Delta G^\circ = -RT \ln K = -(8.314 \text{ J/K mol})(298 \text{ K}) \ln(2.4 \times 10^{-6}) = 3.21 \times 10^4 \text{ J/mol}$$

Reaction 2:

$$\Delta G^\circ = -nFE^\circ = -(2)(96,485 \text{ C/mol})(-0.440 \text{ J/C}) = 8.49 \times 10^4 \text{ J/mol}$$

Then  $\Delta G^\circ$  for reaction 3, the one we want, is the sum of the  $\Delta G^\circ$  values for reactions 1 and 2:

$$3.21 \times 10^4 \text{ J/mol} + 8.49 \times 10^4 \text{ J/mol} = 1.17 \times 10^5 \text{ J/mol}$$

We can convert this to  $E^\circ$  from the relationship  $\Delta G^\circ = -nFE^\circ$ :

$$1.17 \times 10^5 \text{ J/mol} = -(2)(96,485 \text{ C/mol})E^\circ$$

$$E^\circ = \frac{1.17 \times 10^5 \text{ J/mol}}{-(2)(96,485 \text{ C/mol})} = -0.606 \text{ J/C} = -0.606 \text{ V}$$

- (c) The standard reduction potential for  $\text{FeF}_2$  ( $-0.606 \text{ V}$ ) is more negative than that for  $\text{Fe}^{2+}$  ( $-0.440 \text{ V}$ ), telling us that the reduction of  $\text{FeF}_2$  is the less favorable process. When  $\text{FeF}_2$  is reduced, we not only reduce the  $\text{Fe}^{2+}$  but also break up the ionic solid. Because this additional energy must be overcome, the reduction of  $\text{FeF}_2$  is less favorable than the reduction of  $\text{Fe}^{2+}$ .

## Chapter Summary and Key Terms

### OXIDATION STATES AND OXIDATION-REDUCTION REACTIONS (INTRODUCTION AND SECTION 20.1)

In this chapter, we have focused on **electrochemistry**, the branch of chemistry that relates electricity and chemical reactions. Electrochemistry involves oxidation-reduction reactions, also called redox reactions. These reactions involve a change in the oxidation state of one or more elements. In every oxidation-reduction reaction one substance is oxidized (its oxidation state, or number, increases) and one substance is reduced (its oxidation state, or number, decreases). The substance that is oxidized is referred to as a **reducing agent**, or **reductant**, because it causes the reduction of some other substance. Similarly, the substance that is reduced is referred to as an **oxidizing agent**, or **oxidant**, because it causes the oxidation of some other substance.

**BALANCING REDOX EQUATIONS (SECTION 20.2)** An oxidation-reduction reaction can be balanced by dividing the reaction into two **half-reactions**, one for oxidation and one for reduction. A half-reaction is a balanced chemical equation that includes electrons. In oxidation half-reactions, the electrons are on the product (right) side of the equation. In reduction half-reactions, the electrons are on the reactant (left) side of the equation. Each half-reaction is balanced separately, and the two are brought together with proper coefficients to balance the electrons on each side of the equation, so the electrons cancel when the half-reactions are added.

**VOLTAIC CELLS (SECTION 20.3)** A **voltaic** (or **galvanic**) **cell** uses a spontaneous oxidation-reduction reaction to generate electricity. In a voltaic cell the oxidation and reduction half-reactions often occur in separate half-cells. Each half-cell has a solid surface called an electrode, where the half-reaction occurs. The electrode where oxidation occurs is called the **anode**, and the electrode where reduction occurs is called the **cathode**. The electrons released at the anode flow through an external circuit (where they do electrical work) to the cathode.

Electrical neutrality in the solution is maintained by the migration of ions between the two half-cells through a device such as a salt bridge.

### CELL POTENTIALS UNDER STANDARD CONDITIONS (SECTION 20.4)

A voltaic cell generates an **electromotive force (emf)** that moves the electrons from the anode to the cathode through the external circuit. The origin of emf is a difference in the electrical potential energy of the two electrodes in the cell. The emf of a cell is called its **cell potential**,  $E_{\text{cell}}$  and is measured in volts ( $1 \text{ V} = 1 \text{ J/C}$ ). The cell potential under standard conditions is called the **standard emf**, or the **standard cell potential**, and is denoted  $E_{\text{cell}}^\circ$ .

A **standard reduction potential**,  $E_{\text{red}}^\circ$ , can be assigned for an individual half-reaction. This is achieved by comparing the potential of the half-reaction to that of the **standard hydrogen electrode (SHE)**, which is defined to have  $E_{\text{red}}^\circ = 0 \text{ V}$ .

The standard cell potential of a voltaic cell is the difference between the standard reduction potentials of the half-reactions that occur at the cathode and the anode:

$$E_{\text{cell}}^\circ = E_{\text{red}}^\circ (\text{cathode}) - E_{\text{red}}^\circ (\text{anode}).$$

The value of  $E_{\text{cell}}^\circ$  is positive for a voltaic cell.

For a reduction half-reaction,  $E_{\text{red}}^\circ$  is a measure of the tendency of the reduction to occur; the more positive the value for  $E_{\text{red}}^\circ$ , the greater the tendency of the substance to be reduced. Substances that are easily reduced act as strong oxidizing agents; thus,  $E_{\text{red}}^\circ$  provides a measure of the oxidizing strength of a substance. Substances that are strong oxidizing agents produce products that are weak reducing agents and vice versa.

### FREE ENERGY AND REDOX REACTIONS (SECTION 20.5)

The emf,  $E$ , is related to the change in the Gibbs free energy,  $\Delta G = -nFE$ , where  $n$  is the number of moles of electrons transferred during the redox process and  $F$  is the **Faraday constant**, defined as the quantity

of electrical charge on one mole of electrons:  $F = 96,485 \text{ C/mol}$ . Because  $E$  is related to  $\Delta G$ , the sign of  $E$  indicates whether a redox process is spontaneous:  $E > 0$  indicates a spontaneous process, and  $E < 0$  indicates a nonspontaneous one. Because  $\Delta G$  is also related to the equilibrium constant for a reaction ( $\Delta G^\circ = -RT \ln K$ ), we can relate  $E$  to  $K$  as well.

**CELL POTENTIALS UNDER NONSTANDARD CONDITIONS (SECTION 20.6)** The emf of a redox reaction varies with temperature and with the concentrations of reactants and products. The **Nernst equation** relates the emf under nonstandard conditions to the standard emf and the reaction quotient  $Q$ :

$$E = E^\circ - (RT/nF) \ln Q = E^\circ - (0.0592/n) \log Q$$

The factor 0.0592 is valid when  $T = 298 \text{ K}$ . A **concentration cell** is a voltaic cell in which the same half-reaction occurs at both the anode and the cathode but with different concentrations of reactants in each half-cell. At equilibrium,  $Q = K$  and  $E = 0$ .

**BATTERIES AND FUEL CELLS (SECTION 20.7)** A **battery** is a self-contained electrochemical power source that contains one or more voltaic cells. Batteries are based on a variety of different redox reactions. Batteries that cannot be recharged are called **primary cells**, while those that can be recharged are called **secondary cells**. The common alkaline dry cell battery is an example of a primary cell battery. Lead-acid, nickel-cadmium, nickel-metal hydride, and lithium-ion batteries are examples of secondary cells. **Fuel cells** are voltaic cells that utilize redox reactions in which reactants

such as  $\text{H}_2$  have to be continuously supplied to the cell to generate voltage.

**CORROSION (SECTION 20.8)** Electrochemical principles help us understand **corrosion**, undesirable redox reactions in which a metal is attacked by some substance in its environment. The corrosion of iron into rust is caused by the presence of water and oxygen, and it is accelerated by the presence of electrolytes, such as road salt. The protection of a metal by putting it in contact with another metal that more readily undergoes oxidation is called **cathodic protection**. Galvanized iron, for example, is coated with a thin layer of zinc; because zinc is oxidized more readily than iron, the zinc serves as a sacrificial anode in the redox reaction.

**ELECTROLYSIS (SECTION 20.9)** An **electrolysis reaction**, which is carried out in an **electrolytic cell**, employs an external source of electricity to drive a nonspontaneous electrochemical reaction. The current-carrying medium within an electrolytic cell may be either a molten salt or an electrolyte solution. The electrodes in an electrolytic cell can be inert or active, meaning that the electrode can be involved in the electrolysis reaction. Active electrodes are important in electroplating and in metallurgical processes.

The quantity of substances formed during electrolysis can be calculated by considering the number of electrons involved in the redox reaction and the amount of electrical charge that passes into the cell. The amount of electrical charge is measured in coulombs and is related to the magnitude of the current and the time it flows ( $1 \text{ C} = 1 \text{ A}\cdot\text{s}$ ).

## Learning Outcomes After studying this chapter, you should be able to:

- Identify oxidation, reduction, oxidizing agent, and reducing agent in a chemical equation. (Section 20.1)  
*Related Exercises: 20.13, 20.14, 20.19*
- Complete and balance redox equations using the method of half-reactions. (Section 20.2) *Related Exercises: 20.25, 20.26*
- Sketch a voltaic cell and identify its cathode, anode, and the directions in which electrons and ions move. (Section 20.3) *Related Exercises: 20.29, 20.30*
- Calculate standard emfs (cell potentials),  $E^\circ_{\text{cell}}$ , from standard reduction potentials. (Section 20.4) *Related Exercises: 20.37–20.40*
- Use reduction potentials to predict whether a redox reaction is spontaneous. (Section 20.4) *Related Exercises: 20.49, 20.50*
- Relate  $E^\circ_{\text{cell}}$  to  $\Delta G^\circ$  and equilibrium constants. (Section 20.5) *Related Exercises: 20.51, 20.52*
- Calculate emf under nonstandard conditions. (Section 20.6) *Related Exercises: 20.67, 20.68*
- Identify the components of common batteries. (Section 20.7) *Related Exercises: 20.73, 20.74*
- Describe the construction of a lithium-ion battery and explain how it works (Section 20.7) *Related Exercises: 20.79, 20.80*
- Describe the construction of a fuel cell and explain how it generates electrical energy. (Section 20.7) *Related Exercises: 20.81, 20.82*
- Explain how corrosion occurs and how it is prevented by cathodic protection. (Section 20.8) *Related Exercises: 20.83, 20.84*
- Describe the reactions in electrolytic cells. (Section 20.9) *Related Exercises: 20.89, 20.90*
- Relate amounts of products and reactants in redox reactions to electrical charge. (Section 20.9) *Related Exercises: 20.93, 20.94*

## Key Equations

- $E^\circ_{\text{cell}} = E^\circ_{\text{red}} (\text{cathode}) - E^\circ_{\text{red}} (\text{anode})$  [20.8] Relating standard emf to standard reduction potentials of the reduction (cathode) and oxidation (anode) half-reactions
- $\Delta G = -nFE$  [20.11] Relating free-energy change and emf
- $E = E^\circ - \frac{0.0592 \text{ V}}{n} \log Q$  (at 298 K) [20.18] The Nernst equation, expressing the effect of concentration on cell potential

## Exercises

### Visualizing Concepts

**20.1** In the Brønsted–Lowry concept of acids and bases, acid–base reactions are viewed as proton-transfer reactions. The stronger the acid, the weaker is its conjugate base. If we were to think of redox reactions in a similar way,

what particle would be analogous to the proton? Would strong oxidizing agents be analogous to strong acids or strong bases? [Sections 20.1 and 20.2]

- 20.2** You may have heard that “antioxidants” are good for your health. Is an “antioxidant” an oxidizing agent or a reducing agent? [Sections 20.1 and 20.2]
- 20.3** The diagram that follows represents a molecular view of a process occurring at an electrode in a voltaic cell.

- (a) Does the process represent oxidation or reduction? (b) Is the electrode the anode or cathode? (c) Why are the atoms in the electrode represented by larger spheres than those in the solution? [Section 20.3]
- 20.4** Assume that you want to construct a voltaic cell that uses the following half-reactions:

You begin with the incomplete cell pictured here in which the electrodes are immersed in water.

- (a) What additions must you make to the cell for it to generate a standard emf? (b) Which electrode functions as the cathode? (c) Which direction do electrons move through the external circuit? (d) What voltage will the cell generate under standard conditions? [Sections 20.3 and 20.4]
- 20.5** For a spontaneous reaction  $\text{A}(\text{aq}) + \text{B}(\text{aq}) \longrightarrow \text{A}^{-}(\text{aq}) + \text{B}^{+}(\text{aq})$ , answer the following questions:
- (a) If you made a voltaic cell out of this reaction, what half-reaction would be occurring at the cathode, and what half-reaction would be occurring at the anode?
- (b) Which half-reaction from (a) is higher in potential energy?
- (c) What is the sign of  $E_{\text{cell}}^{\circ}$ ? [Section 20.3]
- 20.6** Consider the following table of standard electrode potentials for a series of hypothetical reactions in aqueous solution:

| Reduction Half-Reaction  | $E^{\circ}(\text{V})$ |
|--|-----------------------|
| $\text{A}^{+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{A}(\text{s})$        | 1.33                  |
| $\text{B}^{2+}(\text{aq}) + 2\text{e}^{-} \longrightarrow \text{B}(\text{s})$      | 0.87                  |
| $\text{C}^{3+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{C}^{2+}(\text{aq})$ | -0.12                 |
| $\text{D}^{3+}(\text{aq}) + 3\text{e}^{-} \longrightarrow \text{D}(\text{s})$      | -1.59                 |

- (a) Which substance is the strongest oxidizing agent? Which is weakest?
- (b) Which substance is the strongest reducing agent? Which is weakest?
- (c) Which substance(s) can oxidize  $\text{C}^{2+}$ ? [Sections 20.4 and 20.5]

**20.7** Consider a redox reaction for which  $E^{\circ}$  is a negative number.

- (a) What is the sign of  $\Delta G^{\circ}$  for the reaction?
- (b) Will the equilibrium constant for the reaction be larger or smaller than 1?
- (c) Can an electrochemical cell based on this reaction accomplish work on its surroundings? [Section 20.5]

**20.8** Consider the following voltaic cell:

- (a) Which electrode is the cathode?
- (b) What is the standard emf generated by this cell?
- (c) What is the change in the cell voltage when the ion concentrations in the cathode half-cell are increased by a factor of 10?
- (d) What is the change in the cell voltage when the ion concentrations in the anode half-cell are increased by a factor of 10? [Sections 20.4 and 20.6]
- 20.9** Consider the half-reaction  $\text{Ag}^{+}(\text{aq}) + \text{e}^{-} \longrightarrow \text{Ag}(\text{s})$ . (a) Which of the lines in the following diagram indicates how the reduction potential varies with the concentration of  $\text{Ag}^{+}(\text{aq})$ ? (b) What is the value of  $E_{\text{red}}$  when  $\log[\text{Ag}^{+}] = 0$ ? [Section 20.6]

- 20.10** The electrodes in a silver oxide battery are silver oxide ( $\text{Ag}_2\text{O}$ ) and zinc. (a) Which electrode acts as the anode? (b) Which battery do you think has an energy density most similar to the silver oxide battery: a Li-ion battery, a nickel-cadmium battery, or a lead-acid battery? [Section 20.7]
- 20.11** Bars of iron are put into each of the three beakers as shown here. In which beaker—A, B, or C—would you expect the iron to show the most corrosion? [Section 20.8]

- 20.12** Magnesium, the element, is produced commercially by electrolysis from a molten salt (the “electrolyte”) using a cell similar to the one shown here. (a) What is the most common oxidation number for Mg when it is part of a salt? (b) Chlorine gas is evolved as voltage is applied in the cell. Knowing this, identify the electrolyte. (c) Recall that in an electrolytic cell the anode is given the + sign and the cathode is given the – sign, which is the opposite of what we see in batteries. What half-reaction occurs at the anode in this electrolytic cell? (d) What half-reaction occurs at the cathode? [Section 20.9]

### Oxidation-Reduction Reactions (Section 20.1)

- 20.13** (a) What is meant by the term *oxidation*? (b) On which side of an oxidation half-reaction do the electrons appear? (c) What is meant by the term *oxidant*? (d) What is meant by the term *oxidizing agent*?
- 20.14** (a) What is meant by the term *reduction*? (b) On which side of a reduction half-reaction do the electrons appear? (c) What is meant by the term *reductant*? (d) What is meant by the term *reducing agent*?
- 20.15** Indicate whether each of the following statements is true or false:
- If something is oxidized, it is formally losing electrons.
  - For the reaction  $\text{Fe}^{3+}(\text{aq}) + \text{Co}^{2+}(\text{aq}) \longrightarrow \text{Fe}^{2+}(\text{aq}) + \text{Co}^{3+}(\text{aq})$ ,  $\text{Fe}^{3+}(\text{aq})$  is the reducing agent and  $\text{Co}^{2+}(\text{aq})$  is the oxidizing agent.
  - If there are no changes in the oxidation state of the reactants or products of a particular reaction, that reaction is not a redox reaction.
- 20.16** Indicate whether each of the following statements is true or false:
- If something is reduced, it is formally losing electrons.
  - A reducing agent gets oxidized as it reacts.
  - An oxidizing agent is needed to convert CO into CO<sub>2</sub>.
- 20.17** For each of the following balanced oxidation-reduction reactions, (i) identify the oxidation numbers for all the elements in the reactants and products and (ii) state the total number of electrons transferred in each reaction.
- $\text{I}_2\text{O}_5(\text{s}) + 5 \text{CO}(\text{g}) \longrightarrow \text{I}_2(\text{s}) + 5 \text{CO}_2(\text{g})$
  - $2 \text{Hg}^{2+}(\text{aq}) + \text{N}_2\text{H}_4(\text{aq}) \longrightarrow 2 \text{Hg}(\text{l}) + \text{N}_2(\text{g}) + 4 \text{H}^+(\text{aq})$
  - $3 \text{H}_2\text{S}(\text{aq}) + 2 \text{H}^+(\text{aq}) + 2 \text{NO}_3^-(\text{aq}) \longrightarrow 3 \text{S}(\text{s}) + 2 \text{NO}(\text{g}) + 4 \text{H}_2\text{O}(\text{l})$
- 20.18** For each of the following balanced oxidation-reduction reactions, (i) identify the oxidation numbers for all the elements in the reactants and products and (ii) state the total number of electrons transferred in each reaction.
- $2 \text{MnO}_4^-(\text{aq}) + 3 \text{S}^{2-}(\text{aq}) + 4 \text{H}_2\text{O}(\text{l}) \longrightarrow 3 \text{S}(\text{s}) + 2 \text{MnO}_2(\text{s}) + 8 \text{OH}^-(\text{aq})$
  - $4 \text{H}_2\text{O}_2(\text{aq}) + \text{Cl}_2\text{O}_7(\text{g}) + 2 \text{OH}^-(\text{aq}) \longrightarrow 2 \text{ClO}_2^-(\text{aq}) + 5 \text{H}_2\text{O}(\text{l}) + 4 \text{O}_2(\text{g})$
  - $\text{Ba}^{2+}(\text{aq}) + 2 \text{OH}^-(\text{aq}) + \text{H}_2\text{O}_2(\text{aq}) + 2 \text{ClO}_2(\text{aq}) \longrightarrow \text{Ba}(\text{ClO}_2)_2(\text{s}) + 2 \text{H}_2\text{O}(\text{l}) + \text{O}_2(\text{g})$
- 20.19** Indicate whether the following balanced equations involve oxidation-reduction. If they do, identify the elements that undergo changes in oxidation number.
- $\text{PBr}_3(\text{l}) + 3 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{PO}_3(\text{aq}) + 3 \text{HBr}(\text{aq})$
  - $\text{NaI}(\text{aq}) + 3 \text{HOCl}(\text{aq}) \longrightarrow \text{NaIO}_3(\text{aq}) + 3 \text{HCl}(\text{aq})$
  - $3 \text{SO}_2(\text{g}) + 2 \text{HNO}_3(\text{aq}) + 2 \text{H}_2\text{O}(\text{l}) \longrightarrow 3 \text{H}_2\text{SO}_4(\text{aq}) + 2 \text{NO}(\text{g})$
- 20.20** Indicate whether the following balanced equations involve oxidation-reduction. If they do, identify the elements that undergo changes in oxidation number.
- $2 \text{AgNO}_3(\text{aq}) + \text{CoCl}_2(\text{aq}) \longrightarrow 2 \text{AgCl}(\text{s}) + \text{Co}(\text{NO}_3)_2(\text{aq})$
  - $2 \text{PbO}_2(\text{s}) \longrightarrow 2 \text{PbO}(\text{s}) + \text{O}_2(\text{g})$
  - $2 \text{H}_2\text{SO}_4(\text{aq}) + 2 \text{NaBr}(\text{s}) \longrightarrow \text{Br}_2(\text{l}) + \text{SO}_2(\text{g}) + \text{Na}_2\text{SO}_4(\text{aq}) + 2 \text{H}_2\text{O}(\text{l})$

### Balancing Oxidation-Reduction Reactions (Section 20.2)

- 20.21** At 900 °C, titanium tetrachloride vapor reacts with molten magnesium metal to form solid titanium metal and molten magnesium chloride. (a) Write a balanced equation for this reaction. (b) What is being oxidized, and what is being reduced? (c) Which substance is the reductant, and which is the oxidant?
- 20.22** Hydrazine (N<sub>2</sub>H<sub>4</sub>) and dinitrogen tetroxide (N<sub>2</sub>O<sub>4</sub>) form a self-igniting mixture that has been used as a rocket propellant. The reaction products are N<sub>2</sub> and H<sub>2</sub>O. (a) Write a balanced chemical equation for this reaction. (b) What is being oxidized, and what is being reduced? (c) Which substance serves as the reducing agent and which as the oxidizing agent?
- 20.23** Complete and balance the following half-reactions. In each case, indicate whether the half-reaction is an oxidation or a reduction.
- $\text{Sn}^{2+}(\text{aq}) \longrightarrow \text{Sn}^{4+}(\text{aq})$  (acidic solution)
  - $\text{TiO}_2(\text{s}) \longrightarrow \text{Ti}^{2+}(\text{aq})$  (acidic solution)

- (c)  $\text{ClO}_3^-(aq) \longrightarrow \text{Cl}^-(aq)$  (acidic solution)  
 (d)  $\text{N}_2(g) \longrightarrow \text{NH}_4^+(aq)$  (acidic solution)  
 (e)  $\text{OH}^-(aq) \longrightarrow \text{O}_2(g)$  (basic solution)  
 (f)  $\text{SO}_3^{2-}(aq) \longrightarrow \text{SO}_4^{2-}(aq)$  (basic solution)  
 (g)  $\text{N}_2(g) \longrightarrow \text{NH}_3(g)$  (basic solution)

**20.24** Complete and balance the following half-reactions. In each case indicate whether the half-reaction is an oxidation or a reduction.

- (a)  $\text{Mo}^{3+}(aq) \longrightarrow \text{Mo}(s)$  (acidic solution)  
 (b)  $\text{H}_2\text{SO}_3(aq) \longrightarrow \text{SO}_4^{2-}(aq)$  (acidic solution)  
 (c)  $\text{NO}_3^-(aq) \longrightarrow \text{NO}(g)$  (acidic solution)  
 (d)  $\text{O}_2(g) \longrightarrow \text{H}_2\text{O}(l)$  (acidic solution)  
 (e)  $\text{O}_2(g) \longrightarrow \text{H}_2\text{O}(l)$  (basic solution)  
 (f)  $\text{Mn}^{2+}(aq) \longrightarrow \text{MnO}_2(s)$  (basic solution)  
 (g)  $\text{Cr}(\text{OH})_3(s) \longrightarrow \text{CrO}_4^{2-}(aq)$  (basic solution)

**20.25** Complete and balance the following equations, and identify the oxidizing and reducing agents:

- (a)  $\text{Cr}_2\text{O}_7^{2-}(aq) + \text{I}^-(aq) \longrightarrow \text{Cr}^{3+}(aq) + \text{IO}_3^-(aq)$  (acidic solution)  
 (b)  $\text{MnO}_4^-(aq) + \text{CH}_3\text{OH}(aq) \longrightarrow \text{Mn}^{2+}(aq) + \text{HCOOH}(aq)$  (acidic solution)  
 (c)  $\text{I}_2(s) + \text{OCl}^-(aq) \longrightarrow \text{IO}_3^-(aq) + \text{Cl}^-(aq)$  (acidic solution)  
 (d)  $\text{As}_2\text{O}_3(s) + \text{NO}_3^-(aq) \longrightarrow \text{H}_3\text{AsO}_4(aq) + \text{N}_2\text{O}_3(aq)$  (acidic solution)  
 (e)  $\text{MnO}_4^-(aq) + \text{Br}^-(aq) \longrightarrow \text{MnO}_2(s) + \text{BrO}_3^-(aq)$  (basic solution)  
 (f)  $\text{Pb}(\text{OH})_4^{2-}(aq) + \text{ClO}^-(aq) \longrightarrow \text{PbO}_2(s) + \text{Cl}^-(aq)$  (basic solution)

**20.26** Complete and balance the following equations, and identify the oxidizing and reducing agents. (Recall that the O atoms in hydrogen peroxide,  $\text{H}_2\text{O}_2$ , have an atypical oxidation state.)

- (a)  $\text{NO}_2^-(aq) + \text{Cr}_2\text{O}_7^{2-}(aq) \longrightarrow \text{Cr}^{3+}(aq) + \text{NO}_3^-(aq)$  (acidic solution)  
 (b)  $\text{S}(s) + \text{HNO}_3(aq) \longrightarrow \text{H}_2\text{SO}_3(aq) + \text{N}_2\text{O}(g)$  (acidic solution)  
 (c)  $\text{Cr}_2\text{O}_7^{2-}(aq) + \text{CH}_3\text{OH}(aq) \longrightarrow \text{HCOOH}(aq) + \text{Cr}^{3+}(aq)$  (acidic solution)  
 (d)  $\text{BrO}_3^-(aq) + \text{N}_2\text{H}_4(g) \longrightarrow \text{Br}^-(aq) + \text{N}_2(g)$  (acidic solution)  
 (e)  $\text{NO}_2^-(aq) + \text{Al}(s) \longrightarrow \text{NH}_4^+(aq) + \text{AlO}_2^-(aq)$  (basic solution)  
 (f)  $\text{H}_2\text{O}_2(aq) + \text{ClO}_2(aq) \longrightarrow \text{ClO}_2^-(aq) + \text{O}_2(g)$  (basic solution)

## Voltaic Cells (Section 20.3)

**20.27** Indicate whether each statement is true or false: (a) The cathode is the electrode at which oxidation takes place. (b) A galvanic cell is another name for a voltaic cell. (c) Electrons flow spontaneously from anode to cathode in a voltaic cell.

**20.28** Indicate whether each statement is true or false: (a) The anode is the electrode at which oxidation takes place. (b) A voltaic cell always has a positive emf. (c) A salt bridge or permeable barrier is necessary to allow a voltaic cell to operate.

**20.29** A voltaic cell similar to that shown in Figure 20.5 is constructed. One electrode half-cell consists of a silver strip placed in a solution of  $\text{AgNO}_3$ , and the other has an iron

strip placed in a solution of  $\text{FeCl}_2$ . The overall cell reaction is

- (a) What is being oxidized, and what is being reduced? (b) Write the half-reactions that occur in the two half-cells. (c) Which electrode is the anode, and which is the cathode? (d) Indicate the signs of the electrodes. (e) Do electrons flow from the silver electrode to the iron electrode or from the iron to the silver? (f) In which directions do the cations and anions migrate through the solution?

**20.30** A voltaic cell similar to that shown in Figure 20.5 is constructed. One half-cell consists of an aluminum strip placed in a solution of  $\text{Al}(\text{NO}_3)_3$ , and the other has a nickel strip placed in a solution of  $\text{NiSO}_4$ . The overall cell reaction is

- (a) What is being oxidized, and what is being reduced? (b) Write the half-reactions that occur in the two half-cells. (c) Which electrode is the anode, and which is the cathode? (d) Indicate the signs of the electrodes. (e) Do electrons flow from the aluminum electrode to the nickel electrode or from the nickel to the aluminum? (f) In which directions do the cations and anions migrate through the solution? Assume the Al is not coated with its oxide.

## Cell Potentials under Standard Conditions (Section 20.4)

**20.31** (a) What is the definition of the *volt*? (b) Do all voltaic cells produce a positive cell potential?

**20.32** (a) Which electrode of a voltaic cell, the cathode or the anode, corresponds to the higher potential energy for the electrons? (b) What are the units for electrical potential? How does this unit relate to energy expressed in joules?

**20.33** (a) Write the half-reaction that occurs at a hydrogen electrode in acidic aqueous solution when it serves as the cathode of a voltaic cell. (b) Write the half-reaction that occurs at a hydrogen electrode in acidic aqueous solution when it serves as the anode of a voltaic cell. (c) What is *standard* about the standard hydrogen electrode?

**20.34** (a) What conditions must be met for a reduction potential to be a *standard reduction potential*? (b) What is the standard reduction potential of a standard hydrogen electrode? (c) Why is it impossible to measure the standard reduction potential of a single half-reaction?

**20.35** A voltaic cell that uses the reaction

has a measured standard cell potential of +1.19 V. (a) Write the two half-cell reactions. (b) By using data from Appendix E, determine  $E_{\text{red}}^\circ$  for the reduction of  $\text{Ti}^{3+}(aq)$  to  $\text{Ti}^+(aq)$ . (c) Sketch the voltaic cell, label the anode and cathode, and indicate the direction of electron flow.

**20.36** A voltaic cell that uses the reaction

has a measured standard cell potential of +1.03 V. (a) Write the two half-cell reactions. (b) By using data from Appendix E, determine  $E_{\text{red}}^\circ$  for the reaction involving Pd. (c) Sketch the voltaic cell, label the anode and cathode, and indicate the direction of electron flow.

**20.37** Using standard reduction potentials (Appendix E), calculate the standard emf for each of the following reactions:

- (a)  $\text{Cl}_2(g) + 2\text{I}^-(aq) \longrightarrow 2\text{Cl}^-(aq) + \text{I}_2(s)$   
 (b)  $\text{Ni}(s) + 2\text{Ce}^{4+}(aq) \longrightarrow \text{Ni}^{2+}(aq) + 2\text{Ce}^{3+}(aq)$

- (c)  $\text{Fe}(s) + 2\text{Fe}^{3+}(aq) \longrightarrow 3\text{Fe}^{2+}(aq)$   
 (d)  $2\text{NO}_3^-(aq) + 8\text{H}^+(aq) + 3\text{Cu}(s) \longrightarrow 2\text{NO}(g) + 4\text{H}_2\text{O}(l) + 3\text{Cu}^{2+}(aq)$

**20.38** Using data in Appendix E, calculate the standard emf for each of the following reactions:

- (a)  $\text{H}_2(g) + \text{F}_2(g) \longrightarrow 2\text{H}^+(aq) + 2\text{F}^-(aq)$   
 (b)  $\text{Cu}^{2+}(aq) + \text{Ca}(s) \longrightarrow \text{Cu}(s) + \text{Ca}^{2+}(aq)$   
 (c)  $3\text{Fe}^{2+}(aq) \longrightarrow \text{Fe}(s) + 2\text{Fe}^{3+}(aq)$   
 (d)  $2\text{ClO}_3^-(aq) + 10\text{Br}^-(aq) + 12\text{H}^+(aq) \longrightarrow \text{Cl}_2(g) + 5\text{Br}_2(l) + 6\text{H}_2\text{O}(l)$

**20.39** The standard reduction potentials of the following half-reactions are given in Appendix E:

(a) Determine which combination of these half-cell reactions leads to the cell reaction with the largest positive cell potential and calculate the value. (b) Determine which combination of these half-cell reactions leads to the cell reaction with the smallest positive cell potential and calculate the value.

**20.40** Given the following half-reactions and associated standard reduction potentials:

(a) Write the equation for the combination of these half-cell reactions that leads to the largest positive emf and calculate the value. (b) Write the equation for the combination of half-cell reactions that leads to the smallest positive emf and calculate that value.

**20.41** A 1 M solution of  $\text{Cu}(\text{NO}_3)_2$  is placed in a beaker with a strip of Cu metal. A 1 M solution of  $\text{SnSO}_4$  is placed in a second beaker with a strip of Sn metal. A salt bridge connects the two beakers, and wires to a voltmeter link the two metal electrodes. (a) Which electrode serves as the anode, and which as the cathode? (b) Which electrode gains mass, and which loses mass as the cell reaction proceeds? (c) Write the equation for the overall cell reaction. (d) What is the emf generated by the cell under standard conditions?

**20.42** A voltaic cell consists of a strip of cadmium metal in a solution of  $\text{Cd}(\text{NO}_3)_2$  in one beaker, and in the other beaker a platinum electrode is immersed in a NaCl solution, with  $\text{Cl}_2$  gas bubbled around the electrode. A salt bridge connects the two beakers. (a) Which electrode serves as the anode, and which as the cathode? (b) Does the Cd electrode gain or lose mass as the cell reaction proceeds? (c) Write the equation for the overall cell reaction. (d) What is the emf generated by the cell under standard conditions?

- (a)  $\text{Fe}(s)$  or  $\text{Mg}(s)$   
 (b)  $\text{Ca}(s)$  or  $\text{Al}(s)$   
 (c)  $\text{H}_2(g, \text{acidic solution})$  or  $\text{H}_2\text{S}(g)$   
 (d)  $\text{BrO}_3^-(aq)$  or  $\text{IO}_3^-(aq)$

**20.44** From each of the following pairs of substances, use data in Appendix E to choose the one that is the stronger oxidizing agent:

- (a)  $\text{Cl}_2(g)$  or  $\text{Br}_2(l)$   
 (b)  $\text{Zn}^{2+}(aq)$  or  $\text{Cd}^{2+}(aq)$   
 (c)  $\text{Cl}^-(aq)$  or  $\text{ClO}_3^-(aq)$   
 (d)  $\text{H}_2\text{O}_2(aq)$  or  $\text{O}_3(g)$

**20.45** By using the data in Appendix E, determine whether each of the following substances is likely to serve as an oxidant or a reductant: (a)  $\text{Cl}_2(g)$ , (b)  $\text{MnO}_4^-(aq, \text{acidic solution})$ , (c)  $\text{Ba}(s)$ , (d)  $\text{Zn}(s)$ .

**20.46** Is each of the following substances likely to serve as an oxidant or a reductant: (a)  $\text{Ce}^{3+}(aq)$ , (b)  $\text{Ca}(s)$ , (c)  $\text{ClO}_3^-(aq)$ , (d)  $\text{N}_2\text{O}_5(g)$ ?

**20.47** (a) Assuming standard conditions, arrange the following in order of increasing strength as oxidizing agents in acidic solution:  $\text{Cr}_2\text{O}_7^{2-}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{Cu}^{2+}$ ,  $\text{Cl}_2$ ,  $\text{O}_2$ . (b) Arrange the following in order of increasing strength as reducing agents in acidic solution:  $\text{Zn}$ ,  $\text{I}^-$ ,  $\text{Sn}^{2+}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{Al}$ .

**20.48** Based on the data in Appendix E, (a) which of the following is the strongest oxidizing agent, and which is the weakest in acidic solution:  $\text{Br}_2$ ,  $\text{H}_2\text{O}_2$ ,  $\text{Zn}$ ,  $\text{Cr}_2\text{O}_7^{2-}$ ? (b) Which of the following is the strongest reducing agent, and which is the weakest in acidic solution:  $\text{F}^-$ ,  $\text{Zn}$ ,  $\text{N}_2\text{H}_5^+$ ,  $\text{I}_2$ ,  $\text{NO}$ ?

**20.49** The standard reduction potential of  $\text{Eu}^{2+}(aq)$  is  $-0.43\text{ V}$ . Using Appendix E, which of the following substances is capable of reducing  $\text{Eu}^{3+}(aq)$  to  $\text{Eu}^{2+}(aq)$  under standard conditions:  $\text{Al}$ ,  $\text{Co}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{N}_2\text{H}_5^+$ ,  $\text{H}_2\text{C}_2\text{O}_4$ ?

**20.50** The standard reduction potential for the reduction of  $\text{RuO}_4^-(aq)$  to  $\text{RuO}_4^{2-}(aq)$  is  $+0.59\text{ V}$ . By using Appendix E, which of the following substances can oxidize  $\text{RuO}_4^{2-}(aq)$  to  $\text{RuO}_4^-(aq)$  under standard conditions:  $\text{Br}_2(l)$ ,  $\text{BrO}_3^-(aq)$ ,  $\text{Mn}^{2+}(aq)$ ,  $\text{O}_2(g)$ ,  $\text{Sn}^{2+}(aq)$ ?

## Free Energy and Redox Reactions (Section 20.5)

**20.51** Given the following reduction half-reactions:

- (a) Write balanced chemical equations for the oxidation of  $\text{Fe}^{2+}(aq)$  by  $\text{S}_2\text{O}_6^{2-}(aq)$ , by  $\text{N}_2\text{O}(aq)$ , and by  $\text{VO}_2^+(aq)$ . (b) Calculate  $\Delta G^\circ$  for each reaction at 298 K. (c) Calculate the equilibrium constant  $K$  for each reaction at 298 K.

**20.52** For each of the following reactions, write a balanced equation, calculate the standard emf, calculate  $\Delta G^\circ$  at 298 K, and calculate the equilibrium constant  $K$  at 298 K. (a) Aqueous iodide ion is oxidized to  $\text{I}_2(s)$  by  $\text{Hg}_2^{2+}(aq)$ . (b) In acidic solution, copper(I) ion is oxidized to copper(II) ion by nitrate ion. (c) In basic solution,  $\text{Cr}(\text{OH})_3(s)$  is oxidized to  $\text{CrO}_4^{2-}(aq)$  by  $\text{ClO}^-(aq)$ .

**20.53** If the equilibrium constant for a two-electron redox reaction at 298 K is  $1.5 \times 10^{-4}$ , calculate the corresponding  $\Delta G^\circ$  and  $E^\circ$ .

**20.54** If the equilibrium constant for a one-electron redox reaction at 298 K is  $8.7 \times 10^4$ , calculate the corresponding  $\Delta G^\circ$  and  $E^\circ$ .

## Strengths of Oxidizing and Reducing Agents (Section 20.4)

**20.43** From each of the following pairs of substances, use data in Appendix E to choose the one that is the stronger reducing agent:

**20.55** Using the standard reduction potentials listed in Appendix E, calculate the equilibrium constant for each of the following reactions at 298 K:

- (a)  $\text{Fe}(s) + \text{Ni}^{2+}(aq) \longrightarrow \text{Fe}^{2+}(aq) + \text{Ni}(s)$   
 (b)  $\text{Co}(s) + 2\text{H}^{+}(aq) \longrightarrow \text{Co}^{2+}(aq) + \text{H}_2(g)$   
 (c)  $10\text{Br}^{-}(aq) + 2\text{MnO}_4^{-}(aq) + 16\text{H}^{+}(aq) \longrightarrow 2\text{Mn}^{2+}(aq) + 8\text{H}_2\text{O}(l) + 5\text{Br}_2(l)$

**20.56** Using the standard reduction potentials listed in Appendix E, calculate the equilibrium constant for each of the following reactions at 298 K:

- (a)  $\text{Cu}(s) + 2\text{Ag}^{+}(aq) \longrightarrow \text{Cu}^{2+}(aq) + 2\text{Ag}(s)$   
 (b)  $3\text{Ce}^{4+}(aq) + \text{Bi}(s) + \text{H}_2\text{O}(l) \longrightarrow 3\text{Ce}^{3+}(aq) + \text{BiO}^{+}(aq) + 2\text{H}^{+}(aq)$   
 (c)  $\text{N}_2\text{H}_5^{+}(aq) + 4\text{Fe}(\text{CN})_6^{3-}(aq) \longrightarrow \text{N}_2(g) + 5\text{H}^{+}(aq) + 4\text{Fe}(\text{CN})_6^{4-}(aq)$

**20.57** A cell has a standard cell potential of +0.177 V at 298 K. What is the value of the equilibrium constant for the reaction (a) if  $n = 1$ ? (b) if  $n = 2$ ? (c) if  $n = 3$ ?

**20.58** At 298 K a cell reaction has a standard cell potential of +0.17 V. The equilibrium constant for the reaction is  $5.5 \times 10^5$ . What is the value of  $n$  for the reaction?

**20.59** A voltaic cell is based on the reaction

Under standard conditions, what is the maximum electrical work, in joules, that the cell can accomplish if 75.0 g of Sn is consumed?

**20.60** Consider the voltaic cell illustrated in Figure 20.5, which is based on the cell reaction

Under standard conditions, what is the maximum electrical work, in joules, that the cell can accomplish if 50.0 g of copper is formed?

## Cell EMF under Nonstandard Conditions (Section 20.6)

**20.61** (a) In the Nernst equation, what is the numerical value of the reaction quotient,  $Q$ , under standard conditions? (b) Can the Nernst equation be used at temperatures other than room temperature?

**20.62** A voltaic cell is constructed with all reactants and products in their standard states. Will the concentration of the reactants increase, decrease, or remain the same as the cell operates?

**20.63** What is the effect on the emf of the cell shown in Figure 20.9, which has the overall reaction  $\text{Zn}(s) + 2\text{H}^{+}(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{H}_2(g)$ , for each of the following changes? (a) The pressure of the  $\text{H}_2$  gas is increased in the cathode half-cell. (b) Zinc nitrate is added to the anode half-cell. (c) Sodium hydroxide is added to the cathode half-cell, decreasing  $[\text{H}^{+}]$ . (d) The surface area of the anode is doubled.

**20.64** A voltaic cell utilizes the following reaction:

What is the effect on the cell emf of each of the following changes? (a) Water is added to the anode half-cell, diluting the solution. (b) The size of the aluminum electrode is increased. (c) A solution of  $\text{AgNO}_3$  is added to the cathode half-cell, increasing the quantity of  $\text{Ag}^{+}$  but not changing its concentration. (d)  $\text{HCl}$  is added to the  $\text{AgNO}_3$  solution, precipitating some of the  $\text{Ag}^{+}$  as  $\text{AgCl}$ .

**20.65** A voltaic cell is constructed that uses the following reaction and operates at 298 K:

(a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when  $[\text{Ni}^{2+}] = 3.00\text{ M}$  and  $[\text{Zn}^{2+}] = 0.100\text{ M}$ ? (c) What is the emf of the cell when  $[\text{Ni}^{2+}] = 0.200\text{ M}$  and  $[\text{Zn}^{2+}] = 0.900\text{ M}$ ?

**20.66** A voltaic cell utilizes the following reaction and operates at 298 K:

(a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when  $[\text{Ce}^{4+}] = 3.0\text{ M}$ ,  $[\text{Ce}^{3+}] = 0.10\text{ M}$ , and  $[\text{Cr}^{3+}] = 0.010\text{ M}$ ? (c) What is the emf of the cell when  $[\text{Ce}^{4+}] = 0.010\text{ M}$ ,  $[\text{Ce}^{3+}] = 2.0\text{ M}$ , and  $[\text{Cr}^{3+}] = 1.5\text{ M}$ ?

**20.67** A voltaic cell utilizes the following reaction:

(a) What is the emf of this cell under standard conditions? (b) What is the emf of this cell when  $[\text{Fe}^{2+}] = 1.3\text{ M}$ ,  $[\text{Fe}^{3+}] = 0.010\text{ M}$ ,  $P_{\text{O}_2} = 0.50\text{ atm}$ , and the pH of the solution in the cathode half-cell is 3.50?

**20.68** A voltaic cell utilizes the following reaction:

(a) What is the emf of this cell under standard conditions? (b) What is the emf for this cell when  $[\text{Fe}^{3+}] = 3.50\text{ M}$ ,  $P_{\text{H}_2} = 0.95\text{ atm}$ ,  $[\text{Fe}^{2+}] = 0.0010\text{ M}$ , and the pH in both half-cells is 4.00?

**20.69** A voltaic cell is constructed with two  $\text{Zn}^{2+} - \text{Zn}$  electrodes. The two half-cells have  $[\text{Zn}^{2+}] = 1.8\text{ M}$  and  $[\text{Zn}^{2+}] = 1.00 \times 10^{-2}\text{ M}$ , respectively. (a) Which electrode is the anode of the cell? (b) What is the standard emf of the cell? (c) What is the cell emf for the concentrations given? (d) For each electrode, predict whether  $[\text{Zn}^{2+}]$  will increase, decrease, or stay the same as the cell operates.

**20.70** A voltaic cell is constructed with two silver-silver chloride electrodes, each of which is based on the following half-reaction:

The two half-cells have  $[\text{Cl}^{-}] = 0.0150\text{ M}$  and  $[\text{Cl}^{-}] = 2.55\text{ M}$ , respectively. (a) Which electrode is the cathode of the cell? (b) What is the standard emf of the cell? (c) What is the cell emf for the concentrations given? (d) For each electrode, predict whether  $[\text{Cl}^{-}]$  will increase, decrease, or stay the same as the cell operates.

**20.71** The cell in Figure 20.9 could be used to provide a measure of the pH in the cathode half-cell. Calculate the pH of the cathode half-cell solution if the cell emf at 298 K is measured to be +0.684 V when  $[\text{Zn}^{2+}] = 0.30\text{ M}$  and  $P_{\text{H}_2} = 0.90\text{ atm}$ .

**20.72** A voltaic cell is constructed that is based on the following reaction:

(a) If the concentration of  $\text{Sn}^{2+}$  in the cathode half-cell is  $1.00\text{ M}$  and the cell generates an emf of +0.22 V, what is the concentration of  $\text{Pb}^{2+}$  in the anode half-cell? (b) If the anode half-cell contains  $[\text{SO}_4^{2-}] = 1.00\text{ M}$  in equilibrium with  $\text{PbSO}_4(s)$ , what is the  $K_{\text{sp}}$  of  $\text{PbSO}_4$ ?

## Batteries and Fuel Cells (Section 20.7)

**20.73** During a period of discharge of a lead-acid battery, 402 g of Pb from the anode is converted into  $\text{PbSO}_4(s)$ . (a) What

mass of  $\text{PbO}_2(\text{s})$  is reduced at the cathode during this same period? **(b)** How many coulombs of electrical charge are transferred from Pb to  $\text{PbO}_2$ ?

- 20.74** During the discharge of an alkaline battery, 4.50 g of Zn is consumed at the anode of the battery. **(a)** What mass of  $\text{MnO}_2$  is reduced at the cathode during this discharge? **(b)** How many coulombs of electrical charge are transferred from Zn to  $\text{MnO}_2$ ?

- 20.75** Heart pacemakers are often powered by lithium–silver chromate “button” batteries. The overall cell reaction is

**(a)** Lithium metal is the reactant at one of the electrodes of the battery. Is it the anode or the cathode? **(b)** Choose the two half-reactions from Appendix E that *most closely approximate* the reactions that occur in the battery. What standard emf would be generated by a voltaic cell based on these half-reactions? **(c)** The battery generates an emf of +3.5 V. How close is this value to the one calculated in part (b)? **(d)** Calculate the emf that would be generated at body temperature, 37 °C. How does this compare to the emf you calculated in part (b)?

- 20.76** Mercuric oxide dry-cell batteries are often used where a flat discharge voltage and long life are required, such as in watches and cameras. The two half-cell reactions that occur in the battery are

**(a)** Write the overall cell reaction. **(b)** The value of  $E^\circ_{\text{red}}$  for the cathode reaction is +0.098 V. The overall cell potential is +1.35 V. Assuming that both half-cells operate under standard conditions, what is the standard reduction potential for the anode reaction? **(c)** Why is the potential of the anode reaction different than would be expected if the reaction occurred in an acidic medium?

- 20.77** **(a)** Suppose that an alkaline battery was manufactured using cadmium metal rather than zinc. What effect would this have on the cell emf? **(b)** What environmental advantage is provided by the use of nickel–metal hydride batteries over nickel–cadmium batteries?

- 20.78** In some applications nickel–cadmium batteries have been replaced by nickel–zinc batteries. The overall cell reaction for this relatively new battery is:

**(a)** What is the cathode half-reaction? **(b)** What is the anode half-reaction? **(c)** A single nickel–cadmium cell has a voltage of 1.30 V. Based on the difference in the standard reduction potentials of  $\text{Cd}^{2+}$  and  $\text{Zn}^{2+}$ , what voltage would you estimate a nickel–zinc battery will produce? **(d)** Would you expect the specific energy density of a nickel–zinc battery to be higher or lower than that of a nickel–cadmium battery?

- 20.79** In a Li-ion battery the composition of the cathode is  $\text{LiCoO}_2$  when completely discharged. On charging, approximately 50% of the  $\text{Li}^+$  ions can be extracted from the cathode and transported to the graphite anode where they intercalate between the layers. **(a)** What is the composition of the cathode when the battery is fully charged? **(b)** If the  $\text{LiCoO}_2$  cathode has a mass of 10 g (when fully discharged), how many coulombs of electricity can be delivered on completely discharging a fully charged battery?

- 20.80** Li-ion batteries used in automobiles typically use a  $\text{LiMn}_2\text{O}_4$  cathode in place of the  $\text{LiCoO}_2$  cathode found in

most Li-ion batteries. **(a)** Calculate the mass percent lithium in each electrode material. **(b)** Which material has a higher percentage of lithium? Does this help to explain why batteries made with  $\text{LiMn}_2\text{O}_4$  cathodes deliver less power on discharging? **(c)** In a battery that uses a  $\text{LiCoO}_2$  cathode, approximately 50% of the lithium migrates from the cathode to the anode on charging. In a battery that uses a  $\text{LiMn}_2\text{O}_4$  cathode, what fraction of the lithium in  $\text{LiMn}_2\text{O}_4$  would need to migrate out of the cathode to deliver the same amount of lithium to the graphite anode?

- 20.81** **(a)** Which reaction is spontaneous in the hydrogen fuel cell: hydrogen gas plus oxygen gas makes water, or water makes hydrogen gas plus oxygen gas? **(b)** Using the standard reduction potentials in Appendix E, calculate the standard voltage generated by the hydrogen fuel cell in acidic solution.

- 20.82** **(a)** What is the difference between a battery and a fuel cell? **(b)** Can the “fuel” of a fuel cell be a solid?

## Corrosion (Section 20.8)

- 20.83** **(a)** Write the anode and cathode reactions that cause the corrosion of iron metal to aqueous iron(II). **(b)** Write the balanced half-reactions involved in the air oxidation of  $\text{Fe}^{2+}(\text{aq})$  to  $\text{Fe}_2\text{O}_3 \cdot 3 \text{H}_2\text{O}(\text{s})$ .

- 20.84** **(a)** Based on standard reduction potentials, would you expect copper metal to oxidize under standard conditions in the presence of oxygen and hydrogen ions? **(b)** When the Statue of Liberty was refurbished, Teflon spacers were placed between the iron skeleton and the copper metal on the surface of the statue. What role do these spacers play?

- 20.85** **(a)** Magnesium metal is used as a sacrificial anode to protect underground pipes from corrosion. Why is the magnesium referred to as a “sacrificial anode”? **(b)** Looking in Appendix E, suggest what metal the underground pipes could be made from in order for magnesium to be successful as a sacrificial anode.

- 20.86** An iron object is plated with a coating of cobalt to protect against corrosion. Does the cobalt protect iron by cathodic protection?

- 20.87** Iron corrodes to produce rust,  $\text{Fe}_2\text{O}_3$ , but other corrosion products that can form are  $\text{Fe}(\text{O})(\text{OH})$ , iron oxyhydroxide, and magnetite,  $\text{Fe}_3\text{O}_4$ . **(a)** What is the oxidation number of Fe in iron oxyhydroxide, assuming oxygen’s oxidation number is –2? **(b)** The oxidation number for Fe in magnetite was controversial for a long time. If we assume that oxygen’s oxidation number is –2, and Fe has a unique oxidation number, what is the oxidation number for Fe in magnetite? **(c)** It turns out that there are two different kinds of Fe in magnetite that have different oxidation numbers. Suggest what these oxidation numbers are and what their relative stoichiometry must be, assuming oxygen’s oxidation number is –2.

- 20.88** Copper corrodes to cuprous oxide,  $\text{Cu}_2\text{O}$ , or cupric oxide,  $\text{CuO}$ , depending on environmental conditions. **(a)** What is the oxidation state of copper in cuprous oxide? **(b)** What is the oxidation state of copper in cupric oxide? **(c)** Copper peroxide is another oxidation product of elemental copper. Suggest a formula for copper peroxide based on its name. **(d)** Copper(III) oxide is another unusual oxidation product of elemental copper. Suggest a chemical formula for copper(III) oxide.

## Electrolysis (Section 20.9)

- 20.89** **(a)** What is *electrolysis*? **(b)** Are electrolysis reactions thermodynamically spontaneous? **(c)** What process occurs at

the anode in the electrolysis of molten NaCl? **(d)** Why is sodium metal not obtained when an aqueous solution of NaCl undergoes electrolysis?

- 20.90** **(a)** What is an *electrolytic cell*? **(b)** The negative terminal of a voltage source is connected to an electrode of an electrolytic cell. Is the electrode the anode or the cathode of the cell? Explain. **(c)** The electrolysis of water is often done with a small amount of sulfuric acid added to the water. What is the role of the sulfuric acid? **(d)** Why are active metals such as Al obtained by electrolysis using molten salts rather than aqueous solutions?

- 20.91** **(a)** A  $\text{Cr}^{3+}(\text{aq})$  solution is electrolyzed, using a current of 7.60 A. What mass of Cr(s) is plated out after 2.00 days? **(b)** What amperage is required to plate out 0.250 mol Cr from a  $\text{Cr}^{3+}$  solution in a period of 8.00 h?

- 20.92** Metallic magnesium can be made by the electrolysis of molten  $\text{MgCl}_2$ . **(a)** What mass of Mg is formed by passing a current of 4.55 A through molten  $\text{MgCl}_2$ , for 4.50 days? **(b)** How many minutes are needed to plate out 25.00 g Mg from molten  $\text{MgCl}_2$  using 3.50 A of current?

- 20.93** **(a)** Calculate the mass of Li formed by electrolysis of molten LiCl by a current of  $7.5 \times 10^4$  A flowing for a period of

24 h. Assume the electrolytic cell is 85% efficient. **(b)** What is the minimum voltage required to drive the reaction?

- 20.94** Elemental calcium is produced by the electrolysis of molten  $\text{CaCl}_2$ . **(a)** What mass of calcium can be produced by this process if a current of  $7.5 \times 10^3$  A is applied for 48 h? Assume that the electrolytic cell is 68% efficient. **(b)** What is the minimum voltage needed to cause the electrolysis?

- 20.95** Metallic gold is collected from below the anode when a mixture of copper and gold metals is refined by electrolysis. Explain this behavior.

- 20.96** A mixture of copper and gold metals that is subjected to electrorefining contains tellurium as an impurity. The standard reduction potential between tellurium and its lowest common oxidation state,  $\text{Te}^{4+}$ , is

Given this information, describe the probable fate of tellurium impurities during electrorefining. Do the impurities fall to the bottom of the refining bath, unchanged, as copper is oxidized, or do they go into solution as ions? If they go into solution, do they plate out on the cathode?

## Additional Exercises

- 20.97** A *disproportionation* reaction is an oxidation–reduction reaction in which the same substance is oxidized and reduced. Complete and balance the following disproportionation reactions:

- (a)**  $\text{Ni}^+(\text{aq}) \longrightarrow \text{Ni}^{2+}(\text{aq}) + \text{Ni}(\text{s})$  (acidic solution)  
**(b)**  $\text{MnO}_4^{2-}(\text{aq}) \longrightarrow \text{MnO}_4^-(\text{aq}) + \text{MnO}_2(\text{s})$  (acidic solution)  
**(c)**  $\text{H}_2\text{SO}_3(\text{aq}) \longrightarrow \text{S}(\text{s}) + \text{HSO}_4^-(\text{aq})$  (acidic solution)  
**(d)**  $\text{Cl}_2(\text{aq}) \longrightarrow \text{Cl}^-(\text{aq}) + \text{ClO}^-(\text{aq})$  (basic solution)

- 20.98** A common shorthand way to represent a voltaic cell is

A double vertical line represents a salt bridge or a porous barrier. A single vertical line represents a change in phase, such as from solid to solution. **(a)** Write the half-reactions and overall cell reaction represented by  $\text{Fe} | \text{Fe}^{2+} || \text{Ag}^+ | \text{Ag}$ ; calculate the standard cell emf using data in Appendix E. **(b)** Write the half-reactions and overall cell reaction represented by  $\text{Zn} | \text{Zn}^{2+} || \text{H}^+ | \text{H}_2$ ; calculate the standard cell emf using data in Appendix E and use Pt for the hydrogen electrode. **(c)** Using the notation just described, represent a cell based on the following reaction:

Pt is used as an inert electrode in contact with the  $\text{ClO}_3^-$  and  $\text{Cl}^-$ . Calculate the standard cell emf given:  $\text{ClO}_3^-(\text{aq}) + 6\text{H}^+(\text{aq}) + 6\text{e}^- \longrightarrow \text{Cl}^-(\text{aq}) + 3\text{H}_2\text{O}(\text{l})$ ;  $E^\circ = 1.45\text{ V}$ .

- 20.99** Predict whether the following reactions will be spontaneous in acidic solution under standard conditions: **(a)** oxidation of Sn to  $\text{Sn}^{2+}$  by  $\text{I}_2$  (to form  $\text{I}^-$ ), **(b)** reduction of  $\text{Ni}^{2+}$  to Ni by  $\text{I}^-$  (to form  $\text{I}_2$ ), **(c)** reduction of  $\text{Ce}^{4+}$  to  $\text{Ce}^{3+}$  by  $\text{H}_2\text{O}_2$ , **(d)** reduction of  $\text{Cu}^{2+}$  to Cu by  $\text{Sn}^{2+}$  (to form  $\text{Sn}^{4+}$ ).

- [20.100]** Gold exists in two common positive oxidation states, +1 and +3. The standard reduction potentials for these oxidation states are

**(a)** Can you use these data to explain why gold does not tarnish in the air? **(b)** Suggest several substances that should be strong enough oxidizing agents to oxidize gold metal. **(c)** Miners obtain gold by soaking gold-containing ores in an aqueous solution of sodium cyanide. A very soluble complex ion of gold forms in the aqueous solution because of the redox reaction

What is being oxidized, and what is being reduced in this reaction? **(d)** Gold miners then react the basic aqueous product solution from part (c) with Zn dust to get gold metal. Write a balanced redox reaction for this process. What is being oxidized, and what is being reduced?

- 20.101** A voltaic cell is constructed from an  $\text{Ni}^{2+}(\text{aq}) - \text{Ni}(\text{s})$  half-cell and an  $\text{Ag}^+(\text{aq}) - \text{Ag}(\text{s})$  half-cell. The initial concentration of  $\text{Ni}^{2+}(\text{aq})$  in the  $\text{Ni}^{2+} - \text{Ni}$  half-cell is  $[\text{Ni}^{2+}] = 0.0100\text{ M}$ . The initial cell voltage is +1.12 V. **(a)** By using data in Appendix E, calculate the standard emf of this voltaic cell. **(b)** Will the concentration of  $\text{Ni}^{2+}(\text{aq})$  increase or decrease as the cell operates? **(c)** What is the initial concentration of  $\text{Ag}^+(\text{aq})$  in the  $\text{Ag}^+ - \text{Ag}$  half-cell?

- [20.102]** A voltaic cell is constructed that uses the following half-cell reactions:

The cell is operated at 298 K with  $[\text{Cu}^+] = 0.25\text{ M}$  and  $[\text{I}^-] = 0.035\text{ M}$ . **(a)** Determine  $E$  for the cell at these concentrations. **(b)** Which electrode is the anode of the cell? **(c)** Is the answer to part (b) the same as it would be if the cell were operated under standard conditions? **(d)** If  $[\text{Cu}^+]$  were equal to 0.15 M, at what concentration of  $\text{I}^-$  would the cell have zero potential?

- 20.103** Using data from Appendix E, calculate the equilibrium constant for the disproportionation of the copper(I) ion at room temperature:

- 20.104** (a) Write the reactions for the discharge and charge of a nickel-cadmium (nicad) rechargeable battery. (b) Given the following reduction potentials, calculate the standard emf of the cell:

$$E_{\text{red}}^\circ = -0.76\text{ V}$$

$$E_{\text{red}}^\circ = +0.49\text{ V}$$

(c) A typical nicad voltaic cell generates an emf of +1.30 V. Why is there a difference between this value and the one you calculated in part (b)? (d) Calculate the equilibrium constant for the overall nicad reaction based on this typical emf value.

- 20.105** The capacity of batteries such as the typical AA alkaline battery is expressed in units of milliamp-hours (mAh). An AA alkaline battery yields a nominal capacity of 2850 mAh. (a) What quantity of interest to the consumer is being expressed by the units of mAh? (b) The starting voltage of a fresh alkaline battery is 1.55 V. The voltage decreases during discharge and is 0.80 V when the battery has delivered its rated capacity. If we assume that the voltage declines linearly as current is withdrawn, estimate the total maximum electrical work the battery could perform during discharge.

- 20.106** Disulfides are compounds that have S—S bonds, like peroxides have O—O bonds. Thiols are organic compounds that have the general formula R—SH, where R is a generic hydrocarbon. The SH<sup>−</sup> ion is the sulfur counterpart of hydroxide, OH<sup>−</sup>. Two thiols can react to make a disulfide, R—S—S—R. (a) What is the oxidation state of sulfur in a thiol? (b) What is the oxidation state of sulfur in a disulfide? (c) If you react two thiols to make a disulfide, are you oxidizing or reducing the thiols? (d) If you wanted to convert a disulfide to two thiols, should you add a reducing agent or oxidizing agent to the solution? (e) Suggest what happens to the H's in the thiols when they form disulfides.

- [20.107]** (a) How many coulombs are required to plate a layer of chromium metal 0.25 mm thick on an auto bumper with a total area of 0.32 m<sup>2</sup> from a solution containing CrO<sub>4</sub><sup>2−</sup>? The density of chromium metal is 7.20 g/cm<sup>3</sup>. (b) What current flow is required for this electroplating if the bumper is to be plated in 10.0 s? (c) If the external source has an emf of +6.0 V and the electrolytic cell is 65% efficient, how much electrical power is expended to electroplate the bumper?

- 20.108** Magnesium is obtained by electrolysis of molten MgCl<sub>2</sub>. (a) Why is an aqueous solution of MgCl<sub>2</sub> not used in the electrolysis? (b) Several cells are connected in parallel by very large copper bars that convey current to the cells. Assuming that the cells are 96% efficient in producing the desired products in electrolysis, what mass of Mg is formed by passing a current of 97,000 A for a period of 24 h?

- 20.109** Calculate the number of kilowatt-hours of electricity required to produce 1.0 × 10<sup>3</sup> kg (1 metric ton) of aluminum by electrolysis of Al<sup>3+</sup> if the applied voltage is 4.50 V and the process is 45% efficient.

- 20.110** Some years ago a unique proposal was made to raise the *Titanic*. The plan involved placing pontoons within the ship using a surface-controlled submarine-type vessel. The pontoons would contain cathodes and would be filled with hydrogen gas formed by the electrolysis of water. It has been estimated that it would require about 7 × 10<sup>8</sup> mol of H<sub>2</sub> to provide the buoyancy to lift the ship (*J. Chem. Educ.*, 1973, Vol. 50, 61). (a) How many coulombs of electrical charge would be required? (b) What is the minimum voltage required to generate H<sub>2</sub> and O<sub>2</sub> if the pressure on the gases at the depth of the wreckage (2 mi) is 300 atm? (c) What is the minimum electrical energy required to raise the *Titanic* by electrolysis? (d) What is the minimum cost of the electrical energy required to generate the necessary H<sub>2</sub> if the electricity costs 85 cents per kilowatt-hour to generate at the site?

## Integrative Exercises

- 20.111** The Haber process is the principal industrial route for converting nitrogen into ammonia:

(a) What is being oxidized, and what is being reduced? (b) Using the thermodynamic data in Appendix C, calculate the equilibrium constant for the process at room temperature. (c) Calculate the standard emf of the Haber process at room temperature.

- [20.112]** In a galvanic cell the cathode is an Ag<sup>+</sup>(1.00 M)/Ag(s) half-cell. The anode is a standard hydrogen electrode immersed in a buffer solution containing 0.10 M benzoic acid (C<sub>6</sub>H<sub>5</sub>COOH) and 0.050 M sodium benzoate (C<sub>6</sub>H<sub>5</sub>COO<sup>−</sup>Na<sup>+</sup>). The measured cell voltage is 1.030 V. What is the pK<sub>a</sub> of benzoic acid?

- 20.113** Aqueous solutions of ammonia (NH<sub>3</sub>) and bleach (active ingredient NaOCl) are sold as cleaning fluids, but bottles of both of them warn: "Never mix ammonia and bleach, as toxic gases may be produced." One of the toxic gases that can be produced is chloramine, NH<sub>2</sub>Cl. (a) What is the oxidation number of chlorine in bleach? (b) What is the oxidation number of chlorine in chloramine? (c) Is Cl oxidized, reduced, or neither, upon the conversion of bleach to chloramine? (d) Another toxic gas that can be produced is nitrogen trichloride, NCl<sub>3</sub>. What is the oxidation number of N in nitrogen trichloride? (e) Is N oxidized, reduced,

or neither, upon the conversion of ammonia to nitrogen trichloride?

- 20.114** A voltaic cell is based on Ag<sup>+</sup>(aq)/Ag(s) and Fe<sup>3+</sup>(aq)/Fe<sup>2+</sup>(aq) half-cells. (a) What is the standard emf of the cell? (b) Which reaction occurs at the cathode and which at the anode of the cell? (c) Use S<sup>°</sup> values in Appendix C and the relationship between cell potential and free-energy change to predict whether the standard cell potential increases or decreases when the temperature is raised above 25 °C.

- 20.115** Hydrogen gas has the potential for use as a clean fuel in reaction with oxygen. The relevant reaction is

Consider two possible ways of utilizing this reaction as an electrical energy source: (i) Hydrogen and oxygen gases are combusted and used to drive a generator, much as coal is currently used in the electric power industry; (ii) hydrogen and oxygen gases are used to generate electricity directly by using fuel cells that operate at 85 °C. (a) Use data in Appendix C to calculate ΔH<sup>°</sup> and ΔS<sup>°</sup> for the reaction. We will assume that these values do not change appreciably with temperature. (b) Based on the values from part (a), what trend would you expect for the magnitude of ΔG for the reaction as the temperature increases? (c) What is the significance of the change in the magnitude of ΔG with temperature with respect to

the utility of hydrogen as a fuel? **(d)** Based on the analysis here, would it be more efficient to use the combustion method or the fuel-cell method to generate electrical energy from hydrogen?

- 20.116** Cytochrome, a complicated molecule that we will represent as  $\text{CyFe}^{2+}$ , reacts with the air we breathe to supply energy required to synthesize adenosine triphosphate (ATP). The body uses ATP as an energy source to drive other reactions (Section 19.7). At pH 7.0 the following reduction potentials pertain to this oxidation of  $\text{CyFe}^{2+}$ :

**(a)** What is  $\Delta G$  for the oxidation of  $\text{CyFe}^{2+}$  by air? **(b)** If the synthesis of 1.00 mol of ATP from adenosine diphosphate (ADP) requires a  $\Delta G$  of 37.7 kJ, how many moles of ATP are synthesized per mole of  $\text{O}_2$ ?

- [20.117]** The standard potential for the reduction of  $\text{AgSCN}(s)$  is +0.09 V.

Using this value and the electrode potential for  $\text{Ag}^+(aq)$ , calculate the  $K_{sp}$  for  $\text{AgSCN}$ .

- [20.118]** The  $K_{sp}$  value for  $\text{PbS}(s)$  is  $8.0 \times 10^{-28}$ . By using this value together with an electrode potential from Appendix E, determine the value of the standard reduction potential for the reaction

- 20.119** A student designs an ammeter (a device that measures electrical current) that is based on the electrolysis of water into hydrogen and oxygen gases. When electrical current of unknown magnitude is run through the device for 2.00 min, 12.3 mL of water-saturated  $\text{H}_2(g)$  is collected. The temperature of the system is 25.5 °C, and the atmospheric pressure is 768 torr. What is the magnitude of the current in amperes?

## Design an Experiment

You are asked to construct a voltaic cell that would simulate an alkaline battery by providing an electrical output of 1.50 V at the beginning of its discharge. After you complete it, your voltaic cell will be used to power an external device that draws a constant current of 0.50 amperes for 2.0 hours. You are given the following supplies: electrodes of each transition metal from manganese to zinc, the chloride salts of the +2 transition metal ions from  $\text{Mn}^{2+}$  to  $\text{Zn}^{2+}$  ( $\text{MnCl}_2$ ,  $\text{FeCl}_2$ ,  $\text{CoCl}_2$ ,  $\text{NiCl}_2$ ,  $\text{CuCl}_2$ , and  $\text{ZnCl}_2$ ), two 100 mL beakers, a salt bridge, a voltmeter, and wires to make electrical connections between the electrodes and the voltmeter. **(a)** Sketch out your

voltaic cell labeling the metal used for each electrode and the type and concentration of the solutions in which each electrode is immersed. Be sure to describe how many grams of the salt are dissolved and the total volume of solution in each beaker. **(b)** What will be the concentrations of the transition metal ion in each solution at the end of the 2-h discharge? **(c)** What voltage will the cell register at the end of the discharge? **(d)** How long would your cell run before it died because the reactant in one of the half-cells was completely consumed? Assume the current stays constant throughout the discharge.

# NUCLEAR CHEMISTRY

In our study of the structure and properties of matter, we have seen electrons as the major players. Chemical reactions involve the making and breaking of bonds, resulting in various changes in the electronic environments of the atoms involved. Nuclei, though certainly not unimportant, remain unchanged during chemical reactions. There is, however, another kind of reaction that we have yet to examine, one in which nuclei undergo change, thereby altering the very identities of the atoms involved.

Transformations of atomic nuclei are fittingly called **nuclear reactions**. Some nuclei change spontaneously at room temperature, emitting radiation. They are then said to be **radioactive**. As we will see, there are also other kinds of nuclear changes.

Nuclear reactions are the source of the energy in nuclear power plants, nuclear weapons, and stars. They are involved in various radiation therapies utilized to both diagnose and treat diseases. In addition, radioactive elements are used to help determine the mechanisms of chemical reactions, to trace the movement of atoms in biological systems and in the environment, and to date historical artifacts.

Nuclear reactions can release enormous amounts of energy—far more than the amounts involved in even the most energetic chemical reactions. Our chapter-opening photo shows the surface of the Sun. The tremendous energy that it releases is generated by nuclear reactions, principally by fusing hydrogen nuclei to form helium nuclei. Without nuclear reactions, there would be no sunlight and consequently no life on Earth.

◀ **THE SUN IS A HUGE SPHERE** so hot that nuclei and electrons move independently. It accounts for 99.86% of the mass of our solar system and is composed of 73.8% hydrogen, 24.8% helium, and 1.4% other elements. Most of the Sun's energy is generated in its core by the fusion of hydrogen nuclei to form helium nuclei. The Sun's surface releases this energy as electromagnetic radiation accompanied by a stream of charged particles called the solar wind. Bursts of radiation and particles continuously erupt from the surface, producing solar flares.

## WHAT'S AHEAD

- 21.1 ▶ Radioactivity and Nuclear Equations** Learn to describe nuclear reactions using equations analogous to chemical equations, in which the nuclear charges and masses of reactants and products are in balance. Also learn that radioactive nuclei most commonly decay by emission of *alpha*, *beta*, or *gamma* radiation.
- 21.2 ▶ Patterns of Nuclear Stability** Recognize that nuclear stability is determined largely by the *neutron-to-proton ratio*. For stable nuclei, this ratio increases with increasing atomic number. All nuclei with 84 or more protons are radioactive. Heavy nuclei gain stability by a series of nuclear disintegrations leading to stable nuclei.
- 21.3 ▶ Nuclear Transmutations** Explore *nuclear transmutations*, which are nuclear reactions induced by bombardment of a nucleus by a neutron or an accelerated charged particle.
- 21.4 ▶ Rates of Radioactive Decay** Learn that radioisotope decays are first-order kinetic processes with characteristic half-lives. Decay rates can be used to determine the age of ancient artifacts and geological formations.
- 21.5 ▶ Detection of Radioactivity** Learn that the radiation emitted by a radioactive substance can be detected by a variety of devices, including dosimeters, Geiger counters, and scintillation counters.
- 21.6 ▶ Energy Changes in Nuclear Reactions** Learn that energy changes in nuclear reactions are related to mass changes via Einstein's equation,  $E = mc^2$ . The *nuclear binding energy* of a nucleus is the difference between the mass of the nucleus and the sum of the masses of its nucleons.
- 21.7 ▶ Nuclear Power: Fission** Explore *nuclear fission*, in which a heavy nucleus splits to form two or more product nuclei. Nuclear fission is the energy source for nuclear power plants.
- 21.8 ▶ Nuclear Power: Fusion** Learn that in *nuclear fusion* two light nuclei are fused together to form a more stable, heavier nucleus.
- 21.9 ▶ Radiation in the Environment and Living Systems** Discover that naturally occurring radioisotopes bathe our planet—and us—with low levels of radiation. The radiation emitted in nuclear reactions can damage living cells but also has diagnostic and therapeutic applications.

In this chapter, we examine various common kinds of nuclear reactions and the factors that relate to the stability of the nucleus. We also consider how the rates of nuclear reactions are described and used, how radioactivity is detected, and how energy changes associated with nuclear reactions can be calculated. Finally, we discuss the effects of radiation on matter, especially living systems.

## 21.1 | Radioactivity and Nuclear Equations

To understand nuclear reactions, we must review and develop some ideas introduced in Section 2.3:

- Two types of subatomic particles reside in the nucleus: *protons* and *neutrons*. We will refer to these particles as **nucleons**.
- All atoms of a given element have the same number of protons; this number is the element's *atomic number*.
- Atoms of a given element can have different numbers of neutrons, which means they can have different mass numbers. The *mass number* is the total number of nucleons in the nucleus.
- Atoms with the same atomic number but different mass numbers are known as *isotopes*.

The different isotopes of an element are distinguished by their mass numbers. For example, the three naturally occurring isotopes of uranium are uranium-234, uranium-235, and uranium-238, where the numerical suffixes represent the mass numbers. These isotopes are also written  $^{234}_{92}\text{U}$ ,  $^{235}_{92}\text{U}$ , and  $^{238}_{92}\text{U}$ , where the superscript is the mass number and the subscript is the atomic number.\*

Different isotopes of an element have different natural abundances. For example, 99.3% of naturally occurring uranium is uranium-238, 0.7% is uranium-235, and only a trace is uranium-234. Different isotopes of an element also have different stabilities. Indeed, the nuclear properties of any given isotope depend on the number of protons and neutrons in its nucleus.

A *nuclide* is a nucleus containing a specified number of protons and neutrons. Nuclides that are radioactive are called **radionuclides**, and atoms containing these nuclei are called **radioisotopes**.

### Nuclear Equations

Most nuclei in nature are stable and remain intact indefinitely. Radionuclides, however, are unstable and spontaneously emit particles and electromagnetic radiation. Emission of radiation is one of the ways in which an unstable nucleus is transformed into a more stable one that has less energy. The emitted radiation is the carrier of the excess energy. Uranium-238, for example, is radioactive, undergoing a nuclear reaction emitting helium-4 nuclei. The helium-4 particles are known as **alpha ( $\alpha$ ) particles**, and a stream of them is called *alpha radiation*. When a  $^{238}_{92}\text{U}$  nucleus loses an alpha particle, the remaining fragment has an atomic number of 90 and a mass number of 234. The element with atomic number 90 is Th, thorium. Therefore, the products of uranium-238 decomposition are an alpha particle and a thorium-234 nucleus. We represent this reaction by the *nuclear equation*

\*As noted in Section 2.3, we often do not explicitly write the atomic number of an isotope because the element symbol is specific to the atomic number. In studying nuclear chemistry, however, it is often useful to include the atomic number in order to help us keep track of changes in the nuclei.

When a nucleus spontaneously decomposes in this way, it is said to be *radioactive* and to have decayed or to have undergone *radioactive decay*. Because an alpha particle is involved in this reaction, scientists also describe the process as **alpha decay** or **alpha emission**.

### Give It Some Thought

What change in the mass number of a nucleus occurs when the nucleus emits an alpha particle?

In Equation 21.1 the sum of the mass numbers is the same on both sides of the equation ( $238 = 234 + 4$ ). Likewise, the sum of the atomic numbers on both sides of the equation is equal ( $92 = 90 + 2$ ). Mass numbers and atomic numbers must be balanced in all nuclear equations.

The radioactive properties of the nucleus in an atom are independent of the chemical state of the atom. In writing nuclear equations, therefore, we are not concerned with the chemical form (element or compound) of the atom in which the nucleus resides.

### Sample Exercise 21.1

#### Predicting the Product of a Nuclear Reaction

What product is formed when radium-226 undergoes alpha emission?

#### SOLUTION

**Analyze** We are asked to determine the nucleus that results when radium-226 loses an alpha particle.

**Plan** We can best do this by writing a balanced nuclear reaction for the process.

**Solve** The periodic table shows that radium has an atomic number of 88. The complete chemical symbol for radium-226 is therefore  $^{226}_{88}\text{Ra}$ . An alpha particle is a helium-4 nucleus, and so its symbol is  $^4_2\text{He}$ . The alpha particle is a product of the nuclear reaction, and so the equation is of the form

where  $A$  is the mass number of the product nucleus and  $Z$  is its atomic number. Mass numbers and atomic numbers must balance, so

$$226 = A + 4$$

and

$$88 = Z + 2$$

Hence,

$$A = 222 \quad \text{and} \quad Z = 86$$

Again, from the periodic table, the element with  $Z = 86$  is radon (Rn). The product, therefore, is  $^{222}_{86}\text{Rn}$ , and the nuclear equation is

#### Practice Exercise 1

What product forms when plutonium-238 undergoes alpha emission?

- (a) Plutonium-234   (b) Uranium-234   (c) Uranium-238  
(d) Thorium-236   (e) Neptunium-237

#### Practice Exercise 2

Which element undergoes alpha emission to form lead-208?

## Types of Radioactive Decay

The three most common kinds of radiation given off when a radionuclide decays are alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) radiation. [Section 2.2](#) Table 21.1 summarizes some of the important properties of these types of radiation.

**Alpha Radiation** As described earlier, alpha radiation consists of a stream of helium-4 nuclei known as alpha particles, which we denote as  $^4_2\text{He}$  or simply  $\alpha$ .

TABLE 21.1 Properties of Alpha, Beta, and Gamma Radiation

| Property                   | Type of Radiation                |                                  |                     |
|----------------------------|----------------------------------|----------------------------------|---------------------|
|                            | $\alpha$                         | $\beta$                          | $\gamma$            |
| Charge                     | 2+                               | 1−                               | 0                   |
| Mass                       | $6.64 \times 10^{-24} \text{ g}$ | $9.11 \times 10^{-28} \text{ g}$ | 0                   |
| Relative penetrating power | 1                                | 100                              | 10,000              |
| Nature of radiation        | $^4_2\text{He}$ nuclei           | Electrons                        | High-energy photons |

**Beta Radiation** *Beta radiation* consists of streams of **beta ( $\beta$ ) particles**, which are high-speed electrons emitted by an unstable nucleus. Beta particles are represented in nuclear equations by  ${}_{-1}^0\text{e}$  or more commonly by  $\beta^-$ . The superscript 0 indicates that the mass of the electron is exceedingly small relative to the mass of a nucleon. The subscript  $-1$  represents the negative charge of the beta particle, which is opposite that of the proton.

Iodine-131 is an isotope that undergoes decay by **beta emission**:

We see from this equation that beta decay causes the atomic number of the reactant to increase from 53 to 54, which means a proton was created. Therefore, beta emission is equivalent to the conversion of a neutron ( ${}_0^1\text{n}$  or simply  $\text{n}$ ) to a proton ( ${}_1^1\text{H}$  or simply  $\text{p}$ ):

Just because an electron is emitted from a nucleus in beta decay, we should not think that the nucleus is composed of these particles any more than we consider a match to be composed of sparks simply because it gives them off when struck. The beta-particle electron comes into being only when the nucleus undergoes a nuclear reaction. Furthermore, the speed of the beta particle is sufficiently high that it does not end up in an orbital of the decaying atom.

**Gamma Radiation** *Gamma ( $\gamma$ ) radiation* (or **gamma rays**) consists of high-energy photons (that is, electromagnetic radiation of very short wavelength). It changes neither the atomic number nor the mass number of a nucleus and is represented as either  ${}_0^0\gamma$  or simply  $\gamma$ . Gamma radiation usually accompanies other radioactive emission because it represents the energy lost when the nucleons in a nuclear reaction reorganize into more stable arrangements. Often gamma rays are not explicitly shown when writing nuclear equations.

**Positron Emission and Electron Capture** Two other types of radioactive decay are positron emission and electron capture. A **positron**, represented as  ${}_{+1}^0\text{e}$ , or simply as  $\beta^+$ , is a particle that has the same mass as an electron (thus, we use the letter  $\text{e}$  and superscript 0 for the mass) but the opposite charge (represented by the  $+1$  subscript).\*

The isotope carbon-11 decays by **positron emission**:

Positron emission causes the atomic number of the reactant in this equation to decrease from 6 to 5. In general, positron emission has the effect of converting a proton to a neutron, thereby decreasing the atomic number of the nucleus by 1 while not changing the mass number:

**Electron capture** is the capture by the nucleus of an electron from the electron cloud surrounding the nucleus, as in this rubidium-81 decay:

Because the electron is consumed rather than formed in the process, it is shown on the reactant side of the equation. Electron capture, like positron emission, has the effect of converting a proton to a neutron:

**Table 21.2** summarizes the symbols used to represent the particles commonly encountered in nuclear reactions. The various types of radioactive decay are summarized in **Table 21.3**.

**TABLE 21.2** Particles Found in Nuclear Reactions

| Particle       | Symbol                           |
|----------------|----------------------------------|
| Neutron        | ${}_0^1\text{n}$ or $\text{n}$   |
| Proton         | ${}_1^1\text{H}$ or $\text{p}$   |
| Electron       | ${}_{-1}^0\text{e}$              |
| Alpha particle | ${}_2^4\text{He}$ or $\alpha$    |
| Beta particle  | ${}_{-1}^0\text{e}$ or $\beta^-$ |
| Positron       | ${}_{+1}^0\text{e}$ or $\beta^+$ |

\*The positron has a very short life because it is annihilated when it collides with an electron, producing gamma rays:  ${}_{+1}^0\text{e} + {}_{-1}^0\text{e} \longrightarrow 2 {}_0^0\gamma$ .

TABLE 21.3 Types of Radioactive Decay

| Type              | Nuclear Equation  | Change in Atomic Number | Change in Mass Number |
|-------------------|---|-------------------------|-----------------------|
| Alpha emission    | ${}_Z^AX \longrightarrow {}_{Z-2}^{A-4}Y + {}_2^4\text{He}$ | -2                      | -4                    |
| Beta emission     | ${}_Z^AX \longrightarrow {}_{Z+1}^AY + {}_{-1}^0\text{e}$   | +1                      | Unchanged             |
| Positron emission | ${}_Z^AX \longrightarrow {}_{Z-1}^AY + {}_{+1}^0\text{e}$   | -1                      | Unchanged             |
| Electron capture* | ${}_Z^AX + {}_{-1}^0\text{e} \longrightarrow {}_Z^AY$       | -1                      | Unchanged             |

\*The electron captured comes from the electron cloud surrounding the nucleus.

### Give It Some Thought

Which type of radioactive decay converts a neutron into a proton?

## Sample Exercise 21.2

### Writing Nuclear Equations

Write nuclear equations for (a) mercury-201 undergoing electron capture; (b) thorium-231 decaying to protactinium-231.

### SOLUTION

**Analyze** We must write balanced nuclear equations in which the masses and charges of reactants and products are equal.

**Plan** We can begin by writing the complete chemical symbols for the nuclei and decay particles that are given in the problem.

#### Solve

(a) The information given in the question can be summarized as

The mass numbers must have the same sum on both sides of the equation:

$$201 + 0 = A$$

Thus, the product nucleus must have a mass number of 201. Similarly, balancing the atomic numbers gives

$$80 - 1 = Z$$

Thus, the atomic number of the product nucleus must be 79, which identifies it as gold (Au):

(b) In this case, we must determine what type of particle is emitted in the course of the radioactive decay:

From  $231 = 231 + A$  and  $90 = 91 + Z$ , we deduce  $A = 0$  and  $Z = -1$ . According to Table 21.2, the particle with these characteristics is the beta particle (electron). We therefore write

### Practice Exercise 1

The radioactive decay of thorium-232 occurs in multiple steps, called a *radioactive decay chain*. The second product produced in this chain is actinium-228. Which of the following processes could lead to this product starting with thorium-232?

- (a) Alpha decay followed by beta emission
- (b) Beta emission followed by electron capture
- (c) Positron emission followed by alpha decay
- (d) Electron capture followed by positron emission
- (e) More than one of the above is consistent with the observed transformation.

### Practice Exercise 2

Write a balanced nuclear equation for the reaction in which oxygen-15 undergoes positron emission.

## 21.2 | Patterns of Nuclear Stability

Some nuclides, such as  ${}_{6}^{12}\text{C}$  and  ${}_{6}^{13}\text{C}$  are stable, whereas others, such as  ${}_{6}^{14}\text{C}$ , are unstable and undergo radioactive decay. Why does a small difference in the number of neutrons affect the stability of a nuclide? No single rule allows us to predict whether a particular nucleus is radioactive and, if it is, how it might decay. However, several empirical observations can help us predict the stability of a nucleus.

### Neutron-to-Proton Ratio

Because like charges repel each other, it may seem surprising that a large number of protons can reside within the small volume of the nucleus. At close distances, however, a

strong force of attraction, called the *strong nuclear force*, exists between nucleons. Neutrons are intimately involved in this attractive force.

All nuclei other than  ${}^1_1\text{H}$  contain neutrons. As the number of protons in a nucleus increases, there is an ever greater need for neutrons to counteract the proton–proton repulsions. Stable nuclei with atomic numbers up to about 20 have approximately equal numbers of neutrons and protons. For nuclei with atomic number above 20, the number of neutrons exceeds the number of protons. Indeed, the number of neutrons necessary to create a stable nucleus increases more rapidly than the number of protons. Thus, the neutron-to-proton ratios of stable nuclei increase with increasing atomic number, as illustrated by the following isotopes:  ${}^{12}_6\text{C}$  ( $n/p = 1$ ), manganese,  ${}^{55}_{25}\text{Mn}$  ( $n/p = 1.20$ ), and gold,  ${}^{197}_{79}\text{Au}$  ( $n/p = 1.49$ ).

**Figure 21.1** shows all known isotopes of the elements through  $Z = 100$  plotted according to their numbers of protons and neutrons. Notice how the plot goes above the line for 1:1 neutron-to-proton for heavier elements. The dark blue dots in the figure represent stable (nonradioactive) isotopes. The region of the graph covered by these dark blue dots is known as the *belt of stability*. The belt of stability ends at element 83 (bismuth), which means that *all nuclei with 84 or more protons are radioactive*. For example, all isotopes of uranium,  $Z = 92$ , are radioactive.

Different radionuclides decay in different ways. The type of decay that occurs depends largely on a nuclide's neutron-to-proton ratio and how it compares with the

### Go Figure

Estimate the optimal number of neutrons for a nucleus containing 70 protons.

**▲ Figure 21.1** Stable and radioactive isotopes as a function of numbers of neutrons and protons in a nucleus. The stable nuclei (dark blue dots) define a region known as the belt of stability.

ratio of nearby nuclei that lie within the belt of stability. We can envision three general situations, which are labeled 1, 2, and 3, in Figure 21.1.

- 1. Nuclei above the belt of stability (high neutron-to-proton ratios).** These neutron-rich nuclei can lower their ratio and thereby move toward the belt of stability by emitting a beta particle because beta emission decreases the number of neutrons and increases the number of protons (Equation 21.3).
- 2. Nuclei below the belt of stability (low neutron-to-proton ratios).** These proton-rich nuclei can increase their ratio and so move closer to the belt of stability by either positron emission or electron capture because both decays increase the number of neutrons and decrease the number of protons (Equations 21.5 and 21.7). Positron emission is more common among lighter nuclei. Electron capture becomes increasingly common as the nuclear charge increases.
- 3. Nuclei with atomic numbers  $\geq 84$ .** These heavy nuclei tend to undergo alpha emission, which decreases both the number of neutrons and the number of protons by two, moving the nucleus diagonally toward the belt of stability.

### Sample Exercise 21.3

#### Predicting Modes of Nuclear Decay

Predict the mode of decay of (a) carbon-14, (b) xenon-118.

#### SOLUTION

**Analyze** We are asked to predict the modes of decay of two nuclei.

**Plan** To do this, we must locate the respective nuclei in Figure 21.1 and determine their positions with respect to the belt of stability in order to predict the most likely mode of decay.

#### Solve

- (a) Carbon is element 6. Thus, carbon-14 has 6 protons and  $14 - 6 = 8$  neutrons, giving it a neutron-to-proton ratio of 1.25. Elements with  $Z < 20$  normally have stable nuclei that contain approximately equal numbers of neutrons and protons ( $n/p = 1$ ). Thus, carbon-14 is located above the belt of stability, and we expect it to decay by emitting a beta particle to decrease the  $n/p$  ratio:

This is indeed the mode of decay observed for carbon-14, a reaction that lowers the  $n/p$  ratio from 1.25 to 1.0.

- (b) Xenon is element 54. Thus, xenon-118 has 54 protons and  $118 - 54 = 64$  neutrons, giving it an  $n/p$  ratio of 1.18. According to Figure 21.1, stable nuclei in this region of the belt of stability have higher neutron-to-proton ratios than

xenon-118. The nucleus can increase this ratio by either positron emission or electron capture:

In this case, both modes of decay are observed.

**Comment** Keep in mind that our guidelines do not always work. For example, thorium-233, which we might expect to undergo alpha decay, actually undergoes beta emission. Furthermore, a few radioactive nuclei lie within the belt of stability. Both  $^{146}_{60}\text{Nd}$  and  $^{148}_{60}\text{Nd}$ , for example, are stable and lie in the belt of stability.  $^{147}_{60}\text{Nd}$ , however, which lies between them, is radioactive.

#### ► Practice Exercise 1

Which of the following radioactive nuclei is most likely to decay via emission of a  $\beta^-$  particle?

- (a) nitrogen-13 (b) magnesium-23 (c) rubidium-83  
(d) iodine-131 (e) neptunium-237

#### ► Practice Exercise 2

Predict the mode of decay of (a) plutonium-239, (b) indium-120.

## Radioactive Decay Chains

Some nuclei cannot gain stability by a single emission. Consequently, a series of successive emissions occurs as shown for uranium-238 in Figure 21.2. Decay continues until a stable nucleus—lead-206 in this case—is formed. A series of nuclear reactions that begins with an unstable nucleus and terminates with a stable one is known as a **radioactive decay chain** or a **nuclear disintegration series**. Three such series occur in nature: uranium-238 to lead-206, uranium-235 to lead-207, and thorium-232 to lead-208. All of the decay processes in these series are either alpha emissions or beta emissions.

## Go Figure

Write the nuclear equation for the step shown for the first decay of Th.

▲ **Figure 21.2** Nuclear decay chain for uranium-238. The decay continues until the stable nucleus  $^{206}\text{Pb}$  is formed.

## Further Observations

Two further observations can help us to predict stable nuclei:

- Nuclei with the **magic numbers** of 2, 8, 20, 28, 50, or 82 protons or 2, 8, 20, 28, 50, 82, or 126 neutrons are generally more stable than nuclei that do not contain these numbers of nucleons.
- Nuclei with even numbers of protons, neutrons, or both are more likely to be stable than those with odd numbers of protons and/or neutrons. Approximately 60% of stable nuclei have an even number of both protons and neutrons, whereas less than 2% have odd numbers of both (Table 21.4).

**TABLE 21.4** Number of Stable Isotopes with Even and Odd Numbers of Protons and Neutrons

| Number of Stable Isotopes | Proton Number | Neutron Number |
|---------------------------|---------------|----------------|
| 157                       | Even          | Even           |
| 53                        | Even          | Odd            |
| 50                        | Odd           | Even           |
| 5                         | Odd           | Odd            |

These observations can be understood in terms of the *shell model of the nucleus*, in which nucleons are described as residing in shells analogous to the shell structure for electrons in atoms. Just as certain numbers of electrons correspond to stable filled-shell electron configurations, so too do certain numbers (known as magic numbers) of nucleons represent filled shells in nuclei.

There are several examples of the stability of nuclei with magic numbers of nucleons. For example, the radioactive series in Figure 21.2 ends with the stable  $^{206}_{82}\text{Pb}$  nucleus, which has a magic number of protons (82). Another example is the observation that tin, which has a magic number of protons (50), has ten stable isotopes, more than any other element.

Evidence also suggests that pairs of protons and pairs of neutrons have a special stability, analogous to the pairs of electrons in molecules. This evidence accounts for the

## Go Figure

Among the elements shown here, how many have an even number of protons and fewer than three stable isotopes? How many have an odd number of protons and more than two stable isotopes?

|                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                     |  |                                      |  |                                     |  |                                     |  |                                     |  |                                     |  |

▲ Figure 21.3 Number of stable isotopes for elements 1–54.

observation that stable nuclei with an even number of protons and/or neutrons are far more numerous than those with odd numbers. The preference for even numbers of protons is illustrated in Figure 21.3, which shows the number of stable isotopes for all elements up to Xe. Notice that once we move past nitrogen, the elements with an odd number of protons invariably have fewer stable isotopes than their neighbors with an even number of protons.

## Give It Some Thought

What can you say about the number of neutrons in the stable isotopes of fluorine, sodium, aluminum, and phosphorus?

## 21.3 | Nuclear Transmutations

Thus far we have examined nuclear reactions in which a nucleus decays spontaneously. A nucleus can also change identity if it is struck by a neutron or by another nucleus. Nuclear reactions induced in this way are known as **nuclear transmutations**.

In 1919, Ernest Rutherford performed the first conversion of one nucleus into another, using alpha particles emitted by radium to convert nitrogen-14 into oxygen-17:

Such reactions have allowed scientists to synthesize hundreds of radioisotopes in the laboratory.

A shorthand notation often used to represent nuclear transmutations lists the target nucleus, the bombarding particle and the ejected particle in parentheses, followed by the product nucleus. Using this condensed notation we see that, Equation 21.8 becomes

## Sample Exercise 21.4

## Writing a Balanced Nuclear Equation

Write the balanced nuclear equation for the process summarized as  ${}^{27}_{13}\text{Al}(n, \alpha){}^{24}_{11}\text{Na}$ .

## SOLUTION

**Analyze** We must go from the condensed descriptive form of the reaction to the balanced nuclear equation.

**Plan** We arrive at the balanced equation by writing  $n$  and  $\alpha$ , each with its associated subscripts and superscripts.

**Solve** The  $n$  is the abbreviation for a neutron ( ${}_0^1n$ ), and  $\alpha$  represents an alpha particle ( ${}_2^4\text{He}$ ). The neutron is the bombarding particle, and the alpha particle is a product. Therefore, the nuclear equation is

## Practice Exercise 1

Consider the following nuclear transmutation:  ${}^{238}_{92}\text{U}(n, \beta^-)\text{X}$ . What is the identity of nucleus X?

(a)  ${}^{238}_{93}\text{Np}$  (b)  ${}^{239}_{92}\text{U}$  (c)  ${}^{239}_{92}\text{U}^+$  (d)  ${}^{235}_{90}\text{Th}$  (e)  ${}^{239}_{93}\text{Np}$

## Practice Exercise 2

Write the condensed version of the nuclear reaction

(a)

(b)

▲ Figure 21.4 The linear accelerator.

## Accelerating Charged Particles

Alpha particles and other positively charged particles must move very fast to overcome the electrostatic repulsion between them and the target nucleus. The higher the nuclear charge on either the bombarding particle or the target nucleus, the faster the bombarding particle must move to bring about a nuclear reaction. Many methods have been devised to accelerate charged particles, using strong magnetic and electrostatic fields. These **particle accelerators**, popularly called “atom smashers,” bear such names as *cyclotron* and *synchrotron*.

A common theme of all particle accelerators is the need to create charged particles so that they can be manipulated by electric and magnetic fields. In addition, the region through which the particles move must be kept at high vacuum so that they do not collide with any gas-phase molecules.

Figure 21.4(a) shows a multistage linear accelerator. A charged particle, such as a proton, is accelerated through a series of tubes of increasing length. The electrical charge on the tubes is changed from positive to negative, so that the particle is always attracted to the tube it is approaching and repelled by the one it is leaving. As a result, the particle accelerates until it has sufficient kinetic energy to smash into a target nucleus. Figure 21.4(b) shows the

Stanford linear accelerator, which is 2.0 mi in length.

Figure 21.5(a) shows a *cyclotron*. In this device, charged particles move in a spiral path within two D-shaped electrodes. Alternating charges on the electrodes accelerate the particles, while magnets above and below the device constrain the particles to a spiral path of increasing radius. In a *synchrotron*, the magnetic fields are synchronized so that the particle moves in a circular rather than a spiral path. Figure 21.5(b) shows the Fermi National Accelerator Lab at Batavia, Illinois, which has a circumference of 3.9 mi.

## Reactions Involving Neutrons

Most synthetic isotopes used in medicine and scientific research are made using neutrons as the bombarding particles. Because neutrons are neutral, they are not repelled by the nucleus. Consequently, they do not need to be accelerated to cause nuclear reactions. The neutrons are produced in nuclear reactors (see Section 21.7). For example, cobalt-60, which is used in cancer radiation therapy, is produced by neutron capture. Iron-58 is placed in a nuclear reactor and bombarded by neutrons to trigger the following sequence of reactions:

## Transuranium Elements

Nuclear transmutations have been used to produce the elements with atomic number above 92, collectively known as the **transuranium elements** because they follow uranium in the periodic table. Elements 93 (neptunium, Np) and 94 (plutonium, Pu) were produced in 1940 by bombarding uranium-238 with neutrons:

Elements with still larger atomic numbers are normally formed in small quantities in particle accelerators. Curium-242, for example, is formed when a plutonium-239 target is bombarded with accelerated alpha particles:

▲ Figure 21.5 The cyclotron.

New advances in the detection of the decay patterns of single atoms have led to recent additions to the periodic table. Between 1994 and 2010, elements 110 through 118 were discovered via the nuclear reactions that occur when nuclei of much lighter elements collide with high energy. For example, in 1996 a team of European scientists based in Germany synthesized element 112, copernicium, Cn, by bombarding a lead target continuously for three weeks with a beam of zinc atoms:

Amazingly, their discovery was based on the detection of only one atom of the new element, which decays after roughly  $100\ \mu\text{s}$  by alpha decay to form darmstadtium-273 (element 110). Within one minute, another five alpha decays take place producing fermium-253 (element 100). The finding has been verified in both Japan and Russia.

Because experiments to create new elements are very complicated and produce only a very small number of atoms of the new elements, they need to be carefully evaluated and reproduced before the new element is made an official part of the periodic table.

The International Union for Pure and Applied Chemistry (IUPAC) is the international body that authorizes names of new elements after their experimental discovery and confirmation. According to the IUPAC, new elements can be named after a mythological concept, a mineral, a place or country, a property, or a scientist. In 2016, IUPAC approved the following names and symbols for elements 113, 115, 117, and 118, as suggested by their discoverers: nihonium, Nh, for element 113; moscovium, Mc, for element 115; tennessine, Ts, for element 117; and oganesson, Og, for element 118.

## 21.4 | Rates of Radioactive Decay

Some radioisotopes, such as uranium-238, are found in nature even though they are not stable. Other radioisotopes do not exist in nature but can be synthesized in nuclear reactions. To understand this distinction, we must realize that different nuclei undergo radioactive decay at different rates. Many radioisotopes decay essentially completely in fractions of a second, so we do not find them in nature. Uranium-238, on the other hand, decays very slowly. Therefore, despite its instability, we can still observe what remains from its formation in the early history of the universe.

Radioactive decay is a first-order kinetic process. Recall that a first-order process has a characteristic **half-life**, which is the time required for half of any given quantity of a substance to react.  (Section 14.4) Nuclear decay rates are commonly expressed in terms of half-lives. Each radioisotope has its own characteristic half-life. For example, strontium-90 has a half-life of 28.8 yr:

Thus, if we start with 10.0 g of strontium-90, only 5.0 g of that isotope remains after 28.8 yr, 2.5 g remains after another 28.8 yr, and so on (Figure 21.6).

Half-lives as short as millionths of a second and as long as billions of years are known. The half-lives of some radioisotopes are listed in Table 21.5. One important feature of half-lives for nuclear decay is that they are unaffected by external conditions such as temperature, pressure, or state of chemical combination. Unlike toxic chemicals, therefore, radioactive atoms cannot be rendered harmless by chemical reaction or by any other practical treatment.

### Go Figure

If we start with a 50.0-g sample, how much remains after three half-lives have passed?

▲ **Figure 21.6** Decay of a 10.0-g sample of strontium-90 ( $t_{1/2} = 28.8\ \text{yr}$ ). The  $10 \times 10$  grids show how much of the radioactive isotope remains after various amounts of time.

**TABLE 21.5 The Half-Lives and Type of Decay for Several Radioisotopes**

|                                | Isotope                | Half-Life (yr)       | Type of Decay |
|--------------------------------|------------------------|----------------------|---------------|
| <b>Natural radioisotopes</b>   | $^{238}_{92}\text{U}$  | $4.5 \times 10^9$    | Alpha         |
|                                | $^{235}_{92}\text{U}$  | $7.0 \times 10^8$    | Alpha         |
|                                | $^{232}_{90}\text{Th}$ | $1.4 \times 10^{10}$ | Alpha         |
|                                | $^{40}_{19}\text{K}$   | $1.3 \times 10^9$    | Beta          |
|                                | $^{14}_6\text{C}$      | 5700                 | Beta          |
| <b>Synthetic radioisotopes</b> | $^{239}_{94}\text{Pu}$ | 24,000               | Alpha         |
|                                | $^{137}_{55}\text{Cs}$ | 30.2                 | Beta          |
|                                | $^{90}_{38}\text{Sr}$  | 28.8                 | Beta          |
|                                | $^{131}_{53}\text{I}$  | 0.022                | Beta          |

**Sample Exercise 21.5****Calculation Involving Half-Lives**

The half-life of cobalt-60 is 5.27 yr. How much of a 1.000-mg sample of cobalt-60 is left after 15.81 yr?

**SOLUTION**

**Analyze** We are given the half-life for cobalt-60 and asked to calculate the amount of cobalt-60 remaining from an initial 1.000-mg sample after 15.81 yr.

**Plan** We will use the fact that the amount of a radioactive substance decreases by 50% for every half-life that passes.

**Solve** Because  $5.27 \times 3 = 15.81$ , 15.81 yr is three half-lives for cobalt-60. At the end of one half-life, 0.500 mg of cobalt-60 remains, 0.250 mg at the end of two half-lives, and 0.125 mg at the end of three half-lives.

**Practice Exercise 1**

A radioisotope of technetium is useful in medical imaging techniques. A sample initially contains 80.0 mg of this

isotope. After 24.0 h, only 5.0 mg of the technetium isotope remains. What is the half-life of the isotope?

(a) 3.0 h (b) 6.0 h (c) 12.0 h (d) 16.0 h (e) 24.0 h

**Practice Exercise 2**

Carbon-11, used in medical imaging, has a half-life of 20.4 min. The carbon-11 nuclides are formed, and the carbon atoms are then incorporated into an appropriate compound. The resulting sample is injected into a patient, and the medical image is obtained. If the entire process takes five half-lives, what percentage of the original carbon-11 remains at this time?

**Radiometric Dating**

Because the half-life of any particular nuclide is constant, the half-life can serve as a “nuclear clock” to determine the age of objects. The method of dating objects based on their isotopes and isotope abundances is called *radiometric dating*.

When carbon-14 is used in radiometric dating, the technique is known as *radio-carbon dating*. The procedure is based on the formation of carbon-14 as neutrons created by cosmic rays in the upper atmosphere convert nitrogen-14 into carbon-14 (Figure 21.7). The  $^{14}\text{C}$  reacts with oxygen to form  $^{14}\text{CO}_2$  in the atmosphere, and this “labeled”  $\text{CO}_2$  is taken up by plants and introduced into the food chain through photosynthesis. This process provides a small but reasonably constant source of carbon-14, which is radioactive and undergoes beta decay with a half-life of 5700 yr (to two significant figures):

Because a living plant or animal has a constant intake of carbon compounds, it is able to maintain a ratio of carbon-14 to carbon-12 that is nearly identical with that of the atmosphere. Once the organism dies, however, it no longer ingests carbon compounds

## Go Figure

How does  $^{14}\text{CO}_2$  become incorporated into the mammalian food chain?

▲ **Figure 21.7** Creation and distribution of carbon-14. The ratio of carbon-14 to carbon-12 in a dead animal or plant is related to the time since death occurred.

to replenish the carbon-14 lost through radioactive decay. The ratio of carbon-14 to carbon-12 therefore decreases. By measuring this ratio and comparing it with that of the atmosphere, we can estimate the age of an object. For example, if the ratio diminishes to half that of the atmosphere, we can conclude that the object is one half-life, or 5700 yr, old.

This method cannot be used to date objects older than about 50,000 yr because after this length of time the radioactivity is too low to be measured accurately.

In radiocarbon dating, a reasonable assumption is that the ratio of carbon-14 to carbon-12 in the atmosphere has been relatively constant for the past 50,000 yr. However, because variations in solar activity control the amount of carbon-14 produced in the atmosphere, that ratio can fluctuate. We can correct for this effect by using other kinds of data. Recently, scientists have compared carbon-14 data with data from tree rings, corals, lake sediments, ice cores, and other natural sources to correct variations in the carbon-14 “clock” back to 26,000 yr.

Other isotopes can be similarly used to date other types of objects. For example, it takes  $4.5 \times 10^9$  yr for half of a sample of uranium-238 to decay to lead-206. The age of rocks containing uranium can therefore be determined by measuring the ratio of lead-206 to uranium-238. If the lead-206 had somehow become incorporated into the rock by normal chemical processes instead of by radioactive decay, the rock would also contain large amounts of the more abundant isotope lead-208. In the absence of large amounts of this “geonormal” isotope of lead, it is assumed that all of the lead-206 was at one time uranium-238.

The oldest rocks found on Earth are approximately  $3 \times 10^9$  yr old. This age indicates that Earth’s crust has been solid for at least this length of time. Scientists estimate that it required  $1 \times 10^9$  to  $1.5 \times 10^9$  yr for Earth to cool and its surface to become solid, making the age of Earth 4.0 to  $4.5 \times 10^9$  yr.

## Calculations Based on Half-Life

The rate at which a sample decays is called its **activity**, and it is often expressed as number of disintegrations per unit time. The **becquerel** (Bq) is the SI unit for expressing activity. A becquerel is defined as one nuclear disintegration per second. An older, but still widely used, unit of activity is the **curie** (Ci), defined as  $3.7 \times 10^{10}$  disintegrations per second, which is the rate of decay of 1 g of radium. Thus, a 4.0-mCi sample of cobalt-60 undergoes

$$4.0 \times 10^{-3} \text{ Ci} \times \frac{3.7 \times 10^{10} \text{ disintegrations/s}}{1 \text{ Ci}} = 1.5 \times 10^8 \text{ disintegrations/s}$$

and so has an activity of  $1.5 \times 10^8$  Bq.

As a radioactive sample decays, the amount of radiation emanating from the sample decays as well. For example, the half-life of cobalt-60 is 5.27 yr. The 4.0-mCi sample of cobalt-60 would, after 5.27 yr, have a radiation activity of 2.0 mCi, or  $7.5 \times 10^7$  Bq.

### Give It Some Thought

If the size of a radioactive sample is doubled, what happens to the activity of the sample in Bq?

Because radioactive decay is a first-order kinetic process, its rate is proportional to the number of radioactive nuclei  $N$  in a sample:

$$\text{Rate} = kN \quad [21.18]$$

The first-order rate constant,  $k$ , is called the *decay constant* and is related to the half-life:

$$k = \frac{0.693}{t_{1/2}} \quad [21.19]$$

Thus, if we know the value of either the half-life or the decay constant, we can calculate the value of the other.

As we saw in Section 14.4, a first-order rate law can be expressed in the following form:

$$\ln \frac{N_t}{N_0} = -kt \quad [21.20]$$

In this equation  $t$  is the time interval of decay,  $k$  is the decay constant,  $N_0$  is the initial number of nuclei (at time zero), and  $N_t$  is the number remaining after the time interval. Both the mass of a particular radioisotope and its activity are proportional to the number of radioactive nuclei. Thus, either the ratio of the mass at any time  $t$  to the mass at time  $t = 0$  or the ratio of the activities at time  $t$  and  $t = 0$  can be substituted for  $N_t/N_0$  in Equation 21.20.

## Sample Exercise 21.6

### Calculating the Age of Objects Using Radioactive Decay

A rock contains 0.257 mg of lead-206 for every milligram of uranium-238. The half-life for the decay of uranium-238 to lead-206 is  $4.5 \times 10^9$  yr. How old is the rock?

#### SOLUTION

**Analyze** We are asked to calculate the age of a rock containing uranium-238 and lead-206, given the half-life of the uranium-238 and the relative amounts of the uranium-238 and lead-206.

**Plan** Lead-206 is the product of the radioactive decay of uranium-238. We will assume that the only source of lead-206 in

the rock is from the decay of uranium-238, which has a known half-life. To apply first-order kinetics expressions (Equations 21.19 and 21.20) to calculate the time elapsed since the rock was formed, we first need to calculate how much initial uranium-238 there was for every 1 mg that remains today.

*Continued*

**Solve** Let's assume that the rock currently contains 1.000 mg of uranium-238 and therefore 0.257 mg of lead-206. The amount of uranium-238 in the rock when it was first formed therefore equals 1.000 mg plus the quantity that has decayed to lead-206. Because the mass of lead atoms is not the same as the mass of uranium atoms, we cannot just add 1.000 mg and 0.257 mg. We have to multiply the present mass of lead-206 (0.257 mg) by the ratio of the mass number of uranium to that of lead, into which it has decayed. Therefore, the original mass of  $^{238}_{92}\text{U}$  was

$$\begin{aligned}\text{Original } ^{238}_{92}\text{U} &= 1.000 \text{ mg} + \frac{238}{206}(0.257 \text{ mg}) \\ &= 1.297 \text{ mg}\end{aligned}$$

Using Equation 21.19, we can calculate the decay constant for the process from its half-life:

$$k = \frac{0.693}{4.5 \times 10^9 \text{ yr}} = 1.5 \times 10^{-10} \text{ yr}^{-1}$$

Rearranging Equation 21.20 to solve for time,  $t$ , and substituting known quantities gives

$$t = -\frac{1}{k} \ln \frac{N_t}{N_0} = -\frac{1}{1.5 \times 10^{-10} \text{ yr}^{-1}} \ln \frac{1.000}{1.297} = 1.7 \times 10^9 \text{ yr}$$

### Practice Exercise 1

Cesium-137, which has a half-life of 30.2 yr, is a component of the radioactive waste from nuclear power plants. If the activity due to cesium-137 in a sample of radioactive waste has decreased to 35.2% of its initial value, how old is the sample? (a) 1.04 yr (b) 15.4 yr (c) 31.5 yr (d) 45.5 yr (e) 156 yr

### Practice Exercise 2

A wooden object from an archeological site is subjected to radiocarbon dating. The activity due to  $^{14}\text{C}$  is measured to be 11.6 disintegrations per second. The activity of a carbon sample of equal mass from fresh wood is 15.2 disintegrations per second. The half-life of  $^{14}\text{C}$  is 5700 yr. What is the age of the archeological sample?

## Sample Exercise 21.7

### Calculations Involving Radioactive Decay and Time

If we start with 1.000 g of strontium-90, 0.953 g will remain after 2.00 yr. (a) What is the half-life of strontium-90? (b) How much strontium-90 will remain after 5.00 yr?

### SOLUTION

**Analyze** (a) We are asked to calculate a half-life,  $t_{1/2}$ , based on data that tell us how much of a radioactive nucleus has decayed in a time interval  $t = 2.00$  yr and the information  $N_0 = 1.000$  g,  $N_t = 0.953$  g. (b) We are asked to calculate the amount of a radionuclide remaining after a given period of time.

**Plan** (a) We first calculate the rate constant for the decay,  $k$ , and then we use that to compute  $t_{1/2}$ . (b) We need to calculate  $N_t$ , the amount of strontium present at time  $t$ , using the initial quantity,  $N_0$ , and the rate constant for decay,  $k$ , calculated in part (a).

### Solve

(a) Equation 21.20 is solved for the decay constant,  $k$ , and then Equation 21.19 is used to calculate half-life,  $t_{1/2}$ :

$$\begin{aligned}k &= -\frac{1}{t} \ln \frac{N_t}{N_0} = -\frac{1}{2.00 \text{ yr}} \ln \frac{0.953 \text{ g}}{1.000 \text{ g}} \\ &= -\frac{1}{2.00 \text{ yr}} (-0.0481) = 0.0241 \text{ yr}^{-1} \\ t_{1/2} &= \frac{0.693}{k} = \frac{0.693}{0.0241 \text{ yr}^{-1}} = 28.8 \text{ yr}\end{aligned}$$

(b) Again using Equation 21.20, with  $k = 0.0241 \text{ yr}^{-1}$ , we have:

$N_t/N_0$  is calculated from  $\ln(N_t/N_0) = -0.120$  using the  $e^x$  or INV LN function of a calculator:

Because  $N_0 = 1.000$  g, we have:

$$\ln \frac{N_t}{N_0} = -kt = -(0.0241 \text{ yr}^{-1})(5.00 \text{ yr}) = -0.120$$

$$\frac{N_t}{N_0} = e^{-0.120} = 0.887$$

$$N_t = (0.887)N_0 = (0.887)(1.000 \text{ g}) = 0.887 \text{ g}$$

### Practice Exercise 1

As mentioned in the previous Practice Exercise 1, cesium-137, a component of radioactive waste, has a half-life of 30.2 yr. If a sample of waste has an initial activity of 15.0 Ci due to cesium-137, how long will it take for the activity due to cesium-137 to drop to 0.250 Ci?

(a) 0.728 yr (b) 60.4 yr (c) 78.2 yr (d) 124 yr (e) 178 yr

### Practice Exercise 2

A sample to be used for medical imaging is labeled with  $^{18}\text{F}$ , which has a half-life of 110 min. What percentage of the original activity in the sample remains after 300 min?

## Go Figure

Which type of radiation—alpha, beta, or gamma—is likely to fog a film that is sensitive to X rays?

The film strip is white before exposure to radiation.

The film strip is darkened on exposure to radiation.

▲ **Figure 21.8** Badge dosimeters monitor the extent to which the individual has been exposed to high-energy radiation. The radiation dose is determined from the extent of darkening of the film in the dosimeter.

## 21.5 | Detection of Radioactivity

A variety of methods have been devised to detect emissions from radioactive substances. Henri Becquerel discovered radioactivity because radiation caused fogging of photographic plates, and since that time photographic plates and film have been used to detect radioactivity. The radiation affects photographic film in much the same way as X-rays do. The greater the extent of exposure to radiation, the darker the area of the developed negative. People who work with radioactive substances carry film badges to record the extent of their exposure to radiation (**Figure 21.8**).

Radioactivity can also be detected and measured by a Geiger counter. The operation of this device is based on the fact that radiation is able to ionize matter. The ions and electrons produced by the ionizing radiation permit conduction of an electrical current. The basic design of a Geiger counter is shown in **Figure 21.9**. A current pulse between the anode and the metal cylinder occurs whenever entering radiation produces ions. Each pulse is counted in order to estimate the amount of radiation.

Some substances, called *phosphors*, emit light when radiation strikes or passes through them. The radioactivity excites the atoms, ions, or molecules of the phosphor to a higher energy state, and they release this energy as light as they return to their ground states. For example, ZnS responds this way to alpha radiation. An instrument called a *scintillation counter* detects and counts the flashes of light produced when radiation strikes the phosphor. The flashes of light are magnified electronically and counted to measure the amount of radiation.

### Radiotracers

Because radioisotopes can be detected readily, they can be used to follow an element through its chemical reactions. The incorporation of carbon atoms from CO<sub>2</sub> into glucose during photosynthesis, for example, has been studied using CO<sub>2</sub> enriched in carbon-14:

Use of the carbon-14 label provides direct experimental evidence that carbon dioxide in the environment is chemically converted to glucose in plants. Analogous labeling experiments using oxygen-18 show that the O<sub>2</sub> produced during photosynthesis comes from water, not carbon dioxide. When it is possible to isolate and purify intermediates and products from reactions, detection devices such as scintillation counters can be used to “follow” the radioisotope as it moves from starting material through intermediates to

## Go Figure

Which property of the atoms of gas inside a Geiger counter is most relevant to the operation of the device?

▲ Figure 21.9 Schematic drawing of a Geiger counter.

final product. These types of experiments are useful for identifying elementary steps in a reaction mechanism. [Section 14.6](#)

The use of radioisotopes is possible because all isotopes of an element have essentially identical chemical properties. When a small quantity of a radioisotope is mixed with the naturally occurring stable isotopes of the same element, all the isotopes go through the same reactions together. The element's path is revealed by the radioactivity of the radioisotope. Because the radioisotope can be used to trace the path of the element, it is called a **radiotracer**.

## Give It Some Thought

Can you think of a process not involving radioactive decay for which  $^{14}\text{CO}_2$  would behave *differently* from  $^{12}\text{CO}_2$ ?

## CHEMISTRY AND LIFE Medical Applications of Radiotracers

Radiotracers have found wide use as diagnostic tools in medicine. [Table 21.6](#) lists some radiotracers and their uses. These radioisotopes are incorporated into a compound that is administered to the patient, usually intravenously. The diagnostic use of these isotopes is based on the ability of the radioactive compound to localize and concentrate in the organ or tissue under investigation. Iodine-131, for example, has been used to test the activity of the thyroid gland. This gland is the only place in which iodine is incorporated significantly in the body. The patient drinks a solution of NaI containing iodine-131. Only a very small amount is used so that the patient does not receive a harmful dose of radioactivity. A Geiger counter placed close to the thyroid, in the neck region, determines the ability of the thyroid to take up the iodine. A normal thyroid will absorb about 12% of the iodine within a few hours.

**TABLE 21.6** Some Radionuclides Used as Radiotracers

| Nuclide                    | Half-Life  | Area of the Body Studied       |
|----------------------------|------------|--------------------------------|
| Iodine-131                 | 8.04 days  | Thyroid                        |
| Iron-59                    | 44.5 days  | Red blood cells                |
| Phosphorus-32              | 14.3 days  | Eyes, liver, tumors            |
| Technetium-99 <sup>a</sup> | 6.0 hours  | Heart, bones, liver, and lungs |
| Thallium-201               | 73 hours   | Heart, arteries                |
| Sodium-24                  | 14.8 hours | Circulatory system             |

<sup>a</sup>The isotope of technetium is actually a special isotope of Tc-99 called Tc-99m, where the *m* indicates a so-called *metastable* isotope.

The medical applications of radiotracers are further illustrated by *positron emission tomography* (PET). PET is used for clinical diagnosis of many diseases. In this method, compounds containing radionuclides that decay by positron emission are injected into a patient. These compounds are chosen to enable researchers to monitor blood flow, oxygen and glucose metabolic rates, and other biological functions. Some of the most interesting work involves study of the brain, which depends on glucose for most of its energy. Changes in how this sugar is metabolized or used by the brain may signal a disease such as cancer, epilepsy, Parkinson's disease, or schizophrenia.

The radionuclides that are most widely used in PET are carbon-11 ( $t_{1/2} = 20.4$  min), fluorine-18 ( $t_{1/2} = 110$  min), oxygen-15 ( $t_{1/2} = 2$  min), and nitrogen-13 ( $t_{1/2} = 10$  min). Glucose, for example, can be labeled with carbon-11. Because the half-lives of positron emitters are so short, they must be generated on site using a cyclotron and the chemist must quickly incorporate the radionuclide into the sugar (or other appropriate) molecule and inject the com-

pound immediately. The patient is placed in an instrument that measures the positron emission and constructs a computer-based image of the organ in which the emitting compound is localized. When the element decays, the emitted positron quickly collides with an electron. The positron and electron are annihilated in the collision, producing two gamma rays that move in opposite directions. The gamma rays are detected by an encircling ring of scintillation counters (Figure 21.10). Because the rays move in opposite directions but were created in the same place at the same time, it is possible to accurately locate the point in the body where the radioactive isotope decayed. The nature of this image provides clues to the presence of disease or other abnormality and helps medical researchers understand how a particular disease affects the functioning of the brain. For example, the images shown in Figure 21.11 reveal that levels of activity in brains of patients with Alzheimer's disease are different from the levels in those without the disease.

## 21.6 | Energy Changes in Nuclear Reactions

Why are the energies associated with nuclear reactions so large, in many cases orders of magnitude larger than those associated with nonnuclear chemical reactions? The answer to this question begins with Einstein's celebrated equation from the theory of relativity that relates mass and energy:

$$E = mc^2 \quad [21.22]$$

In this equation  $E$  stands for energy,  $m$  for mass, and  $c$  for the speed of light,  $2.9979 \times 10^8$  m/s. This equation states that mass and energy are equivalent and can be converted into one another. If a system loses mass, it loses energy; if it gains mass, it gains energy. Because the proportionality constant between energy and mass,  $c^2$ , is such a large number, even small changes in mass are accompanied by large changes in energy.

The mass changes in chemical reactions are too small to detect. For example, the mass change associated with the combustion of 1 mol of  $\text{CH}_4$  (an exothermic process) is  $-9.9 \times 10^{-9}$  g. Because the mass change is so small, it is possible to treat chemical reactions as though mass is conserved.  $\infty$  (Section 2.1)

The mass changes and the associated energy changes in nuclear reactions are much greater than those in chemical reactions. The mass change accompanying the radioactive decay of 1 mol of uranium-238, for example, is 50,000 times greater than that for the combustion of 1 mol of  $\text{CH}_4$ . Let's examine the energy change for the nuclear reaction

The masses of the nuclei are  ${}_{92}^{238}\text{U}$ , 238.0003 amu;  ${}_{90}^{234}\text{Th}$ , 233.9942 amu; and  ${}_2^4\text{He}$ , 4.0015 amu. The mass change,  $\Delta m$ , is the total mass of the products minus the total mass of the

reactants. The mass change for the decay of 1 mol of uranium-238 can then be expressed in grams:

$$233.9942 \text{ g} + 4.0015 \text{ g} - 238.0003 \text{ g} = -0.0046 \text{ g}$$

The fact that the system has lost mass indicates that the process is exothermic. All spontaneous nuclear reactions are exothermic.

The energy change per mole associated with this reaction is

$$\begin{aligned}\Delta E &= \Delta(mc^2) = c^2\Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2(-0.0046 \text{ g})\left(\frac{1 \text{ kg}}{1000 \text{ g}}\right) \\ &= -4.1 \times 10^{11} \frac{\text{kg}\cdot\text{m}^2}{\text{s}^2} = -4.1 \times 10^{11} \text{ J}\end{aligned}$$

Notice that  $\Delta m$  must be converted to kilograms, the SI unit of mass, to obtain  $\Delta E$  in joules, the SI unit of energy. The negative sign for the energy change indicates that energy is released in the reaction—in this case, over 400 billion joules per mole of uranium! This energy would provide the average annual household electricity for about 10,000 homes in the United States.

## Sample Exercise 21.8

### Calculating Mass Change in a Nuclear Reaction

How much energy is lost or gained when 1 mol of cobalt-60 undergoes beta decay,  ${}^{60}_{27}\text{Co} \longrightarrow {}^{60}_{28}\text{Ni} + {}^0_{-1}\text{e}$ ? The mass of a  ${}^{60}_{27}\text{Co}$  atom is 59.933819 amu, and that of a  ${}^{60}_{28}\text{Ni}$  atom is 59.930788 amu.

### SOLUTION

**Analyze** We are asked to calculate the energy change in a nuclear reaction.

**Plan** We must first calculate the mass change in the process. We are given atomic masses, but we need the masses of the nuclei in the reaction. We calculate these by taking account of the masses of the electrons that contribute to the atomic masses.

### Solve

A  ${}^{60}_{27}\text{Co}$  atom has 27 electrons. The mass of an electron is  $5.4858 \times 10^{-4}$  amu. (See the list of fundamental constants in the back inside cover.) We subtract the mass of the 27 electrons from the mass of the  ${}^{60}_{27}\text{Co}$  atom to find the mass of the  ${}^{60}_{27}\text{Co}$  nucleus:

$$\begin{aligned}59.933819 \text{ amu} - (27)(5.4858 \times 10^{-4} \text{ amu}) \\ = 59.919007 \text{ amu (or } 59.919007 \text{ g/mol)}\end{aligned}$$

Likewise, for  ${}^{60}_{28}\text{Ni}$ , the mass of the nucleus is:

$$\begin{aligned}59.930788 \text{ amu} - (28)(5.4858 \times 10^{-4} \text{ amu}) \\ = 59.915428 \text{ amu (or } 59.915428 \text{ g/mol)}\end{aligned}$$

The mass change in the nuclear reaction is the total mass of the products minus the mass of the reactant:

$$\begin{aligned}\Delta m &= \text{mass of electron} + \text{mass } {}^{60}_{28}\text{Ni nucleus} - \text{mass of } {}^{60}_{27}\text{Co nucleus} \\ &= 0.00054858 \text{ amu} + 59.915428 \text{ amu} - 59.919007 \text{ amu} \\ &= -0.003030 \text{ amu}\end{aligned}$$

Thus, when a mole of cobalt-60 decays,

$$\Delta m = -0.003030 \text{ g}$$

Because the mass decreases ( $\Delta m < 0$ ), energy is released ( $\Delta E < 0$ ). The quantity of energy released *per mole* of cobalt-60 is calculated using Equation 21.22:

$$\begin{aligned}\Delta E &= c^2\Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2(-0.003030 \text{ g})\left(\frac{1 \text{ kg}}{1000 \text{ g}}\right) \\ &= -2.723 \times 10^{11} \frac{\text{kg}\cdot\text{m}^2}{\text{s}^2} = -2.723 \times 10^{11} \text{ J}\end{aligned}$$

**Practice Exercise 1**

Electricity is generated in space vehicles from the heat produced by the radioactive decay of plutonium-238:  ${}^{238}_{94}\text{Pu} \longrightarrow {}^{234}_{92}\text{U} + {}^4_2\text{He}$ . The atomic masses of plutonium-238 and uranium-234 are 238.049554 amu and 234.040946 amu, respectively. The mass of an alpha particle is 4.001506 amu. How much energy in kJ is released when 1.00 g of plutonium-238 decays to uranium-234?

- (a)  $2.27 \times 10^6$  kJ   (b)  $2.68 \times 10^6$  kJ   (c)  $3.10 \times 10^6$  kJ  
(d)  $3.15 \times 10^6$  kJ   (e)  $7.37 \times 10^8$  kJ

**Practice Exercise 2**

Positron emission from  ${}^{11}\text{C}$ ,  ${}^{11}_6\text{C} \longrightarrow {}^{11}_5\text{B} + {}^0_{+1}\text{e}$ , occurs with release of  $2.87 \times 10^{11}$  J per mole of  ${}^{11}\text{C}$ . What is the mass change per mole of  ${}^{11}\text{C}$  in this nuclear reaction? The masses of  ${}^{11}\text{B}$  and  ${}^{11}\text{C}$  are 11.009305 and 11.011434 amu, respectively.

## Nuclear Binding Energies

Scientists discovered in the 1930s that the masses of nuclei are always less than the masses of the individual nucleons of which they are composed. For example, the helium-4 nucleus (an alpha particle) has a mass of 4.00150 amu. The mass of a proton is 1.00728 amu and that of a neutron is 1.00866 amu. Consequently, two protons and two neutrons have a total mass of 4.03188 amu:

$$\begin{aligned}\text{Mass of two protons} &= 2(1.00728 \text{ amu}) = 2.01456 \text{ amu} \\ \text{Mass of two neutrons} &= 2(1.00866 \text{ amu}) = 2.01732 \text{ amu} \\ \text{Total mass} &= 4.03188 \text{ amu}\end{aligned}$$

The mass of the individual nucleons is 0.03038 amu greater than that of the helium-4 nucleus:

$$\begin{aligned}\text{Mass of two protons and two neutrons} &= 4.03188 \text{ amu} \\ \text{Mass of } {}^4_2\text{He nucleus} &= 4.00150 \text{ amu} \\ \text{Mass difference } \Delta m &= 0.03038 \text{ amu}\end{aligned}$$

The mass difference between a nucleus and its constituent nucleons is called the **mass defect**. The origin of the mass defect is readily understood if we consider that energy must be added to a nucleus to break it into separated protons and neutrons:

By Einstein's relation, the addition of energy to a system must be accompanied by a proportional increase in mass. The mass change we just calculated for the conversion of helium-4 into separated nucleons is  $\Delta m = 0.03038$  amu. Therefore, the energy required for this process is

$$\begin{aligned}\Delta E &= c^2 \Delta m \\ &= (2.9979 \times 10^8 \text{ m/s})^2 (0.03038 \text{ amu}) \left( \frac{1 \text{ g}}{6.022 \times 10^{23} \text{ amu}} \right) \left( \frac{1 \text{ kg}}{1000 \text{ g}} \right) \\ &= 4.534 \times 10^{-12} \text{ J}\end{aligned}$$

The energy required to separate a nucleus into its individual nucleons is called the **nuclear binding energy**. The mass defect and nuclear binding energy for three elements are compared in Table 21.7.

### Give It Some Thought

The mass of a single atom of iron-56 is 55.93494 amu. Why is this number different from the mass of the nucleus given in Table 21.7?

**TABLE 21.7** Mass Defects and Binding Energies for Three Nuclei

| Nucleus                 | Mass of Nucleus (amu) | Mass of Individual Nucleons (amu) | Mass Defect (amu) | Binding Energy (J)     | Binding Energy per Nucleon (J) |
|-------------------------|-----------------------|-----------------------------------|-------------------|------------------------|--------------------------------|
| ${}^4_2\text{He}$       | 4.00150               | 4.03188                           | 0.03038           | $4.53 \times 10^{-12}$ | $1.13 \times 10^{-12}$         |
| ${}^{56}_{26}\text{Fe}$ | 55.92068              | 56.44914                          | 0.52846           | $7.90 \times 10^{-11}$ | $1.41 \times 10^{-12}$         |
| ${}^{238}_{92}\text{U}$ | 238.00031             | 239.93451                         | 1.93420           | $2.89 \times 10^{-10}$ | $1.21 \times 10^{-12}$         |

▲ **Figure 21.12 Nuclear binding energies.** The average binding energy per nucleon increases initially as the mass number increases and then decreases slowly. Because of these trends, fusion of light nuclei and fission of heavy nuclei are exothermic processes.

Values of binding energies per nucleon can be used to compare the stabilities of different combinations of nucleons (such as two protons and two neutrons arranged either as  ${}^4_2\text{He}$  or as  $2\,{}^2_1\text{H}$ ). **Figure 21.12** shows average binding energy per nucleon plotted against mass number. Binding energy per nucleon at first increases in magnitude as mass number increases, reaching about  $1.4 \times 10^{-12}\text{J}$  for nuclei whose mass numbers are in the vicinity of iron-56. It then decreases slowly to about  $1.2 \times 10^{-12}\text{J}$  for very heavy nuclei. *This trend indicates that nuclei of intermediate mass numbers are more tightly bound (and therefore more stable) than those with either smaller or larger mass numbers.*

This trend has two significant consequences: First, heavy nuclei gain stability and therefore give off energy if they are fragmented into two midsize nuclei. This process, known as **fission**, is used to generate energy in nuclear power plants. Second, because of the sharp increase in the graph for small mass numbers, even greater amounts of energy are released if very light nuclei are combined, or fused together, to give more massive nuclei. This **fusion** process is the essential energy-producing process in the Sun and other stars.

### Give It Some Thought

Would fusing two stable nuclei that have mass numbers in the vicinity of 100 be an energy-releasing process?

## 21.7 | Nuclear Power: Fission

Nuclear fission is the process used to generate energy in nuclear power plants. Over 11% of the electricity generated worldwide comes from nuclear power plants, though the percentage varies from one country to the next, as **Figure 21.13** shows. There are 440 commercial nuclear power plants in operation in 31 countries, and approximately another 65 are under construction.

Most nuclear reactors rely on the fission of uranium-235. This was the first nuclear fission reaction to be discovered. This nucleus, as well as those of uranium-233

▲ **Figure 21.13** Sources of electricity generation, worldwide and for select countries.

(Sources: The Shift Project and the World Bank, 2014 data)

and plutonium-239, undergoes fission when struck by a slow-moving neutron (**Figure 21.14**).\*

A heavy nucleus can split in many ways, giving rise to a variety of smaller nuclei. Two ways that the uranium-235 nucleus splits, for instance, are

The nuclei produced in Equations 21.24 and 21.25—called the *fission products*—are themselves radioactive and undergo further nuclear decay. More than 200 isotopes of 35 elements have been found among the fission products of uranium-235. Most of them are radioactive.

Slow-moving neutrons are required for the fission of uranium-235 because the process involves initial absorption of the neutron by the nucleus. The resulting more massive nucleus is extremely unstable and spontaneously undergoes fission. Fast neutrons tend to bounce off the nucleus, and little fission occurs.

Note that the coefficients of the neutrons produced in Equations 21.24 and 21.25 are 2 and 3, respectively. On average, 2.4 neutrons are produced by every fission of a uranium-235 nucleus. If one fission produces two neutrons, the two neutrons can cause two additional fissions, each producing two neutrons. The four neutrons thereby released

### Go Figure

What is the relationship between the sum of the mass numbers on the two sides of this reaction?

▲ **Figure 21.14** Uranium-235 fission. This is just one of many fission patterns. In this reaction,  $3.5 \times 10^{-11}$  J of energy is released per  ${}^{235}\text{U}$  nucleus that is split.

\*Other heavy nuclei can also undergo fission. However, these three are the only ones of practical importance.

## Go Figure

If this figure were extended one more “generation” down, how many neutrons would be produced?

▲ Figure 21.15 Fission chain reaction.

can produce four fissions, and so forth, as shown in Figure 21.15. The number of fissions and the energy released quickly escalate, and if the process is unchecked, the result is a violent explosion. Reactions that multiply in this fashion are called **chain reactions**.

For a fission chain reaction to occur, the sample of fissionable material must have a certain minimum mass. Otherwise, neutrons escape from the sample before they have the opportunity to strike other nuclei and cause additional fission. The amount of fissionable material large enough to maintain a chain reaction with a constant rate of fission is called the **critical mass**. When a critical mass of material is present, one neutron on average from each fission is subsequently effective in producing another fission and the fission continues at a constant, controllable rate. The critical mass of uranium-235 is about 50 kg for a bare sphere of the metal.\*

If more than a critical mass of fissionable material is present, very few neutrons escape. The chain reaction thus multiplies the number of fissions, which can lead to a nuclear explosion. A mass in excess of a critical mass is referred to as a **supercritical mass**. The effect of mass on a fission reaction is illustrated in Figure 21.16.

## Go Figure

Which of these criticality scenarios—subcritical, critical, or supercritical—is desirable in a nuclear power plant that generates electricity?

▲ Figure 21.16 Subcritical, critical, and supercritical nuclear fission.

\*The exact value of the critical mass depends on the shape of the radioactive substance. The critical mass can be reduced if the radioisotope is surrounded by a material that reflects some neutrons.

**Figure 21.17** shows a schematic diagram of the first atomic bomb used in warfare, the bomb, code-named “Little Boy,” that was dropped on Hiroshima, Japan, on August 6, 1945. The bomb contained about 64 kg of uranium-235, which had been separated from the nonfissionable uranium-238 primarily by gaseous diffusion of uranium hexafluoride,  $\text{UF}_6$ . (Section 10.8) To trigger the fission reaction, two subcritical masses of uranium-235 were slammed together using chemical explosives. The combined masses of the uranium formed a supercritical mass, which led to a rapid, uncontrolled chain reaction and, ultimately, a nuclear explosion. The energy released by the bomb dropped on Hiroshima was equivalent to that of 16,000 tons of TNT (it therefore is called a *16-kiloton* bomb). Unfortunately, the basic design of a fission-based atomic bomb is quite simple, and the fissionable materials are potentially available to any nation with a nuclear reactor. The combination of design simplicity and materials availability has generated international concerns about the proliferation of atomic weapons.

▲ **Figure 21.17** Schematic drawing of an atomic bomb. A conventional explosive is used to bring two subcritical masses together to form a supercritical mass.

## A CLOSER LOOK The Dawning of the Nuclear Age

Uranium-235 fission was first achieved during the late 1930s by Enrico Fermi and coworkers in Rome and shortly thereafter by Otto Hahn and coworkers in Berlin. Both groups were trying to produce transuranium elements. In 1938, Hahn identified barium among his reaction products. He was puzzled by this observation and questioned the identification because the presence of barium was so unexpected. He sent a letter describing his experiments to Lise Meitner, a former coworker who had been forced to leave Germany because of the anti-Semitism of the Third Reich and had settled in Sweden. She surmised that Hahn's experiment indicated a nuclear process was occurring in which the uranium-235 split. She called this process *nuclear fission*.

Meitner passed word of this discovery to her nephew, Otto Frisch, a physicist working at Niels Bohr's institute in Copenhagen. Frisch repeated the experiment, verifying Hahn's observations, and found that tremendous energies were involved. In January 1939, Meitner and Frisch published a short article describing the reaction. In March 1939, Leo Szilard and Walter Zinn at Columbia University discovered that more neutrons are produced than are used in each fission. As we have seen, this result allows a chain reaction to occur.

News of these discoveries and an awareness of their potential use in explosive devices spread rapidly within the scientific community. Several scientists finally persuaded Albert Einstein, the most famous physicist of the time, to write a letter to President Franklin D. Roosevelt explaining the implications of these discoveries. Einstein's letter, written in August 1939, outlined the possible military applications of nuclear fission and emphasized the danger that weapons based on fission would pose if they were developed by the Nazis. Roosevelt judged it imperative that the United States investigate the possibility of such weapons. Late in 1941, the decision was made to build a bomb based on the fission reaction. An enormous research project, known as the Manhattan Project, began.

On December 2, 1942, the first artificial self-sustaining nuclear fission chain reaction was achieved in an abandoned squash court at the University of Chicago. This accomplishment led to the development of the first atomic bomb, at Los Alamos National Laboratory in New Mexico in July 1945 (**Figure 21.18**). In August 1945 the United States dropped atomic bombs on two Japanese cities, Hiroshima and Nagasaki. The nuclear age had arrived, albeit in a sadly destructive fashion. Humanity has struggled with the conflict between the positive potential of nuclear energy and its terrifying potential as a weapon ever since.

▲ **Figure 21.18** The Trinity test for the atom bomb developed during World War II. The first human-made nuclear explosion took place on July 16, 1945, on the Alamogordo test range in New Mexico.

## Nuclear Reactors

Nuclear power plants use nuclear fission to generate energy. The core of a typical nuclear reactor consists of four principal components: fuel elements, control rods, a moderator, and a primary coolant (**Figure 21.19**). The fuel is a fissionable substance, such as uranium-235. The natural isotopic abundance of uranium-235 is only 0.7%, too low to sustain a chain reaction in most reactors. Therefore, the  $^{235}\text{U}$  content of the fuel must be

▲ **Figure 21.19** Schematic diagram of a pressurized water reactor core.

enriched to 3–5% for use in a reactor. The *fuel elements* contain enriched uranium in the form of  $\text{UO}_2$  pellets encased in zirconium or stainless steel tubes.

The *control rods* are composed of materials that absorb neutrons, such as boron-10 or an alloy of silver, indium, and cadmium. These rods regulate the flux of neutrons to keep the reaction chain self-sustaining and also prevent the reactor core from overheating.\*

The probability that a neutron will trigger fission of a  $^{235}\text{U}$  nucleus depends on the speed of the neutron. The neutrons produced by fission have high speeds (typically in excess of 10,000 km/s). The function of the *moderator* is to slow down the neutrons (to speeds of a few kilometers per second) so that they can be captured more readily by the fissionable nuclei. The moderator is typically either water or graphite.

The *primary coolant* is a substance that transports the heat generated by the nuclear chain reaction away from the reactor core. In a *pressurized water reactor*, which is the most common commercial reactor design, water acts as both the moderator and the primary coolant.

The design of a nuclear power plant is basically the same as that of a power plant that burns fossil fuel (except that the burner is replaced by a reactor core). The nuclear power plant design shown in **Figure 21.20**, a pressurized water reactor, is currently the most popular. The primary coolant passes through the core in a closed system, which lessens the chance that radioactive products could escape the core. As an added safety precaution, the reactor is surrounded by a reinforced concrete *containment shell* to shield personnel and nearby residents from radiation and to protect the reactor from external forces. After passing through the reactor core, the very hot primary coolant passes through a heat exchanger where much of its heat is transferred to a *secondary coolant*, converting the latter to high-pressure steam that is used to drive a turbine. The secondary coolant is then condensed by transferring heat to an external source of water, such as a river or lake. The cooling systems of nuclear power plants are necessary for proper and safe operation. The

▲ **Figure 21.20** Basic design of a pressurized water reactor nuclear power plant.

\*The reactor core cannot reach supercritical levels and explode with the violence of an atomic bomb because the concentration of uranium-235 is too low. However, if the core overheats, sufficient damage can lead to release of radioactive materials into the environment.

nuclear disaster in Fukushima, Japan, in March 2011 occurred when a tsunami damaged the reactor cooling systems, resulting in a large-scale release of radioactive materials.

Although about two-thirds of all commercial reactors are pressurized water reactors, there are several variations on this basic design, each with advantages and disadvantages. A *boiling water reactor* generates steam by boiling the primary coolant; thus, no secondary coolant is needed. The reactors at Fukushima, Japan, were boiling water reactors. Pressurized water reactors and boiling water reactors are collectively referred to as *light water reactors* because they use  $\text{H}_2\text{O}$  as moderator and primary coolant. A *heavy water reactor* uses  $\text{D}_2\text{O}$  (D = deuterium,  $^2\text{H}$ ) as moderator and primary coolant, and a *gas-cooled reactor* uses a gas, typically  $\text{CO}_2$ , as primary coolant and graphite as the moderator. Use of either  $\text{D}_2\text{O}$  or graphite as the moderator has the advantage that both substances absorb fewer neutrons than  $\text{H}_2\text{O}$ . Consequently, the uranium fuel does not need to be as enriched.

## Nuclear Waste

The fission products that accumulate as a reactor operates decrease the efficiency of the reactor by capturing neutrons. For this reason, commercial reactors must be stopped periodically to either replace or reprocess the nuclear fuel. When the fuel elements are removed from the reactor, they are initially very radioactive. It was originally intended that they be stored for several months in pools at the reactor site to allow decay of short-lived radioactive nuclei. They were then to be transported in shielded containers to reprocessing plants where the unspent fuel would be separated from the fission products. Reprocessing plants have been plagued with operational difficulties, however, and there is intense opposition in the United States to the transport of nuclear wastes on the nation's roads and rails.

Even if the transportation difficulties could be overcome, the high level of radioactivity of the spent fuel makes reprocessing a hazardous operation. At present in the United States, spent fuel elements are kept in storage at reactor sites. Spent fuel is reprocessed, however, in France, Russia, the United Kingdom, India, and Japan.

Storage of spent nuclear fuel poses a major problem because the fission products are extremely radioactive. It is estimated that 10 half-lives are required for their radioactivity to reach levels acceptable for biological exposure. Based on the 28.8-yr half-life of strontium-90, one of the longer-lived and most dangerous of the products, the wastes must be stored for nearly 300 yr. Plutonium-239 is one of the by-products present in spent fuel elements. It is formed by absorption of a neutron by uranium-238, followed by two successive beta emissions. (Remember that most of the uranium in the fuel elements is uranium-238.) If the elements are reprocessed, the plutonium-239 is largely recovered because it can be used as a nuclear fuel. However, if the plutonium is not removed, spent elements must be stored for a very long time because plutonium-239 has a half-life of 24,000 yr.

A *fast breeder reactor* offers one approach to getting more power out of existing uranium sources and potentially reducing radioactive waste. This type of reactor is so named because it creates (“breeds”) more fissionable material than it consumes. The reactor operates without a moderator, which means the neutrons used are not slowed down. In order to capture the fast neutrons, the fuel must be highly enriched with both uranium-235 and plutonium-239. Water cannot be used as a primary coolant because it would moderate the neutrons, and so a liquid metal, usually sodium, is used. The core is surrounded by a blanket of uranium-238 that captures neutrons that escape the core, producing plutonium-239 in the process. The plutonium can later be separated by reprocessing and used as fuel in a future cycle.

Because fast neutrons are more effective at decaying many radioactive nuclides, the material separated from the uranium and plutonium during reprocessing is less radioactive than waste from other reactors. However, generation of relatively high levels of plutonium coupled with the need for reprocessing is problematic in terms of nuclear nonproliferation. Thus, political factors coupled with increased safety concerns and higher operational costs make fast breeder reactors quite rare.

A considerable amount of research is being devoted to disposal of radioactive wastes. At present, the most attractive possibilities appear to be formation of glass, ceramic, or synthetic rock from the wastes as a means of immobilizing them. These solid materials would then be placed in containers of high corrosion resistance and durability and buried deep underground. The process of selecting appropriate deep repositories for high-level waste and spent fuel is now under way in several countries. In the United States, the Department of Energy (DOE) had designated Yucca Mountain in Nevada as a disposal site, but in 2010 this project was discontinued because of technical and political concerns. Unfortunately, there is now no long-term solution to nuclear waste storage in the United States.

In spite of these difficulties, nuclear power is making a modest comeback as an energy source. Concerns about climate change caused by escalating atmospheric CO<sub>2</sub> levels  (Section 18.2) have increased support for nuclear power as a major energy source in the future. Increasing demand for power in rapidly developing countries, particularly China, has sparked a rise in construction of new nuclear power plants in those parts of the world.

## 21.8 | Nuclear Power: Fusion

Energy is produced when light nuclei fuse into heavier ones. Reactions of this type are responsible for the energy produced by the Sun. Spectroscopic studies indicate that the mass composition of the Sun is 74% H, 25% He, and only 1% all other elements. The following reactions are among the numerous fusion processes believed to occur in the Sun:

Fusion is appealing as an energy source because of the availability of light isotopes on Earth and because fusion products are generally not radioactive. Despite this fact, fusion is not presently used to generate energy. The problem is that extremely high temperatures and pressures are needed to overcome the electrostatic repulsion between nuclei in order to fuse them. The lowest temperature required for any fusion is about 40,000,000 K, the temperature needed to fuse deuterium and tritium:

Fusion reactions are therefore also known as **thermonuclear reactions**.

Such high temperatures have been achieved by using an atomic bomb to initiate fusion. This is the operating principle behind a thermonuclear, or hydrogen, bomb. This approach is obviously unacceptable, however, for a power generation plant.\*

Numerous problems must be overcome before fusion becomes a practical energy source. In addition to the high temperatures necessary to initiate the reaction, there is the problem of confining the reaction. No known structural material is able to withstand the enormous temperatures necessary for fusion. Much research has centered on the use of an apparatus called a *tokamak*, which uses strong magnetic fields to contain and to heat the reaction. Temperatures of over 100,000,000 K have been achieved in a tokamak. Unfortunately, scientists have not yet been able to generate more power than is consumed over a sustained period of time.

---

\*Historically, a nuclear weapon that relies solely on a fission process to release energy is called an atomic bomb, whereas one that also releases energy via a fusion reaction is called a hydrogen bomb.

## A CLOSER LOOK Nuclear Synthesis of the Elements

The lightest elements—hydrogen and helium along with very small amounts of lithium and beryllium—were formed as the universe expanded in the moments following the Big Bang. All the heavier elements owe their existence to subsequent nuclear reactions that occur in stars. These heavier elements are not all created in equal amounts, however. In our solar system, for example, carbon and oxygen are a million times more abundant than lithium and boron, and over 100 million times more abundant than beryllium (Figure 21.21)! In fact, of the elements heavier than helium, carbon and oxygen are the most abundant. This is more than an academic curiosity given the fact that these elements, together with hydrogen, are the most important elements for life on Earth. Let's look at the factors responsible for the relatively high abundance of carbon and oxygen in the universe.

A star is born from a cloud of gas and dust called a *nebula*. When conditions are right, gravitational forces collapse the cloud, and its core density and temperature rise until nuclear fusion commences. Hydrogen nuclei fuse to form deuterium,  ${}^2_1\text{H}$ , and eventually  ${}^4_2\text{He}$  through the reactions shown in Equations 21.26 through 21.29. Because  ${}^4_2\text{He}$  has a larger binding energy than any of its immediate neighbors (Figure 21.12), these reactions release an enormous amount of energy. This process, called *hydrogen burning*, is the dominant process for most of a star's lifetime.

Once a star's supply of hydrogen is nearly exhausted, several important changes occur as the star enters the next phase of its life, and is transformed into a *red giant*. The decrease in nuclear fusion causes the core to contract, triggering an increase in core temperature and pressure. At the same time, the outer regions expand and cool enough to make the star emit red light (thus, the name *red giant*). The star now must use  ${}^4_2\text{He}$  nuclei as its fuel. The simplest reaction that can occur in the He-rich core, fusion of two alpha particles to form a  ${}^8_4\text{Be}$  nucleus, does occur. The binding energy per nucleon for  ${}^8_4\text{Be}$  is very slightly smaller than that for  ${}^4_2\text{He}$ , so this fusion process is very slightly endothermic. The  ${}^8_4\text{Be}$  nucleus is highly unstable (half-life of  $7 \times 10^{-17}$  s) and so falls apart almost immediately. In a tiny fraction of cases, however, a third  ${}^4_2\text{He}$  collides with a  ${}^8_4\text{Be}$  nucleus before it decays, forming carbon-12:

▲ Figure 21.22 Fusion processes going on in a red giant just prior to a supernova explosion.

▲ Figure 21.21 Relative abundance of elements 1–10 in the solar system. Note the logarithmic scale used for the y-axis.

Some of the  ${}^{12}_6\text{C}$  nuclei go on to react with alpha particles to form oxygen-16:

This stage of nuclear fusion is called *helium burning*. Notice that carbon, element 6, is formed without prior formation of elements 3, 4, and 5, explaining in part their unusually low abundance. Nitrogen is relatively abundant because it can be produced from carbon through a series of reactions involving proton capture and positron emission.

Most stars gradually cool and dim as the helium is converted to carbon and oxygen, ending their lives as *white dwarfs*, a phase in which stars become incredibly dense—generally about one million times denser than the Sun. The extreme density of white dwarfs is accompanied by much higher temperatures and pressures at the core, where a variety of fusion processes lead to synthesis of the elements from neon to sulfur. These fusion reactions are collectively called *advanced burning*.

Eventually, progressively heavier elements form at the core until it becomes predominantly  ${}^{56}_{26}\text{Fe}$ , as shown in Figure 21.22. Because this is such a stable nucleus, further fusion to heavier nuclei consumes energy rather than releasing it. When this happens, the fusion reactions that power the star diminish, and immense gravitational forces lead to a dramatic collapse called a *supernova explosion*. Neutron capture coupled with subsequent radioactive decays in the dying moments of such a star are responsible for the presence of all elements heavier than iron and nickel.

Without these dramatic supernova events in the past history of the universe, heavier elements that are so familiar to us, such as silver, gold, iodine, lead, and uranium, would not exist.

**Related Exercises:** 21.73, 21.75

## 21.9 | Radiation in the Environment and Living Systems

We are continuously bombarded by radiation from both natural and artificial sources. We are exposed to infrared, ultraviolet, and visible radiation from the Sun; radio waves from radio and television stations; microwaves from microwave ovens; X rays from medical procedures; and radioactivity from natural materials (Table 21.8). Understanding the different energies of these various kinds of radiation is necessary in order to understand their different effects on matter.

When matter absorbs radiation, the radiation energy can cause atoms in the matter to be either excited or ionized. In general, radiation that causes ionization, called **ionizing radiation**, is far more harmful to biological systems than radiation that does not cause ionization. The latter, called **nonionizing radiation**, is generally of lower energy, such as radiofrequency electromagnetic radiation (Section 6.7) or slow-moving neutrons.

Most living tissue contains at least 70% water by mass. When living tissue is irradiated, water molecules absorb most of the energy of the radiation. Thus, it is common to define ionizing radiation as radiation that can ionize water, a process requiring a minimum energy of 1216 kJ/mol. Alpha, beta, and gamma rays (as well as X rays and higher-energy ultraviolet radiation) possess energies in excess of this quantity and are therefore forms of ionizing radiation.

When ionizing radiation passes through living tissue, electrons are removed from water molecules, forming highly reactive  $\text{H}_2\text{O}^+$  ions. An  $\text{H}_2\text{O}^+$  ion can react with another water molecule to form an  $\text{H}_3\text{O}^+$  ion and a neutral OH molecule:

The unstable and highly reactive OH molecule is a **free radical**, a substance with one or more unpaired electrons, as seen in the Lewis structure shown in the margin. The OH molecule is also called the *hydroxyl radical*, and the presence of the unpaired electron is often emphasized by writing the species with a single dot,  $\cdot\text{OH}$ . In cells and tissues, hydroxyl radicals can attack biomolecules to produce new free radicals, which in turn attack yet other biomolecules. Thus, the formation of a single hydroxyl radical via Equation 21.31 can initiate a large number of chemical reactions that are ultimately able to disrupt the normal operations of cells.

The damage produced by radiation depends on the activity and energy of the radiation, the length of exposure, and whether the source is inside or outside the body. Gamma rays are particularly harmful outside the body because they penetrate human tissue very effectively, just as X rays do. Consequently, their damage is not limited to the skin. In contrast, most alpha rays are stopped by skin, and beta rays are able to penetrate only about 1 cm beyond the skin surface (Figure 21.23). Therefore, neither alpha rays nor beta rays are as dangerous as gamma rays, *unless* the radiation source somehow enters the body. Within the body, alpha rays are particularly dangerous because they transfer their energy efficiently to the surrounding tissue, causing considerable damage.

‡Includes lead-210 and polonium-210, daughter nuclei of uranium-238.

In general, the tissues damaged most by radiation are those that reproduce rapidly, such as bone marrow, blood-forming tissues, and lymph nodes. The principal effect of extended exposure to low doses of radiation is to cause cancer. Cancer is caused by damage to the growth-regulation mechanism of cells, inducing the cells to reproduce uncontrollably. Leukemia, which is characterized by excessive growth of white blood cells, is probably the major type of radiation-caused cancer.

In light of the biological effects of radiation, it is important to determine whether any levels of exposure are safe. Unfortunately, we are hampered in our attempts to set realistic standards because we do not fully understand the effects of long-term exposure. Scientists concerned with setting health standards have used the hypothesis that the effects of radiation are proportional to exposure. *Any* amount of radiation is assumed to cause some finite risk of injury, and the effects of high dosage rates are extrapolated to those of lower ones. Other scientists believe, however, that there is a threshold below which there are no radiation risks. Until scientific evidence enables us to settle the matter with some confidence, it is safer to assume that even low levels of radiation present some danger.

## Radiation Doses

Two units are commonly used to measure exposure to radiation. The **gray** (Gy), the SI unit of absorbed dose, corresponds to the absorption of 1 J of energy per kilogram of tissue. The **rad** (radiation absorbed dose) corresponds to the absorption of  $1 \times 10^{-2}$  J of energy per kilogram of tissue. Thus,  $1 \text{ Gy} = 100 \text{ rad}$ . The rad is the unit most often used in medicine.

Not all forms of radiation harm biological materials to the same extent even at the same level of exposure. For example, 1 rad of alpha radiation can produce more damage than 1 rad of beta radiation. To correct for these differences, the radiation dose is multiplied by a factor that measures the relative damage caused by the radiation. This multiplication factor is known as the *relative biological effectiveness*, *RBE*. The RBE is approximately 1 for gamma and beta radiation, and 10 for alpha radiation.

The exact value of the RBE varies with dose rate, total dose, and type of tissue affected. The product of the radiation dose in rads and the RBE of the radiation give the *effective dosage* in **rem** (roentgen equivalent for man):

$$\text{Number of rem} = (\text{number of rad})(\text{RBE}) \quad [21.32]$$

The SI unit for effective dose is the *sievert* (Sv), obtained by multiplying the RBE times the SI unit for radiation dose, the gray; because a gray is 100 times larger than a rad,  $1 \text{ Sv} = 100 \text{ rem}$ . The rem is the unit of radiation damage usually used in medicine.

### Give It Some Thought

If a 50-kg person is uniformly irradiated by 0.10-J alpha radiation, what is the absorbed dosage in rad and the effective dosage in rem?

The effects of short-term exposure to radiation appear in [Table 21.9](#). An exposure of 600 rem is fatal to most humans. To put this number in perspective, a typical dental X ray entails an exposure of about 0.5 mrem. The average exposure for a person in 1 yr due to all natural sources of ionizing radiation (called *background radiation*) is about 360 mrem ([Figure 21.24](#)).

**TABLE 21.9 Effects of Short-Term Exposures to Radiation**

| Dose (rem) | Effect  |
|------------|---|
| 0–25       | No detectable clinical effects                        |
| 25–50      | Slight, temporary decrease in white blood cell counts |
| 100–200    | Nausea; marked decrease in white blood cell counts    |
| 500        | Death of half the exposed population within 30 days   |

### Go Figure

Why are alpha rays much more dangerous when the source of radiation is located inside the body?

**▲ Figure 21.23** Relative penetrating abilities of alpha, beta, and gamma radiation.

▲ **Figure 21.24** Sources of U.S. average annual exposure to high-energy radiation. The total average annual exposure is 360 mrem.
