THE CENTRAL SCIENCE 14<sup>TH</sup> EDITION

The halide perovskites, exemplified by methylammonium lead iodide ( $\text{CH}_3\text{NH}_3\text{PbI}_3$ ), whose structure is shown on the front cover, have emerged in recent years as alternatives to conventional semiconductors like silicon, gallium arsenide, and cadmium selenide. These materials show tremendous potential for use in devices such as light-emitting diodes and radiation detectors, but no application has generated more excitement than their performance in solar cells. Scientists have been able to prepare halide perovskite-based solar cells that convert sunlight to electricity with 20% efficiency, a figure comparable to the best silicon solar cells on the market. While the high efficiencies are impressive, the truly revolutionary breakthrough is that halide perovskite solar cells can be made from solution using inexpensive, readily available laboratory equipment, whereas fabrication of solar cells from conventional semiconductors requires expensive, sophisticated facilities. Chemists are actively researching alternative perovskite materials that do not contain lead and are less prone to degradation upon exposure to moist air.

# CONTENTS

## PREFACE xxiii

## 1 Introduction: Matter, Energy, and Measurement 2

### 1.1 The Study of Chemistry 4

The Atomic and Molecular Perspective of Chemistry 4  
Why Study Chemistry? 5

### 1.2 Classifications of Matter 7

States of Matter 7 Pure Substances 7  
Elements 8 Compounds 9 Mixtures 10

### 1.3 Properties of Matter 12

Physical and Chemical Changes 12 Separation of  
Mixtures 13

### 1.4 The Nature of Energy 15

Kinetic Energy and Potential Energy 15

### 1.5 Units of Measurement 17

SI Units 17 Length and Mass 19  
Temperature 19 Derived SI Units 20 Volume 20  
Density 21 Units of Energy 21

### 1.6 Uncertainty in Measurement 24

Precision and Accuracy 24 Significant Figures 25  
Significant Figures in Calculations 26

### 1.7 Dimensional Analysis 28

Conversion Factors 28 Using Two or More Conversion  
Factors 30 Conversions Involving Volume 31

**Chapter Summary and Key Terms 33**

**Learning Outcomes 34 Key Equations 34**

**Exercises 35 Additional Exercises 39**

---

**Chemistry Put to Work** Chemistry and the Chemical  
Industry 6

**A Closer Look** The Scientific Method 17

**Chemistry Put to Work** Chemistry in the News 23

**Strategies for Success** Estimating Answers 30

**Strategies for Success** The Importance of  
Practice 32

**Strategies for Success** The Features of This  
Book 32

## 2 Atoms, Molecules, and Ions 42

### 2.1 The Atomic Theory of Matter 44

### 2.2 The Discovery of Atomic Structure 45

Cathode Rays and Electrons 45 Radioactivity 47  
The Nuclear Model of the Atom 48

### 2.3 The Modern View of Atomic Structure 49

Atomic Numbers, Mass Numbers, and Isotopes 51

### 2.4 Atomic Weights 53

The Atomic Mass Scale 53 Atomic Weight 53

### 2.5 The Periodic Table 55

### 2.6 Molecules and Molecular Compounds 58

Molecules and Chemical Formulas 58 Molecular and  
Empirical Formulas 58 Picturing Molecules 59

### 2.7 Ions and Ionic Compounds 60

Predicting Ionic Charges 61 Ionic Compounds 62

### 2.8 Naming Inorganic Compounds 65

Names and Formulas of Ionic Compounds 65  
Names and Formulas of Acids 69 Names and  
Formulas of Binary Molecular Compounds 70

### 2.9 Some Simple Organic Compounds 71

Alkanes 71 Some Derivatives of Alkanes 72

**Chapter Summary and Key Terms 74**

**Learning Outcomes 74 Key Equations 75**

**Exercises 75 Additional Exercises 80**

---

**A Closer Look** Basic Forces 51

**A Closer Look** The Mass Spectrometer 54

**A Closer Look** What Are Coins Made Of? 57

**Chemistry and Life** Elements Required by Living  
Organisms 64

**Strategies for Success** How to Take a Test 73

## 3 Chemical Reactions and Reaction Stoichiometry 82

### 3.1 Chemical Equations 84

Balancing Equations 84 A Step-by-Step Example of Balancing a Chemical Equation 85 Indicating the States of Reactants and Products 87

### 3.2 Simple Patterns of Chemical Reactivity 88

Combination and Decomposition Reactions 88 Combustion Reactions 90

### 3.3 Formula Weights 90

Formula and Molecular Weights 91 Percentage Composition from Chemical Formulas 92

### 3.4 Avogadro's Number and the Mole 93

Molar Mass 94 Interconverting Masses and Moles 96 Interconverting Masses and Numbers of Particles 97

### 3.5 Empirical Formulas from Analyses 98

Molecular Formulas from Empirical Formulas 100 Combustion Analysis 101

### 3.6 Quantitative Information from Balanced Equations 102

### 3.7 Limiting Reactants 106

Theoretical and Percent Yields 108

**Chapter Summary and Key Terms 110**  
**Learning Outcomes 110 Key Equations 110**  
**Exercises 111 Additional Exercises 117**  
**Integrative Exercises 118 Design an Experiment 119**

**Strategies for Success** Problem Solving 92

**Chemistry and Life** Glucose Monitoring 96

**Strategies for Success** Design an Experiment 109

## 4 Reactions in Aqueous Solution 120

### 4.1 General Properties of Aqueous Solutions 122

Electrolytes and Nonelectrolytes 122

How Compounds Dissolve in Water 123 Strong and Weak Electrolytes 124

### 4.2 Precipitation Reactions 126

Solubility Guidelines for Ionic Compounds 126 Exchange (Metathesis) Reactions 127 Ionic Equations and Spectator Ions 129

### 4.3 Acids, Bases, and Neutralization Reactions 130

Acids 130 Bases 131 Strong and Weak Acids and Bases 132 Identifying Strong and Weak Electrolytes 132 Neutralization Reactions and Salts 134 Neutralization Reactions with Gas Formation 136

### 4.4 Oxidation-Reduction Reactions 137

Oxidation and Reduction 137 Oxidation Numbers 138 Oxidation of Metals by Acids and Salts 140 The Activity Series 141

### 4.5 Concentrations of Solutions 144

Molarity 144 Expressing the Concentration of an Electrolyte 145 Interconverting Molarity, Moles, and Volume 146 Dilution 147

### 4.6 Solution Stoichiometry and Chemical Analysis 148

Titration 150

**Chapter Summary and Key Terms 153**

**Learning Outcomes 154 Key Equations 154**

**Exercises 154 Additional Exercises 159**

**Integrative Exercises 160 Design an Experiment 161**

**Chemistry Put to Work** Antacids 136

**Strategies for Success** Analyzing Chemical Reactions 144

## 5 Thermochemistry 162

### 5.1 The Nature of Chemical Energy 164

### 5.2 The First Law of Thermodynamics 166

System and Surroundings 166 Internal Energy 167 Relating  $\Delta E$  to Heat and Work 168 Endothermic and Exothermic Processes 170 State Functions 170

### 5.3 Enthalpy 172

Pressure–Volume Work 172 Enthalpy Change 174

### 5.4 Enthalpies of Reaction 176

### 5.5 Calorimetry 178

Heat Capacity and Specific Heat 179 Constant-Pressure Calorimetry 180 Bomb Calorimetry (Constant-Volume Calorimetry) 182

**5.6 Hess's Law 183****5.7 Enthalpies of Formation 186**

Using Enthalpies of Formation to Calculate Enthalpies of Reaction 188

**5.8 Bond Enthalpies 190**

Bond Enthalpies and the Enthalpies of Reactions 192

**5.9 Foods and Fuels 194**

Foods 194 Fuels 196 Other Energy Sources 197

**Chapter Summary and Key Terms 200**

**Learning Outcomes 201 Key Equations 201**

**Exercises 202 Additional Exercises 208**

**Integrative Exercises 210 Design an Experiment 211**

**A Closer Look** Energy, Enthalpy, and  $P$ - $V$  Work 175

**A Closer Look** Using Enthalpy as a Guide 178

**Chemistry and Life** The Regulation of Body Temperature 183

**Chemistry Put to Work** The Scientific and Political Challenges of Biofuels 198

## 6 Electronic Structure of Atoms 212

**6.1 The Wave Nature of Light 214****6.2 Quantized Energy and Photons 216**

Hot Objects and the Quantization of Energy 216  
The Photoelectric Effect and Photons 217

**6.3 Line Spectra and the Bohr Model 219**

Line Spectra 219 Bohr's Model 220 The Energy States of the Hydrogen Atom 221 Limitations of the Bohr Model 224

**6.4 The Wave Behavior of Matter 224**

The Uncertainty Principle 226

**6.5 Quantum Mechanics and Atomic Orbitals 227**

Orbitals and Quantum Numbers 228

**6.6 Representations of Orbitals 231**

The  $s$  Orbitals 231 The  $p$  Orbitals 233 The  $d$  and  $f$  Orbitals 234

**6.7 Many-Electron Atoms 234**

Orbitals and Their Energies 235 Electron Spin and the Pauli Exclusion Principle 236

**6.8 Electron Configurations 236**

Hund's Rule 238 Condensed Electron Configurations 240 Transition Metals 240  
The Lanthanides and Actinides 241

**6.9 Electron Configurations and the Periodic Table 241**

Anomalous Electron Configurations 244

**Chapter Summary and Key Terms 246**

**Learning Outcomes 247 Key Equations 248**

**Exercises 248 Additional Exercises 253**

**Integrative Exercises 255 Design an Experiment 255**

**A Closer Look** Measurement and the Uncertainty Principle 226

**A Closer Look** Thought Experiments and Schrödinger's Cat 229

**A Closer Look** Probability Density and Radial Probability Functions 233

**Chemistry and Life** Nuclear Spin and Magnetic Resonance Imaging 237

## 7 Periodic Properties of the Elements 256

**7.1 Development of the Periodic Table 258****7.2 Effective Nuclear Charge 259****7.3 Sizes of Atoms and Ions 262**

Periodic Trends in Atomic Radii 264 Periodic Trends in Ionic Radii 264

**7.4 Ionization Energy 268**

Variations in Successive Ionization Energies 268  
Periodic Trends in First Ionization Energies 269  
Electron Configurations of Ions 270

**7.5 Electron Affinity 272**

Periodic Trends in Electron Affinity 273

**7.6 Metals, Nonmetals, and Metalloids 273**

Metals 274 Nonmetals 276 Metalloids 278

**7.7 Trends for Group 1A and Group 2A Metals 278**

Group 1A: The Alkali Metals 278 Group 2A: The Alkaline Earth Metals 282

**7.8 Trends for Selected Nonmetals 283**

Hydrogen 283 Group 6A: The Oxygen Group 284  
Group 7A: The Halogens 285 Group 8A: The Noble Gases 287

**Chapter Summary and Key Terms 288**

**Learning Outcomes 289 Key Equations 289**

**Exercises 290 Additional Exercises 294**

**Integrative Exercises** 296 **Design an Experiment** 297

**A Closer Look** Effective Nuclear Charge 262

**Chemistry Put to Work** Ionic Size and Lithium-Ion Batteries 267

**Chemistry and Life** The Improbable Development of Lithium Drugs 281

## 8 Basic Concepts of Chemical Bonding 298

### 8.1 Lewis Symbols and the Octet Rule 300

The Octet Rule 300

### 8.2 Ionic Bonding 301

Energetics of Ionic Bond Formation 302 Electron Configurations of Ions of the *s*- and *p*-Block Elements 304 Transition Metal Ions 305

### 8.3 Covalent Bonding 306

Lewis Structures 307 Multiple Bonds 308

### 8.4 Bond Polarity and Electronegativity 309

Electronegativity 309 Electronegativity and Bond Polarity 310 Dipole Moments 311 Comparing Ionic and Covalent Bonding 314

### 8.5 Drawing Lewis Structures 315

Formal Charge and Alternative Lewis Structures 317

### 8.6 Resonance Structures 319

Resonance in Benzene 321

### 8.7 Exceptions to the Octet Rule 322

Odd Number of Electrons 323 Less Than an Octet of Valence Electrons 323 More Than an Octet of Valence Electrons 324

### 8.8 Strengths and Lengths of Covalent Bonds 325

**Chapter Summary and Key Terms** 328

**Learning Outcomes** 329 **Key Equations** 329

**Exercises** 329 **Additional Exercises** 334

**Integrative Exercises** 335 **Design an Experiment** 337

**A Closer Look** Calculation of Lattice Energies: The Born–Haber Cycle 305

**A Closer Look** Oxidation Numbers, Formal Charges, and Actual Partial Charges 319

## 9 Molecular Geometry and Bonding Theories 338

### 9.1 Molecular Shapes 340

### 9.2 The VSEPR Model 342

Applying the VSEPR Model to Determine Molecular Shapes 343 Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles 347 Molecules with Expanded Valence Shells 347 Shapes of Larger Molecules 350

### 9.3 Molecular Shape and Molecular Polarity 352

### 9.4 Covalent Bonding and Orbital Overlap 354

### 9.5 Hybrid Orbitals 355

*sp* Hybrid Orbitals 355 *sp*<sup>2</sup> and *sp*<sup>3</sup> Hybrid Orbitals 357 Hypervalent Molecules 359 Hybrid Orbital Summary 359

### 9.6 Multiple Bonds 361

Resonance Structures, Delocalization, and  $\pi$  Bonding 365 General Conclusions about  $\sigma$  and  $\pi$  Bonding 367

### 9.7 Molecular Orbitals 368

Molecular Orbitals of the Hydrogen Molecule 368 Bond Order 370

### 9.8 Bonding in Period 2 Diatomic Molecules 371

Molecular Orbitals for Li<sub>2</sub> and Be<sub>2</sub> 372 Molecular Orbitals from 2*p* Atomic Orbitals 373 Electron Configurations for B<sub>2</sub> through Ne<sub>2</sub> 376 Electron Configurations and Molecular Properties 377 Heteronuclear Diatomic Molecules 380

**Chapter Summary and Key Terms** 382

**Learning Outcomes** 383 **Key Equations** 384

**Exercises** 384 **Additional Exercises** 389

**Integrative Exercises** 392 **Design an Experiment** 393

**Chemistry and Life** The Chemistry of Vision 367

## 10 Gases 394

### 10.1 Characteristics of Gases 396

### 10.2 Pressure 397

Atmospheric Pressure and the Barometer 397

### 10.3 The Gas Laws 400

The Pressure–Volume Relationship: Boyle's Law 400

The Temperature–Volume Relationship: Charles's

Law 401 The Quantity–Volume Relationship:

Avogadro's Law 402

### 10.4 The Ideal-Gas Equation 403

Relating the Ideal-Gas Equation and the Gas  
Laws 406

### 10.5 Further Applications of the Ideal-Gas Equation 407

Gas Densities and Molar Mass 407 Volumes of Gases  
in Chemical Reactions 409

### 10.6 Gas Mixtures and Partial Pressures 410

Partial Pressures and Mole Fractions 411

### 10.7 The Kinetic-Molecular Theory of Gases 412

Distributions of Molecular Speed 413 Application of  
Kinetic-Molecular Theory to the Gas Laws 414

### 10.8 Molecular Effusion and Diffusion 415

Graham's Law of Effusion 416 Diffusion and Mean  
Free Path 417

### 10.9 Real Gases: Deviations from Ideal Behavior 419

The van der Waals Equation 421

**Chapter Summary and Key Terms 423**

**Learning Outcomes 424 Key Equations 424**

**Exercises 424 Additional Exercises 430**

**Integrative Exercises 432 Design an  
Experiment 433**

**Strategies for Success** Calculations Involving Many  
Variables 405

**A Closer Look** The Ideal-Gas Equation 414

**Chemistry Put to Work** Gas Separations 418

## 11 Liquids and Intermolecular Forces 434

### 11.1 A Molecular Comparison of Gases, Liquids, and Solids 436

### 11.2 Intermolecular Forces 438

Dispersion Forces 439 Dipole–Dipole

Interactions 440 Hydrogen Bonding 441

Ion–Dipole Forces 444 Comparing Intermolecular  
Forces 444

### 11.3 Select Properties of Liquids 445

Viscosity 446 Surface Tension 447 Capillary  
Action 448

### 11.4 Phase Changes 449

Energy Changes Accompany Phase Changes 449

Heating Curves 450 Critical Temperature and  
Pressure 451

### 11.5 Vapor Pressure 453

Volatility, Vapor Pressure, and Temperature 454

Vapor Pressure and Boiling Point 455

### 11.6 Phase Diagrams 456

The Phase Diagrams of H<sub>2</sub>O and CO<sub>2</sub> 457

### 11.7 Liquid Crystals 459

Types of Liquid Crystals 459

**Chapter Summary and Key Terms 462 Learning  
Outcomes 463 Exercises 463 Additional  
Exercises 468 Integrative Exercises 470 Design  
an Experiment 471**

## 17 Additional Aspects of Aqueous Equilibria 716

### 17.1 The Common-Ion Effect 718

### 17.2 Buffers 721

Composition and Action of Buffers 721 Calculating the pH of a Buffer 723 Buffer Capacity and pH Range 726 Addition of Strong Acids or Bases to Buffers 726

### 17.3 Acid–Base Titrations 729

Strong Acid–Strong Base Titrations 730 Weak Acid–Strong Base Titrations 732 Titrating with an Acid–Base Indicator 736 Titrations of Polyprotic Acids 738

### 17.4 Solubility Equilibria 739

The Solubility-Product Constant,  $K_{sp}$  740 Solubility and  $K_{sp}$  741

### 17.5 Factors That Affect Solubility 743

The Common-Ion Effect 743 Solubility and pH 744 Formation of Complex Ions 746 Amphoterism 749

### 17.6 Precipitation and Separation of Ions 751

Selective Precipitation of Ions 752

### 17.7 Qualitative Analysis for Metallic Elements 753

Chapter Summary and Key Terms 756

Learning Outcomes 757 Key Equations 757

Exercises 758 Additional Exercises 763

Integrative Exercises 764 Design an Experiment 765

**Chemistry and Life** Blood as a Buffered Solution 729

**A Closer Look** Limitations of Solubility Products 743

**Chemistry and Life** Tooth Decay and Fluoridation 746

**A Closer Look** Lead Contamination in Drinking Water 750

## 18 Chemistry of the Environment 766

### 18.1 Earth's Atmosphere 768

Composition of the Atmosphere 769

Photochemical Reactions in the Atmosphere 770  
Ozone in the Stratosphere 773

### 18.2 Human Activities and Earth's Atmosphere 774

The Ozone Layer and Its Depletion 774 Sulfur Compounds and Acid Rain 776 Nitrogen Oxides and Photochemical Smog 779 Greenhouse Gases: Water Vapor, Carbon Dioxide, and Climate 780

### 18.3 Earth's Water 784

The Global Water Cycle 784 Salt Water: Earth's Oceans and Seas 785 Freshwater and Groundwater 786

### 18.4 Human Activities and Water Quality 787

Dissolved Oxygen and Water Quality 788 Water Purification: Desalination 788 Water Purification: Municipal Treatment 789

### 18.5 Green Chemistry 792

Supercritical Solvents 794 Greener Reagents and Processes 794

Chapter Summary and Key Terms 797

Learning Outcomes 797 Exercises 798

Additional Exercises 803 Integrative

Exercises 804 Design an Experiment 805

**A Closer Look** Other Greenhouse Gases 783

**A Closer Look** The Ogallala Aquifer—A Shrinking Resource 787

**A Closer Look** Fracking and Water Quality 790

**Chemistry and Life** Ocean Acidification 792

## 19 Chemical Thermodynamics 806

### 19.1 Spontaneous Processes 808

Seeking a Criterion for Spontaneity 809 Reversible and Irreversible Processes 810

### 19.2 Entropy and the Second Law of Thermodynamics 812

The Relationship between Entropy and Heat 812  $\Delta S$  for Phase Changes 813 The Second Law of Thermodynamics 814

### 19.3 The Molecular Interpretation of Entropy and the Third Law of Thermodynamics 815

Expansion of a Gas at the Molecular Level 815 Boltzmann's Equation and Microstates 816 Molecular Motions and Energy 818 Making Qualitative Predictions about  $\Delta S$  819 The Third Law of Thermodynamics 821

## 19.4 Entropy Changes in Chemical Reactions 822

Temperature Variation of Entropy 822 Standard Molar Entropies 823 Calculating the Standard Entropy Change for a Reaction 824 Entropy Changes in the Surroundings 824

## 19.5 Gibbs Free Energy 825

Standard Free Energy of Formation 828

## 19.6 Free Energy and Temperature 830

## 19.7 Free Energy and the Equilibrium Constant 832

Free Energy under Nonstandard Conditions 832 Relationship between  $\Delta G^\circ$  and  $K$  834

**Chapter Summary and Key Terms** 836  
**Learning Outcomes** 837 **Key Equations** 837  
**Exercises** 838 **Additional Exercises** 844  
**Integrative Exercises** 846 **Design an Experiment** 847

**A Closer Look** The Entropy Change When a Gas Expands Isothermally 814

**Chemistry and Life** Entropy and Human Society 822

**A Closer Look** What's "Free" About Free Energy? 829

**Chemistry and Life** Driving Nonspontaneous Reactions: Coupling Reactions 835

# 20 Electrochemistry 848

## 20.1 Oxidation States and Oxidation–Reduction Reactions 850

## 20.2 Balancing Redox Equations 852

Half-Reactions 852 Balancing Equations by the Method of Half-Reactions 852 Balancing Equations for Reactions Occurring in Basic Solution 855

## 20.3 Voltaic Cells 857

## 20.4 Cell Potentials under Standard Conditions 860

Standard Reduction Potentials 861 Strengths of Oxidizing and Reducing Agents 866

## 20.5 Free Energy and Redox Reactions 868

Emf, Free Energy, and the Equilibrium Constant 869

## 20.6 Cell Potentials under Nonstandard Conditions 871

The Nernst Equation 872 Concentration Cells 874

## 20.7 Batteries and Fuel Cells 877

Lead–Acid Battery 878 Alkaline Battery 878 Nickel–Cadmium and Nickel–Metal Hydride Batteries 878 Lithium–Ion Batteries 879 Hydrogen Fuel Cells 879

## 20.8 Corrosion 882

Corrosion of Iron (Rusting) 882 Preventing Corrosion of Iron 883

## 20.9 Electrolysis 884

Quantitative Aspects of Electrolysis 886

**Chapter Summary and Key Terms** 889  
**Learning Outcomes** 890 **Key Equations** 890  
**Exercises** 890 **Additional Exercises** 897  
**Integrative Exercises** 898 **Design an Experiment** 899

**A Closer Look** Electrical Work 871

**Chemistry and Life** Heartbeats and Electrocardiography 876

**Chemistry Put to Work** Batteries for Hybrid and Electric Vehicles 880

**Chemistry Put to Work** Electrometallurgy of Aluminum 887

# 21 Nuclear Chemistry 900

## 21.1 Radioactivity and Nuclear Equations 902

Nuclear Equations 902 Types of Radioactive Decay 903

## 21.2 Patterns of Nuclear Stability 905

Neutron-to-Proton Ratio 905 Radioactive Decay Chains 907 Further Observations 908

## 21.3 Nuclear Transmutations 909

Accelerating Charged Particles 910 Reactions Involving Neutrons 911 Transuranium Elements 911

## 21.4 Rates of Radioactive Decay 912

Radiometric Dating 913 Calculations Based on Half-Life 915

## 21.5 Detection of Radioactivity 917

Radiotracers 917

## 21.6 Energy Changes in Nuclear Reactions 919

Nuclear Binding Energies 921

## 21.7 Nuclear Power: Fission 922

Nuclear Reactors 925 Nuclear Waste 927

**21.8 Nuclear Power: Fusion 928****21.9 Radiation in the Environment and Living Systems 930**

Radiation Doses 931

**Chapter Summary and Key Terms 933****Learning Outcomes 934 Key Equations 935****Exercises 935 Additional Exercises 939****Integrative Exercises 940 Design an Experiment 941****Chemistry and Life** Medical Applications of Radiotracers 918**A Closer Look** The Dawning of the Nuclear Age 925**A Closer Look** Nuclear Synthesis of the Elements 929**Chemistry and Life** Radiation Therapy 932

## 22 Chemistry of the Nonmetals 942

**22.1 Periodic Trends and Chemical Reactions 944**

Chemical Reactions 945

**22.2 Hydrogen 946**

Isotopes of Hydrogen 946 Properties of Hydrogen 947 Production of Hydrogen 948 Uses of Hydrogen 949 Binary Hydrogen Compounds 949

**22.3 Group 8A: The Noble Gases 950**

Noble-Gas Compounds 951

**22.4 Group 7A: The Halogens 952**

Properties and Production of the Halogens 952 Uses of the Halogens 954 The Hydrogen Halides 954 Interhalogen Compounds 954 Oxyacids and Oxyanions 954

**22.5 Oxygen 955**

Properties of Oxygen 955 Production of Oxygen 956 Uses of Oxygen 956 Ozone 956 Oxides 956 Peroxides and Superoxides 958

**22.6 The Other Group 6A Elements: S, Se, Te, and Po 958**

Occurrence and Production of S, Se, and Te 959 Properties and Uses of Sulfur, Selenium, and Tellurium 959 Sulfides 959 Oxides, Oxyacids, and Oxyanions of Sulfur 960

**22.7 Nitrogen 962**

Properties of Nitrogen 962 Production and Uses of Nitrogen 962 Hydrogen Compounds of Nitrogen 962 Oxides and Oxyacids of Nitrogen 963

**22.8 The Other Group 5A Elements: P, As, Sb, and Bi 965**

Occurrence, Isolation, and Properties of Phosphorus 966 Phosphorus Halides 966 Oxy Compounds of Phosphorus 967

**22.9 Carbon 969**

Elemental Forms of Carbon 969 Oxides of Carbon 970 Carbonic Acid and Carbonates 971 Carbides 972

**22.10 The Other Group 4A Elements: Si, Ge, Sn, and Pb 972**

General Characteristics of the Group 4A Elements 972 Occurrence and Preparation of Silicon 973 Silicates 973 Glass 975 Silicones 976

**22.11 Boron 976****Chapter Summary and Key Terms 978 Learning Outcomes 979 Exercises 979 Additional Exercises 983 Integrative Exercises 984 Design an Experiment 985****A Closer Look** The Hydrogen Economy 948**Chemistry and Life** Nitroglycerin, Nitric Oxide, and Heart Disease 965**Chemistry and Life** Arsenic in Drinking Water 968**Chemistry Put to Work** Carbon Fibers and Composites 970

## 23 Transition Metals and Coordination Chemistry 986

**23.1 The Transition Metals 988**

Physical Properties 989 Electron Configurations and Oxidation States 990 Magnetism 991

**23.2 Transition-Metal Complexes 992**

The Development of Coordination Chemistry: Werner's Theory 993 The Metal-Ligand Bond 995 Charges, Coordination Numbers, and Geometries 996

**23.3 Common Ligands in Coordination Chemistry 997**

Metals and Chelates in Living Systems 999

**23.4 Nomenclature and Isomerism in Coordination Chemistry 1003**

Isomerism 1005 Structural Isomerism 1005 Stereoisomerism 1006

### 23.5 Color and Magnetism in Coordination Chemistry 1009

Color 1009 Magnetism of Coordination Compounds 1011

### 23.6 Crystal-Field Theory 1011

Electron Configurations in Octahedral Complexes 1015 Tetrahedral and Square-Planar Complexes 1017

**Chapter Summary and Key Terms 1021**

**Learning Outcomes 1021 Exercises 1022**

**Additional Exercises 1026 Integrative Exercises 1028 Design an Experiment 1029**

**A Closer Look** Entropy and the Chelate Effect 1001

**Chemistry and Life** The Battle for Iron in Living Systems 1002

**A Closer Look** Charge-Transfer Color 1019

## 24 The Chemistry of Life: Organic and Biological Chemistry 1030

### 24.1 General Characteristics of Organic Molecules 1032

The Structures of Organic Molecules 1032  
The Stability of Organic Compounds 1033 Solubility and Acid-Base Properties of Organic Compounds 1033

### 24.2 Introduction to Hydrocarbons 1034

Structures of Alkanes 1035 Structural Isomers 1035 Nomenclature of Alkanes 1036 Cycloalkanes 1039 Reactions of Alkanes 1039

### 24.3 Alkenes, Alkynes, and Aromatic Hydrocarbons 1041

Alkenes 1041 Alkynes 1043 Addition Reactions of Alkenes and Alkynes 1044 Aromatic Hydrocarbons 1045 Stabilization of  $\pi$  Electrons by Delocalization 1046 Substitution Reactions of Aromatic Hydrocarbons 1046

### 24.4 Organic Functional Groups 1048

Alcohols 1048 Ethers 1050 Aldehydes and Ketones 1050 Carboxylic Acids and Esters 1051 Amines and Amides 1054

### 24.5 Chirality in Organic Chemistry 1055

### 24.6 Introduction to Biochemistry 1057

### 24.7 Proteins 1057

Amino Acids 1057 Polypeptides and Proteins 1059 Protein Structure 1060

### 24.8 Carbohydrates 1062

Disaccharides 1063 Polysaccharides 1064

### 24.9 Lipids 1065

Fats 1065 Phospholipids 1066

### 24.10 Nucleic Acids 1067

**Chapter Summary and Key Terms 1071**

**Learning Outcomes 1072 Exercises 1072**

**Additional Exercises 1077 Integrative Exercises 1078 Design an Experiment 1079**

**Chemistry Put to Work** Gasoline 1040

**A Closer Look** Mechanism of Addition Reactions 1045

**Strategies for Success** What Now? 1070

## APPENDICES

**A** Mathematical Operations 1080

**B** Properties of Water 1087

**C** Thermodynamic Quantities for Selected Substances at 298.15 K (25 °C) 1088

**D** Aqueous Equilibrium Constants 1092

**E** Standard Reduction Potentials at 25 °C 1094

**ANSWERS TO SELECTED EXERCISES** A-1

**ANSWERS TO GIVE IT SOME THOUGHT** A-31

**ANSWERS TO GO FIGURE** A-37

**ANSWERS TO SELECTED PRACTICE EXERCISES** A-43

**GLOSSARY** G-1

**PHOTO AND ART CREDITS** P-1

**INDEX** I-1

Nuclear Reaction

Sample Exercise 22.4 Predicting Chemical Reactions among  
the Halogens

Sample Exercise 23.2 Determining the Oxidation Number of  
a Metal in a Complex

Sample Exercise 24.1 Naming Alkanes

# PREFACE

## To the Instructor

### Philosophy

We authors of *Chemistry: The Central Science* are delighted and honored that you have chosen us as your instructional partners for your general chemistry class. Collectively we have taught general chemistry to multiple generations of students. So we understand the challenges and opportunities of teaching a class that so many students take. We have also been active researchers who appreciate both the learning and the discovery aspects of the chemical sciences. Our varied, wide-ranging experiences have formed the basis of the close collaborations we have enjoyed as coauthors. In writing our book, our focus is on the students: we try to ensure that the text is not only accurate and up-to-date but also clear and readable. We strive to convey the breadth of chemistry and the excitement that scientists experience in making new discoveries that contribute to our understanding of the physical world. We want the student to appreciate that chemistry is not a body of specialized knowledge that is separate from most aspects of modern life, but central to any attempt to address a host of societal concerns, including renewable energy, environmental sustainability, and improved human health.

Publishing the fourteenth edition of this text bespeaks an exceptionally long record of successful textbook writing. We are appreciative of the loyalty and support the book has received over the years, and mindful of our obligation to justify each new edition. We begin our approach to each new edition with an intensive author retreat, in which we ask ourselves the deep questions that we must answer before we can move forward. What justifies yet another edition? What is changing in the world not only of chemistry, but with respect to science education and the qualities of the students we serve? How can we help your students not only learn the principles of chemistry, but also become critical thinkers who can think more like chemists? The answers lie only partly in the changing face of chemistry itself. The introduction of many new technologies has changed the landscape in the teaching of sciences at all levels. The use of the Internet in accessing information and presenting learning materials has markedly changed the role of the textbook as one element among many tools for student learning. Our challenge as authors is to maintain the text as the primary source of chemical knowledge and practice, while at the same time integrating it with the new avenues for learning made possible by technology. This edition incorporates a number of those new methodologies, including use of computer-based classroom tools, such as Learning Catalytics™, a cloud-based active learning analytics and assessment system, and web-based tools, particularly MasteringChemistry™, which is continually evolving to

provide more effective means of testing and evaluating student performance, while giving the student immediate and helpful feedback. MasteringChemistry™ not only provides feedback on a question by question basis, but using Knewton-enhanced adaptive follow-up assignments and Dynamic Study Modules, it now continually adapts to each student, offering a personalized learning experience.

As authors, we want this text to be a central, indispensable learning tool for students. Whether as a physical book or in electronic form, it can be carried everywhere and used at any time. It is the best place students can go to obtain the information outside of the classroom needed for learning, skill development, reference, and test preparation. The text, more effectively than any other instrument, provides the depth of coverage and coherent background in modern chemistry that students need to serve their professional interests and, as appropriate, to prepare for more advanced chemistry courses.

If the text is to be effective in supporting your role as instructor, it must be addressed to the students. We have done our best to keep our writing clear and interesting and the book attractive and well illustrated. The book has numerous in-text study aids for students, including carefully placed descriptions of problem-solving strategies. We hope that our cumulative experiences as teachers is evident in our pacing, choice of examples, and the kinds of study aids and motivational tools we have employed. We believe students are more enthusiastic about learning chemistry when they see its importance relative to their own goals and interests; therefore, we have highlighted many important applications of chemistry in everyday life. We hope you make use of this material.

It is our philosophy, as authors, that the text and all the supplementary materials provided to support its use must work in concert with you, the instructor. A textbook is only as useful to students as the instructor permits it to be. This book is replete with features that help students learn and that can guide them as they acquire both conceptual understanding and problem-solving skills. There is a great deal here for the students to use, too much for all of it to be absorbed by any student in a one-year course. You will be the guide to the best use of the book. Only with your active help will the students be able to utilize most effectively all that the text and its supplements offer. Students care about grades, of course, and with encouragement they will also become interested in the subject matter and care about learning. Please consider emphasizing features of the book that can enhance student appreciation of chemistry, such as the *Chemistry Put To Work* and *Chemistry and Life* boxes that show how chemistry impacts modern life and its relationship to health and life processes. Also consider emphasizing conceptual understanding (placing less emphasis on simple manipulative, algorithmic problem solving) and urging students to use the rich on-line resources available.

## Organization and Contents

The first five chapters give a largely macroscopic, phenomenological view of chemistry. The basic concepts introduced—such as nomenclature, stoichiometry, and thermochemistry—provide necessary background for many of the laboratory experiments usually performed in general chemistry. We believe that an early introduction to thermochemistry is desirable because so much of our understanding of chemical processes is based on considerations of energy changes. By incorporating bond enthalpies in the Thermochemistry chapter we aim to emphasize the connection between the macroscopic properties of substances and the submicroscopic world of atoms and bonds. We believe we have produced an effective, balanced approach to teaching thermodynamics in general chemistry, as well as providing students with an introduction to some of the global issues involving energy production and consumption. It is no easy matter to walk the narrow pathway between—on the one hand—trying to teach too much at too high a level and—on the other hand—resorting to oversimplifications. As with the book as a whole, the emphasis has been on imparting *conceptual* understanding, as opposed to presenting equations into which students are supposed to plug numbers.

The next four chapters (Chapters 6–9) deal with electronic structure and bonding. For more advanced students, *A Closer Look* boxes in Chapters 6 and 9 highlight radial probability functions and the phases of orbitals. Our approach of placing this latter discussion in *A Closer Look* box in Chapter 9 enables those who wish to cover this topic to do so, while others may wish to bypass it. In treating this topic and others in Chapters 7 and 9, we have materially enhanced the accompanying figures to more effectively bring home their central messages.

In Chapters 10–13, the focus of the text changes to the next level of the organization of matter: examining the states of matter. Chapters 10 and 11 deal with gases, liquids, and intermolecular forces, while Chapter 12 is devoted to solids, presenting a contemporary view of the solid state as well as of modern materials accessible to general chemistry students. The chapter provides an opportunity to show how abstract chemical bonding concepts impact real-world applications. The modular organization of the chapter allows you to tailor your coverage to focus on the materials (semiconductors, polymers, nanomaterials, and so forth) that are most relevant to your students and your own interests. This section of the book concludes with Chapter 13 which covers the formation and properties of solutions.

The next several chapters examine the factors that determine the speed and extent of chemical reactions: kinetics (Chapter 14), equilibria (Chapters 15–17), thermodynamics (Chapter 19), and electrochemistry (Chapter 20). Also in this section is a chapter on environmental chemistry (Chapter 18), in which the concepts developed in preceding chapters are applied to a discussion of the atmosphere and hydrosphere. This chapter has increasingly come to be focused on green chemistry and the impacts of human activities on Earth's water and atmosphere.

After a discussion of nuclear chemistry (Chapter 21), the book ends with three survey chapters. Chapter 22 deals with nonmetals, Chapter 23 with the chemistry of transition

metals, including coordination compounds, and Chapter 24 with the chemistry of organic compounds and elementary biochemical themes. These final four chapters are developed in an independent, modular fashion and can be covered in any order.

Our chapter sequence provides a fairly standard organization, but we recognize that not everyone teaches all the topics in the order we have chosen. We have therefore made sure that instructors can make common changes in teaching sequence with no loss in student comprehension. In particular, many instructors prefer to introduce gases (Chapter 10) after stoichiometry (Chapter 3) rather than with states of matter. The chapter on gases has been written to permit this change with *no* disruption in the flow of material. It is also possible to treat balancing redox equations (Sections 20.1 and 20.2) earlier, after the introduction of redox reactions in Section 4.4. Finally, some instructors like to cover organic chemistry (Chapter 24) right after bonding (Chapters 8 and 9). This, too, is a largely seamless move.

We have brought students into greater contact with descriptive organic and inorganic chemistry by integrating examples throughout the text. You will find pertinent and relevant examples of “real” chemistry woven into all the chapters to illustrate principles and applications. Some chapters, of course, more directly address the “descriptive” properties of elements and their compounds, especially Chapters 4, 7, 11, 18, and 22–24. We also incorporate descriptive organic and inorganic chemistry in the end-of-chapter exercises.

## New in This Edition

As with every new edition of *Chemistry: The Central Science* the book has undergone a great many changes as we strive to keep the content current, and to improve the clarity and effectiveness of the text, the art, and the exercises. Among the myriad changes there are certain points of emphasis that we use to organize and guide the revision process. In creating the fourteenth edition our revision was organized around the following points:

- Our treatment of energy and thermochemistry has been significantly revised. The concept of energy is now introduced in Chapter 1, whereas previously it did not appear until Chapter 5. This change allows instructors greater freedom in the order in which they cover the material. For example, this change would facilitate coverage of Chapters 6 and 7 immediately following Chapter 2, a sequence that is in line with an atoms-first approach to teaching general chemistry. More importantly, bond enthalpies are now integrated into Chapter 5 to emphasize the connection between macroscopic quantities, like reaction enthalpies, and the submicroscopic world of atoms and bonds. We feel this change leads to a better integration of thermochemical concepts with the surrounding chapters. Bond enthalpies are revisited in Chapter 8 after students have developed a more sophisticated view of chemical bonding.
- Considerable effort was made to provide students with a clear discussion, superior problem sets, and better real-

time feedback on their understanding of the material. The author team used an interactive e-book platform to view passages that students highlighted in their reading along with the related notes and questions that detailed what they did not understand. In response, numerous passages were revised for greater clarity.

- Extensive effort has gone into creating enhanced content for the eText version of the book. These features make the eText so much more than just an electronic copy of the physical textbook. New Smart Figures take key figures from the text and bring them to life through animation and narration. Likewise, new Smart Sample Exercises animate key sample exercises from the text, offering students a more in depth and detailed discussion than can be provided in the printed text. These interactive features will also include follow-up questions, which can be assigned in MasteringChemistry™.
- We used metadata from MasteringChemistry™ to inform our revisions. In the thirteenth edition a second *Practice Exercise* was added to accompany each *Sample Exercise*. Nearly all of the additional practice exercises were multiple choice questions with wrong answer distractors written to identify student misconceptions and common mistakes. As implemented in MasteringChemistry™, feedback was provided with each wrong answer to help students recognize their misconceptions. In this new edition we have carefully scrutinized the metadata from MasteringChemistry™ to identify practice exercises that either were not challenging the students or were not being used. Those exercises have either been modified or changed entirely. A similar effort was made to revise *Give It Some Thought* and *Go Figure* questions to make them more effective and amenable to use in MasteringChemistry™. Finally, the number of end-of-chapter exercises that have wrong answer feedback in MasteringChemistry™ has been dramatically expanded. We have also replaced outdated or little-used end-of-chapter exercises (~10 per chapter).
- Finally, subtle but important changes have been made to allow students to quickly reference important concepts and assess their knowledge of the material. Key points are now set in italic with line spaces above and below for greater emphasis. New skills-based *How To...* features offer step-by-step guidance for solving specific types of problems such as Drawing Lewis Structures, Balancing Redox Equations, and Naming Acids. These features, with numbered steps encased by a thin rule, are integrated into the main discussion and are easy to find. Finally, each Learning Objective is now correlated to specific end-of-chapter exercises. This allows students to test their mastery of each learning objective when preparing for quizzes and exams.

## Changes in This Edition

The **New in This Edition** section details changes made throughout this edition. Beyond a mere listing, however, it is worth dwelling on the general goals we set forth in formulating

this new edition. *Chemistry: The Central Science* has traditionally been valued for its clarity of writing, its scientific accuracy and currency, its strong end-of-chapter exercises, and its consistency in level of coverage. In making changes, we have made sure not to compromise these characteristics, and we have also continued to employ an open, clean design in the layout of the book.

The art program for the fourteenth edition continues the trajectory set in the previous two editions: to make greater and more effective use of the figures as learning tools, by drawing the reader more directly into the figure. The style of the art has been revised throughout for enhanced clarity and a cleaner more modern look. This includes: new white-background annotation boxes with crisp, thin leaders; richer and more saturated colors in the art, and expanded use of 3D renderings. An editorial review of every figure in the text resulted in numerous minor revisions to the art and its labels in order to increase clarity. The *Go Figure* questions have been carefully scrutinized. Using statistics from MasteringChemistry™, many have been modified or changed entirely to engage and challenge students to think critically about the concept(s) that underlie each figure. The *Give it Some Thought* feature has been revised in a similar vein to stimulate more thoughtful reading of the text and foster critical thinking.

We provide a valuable overview of each chapter under the *What's Ahead* banner. *Concept links* (🔗) continue to provide easy-to-see cross-references to pertinent material covered earlier in the text. The essays titled *Strategies in Chemistry*, which provide advice to students on problem solving and “thinking like a chemist,” have been renamed *Strategies for Success* to better convey their usefulness to the student.

We have continued to emphasize conceptual exercises in the end-of-chapter problems. In each chapter we begin the exercises with the well-received *Visualizing Concepts* category. These exercises are designed to facilitate conceptual understanding through use of models, graphs, photographs, and other visual materials. They precede the regular end-of-chapter exercises and are identified in each case with the relevant chapter section number. A generous selection of *Integrative Exercises*, which give students the opportunity to solve problems that integrate concepts from the present chapter with those of previous chapters, is included at the end of each chapter. The importance of integrative problem solving is highlighted by the *Sample Integrative Exercise*, which ends each chapter beginning with Chapter 4. In general, we have included more conceptual end-of-chapter exercises and have made sure that there is a good representation of somewhat more difficult exercises to provide a better mix in terms of topic and level of difficulty. Many of the exercises have been restructured to facilitate their use in MasteringChemistry™. We have made extensive use of the metadata from student use of MasteringChemistry™ to analyze end-of-chapter exercises and make appropriate changes, as well as to develop *Learning Outcomes* for each chapter.

New essays in our well-received *Chemistry Put To Work* and *Chemistry and Life* series emphasize world events, scientific discoveries, and medical breakthroughs relevant to topics

developed in each chapter. We maintain our focus on the positive aspects of chemistry without neglecting the problems that can arise in an increasingly technological world. Our goal is to help students appreciate the real-world perspective of chemistry and the ways in which chemistry affects their lives.

It is perhaps a natural tendency for chemistry textbooks to grow in length with succeeding editions, but it is one that we have resisted. There are, nonetheless, many new items in this edition, mostly ones that replace other material considered less pertinent. Here is a list of several significant changes in content:

Chapter 1, and every chapter that follows, begins with a new chapter opening photo and backstory to provide a real world context for the material that follows. A new section on the nature of energy (Section 1.4) has been added to Chapter 1. The inclusion of energy in the opening chapter provides much greater flexibility for the order in which subsequent chapters can be covered. The *Chemistry Put To Work* box, dealing with *Chemistry in the News*, has been completely rewritten, with items that describe diverse ways in which chemistry intersects with the affairs of modern society.

In Chapter 2 the figures depicting the key experiments that led to the discovery of the structure of the atom—Millikan's Oil Drop experiment and Rutherford's Gold Foil experiment—have been enhanced. This is also the first occurrence of the periodic table which has been updated throughout the text to reflect the acceptance and naming of elements 113 (Nihonium), 115 (Moscovium), 117 (Tennessine), and 118 (Oganesson).

Chapter 5 has undergone the most extensive revision in the book. Early parts of the chapter have been modified to reflect the fact that basic concepts of energy are now introduced in Chapter 1. Two new figures have been added. Figure 5.3 qualitatively relates electrostatic potential energy to changes in the bonding of an ionic solid, while Figure 5.16 provides a real-world analogy to help students understand the relationship between spontaneity and reaction enthalpy. The figure illustrating exothermic and endothermic reactions (Figure 5.8) has been modified to show before and after images of the reaction. Finally, to stress the atomistic origins of reaction enthalpies, a new section (Section 5.8) on bond enthalpies has been added, as discussed earlier.

A new Sample Exercise has been added to Chapter 6 that shows how the radii of orbits in the Bohr model of the hydrogen atom depend on the principal quantum number and how the electron behavior changes when a photon is emitted or absorbed.

Chapter 8 has seen some of its content on bond enthalpies moved to Chapter 5. The concepts there are now reinforced here.

In Chapter 11, attention has been paid to the text regarding various intermolecular forces to make clear that chemists usually think about them in units of energy, not units of force. A new checklist art piece replaces old Figure 11.14 in order to make it clear that intermolecular interaction energies are additive.

Chapter 12 has a new *A Closer Look* box entitled *Modern Materials in the Automobile* which discusses the wide range of

materials used in a hybrid automobile, including semiconductors, ionic solids, alloys, polymers, and more. A new *Chemistry Put To Work* entitled *Microporous and Mesoporous Materials* examines materials with different pore sizes and their application in ion exchange and catalytic converters.

In Chapter 15 a new *A Closer Look* box on *Temperature Changes and Le Châtelier's Principle* explains the theoretical underpinnings of the empirical rules that successfully predict how temperature changes influence the equilibrium constants of exothermic and endothermic reactions.

In Chapter 16 a new *A Closer Look* box on *Polyprotic Acids* explicitly shows the speciation of ions as a function of pH.

In Chapter 17 a new *A Closer Look* box entitled *Lead Contamination in Drinking Water* explores the chemistry behind the water quality crisis in Flint, Michigan.

Chapter 18 has been revised to reflect the most up-to-date data on atmospheric CO<sub>2</sub> levels and the ozone hole. Figure 18.4, showing the UV absorption spectrum of ozone, has been added so students can understand its role in filtering out harmful UV radiation from the sun. A new Sample Exercise (18.3) walks students through the steps needed to calculate the amount of CO<sub>2</sub> produced from combustion of a hydrocarbon.

In Chapter 19 we have substantially rewritten the early sections to help students better understand the concepts of spontaneous, nonspontaneous, reversible, and irreversible processes and their relationships. These improvements have led to a clearer definition of entropy.

## To the Student

*Chemistry: The Central Science*, Fourteenth Edition, has been written to introduce you to modern chemistry. As authors, we have, in effect, been engaged by your instructor to help you learn chemistry. Based on the comments of students and instructors who have used this book in its previous editions, we believe that we have done that job well. Of course, we expect the text to continue to evolve through future editions. We invite you to write to tell us what you like about the book so that we will know where we have helped you most. Also, we would like to learn of any shortcomings so we may further improve the book in subsequent editions. Our addresses are given at the end of the Preface.

## Advice for Learning and Studying Chemistry

Learning chemistry requires both the assimilation of many concepts and the development of analytical skills. In this text, we have provided you with numerous tools to help you succeed in both tasks. If you are going to succeed in your chemistry course, you will have to develop good study habits. Science courses, and chemistry in particular, make different demands on your learning skills than do other types of courses. We offer the following tips for success in your study of chemistry:

**Don't fall behind!** As the course moves along, new topics will build on material already presented. If you don't keep up in your reading and problem solving, you will find it much harder to follow the lectures and discussions on current topics. Experienced teachers know that students who read the relevant sections of the text *before* coming to a class learn more from the class and retain greater recall. "Cramming" just before an exam has been shown to be an ineffective way to study any subject, chemistry included. So now you know. How important to you, in this competitive world, is a good grade in chemistry?

**Focus your study.** The amount of information you will be expected to learn may seem overwhelming. It is essential to recognize those concepts and skills that are particularly important. Pay attention to what your instructor is emphasizing. As you work through the *Sample Exercises* and homework assignments, try to see what general principles and skills they employ. Use the *What's Ahead* feature at the beginning of each chapter to help orient yourself to what is important in each chapter. A single reading of a chapter will generally not be enough for successful learning of chapter concepts and problem-solving skills. You will often need to go over assigned materials more than once. Don't skip the *Give It Some Thought* and *Go Figure* features, *Sample Exercises*, and *Practice Exercises*. These are your guides to whether you are learning the material. They are also good preparation for test-taking. The *Learning Outcomes* and *Key Equations* at the end of the chapter will also help you focus your study.

**Keep good lecture notes.** Your lecture notes will provide you with a clear and concise record of what your instructor regards as the most important material to learn. Using your lecture notes in conjunction with this text is the best way to determine which material to study.

**Skim topics in the text before they are covered in lecture.** Reviewing a topic before lecture will make it easier for you to take good notes. First read the *What's Ahead* points and the end-of-chapter *Summary*; then quickly read through the chapter, skipping *Sample Exercises* and supplemental sections. Paying attention to the titles of sections and subsections gives you a feeling for the scope of topics. Try to avoid thinking that you must learn and understand everything right away.

**You need to do a certain amount of preparation before lecture.** More than ever, instructors are using the lecture period not simply as a one-way channel of communication from teacher to student. Rather, they expect students to come to class ready to work on problem solving and critical thinking. Coming to class unprepared is not a good idea for any lecture environment, but it certainly is not an option for an active learning classroom if you aim to do well in the course.

**After lecture, carefully read the topics covered in class.** As you read, pay attention to the concepts presented and to the application of these concepts in the *Sample Exercises*. Once you think you understand a *Sample Exercise*, test your understanding by working the accompanying *Practice Exercise*.

**Learn the language of chemistry.** As you study chemistry, you will encounter many new words. It is important to pay attention to these words and to know their meanings or the entities to which they refer. Knowing how to identify chemical substances from their names is an important skill; it can help you avoid painful mistakes on examinations. For example, "chlorine" and "chloride" refer to very different things.

**Attempt the assigned end-of-chapter exercises.** Working the exercises selected by your instructor provides necessary practice in recalling and using the essential ideas of the chapter. You cannot learn merely by observing; you must be a participant. In particular, try to resist checking the *Solutions Manual* (if you have one) until you have made a sincere effort to solve the exercise yourself. If you get stuck on an exercise, however, get help from your instructor, your teaching assistant, or another student. Spending more than 20 minutes on a single exercise is rarely effective unless you know that it is particularly challenging.

**Learn to think like a scientist.** This book is written by scientists who love chemistry. We encourage you to develop your critical thinking skills by taking advantage of features in this new edition, such as exercises that focus on conceptual learning, and the *Design an Experiment* exercises.

**Use online resources.** Some things are more easily learned by discovery, and others are best shown in three dimensions. If your instructor has included MasteringChemistry™ with your book, take advantage of the unique tools it provides to get the most out of your time in chemistry.

The bottom line is to work hard, study effectively, and use the tools available to you, including this textbook. We want to help you learn more about the world of chemistry and why chemistry is the central science. If you really learn chemistry, you can be the life of the party, impress your friends and parents, and ... well, also pass the course with a good grade.

## Acknowledgments

The production of a textbook is a team effort requiring the involvement of many people besides the authors who contributed hard work and talent to bring this edition to life. Although their names don't appear on the cover of the book, their creativity, time, and support have been instrumental in all stages of its development and production.

Each of us has benefited greatly from discussions with colleagues and from correspondence with instructors and students both here and abroad. Colleagues have also helped immensely by reviewing our materials, sharing their insights, and providing suggestions for improvements. For this edition, we were particularly blessed with an exceptional group of accuracy checkers who read through our materials looking for both technical inaccuracies and typographical errors.

We would also like to express our gratitude to our many team members at Pearson whose hard work, imagination, and commitment have contributed so greatly to the final form of this edition: Chris Hess, our chemistry editor, for many fresh ideas and his unflagging enthusiasm, continuous encouragement, and support; Jennifer Hart, Director of Development, who has brought her experience and insight to oversight of the entire project; Matt Walker, our development editor, whose depth of experience, good judgment, and careful attention to detail were invaluable to this revision, especially in keeping us on task in

terms of consistency and student understanding. The Pearson team is a first-class operation.

There are many others who also deserve special recognition, including the following: Mary Tindle, our production editor, who skillfully kept the process moving and us authors on track; and Roxy Wilson (University of Illinois), who so ably coordinated the difficult job of working out solutions to the end-of-chapter exercises. Finally, we wish to thank our families and friends for their love, support, encouragement, and patience as we brought this fourteenth edition to completion.

# ABOUT THE AUTHORS

**The Brown/Lemay/Bursten/Murphy/Woodward/Stoltzfus Author Team** values collaboration as an integral component to overall success. While each author brings unique talent, research interests, and teaching experiences, the team works together to review and develop the entire text. It is this collaboration that keeps the content ahead of educational trends and contributes to continuous innovations in teaching and learning throughout the text and technology. Some of the new key features in the fourteenth edition and accompanying MasteringChemistry™ course are highlighted on the upcoming pages.

**Theodore L. Brown** received his Ph.D. from Michigan State University in 1956. Since then, he has been a member of the faculty of the University of Illinois, Urbana-Champaign, where he is now Professor of Chemistry, Emeritus. He served as Vice Chancellor for Research, and Dean of The Graduate College, from 1980 to 1986, and

as Founding Director of the Arnold and Mabel Beckman Institute for Advanced Science and Technology from 1987 to 1993. Professor Brown has been an Alfred P. Sloan Foundation Research Fellow and has been awarded a Guggenheim Fellowship. In 1972 he was awarded the American Chemical Society Award for Research in Inorganic Chemistry and received the American Chemical Society Award for Distinguished Service in the Advancement of Inorganic Chemistry in 1993. He has been elected a Fellow of the American Association for the Advancement of Science, the American Academy of Arts and Sciences, and the American Chemical Society.

**H. Eugene Lemay, Jr.**, received his B.S. degree in Chemistry from Pacific Lutheran University (Washington) and his Ph.D. in Chemistry in 1966 from the University of Illinois, Urbana-Champaign. He then joined the faculty of the University of Nevada, Reno, where he is currently Professor of Chemistry, Emeritus. He has

enjoyed Visiting Professorships at the University of North Carolina at Chapel Hill, at the University College of Wales in Great Britain, and at the University of California, Los Angeles. Professor LeMay is a popular and effective teacher, who has taught thousands of students during more than 40 years of university teaching. Known for the clarity of his lectures and his sense of humor, he has received several teaching awards, including the University Distinguished Teacher of the Year Award (1991) and the first Regents' Teaching Award given by the State of Nevada Board of Regents (1997).

**Bruce E. Bursten** received his Ph.D. in Chemistry from the University of Wisconsin in 1978. After two years as a National Science Foundation Postdoctoral Fellow at Texas A&M University, he joined the faculty of The Ohio State University, where he rose to the rank of Distinguished University Professor. In 2005, he moved to the University of Tennessee, Knoxville, as Distinguished Pro-

fessor of Chemistry and Dean of the College of Arts and Sciences. In 2015, he moved to Worcester Polytechnic Institute as Provost and Professor of Chemistry and Biochemistry. Professor Bursten has been a Camille and Henry Dreyfus Foundation Teacher-Scholar and an Alfred P. Sloan Foundation Research Fellow, and he is a Fellow of both the American Association for the Advancement of Science and the American Chemical Society. At Ohio State he received the University Distinguished Teaching Award in

1982 and 1996, the Arts and Sciences Student Council Outstanding Teaching Award in 1984, and the University Distinguished Scholar Award in 1990. He received the Spiers Memorial Prize and Medal of the Royal Society of Chemistry in 2003, and the Morley Medal of the Cleveland Section of the American Chemical Society in 2005. He was President of the American Chemical Society for 2008 and Chair of the Section on Chemistry of the American Association for the Advancement of Science in 2015. In addition to his teaching and service activities, Professor Bursten's research program focuses on compounds of the transition-metal and actinide elements.

**Catherine J. Murphy** received two B.S. degrees, one in Chemistry and one in Biochemistry, from the University of Illinois, Urbana-Champaign, in 1986. She received her Ph.D. in Chemistry from the University of Wisconsin in 1990. She was a National Science Foundation and National Institutes of Health Postdoctoral Fellow at the California Institute of Technology from 1990 to 1993. In 1993, she joined the faculty of the University of South Carolina, Columbia, becoming the Guy F. Lipscomb Professor of Chemistry in 2003. In 2009 she moved to the University of Illinois, Urbana-Champaign, as the Peter C. and Gretchen Miller Markunas Professor of Chemistry. Professor Murphy has been honored for both research and teaching as a Camille Dreyfus Teacher-Scholar, an Alfred P. Sloan Foundation Research Fellow, a Cottrell Scholar of the Research Corporation, a National Science Foundation CAREER Award winner, and a subsequent NSF Award for Special Creativity. She has also received a USC Mortar Board Excellence in Teaching Award, the USC Golden Key Faculty Award for Creative Integration of Research and Undergraduate Teaching, the USC Michael J. Mungo Undergraduate Teaching Award, and the USC Outstanding Undergraduate Research Mentor Award. From 2006–2011, Professor Murphy served as a Senior Editor for the *Journal of Physical Chemistry*; in 2011 she became the Deputy Editor for the *Journal of Physical Chemistry C*. She is an elected Fellow of the American Association for the Advancement of Science (2008), the American Chemical Society (2011), the Royal Society of Chemistry (2014), and the U.S. National Academy of Sciences (2015). Professor Murphy's research program focuses on the synthesis, optical properties, surface chemistry, biological applications, and environmental implications of colloidal inorganic nanomaterials.

**Patrick M. Woodward** received B.S. degrees in both Chemistry and Engineering from Idaho State University in 1991. He received a M.S. degree in Materials Science and a Ph.D. in Chemistry from Oregon State University in 1996. He spent two years as a postdoctoral researcher in the Department of Physics at Brookhaven National Laboratory. In 1998, he joined the faculty of the Chemistry Department at The Ohio State University where he currently holds the rank of

Professor. He has enjoyed visiting professorships at the University of Bordeaux in France and the University of Sydney in Australia. Professor Woodward has been an Alfred P. Sloan Foundation Research Fellow and a National Science Foundation CAREER Award winner. He has served as Vice Chair for Undergraduate Studies in the Department of Chemistry and Biochemistry at Ohio State University, and director of the Ohio REEL program. He is currently the Vice President of the Neutron Scattering Society of America. Professor Woodward's research program focuses on understanding the links between bonding, structure, and properties of solid-state inorganic materials.

**Matthew W. Stoltzfus** received his B.S. degree in Chemistry from Millersville University in 2002 and his Ph. D. in Chemistry in 2007 from The Ohio State University. He spent two years as a teaching postdoctoral assistant for the Ohio REEL program, an NSF-funded center that works to bring authentic research experiments into the general chemistry lab curriculum in 15 colleges and universities across the state of Ohio. In 2009, he joined the faculty of Ohio State where he currently holds the position of Chemistry Lecturer. In addition to lecturing general chemistry, Stoltzfus served as a Faculty Fellow for the Digital First Initiative, inspiring instructors to offer engaging digital learning content to students through emerging technology. Through this initiative, he developed an iTunes U general chemistry course, which has attracted over 200,000 students from all over the world. The iTunes U course, along with the videos at [www.drufus.com](http://www.drufus.com), are designed to supplement the text and can be used by any general chemistry student. Stoltzfus has received several teaching awards, including the inaugural Ohio State University 2013 Provost's Award for Distinguished Teaching by a Lecturer and he is recognized as an Apple Distinguished Educator.

**Michael W. Lufaso** received his B.S. degree in Chemistry from Youngstown State University in 1998 and his Ph.D. in Chemistry from the Ohio State University in 2002. He was a National Research Council Postdoctoral Fellow at the National Institute for Standards and Technology and a postdoctoral fellow at the University of South Carolina. In 2006 he joined the University of North Florida where he currently holds the rank of Associate Professor in the Department of Chemistry. He was a Brian Andreen Cottrell College Science Award winner from Research Corporation. He was named a Munoz Presidential Professor in 2011 and received an Outstanding Faculty Scholarship award in 2014. He has authored laboratory manuals and taught ten different undergraduate courses primarily in the areas of general, inorganic, and solid state chemistry. His undergraduate research program focuses on structure prediction, synthesis, and characterization of the structure and properties of solid state materials.

# New Levels of Student Interaction for Improved Conceptual Understanding

Embedded in eText 2.0, as well as assignable in MasteringChemistry™, new features engage students through interactivity to enhance the reading experience and help them learn challenging chemistry concepts.

**NEW!** 50 Interactive Sample Exercises bring key *Sample Exercises* in the text to life through animation and narration. Author Matt Stoltzfus uses the text's *Analyze/Plan/Solve/Check* technique to guide students through the problem-solving process. Play icons within the text identify each Interactive Sample Exercise. Clicking the icon in the eText launches a visual and conceptual presentation which goes beyond the static page. The *Practice Exercises* within each *Sample Exercise* can also be assigned in MasteringChemistry™ where students will receive answer-specific feedback.

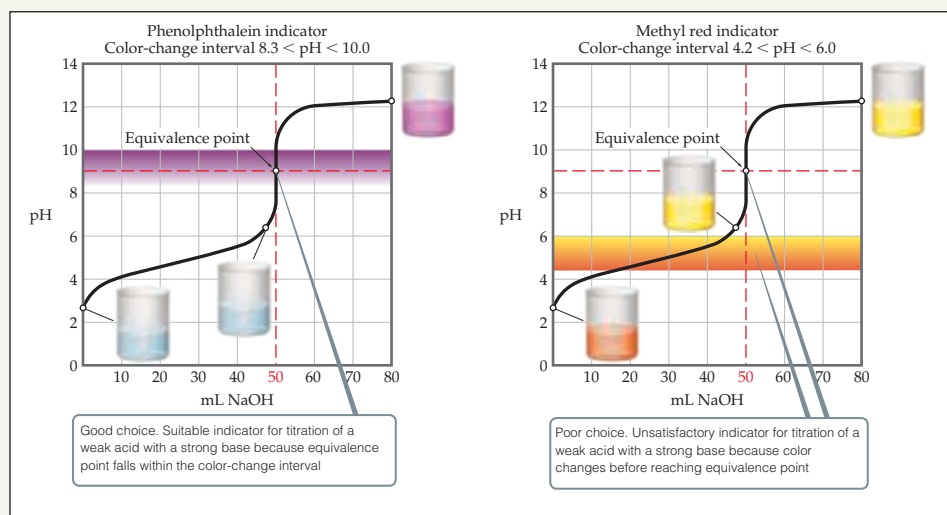

**NEW!** 27 Smart Figures walk students through complex visual representations, dispelling common misconceptions before they take root. Each *Smart Figure* converts a static in-text figure into a dynamic process narrated by author Matt Stoltzfus. Play icons within the text identify each *Smart Figure*. Clicking the icon in the eText launches the animation. Smart Figures are assignable in MasteringChemistry™ where they are accompanied by a multiple-choice question with answer-specific video feedback. Selecting the correct answer launches a brief wrap-up video that highlights the key concepts behind the answer.

# Visually Revised to Better Help Students Build General Chemistry

The visual program has been revised for enhanced clarity and to create a clean, modern look. Style changes include: expanded use of 3D renderings, new white annotation boxes with crisp leader lines, and a more saturated art palette.

**REVISED!** Annotations offer expanded explanations; additional new leaders emphasize key relationships and key points in figures.

**NEW!** Before and after photos clearly show characteristics of endothermic and exothermic reactions. Added reaction equations connect the chemistry to what's happening in the photos.

System =  $\text{NH}_4\text{SCN} + \text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Heat flows from surroundings into system, temperature of beaker and surrounding air drops.

$$60 \text{ Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O} + 2 \text{NH}_4\text{SCN} \longrightarrow \text{Ba}(\text{SCN})_2 + 2 \text{NH}_3 + 10 \text{H}_2\text{O}$$

An endothermic reaction

System =  $\text{K} + \text{H}_2\text{O}$

Heat flows (violently) from system into surroundings, temperature of the water and surrounding air increases.

$$(b) 2 \text{ K} + 2 \text{H}_2\text{O} \longrightarrow 2 \text{ KOH} + \text{H}_2$$

An exothermic reaction

**Figure 5.8** Endothermic and exothermic reactions. In both instances, the system is defined as the reactants and products, while surroundings are the containers and everything else in the universe.

The authors used the wealth of student data in MasteringChemistry™ to identify the areas where students struggle most, revising discussions, figures, and exercises throughout the text to address misconceptions and encourage thinking about the real-world use of chemistry.

**Go Figure**

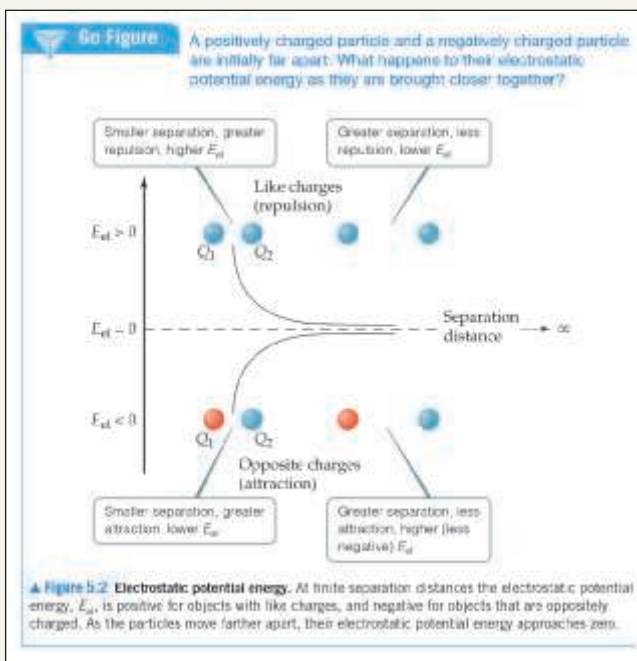

If the white powder were sugar,  $C_{12}H_{22}O_{11}$ , how would we have to change this picture?

**Metallic**  
Atoms held together by a "sea of electrons" surrounding nuclei

**Ionic**  
Ions held together by local electrostatic attractions

**Covalent**  
Atoms held together by sharing electrons in localized bonds

**Figure 9.1** Ionic, covalent, and metallic bonds. The three different substances shown here are held together by different types of chemical bonds.

**UPDATED!** *A Closer Look* features have been updated to reflect recent news and discoveries in the field of chemistry, providing relevance and applications for students. End-of-chapter questions give students the chance to test whether they understood the concept or not.

[illegible]

# Continuous Learning Before, During, and After Class

## NEW! eText 2.0

- **Full eReader functionality** includes page navigation, search, glossary, highlighting, note taking, annotations, and more.
- **A responsive design** allows the eText to reflow and resize to your device or screen. eText 2.0 now works on supported smartphones, tablets, and laptop/desktop computers.
- **In-context glossary** offers students instant access to definitions by simply hovering over key terms.
- **Seamlessly integrated** elinteractives engage students through interactivity to further enhance their learning experience.
  - \* **New!** 50 Interactive Sample Exercises bring key Sample Exercises in the text to life through animation and narration.
  - \* **New!** 27 SmartFigures walk students through complex visual representations, dispelling common misconceptions before they take root.
- **Accessible** (screen-reader ready).
- **Configurable reading settings**, including resizable type and night reading mode.

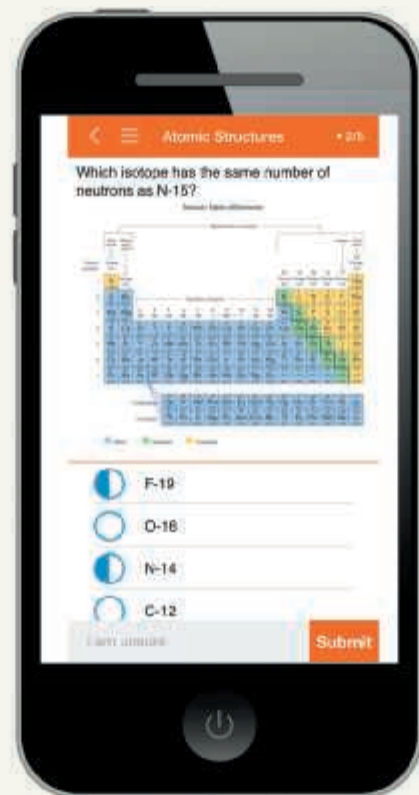

# with MasteringChemistry™

## BEFORE CLASS

**NEW! 66 Dynamic Study Modules** help students study effectively on their own by continuously assessing their activity and performance in real time. Students complete a set of questions with a unique answer format that also asks them to indicate their confidence level. Questions repeat until the student can answer them all correctly and confidently. Once completed, Dynamic Study Modules explain the concept using materials from the text. These are available as graded assignments prior to class, and accessible on smartphones, tablets, and computers.

**NEW! The Chemistry Primer** helps students remediate their chemistry math skills and prepare for their first college chemistry course.

- **Pre-built Assignments** get students up to speed at the beginning of the course.
- **Math is covered** in the context of chemistry, basic chemical literacy, balancing chemical equations, mole theory, and stoichiometry.
- **Scaled to students' needs**, remediation is only suggested to students that perform poorly on initial assessment.
- **Remediation** includes tutorials, wrong-answer specific feedback, video instruction, and step-wise scaffolding to build students' abilities.

## MasteringChemistry™

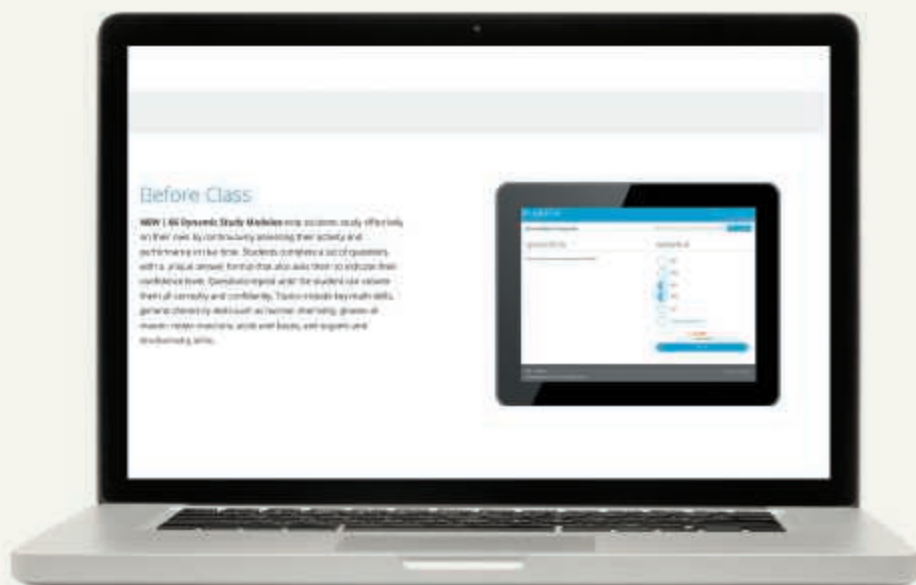

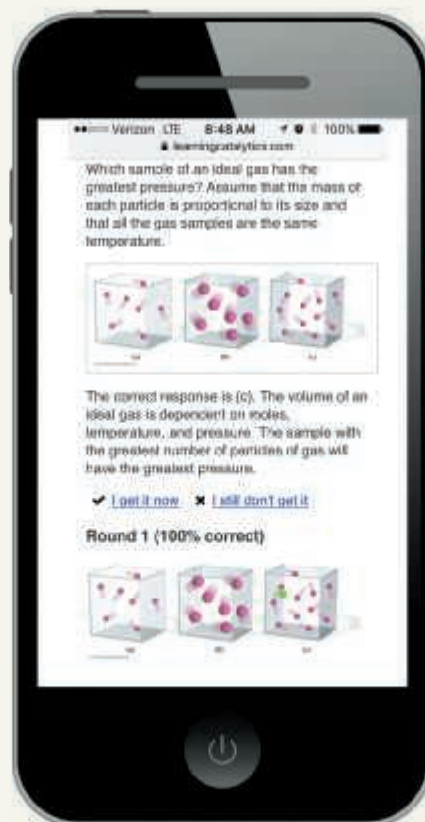

**MasteringChemistry™** delivers engaging, dynamic learning opportunities—focusing on course objectives and responsive to each student’s progress—that are proven to help students absorb course material and understand challenging chemistry processes and concepts.

## DURING CLASS

## Learning Catalytics™

With questions specific to *Chemistry: The Central Science 14e*, **Learning Catalytics** generates class discussion, guides your lecture, and promotes peer-to-peer learning with real-time analytics. MasteringChemistry™ with eText now provides Learning Catalytics—an interactive student response tool that uses students' smartphones, tablets, or laptops to engage them in more sophisticated tasks and individual and group problem-solving. Instructors can:

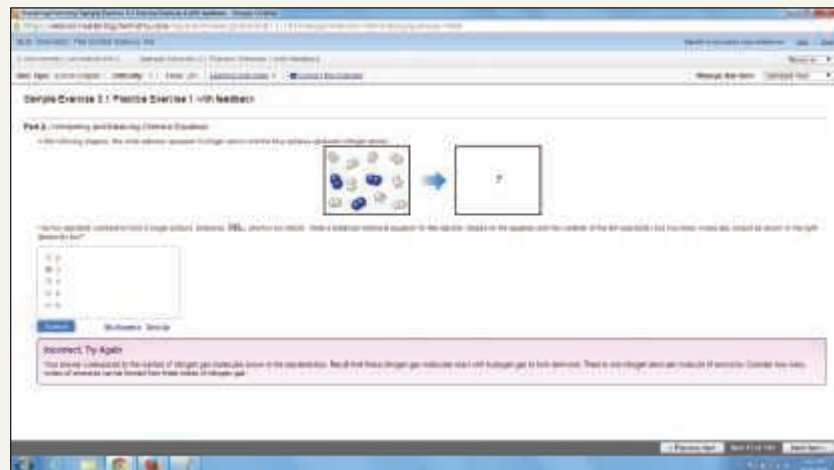

- Upload a full PowerPoint® deck for easy creation of slide questions.
- Help your students develop critical thinking skills.
- Monitor responses to find out where your students are struggling.
- Rely on real-time data to adjust your teaching strategy.
- Automatically group students for discussion, teamwork, and peer-to-peer learning.

## Book-specific questions embedded in library

## AFTER CLASS

Hundreds of new Enhanced EOC questions with wrong-answer-response feedback

**Design An Experiment** feature provides a departure from the usual kinds of end-of-chapter exercises with an inquiry-based, open-ended approach that tries to stimulate the student to “think like a scientist.” Designed to foster critical thinking, each exercise presents the student with a scenario in which various unknowns require investigation. The student is called upon to ponder how experiments might be set up to provide answers to particular questions about observations.

**Adaptive Follow-Up Assignments** allow instructors to deliver content to students—automatically personalized for each individual based on the strengths and weaknesses identified by his or her performance on initial Mastering assignments.

# Instructor and Student Resources

| Resource  | Available in Print | Available Online | Instructor or Student Resource | Description  |
|---|--------------------|------------------|--------------------------------|--|
| <b>TestGen Test Bank</b><br>0134554620  |                    | √                | Instructor                     | TestGen® is a computerized test generator that lets teachers view and edit Test Bank questions, transfer questions to tests, and print tests in a variety of customized formats. This Test Bank includes over 3000 multiple choice, true/false, and answer/essay questions. Questions are rated by difficulty and are correlated to the book's Learning Outcomes.                        |
| <b>Instructor Manual</b><br>0134554604  |                    | √                | Instructor                     | Organized by chapter, this useful guide includes objectives, lecture outlines, references to figures and solved problems, as well as teaching tips.  |
| <b>Instructor Resource Materials</b> 0134557220                               |                    | √                | Instructor                     | The material available for download includes: <ul style="list-style-type: none"> <li>• All illustrations, tables, and photos from the text in JPEG format</li> <li>• Pre-built PowerPoint™ Presentations (lecture, worked examples, images)</li> <li>• TestGen computerized software with the TestGen version of the Testbank</li> <li>• Word.doc files of the Test Item File</li> </ul> |

# CHEMISTRY

THE CENTRAL SCIENCE 14<sup>TH</sup> EDITION

1

# INTRODUCTION: MATTER, ENERGY, AND MEASUREMENT

The title of this book—*Chemistry: The Central Science*—reflects the fact that much of what goes on in the world around us involves chemistry. Everyday chemical processes include the changes that produce brilliant fall colors in leaves, the ways our bodies process the food we eat, and the electrical energy that powers our cell phones.

**Chemistry** is the study of matter, its properties, and the changes that matter undergoes. As you progress in your study, you will come to see how chemical principles operate in all aspects of our lives, from everyday activities like food preparation to more complex processes such as those that operate in the environment. We will also learn how the properties of substances can be tailored for specific applications by controlling their composition and structure. For example, the synthetic pigments chemists developed in the nineteenth century were used extensively by impressionist artists like van Gogh and Monet.

This first chapter provides an overview of what chemistry is about and what chemists do. The “What’s Ahead” list gives an overview of the chapter organization and of some of the ideas we will consider.

## WHAT’S AHEAD

- 1.1** ▶ **The Study of Chemistry** Learn what chemistry is, what chemists do, and why it is useful to study chemistry.
- 1.2** ▶ **Classifications of Matter** Examine fundamental ways to classify matter; distinguish between *pure substances* and *mixtures* and between *elements* and *compounds*.
- 1.3** ▶ **Properties of Matter** Use *properties* to characterize, identify, and separate substances; distinguish between chemical and physical properties.
- 1.4** ▶ **The Nature of Energy** Explore the nature of energy and the forms it takes, notably kinetic energy and potential energy.
- 1.5** ▶ **Units of Measurement** Learn how numbers and units of the metric system are used in science to describe properties.
- 1.6** ▶ **Uncertainty in Measurement** Use significant figures to express the inherent uncertainty in measured quantities and in calculations.
- 1.7** ▶ **Dimensional Analysis** Learn to carry numbers and units through calculations; use units to check if a calculation is correct.

◀ **THE MANUFACTURE OF SYNTHETIC PIGMENTS** is one of the oldest examples of industrial chemistry. The impressionist artists made extensive use of the bold colors of the newly available pigments, as exemplified in van Gogh’s painting *Road with Cypress and Star*.

## 1.1 | The Study of Chemistry

Chemistry is at the heart of many changes we see in the world around us, and it accounts for the myriad different properties we see in matter. To understand how these changes and properties arise, we need to look far beneath the surfaces of our everyday observations.

### The Atomic and Molecular Perspective of Chemistry

Chemistry is the study of the properties and behavior of matter. **Matter** is the physical material of the universe; it is anything that has mass and occupies space. A **property** is any characteristic that allows us to recognize a particular type of matter and to distinguish it from other types. This book, your body, the air you are breathing, and the clothes you are wearing are all samples of matter. We observe a tremendous variety of matter in our world, but countless experiments have shown that all matter is comprised of combinations of only about 100 substances called **elements**. One of our major goals will be to relate the properties of matter to its composition, that is, to the particular elements it contains.

Chemistry also provides a background for understanding the properties of matter in terms of **atoms**, the almost infinitesimally small building blocks of matter. Each element is composed of a unique kind of atom. We will see that the properties of matter relate to both the kinds of atoms the matter contains (*composition*) and the arrangements of these atoms (*structure*).

In **molecules**, two or more atoms are joined in specific shapes. Throughout this text you will see molecules represented using colored spheres to show how the atoms are connected (Figure 1.1). The color provides a convenient way to distinguish between

#### Go Figure

Which molecule has the most carbon atoms? How many carbon atoms does it contain?

Oxygen

Water

Carbon dioxide

Ethanol

atoms of different elements. For example, notice that the molecules of ethanol and ethylene glycol in Figure 1.1 have different compositions and structures. Ethanol contains one oxygen atom, depicted by one red sphere. In contrast, ethylene glycol contains two oxygen atoms.

Even apparently minor differences in the composition or structure of molecules can cause profound differences in properties. For example, let's compare ethanol and ethylene glycol, which appear in Figure 1.1 to be quite similar. Ethanol is the alcohol in beverages such as beer and wine, whereas ethylene glycol is a viscous liquid used as automobile antifreeze. The properties of these two substances differ in many ways, as do their biological activities. Ethanol is consumed throughout the world, but you should *never* consume ethylene glycol because it is highly toxic. One of the challenges chemists undertake is to alter the composition or structure of molecules in a controlled way, creating new substances with different properties. For example, the common drug aspirin, shown in Figure 1.1, was first synthesized in 1897 in a successful attempt to improve on a natural product extracted from willow bark that had long been used to alleviate pain.

Every change in the observable world—from boiling water to the changes that occur as our bodies combat invading viruses—has its basis in the world of atoms and molecules. Thus, as we proceed with our study of chemistry, we will find ourselves thinking in two realms: the *macroscopic* realm of ordinary-sized objects (*macro* = large) and the *submicroscopic* realm of atoms and molecules. We make our observations in the macroscopic world, but to understand that world, we must visualize how atoms and molecules behave at the submicroscopic level. Chemistry is the science that seeks to understand the properties and behavior of matter by studying the properties and behavior of atoms and molecules.

### Give It Some Thought

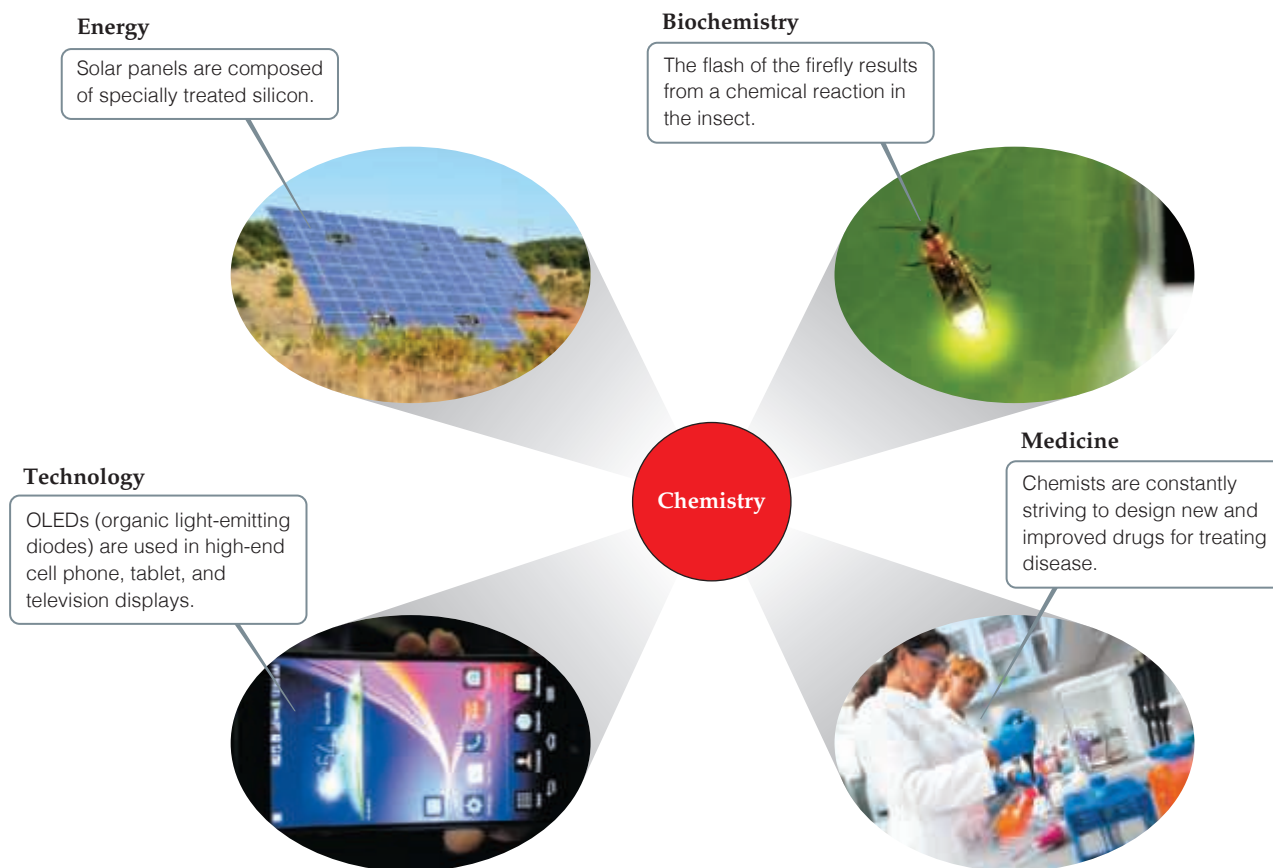

- (a) Approximately how many elements are there?
- (b) What submicroscopic particles are the building blocks of matter?

## Why Study Chemistry?

Chemistry lies near the heart of many matters of public concern, such as improvement of health care, conservation of natural resources, protection of the environment, and the supply of energy needed to keep society running. Using chemistry, we have discovered and continually improved upon pharmaceuticals, fertilizers and pesticides, plastics, solar panels, light-emitting diodes (LEDs), and building materials. We have also discovered that some chemicals are harmful to our health or the environment. This means that we must be sure that the materials with which we come into contact are safe. As a citizen and consumer, it is in your best interest to understand the effects, both positive and negative, that chemicals can have, in order to arrive at a balanced outlook regarding their uses.

You may be studying chemistry because it is an essential part of your curriculum. Your major might be chemistry, or it could be biology, engineering, pharmacy, agriculture, geology, or some other field. Chemistry is central to a fundamental understanding of governing principles in many science-related fields. For example, our interactions with the material world raise basic questions about the materials around us. [Figure 1.2](#) illustrates how chemistry is central to several different realms of modern life.

▲ **Figure 1.2** Chemistry is central to our understanding of the world around us.

## CHEMISTRY PUT TO WORK Chemistry and the Chemical Industry

Chemistry is all around us. We are all familiar with household chemicals, particularly those used for cleaning as shown in [Figure 1.3](#). However, few realize the size and importance of the chemical industry. The chemical industry in the United States is estimated to be an \$800 billion enterprise that employs over 800,000 people and accounts for 14% of all U.S. exports.

**Who are chemists, and what do they do?** People who have degrees in chemistry hold a variety of positions in industry, government, and academia. Those in industry work as laboratory chemists, developing new products (research and development); analyzing materials (quality control); or assisting customers in using products (sales and service). Those with more experience or training may work as managers or company directors. Chemists are important members of the scientific workforce in government (the National Institutes of Health, Department of Energy, and Environmental Protection Agency all employ chemists) and at universities. A chemistry degree is also good preparation for careers in teaching, medicine, biomedical research, information science, environmental work, technical sales, government regulatory agencies, and patent law.

Fundamentally, chemists do three things: They (1) make new types of matter: materials, substances, or combinations of substances with desired properties; (2) measure the properties of matter; and (3) develop models that explain and/or predict the properties of matter. One chemist, for example, may work in the laboratory to discover new drugs. Another may concentrate on the development of new instrumentation to measure properties of matter at the atomic level. Other chemists may use existing

materials and methods to understand how pollutants are transported in the environment or how drugs are processed in the body. Yet another chemist will develop theory, write computer code, and run computer simulations to understand how molecules move and react. The collective chemical enterprise is a rich mix of all of these activities.

▲ **Figure 1.3** Common chemicals used for household cleaning.

## 1.2 | Classifications of Matter

Let's begin our study of chemistry by examining two fundamental ways in which matter is classified. Matter is typically characterized by (1) its physical state (gas, liquid, or solid) and (2) its composition (whether it is an element, a *compound*, or a *mixture*).

### States of Matter

A sample of matter can be a gas, a liquid, or a solid. These three forms, called the **states of matter**, differ in some of their observable properties.

- A **gas** (also known as vapor) has no fixed volume or shape; rather, it uniformly fills its container. A gas can be compressed to occupy a smaller volume, or it can expand to occupy a larger one.
- A **liquid** has a distinct volume independent of its container, assumes the shape of the portion of the container it occupies, and is not compressible to any appreciable extent.
- A **solid** has both a definite shape and a definite volume and is not compressible to any appreciable extent.

The properties of the states of matter can be understood on the molecular level (Figure 1.4). In a gas the molecules are far apart and moving at high speeds, colliding repeatedly with one another and with the walls of the container. Compressing a gas decreases the amount of space between molecules and increases the frequency of collisions between molecules but does not alter the size or shape of the molecules. In a liquid, the molecules are packed closely together but still move rapidly. The rapid movement allows the molecules to slide over one another; thus, a liquid pours easily. In a solid the molecules are held tightly together, usually in definite arrangements in which the molecules can wiggle only slightly in their otherwise fixed positions. Thus, the distances between molecules are similar in the liquid and solid states, but while the molecules are for the most part locked in place in a solid, they retain considerable freedom of motion in a liquid. Changes in temperature and/or pressure can lead to conversion from one state of matter to another, illustrated by such familiar processes as ice melting or water vapor condensing.

### Pure Substances

Most forms of matter we encounter—the air we breathe (a gas), the gasoline we burn in our cars (a liquid), and the sidewalk we walk on (a solid)—are not chemically pure. We can, however, separate these forms of matter into pure substances. A **pure substance** (usually referred to simply as a *substance*) is matter that has distinct properties and a composition that does not vary from sample to sample. Water and table salt (sodium chloride) are examples of pure substances.

All substances are either elements or compounds.

- **Elements** are substances that cannot be decomposed into simpler substances. On the molecular level, each element is composed of only one kind of atom [Figure 1.5(a and b)].
- **Compounds** are substances composed of two or more elements; they contain two or more kinds of atoms [Figure 1.5(c)]. Water, for example, is a compound composed of two elements: hydrogen and oxygen.

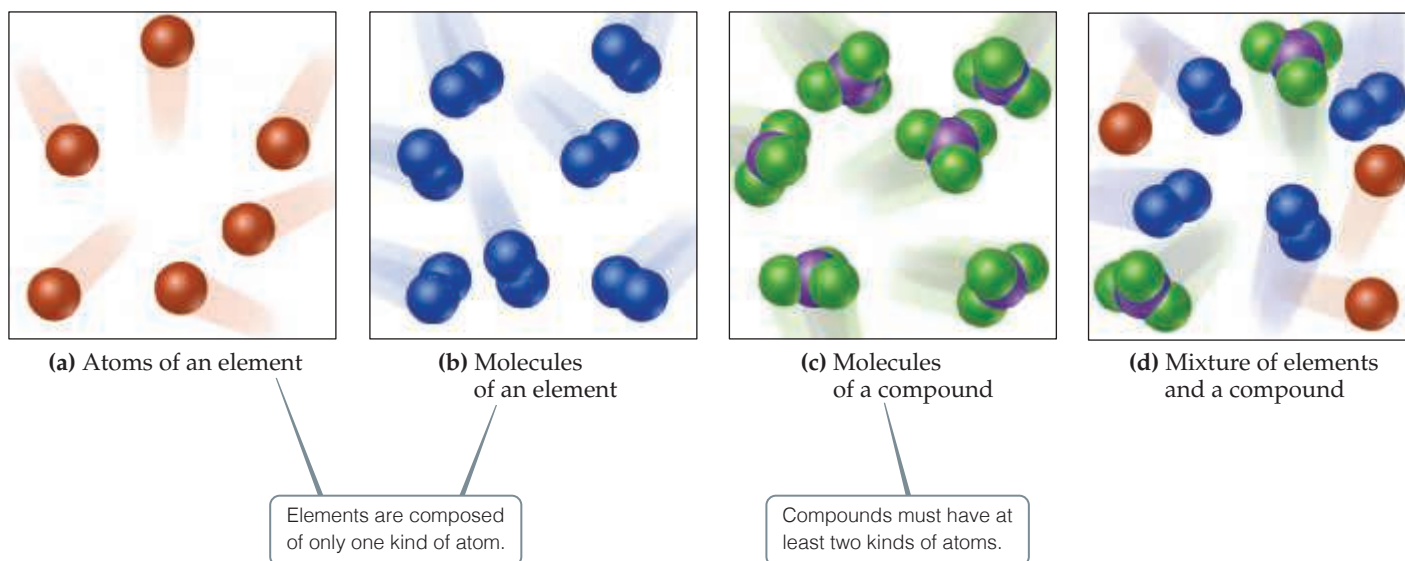

Figure 1.5(d) shows a mixture of substances. **Mixtures** are combinations of two or more substances in which each substance retains its chemical identity.

## Go Figure

How do the molecules of a compound differ from the molecules of an element?

▲ Figure 1.5 Molecular comparison of elements, compounds, and mixtures.

## Go Figure

If the lower pie chart was drawn as the percentage in terms of number of atoms rather than the percentage in terms of mass, would the hydrogen slice of the pie get larger or smaller?

Earth's crust

Human body

▲ Figure 1.6 Relative abundances of elements.\*  
Elements in percent by mass in Earth's crust (including oceans and atmosphere) and the human body.

## Elements

Currently, 118 elements are known, though they vary widely in abundance. Hydrogen constitutes about 74% of the mass in the Milky Way galaxy, and helium constitutes 24%. Closer to home, only five elements—oxygen, silicon, aluminum, iron, and calcium—account for over 90% of Earth's crust (including oceans and atmosphere), and only three—oxygen, carbon, and hydrogen—account for over 90% of the mass of the human body (Figure 1.6).

Table 1.1 lists some common elements, along with the chemical symbols used to denote them. The symbol for each element consists of one or two letters, with the first letter capitalized. These symbols are derived mostly from the English names of the elements, but sometimes they are derived from a foreign name instead (last column in Table 1.1). You will need to know these symbols and learn others as we encounter them in the text.

All of the known elements and their symbols are listed on the front inside cover of this text in a table known as the *periodic table*. In the periodic table, the elements are arranged in columns so that closely related elements are grouped together. We describe the periodic table in more detail in

TABLE 1.1 Some Common Elements and Their Symbols

|            |   |           |    |           |                               |
|------------|---|-----------|----|-----------|-------------------------------|
| Carbon     | C | Aluminum  | Al | Copper    | Cu (from <i>cuprum</i> )      |
| Fluorine   | F | Bromine   | Br | Iron      | Fe (from <i>ferrum</i> )      |
| Hydrogen   | H | Calcium   | Ca | Lead      | Pb (from <i>plumbum</i> )     |
| Iodine     | I | Chlorine  | Cl | Mercury   | Hg (from <i>hydrargyrum</i> ) |
| Nitrogen   | N | Helium    | He | Potassium | K (from <i>kalium</i> )       |
| Oxygen     | O | Lithium   | Li | Silver    | Ag (from <i>argentum</i> )    |
| Phosphorus | P | Magnesium | Mg | Sodium    | Na (from <i>natrium</i> )     |
| Sulfur     | S | Silicon   | Si | Tin       | Sn (from <i>stannum</i> )     |

\*U.S. Geological Survey Circular 285, U.S Department of the Interior.

Section 2.5 and consider the periodically repeating properties of the elements in Chapter 7.

## Compounds

Most elements can interact with other elements to form compounds. For example, when hydrogen gas burns in oxygen gas, the elements hydrogen and oxygen combine to form the compound water. Conversely, water can be decomposed into its elements by passing an electrical current through it (**Figure 1.7**).

### Go Figure

Is the volume of  $\text{H}_2$  produced larger than the volume of  $\text{O}_2$  produced because (a) hydrogen atoms are lighter than oxygen atoms, (b) hydrogen atoms are larger than oxygen atoms, or (c) each water molecule contains one oxygen atom and two hydrogen atoms?

▲ **Figure 1.7** **Electrolysis of water.** Water decomposes into its component elements, hydrogen and oxygen, when an electrical current is passed through it. The volume of hydrogen, collected in the right test tube, is twice the volume of oxygen.

Decomposing pure water into its constituent elements shows that it contains 11% hydrogen and 89% oxygen by mass, regardless of its source. This ratio is constant because every water molecule has the same number of hydrogen and oxygen atoms. While the mass percentages make it seem that water is mostly oxygen, there are actually two hydrogen atoms and only one oxygen atom per molecule. The explanation for this apparent discrepancy comes from the fact that hydrogen atoms are much lighter than oxygen atoms. This macroscopic composition corresponds to the molecular composition, which consists of two hydrogen atoms combined with one oxygen atom:

**TABLE 1.2 Comparison of Water, Hydrogen, and Oxygen**

|                      | Water    | Hydrogen  | Oxygen   |
|----------------------|----------|-----------|----------|
| State <sup>a</sup>   | Liquid   | Gas       | Gas      |
| Normal boiling point | 100 °C   | −253 °C   | −183 °C  |
| Density <sup>a</sup> | 1000 g/L | 0.084 g/L | 1.33 g/L |
| Flammable            | No       | Yes       | No       |

<sup>a</sup> At room temperature and atmospheric pressure.

The elements hydrogen and oxygen themselves exist naturally as diatomic (two-atom) molecules:

As seen in **Table 1.2**, the properties of water bear no resemblance to the properties of its component elements. Hydrogen, oxygen, and water are each a unique substance, a consequence of the uniqueness of their respective molecules.

The observation that the elemental composition of a compound is always the same is known as the **law of constant composition** (or the **law of definite proportions**). French chemist Joseph Louis Proust (1754–1826) first stated the law in about 1800. Although this law has been known for 200 years, the belief persists among some people that a fundamental difference exists between compounds prepared in the laboratory and the corresponding compounds found in nature. This simply is not true. Regardless of its source—nature or a laboratory—a pure compound has the same composition and properties under the same conditions. Both chemists and nature must use the same elements and operate under the same natural laws. When two materials differ in composition or properties, either they are composed of different compounds or they differ in purity.

### Give It Some Thought

Hydrogen, oxygen, and water are all composed of molecules. What is it about a molecule of water that makes it a compound, whereas hydrogen and oxygen are elements?

## Mixtures

Most of the matter we encounter consists of mixtures of different substances. Each substance in a mixture retains its chemical identity and properties. In contrast to a pure substance, which by definition has a fixed composition, the composition of a mixture can vary. A cup of sweetened coffee, for example, can contain either a little sugar or a lot. The substances making up a mixture are called *components* of the mixture.

Some mixtures do not have the same composition, properties, and appearance throughout. Rocks and wood, for example, vary in texture and appearance in any typical sample. Such mixtures are *heterogeneous* [**Figure 1.8(a)**]. Mixtures that are uniform throughout are *homogeneous*. Air is a homogeneous mixture of nitrogen, oxygen, and smaller amounts of other gases. The nitrogen in air has all the properties of pure nitrogen because both the pure substance and the mixture contain the same nitrogen molecules. Salt, sugar, and many other substances dissolve in water to form homogeneous mixtures [**Figure 1.8(b)**]. Homogeneous mixtures are also called **solutions**. Although the term *solution* conjures an image of a liquid, solutions can be solids, liquids, or gases.

**Figure 1.9** summarizes the classification of matter into elements, compounds, and mixtures.

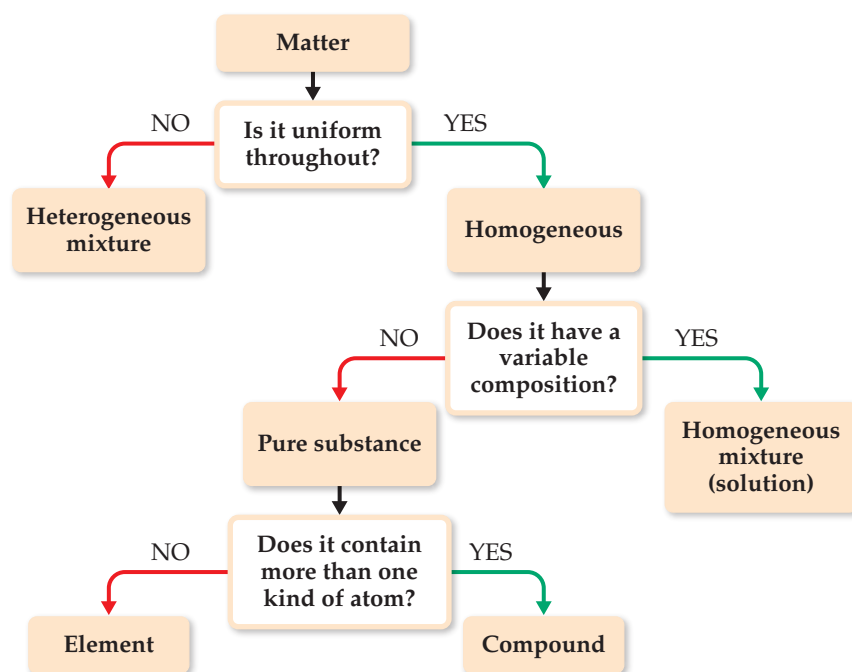

(a)

(b)

◀ **Figure 1.8 Mixtures.** (a) Many common materials, including rocks, are heterogeneous mixtures. This photograph of granite shows a heterogeneous mixture of silicon dioxide and other metal oxides. (b) Homogeneous mixtures are called solutions. Many substances, including the blue solid shown here [copper(II) sulfate pentahydrate], dissolve in water to form solutions.

◀ **Figure 1.9 Classification of matter.** All pure matter is classified ultimately as either an element or a compound.

### Sample Exercise 1.1

#### Distinguishing among Elements, Compounds, and Mixtures

“White gold” contains gold and a “white” metal, such as palladium. Two samples of white gold differ in the relative amounts of gold and palladium they contain. Both samples are uniform in composition throughout. Use Figure 1.9 to classify white gold.

#### SOLUTION

Because the material is uniform throughout, it is homogeneous. Because its composition differs for the two samples, it cannot be a compound. Instead, it must be a homogeneous mixture.

#### Practice Exercise 1

Which of the following is the correct description of the inside of a grapefruit?

- (a) It is a pure compound.
- (b) It consists of a homogeneous mixture of compounds.

- (c) It consists of a heterogeneous mixture of compounds.
- (d) It consists of a heterogeneous mixture of elements and compounds.
- (e) It consists of a single compound in different states.

#### Practice Exercise 2

Aspirin is composed of 60.0% carbon, 4.5% hydrogen, and 35.5% oxygen by mass, regardless of its source. Use Figure 1.9 to classify aspirin.

## 1.3 | Properties of Matter

Every substance has unique properties. For example, the properties listed in Table 1.2 allow us to distinguish hydrogen, oxygen, and water from one another. The properties of matter can be categorized as physical or chemical. **Physical properties** can be observed without changing the identity and composition of the substance. These properties include color, odor, density, melting point, boiling point, and hardness. **Chemical properties** describe the way a substance may change, or *react*, to form other substances. A common chemical property is flammability, the ability of a substance to burn in the presence of oxygen.

Some properties, such as temperature and melting point, are *intensive properties*. **Intensive properties** do not depend on the amount of sample being examined and are particularly useful in chemistry because many intensive properties can be used to *identify* substances. **Extensive properties** depend on the amount of sample, with two examples being mass and volume. Extensive properties relate to the *amount* of substance present.

### Give It Some Thought

When we say that lead is a denser metal than aluminum, are we talking about an extensive or intensive property?

## Physical and Chemical Changes

The changes substances undergo are either physical or chemical. During a **physical change**, a substance changes its physical appearance but not its composition. (That is, it is the same substance before and after the change.) The evaporation of water is a physical change. When water evaporates, it changes from the liquid state to the gas state, but it is still composed of water molecules, as depicted in Figure 1.4. All **changes of state** (for example, from liquid to gas or from liquid to solid) are physical changes.

In a **chemical change** (also called a **chemical reaction**), a substance is transformed into a chemically different substance. When hydrogen burns in air, for example, it undergoes a chemical change because it combines with oxygen to form water (Figure 1.10).

Chemical changes can be dramatic. In the account given in Figure 1.11, Ira Remsen, author of a popular chemistry text published in 1901, describes his first experiences with chemical reactions.

▲ Figure 1.10 A chemical reaction.

While reading a textbook of chemistry, I came upon the statement “nitric acid acts upon copper,” and I determined to see what this meant. Having located some nitric acid, I had only to learn what the words “act upon” meant. In the interest of knowledge I was even willing to sacrifice one of the few copper cents then in my possession. I put one of them on the table, opened a bottle labeled “nitric acid,” poured some of the liquid on the copper, and prepared to make an observation. But what was this wonderful thing which I beheld? The cent was already changed, and it was no small change either. A greenish-blue liquid foamed and fumed over the cent and over the table. The air became colored dark red. How could I stop this? I tried by picking the cent up and throwing it out the window. I learned another fact: nitric acid acts upon fingers. The pain led to another unpremeditated experiment. I drew my fingers across my trousers and discovered nitric acid acts upon trousers. That was the most impressive experiment I have ever performed. I tell of it even now with interest. It was a revelation to me. Plainly the only way to learn about such remarkable kinds of action is to see the results, to experiment, to work in the laboratory.\*

▲ **Figure 1.11** The chemical reaction between a copper penny and nitric acid. The dissolved copper produces the blue-green solution; the reddish brown gas produced is nitrogen dioxide.

### Give It Some Thought

Which of these changes are physical and which are chemical? Explain.

- (a) Plants make sugar from carbon dioxide and water.
- (b) Water vapor in the air forms frost.
- (c) A goldsmith melts a nugget of gold and pulls it into a wire.

## Separation of Mixtures

We can separate a mixture into its components by taking advantage of differences in their properties. For example, a heterogeneous mixture of iron filings and gold filings could be sorted by color into iron and gold. A less tedious approach would be to use a magnet to attract the iron filings, leaving the gold ones behind. We can also take advantage of an important chemical difference between these two metals: Many acids dissolve iron but not gold. Thus, if we put our mixture into an appropriate acid, the acid would dissolve the iron and the solid gold would be left behind. The two could then be separated by *filtration* (Figure 1.12). We would have to use other chemical reactions, which we will learn about later, to transform the dissolved iron back into metal.

An important method of separating the components of a homogeneous mixture is **distillation**, a process that depends on the different abilities of substances to form gases. For example, if we boil a solution of salt and water, the water evaporates, forming a gas, and the salt is left behind. The gaseous water can be converted back to a liquid on the walls of a condenser, as shown in Figure 1.13.

\*Remsen, *The Principles of Theoretical Chemistry*, 1887.

▲ **Figure 1.12** Separation by filtration. A mixture of a solid and a liquid is poured through filter paper. The liquid passes through the paper while the solid remains on the paper.

▲ **Figure 1.13** Distillation. Apparatus for separating a sodium chloride solution (salt water) into its components.

The differing abilities of substances to adhere to the surfaces of solids can also be used to separate mixtures. This ability is the basis of *chromatography*, a technique shown in [Figure 1.14](#).

### Go Figure

Is the separation of the mixture shown here a physical or chemical process?

▲ **Figure 1.14** Separation of three substances using column chromatography.

## 1.4 | The Nature of Energy

All objects in the universe are made of matter, but matter alone is not enough to describe the behavior of the world around us. The water in an alpine lake and a pot of boiling water are both made from the same substance, but your body will experience a very different sensation if you put your hand in each. The difference between the two is their energy content; boiling water has more energy than chilled water. To understand chemistry, we must also understand energy and the changes in energy that accompany chemical processes.

Unlike matter, energy does not have mass and cannot be held in our hands, but its effects can be observed and measured. **Energy** is defined as the capacity to do work or transfer heat. **Work** is the energy transferred when a force exerted on an object causes a displacement of that object, and **heat** is the energy used to cause the temperature of an object to increase (Figure 1.15). Although the temperature of an object is intuitive to most people, the definition of work is less apparent. We define work,  $w$ , as the product of the force exerted on the object,  $F$ , and the distance,  $d$ , that it moves:

$$w = F \times d \quad [1.1]$$

where **force** is defined as any push or pull exerted on the object.\* Familiar examples include gravity and the attraction between opposite poles of a bar magnet. It takes work to lift an object off of the floor, or to pull apart two magnets that have come together at the opposite poles.

### Kinetic Energy and Potential Energy

To understand energy we need to grasp its two fundamental forms, kinetic energy and potential energy. Objects, whether they are automobiles, soccer balls, or molecules, can possess **kinetic energy**, the energy of *motion*. The magnitude of kinetic energy,  $E_k$ , of an object depends on its mass,  $m$ , and velocity,  $v$ :

$$E_k = \frac{1}{2}mv^2 \quad [1.2]$$

Thus, the kinetic energy of an object increases as its velocity or speed\*\* increases. For example, a car has greater kinetic energy moving at 65 miles per hour (mi/h) than it does at 25 mi/h. For a given velocity, the kinetic energy increases with increasing mass. Thus, a large truck traveling at 65 mi/h has greater kinetic energy than a motorcycle traveling at the same velocity because the truck has the greater mass.

In chemistry we are interested in the kinetic energy of atoms and molecules. Although these particles are too small to be seen, they have mass and are in motion, and therefore, possess kinetic energy. When a substance is heated, be it a pot of water on the stove or an aluminum can sitting in the sun, the atoms and molecules in that substance gain kinetic energy and their average speed increases. Hence, we see that the transfer of heat is simply the transfer of kinetic energy at the molecular level.

#### Give It Some Thought

Which change will lead to a larger change in the kinetic energy of an object, doubling its mass or doubling its speed?

\*In using this equation, only the component of the force that is acting parallel to the distance traveled is used. That will generally be the case for problems we will encounter in this chapter.

\*\*Strictly speaking, velocity is a vector quantity that has a direction; that is, it tells you how fast an object is moving and in what direction. Speed is a scalar quantity that tells you how fast an object is moving but not the direction of the motion. Unless otherwise stated, we will not be concerned with the direction of motion, and thus velocity and speed are interchangeable quantities for the treatment in this book.

Work done by player on ball to make ball move

Heat added by burner to water makes water temperature rise

(b)

**Figure 1.15 Work and heat, two forms of energy.** (a) *Work* is energy used to cause an object to move against an opposing force. (b) *Heat* is energy used to increase the temperature of an object.

▲ **Figure 1.16 Potential energy and kinetic energy.** The potential energy initially stored in the motionless bicycle and rider at the top of the hill is converted to kinetic energy as the bicycle moves down the hill and loses potential energy.

All other forms of energy—the energy stored in a stretched spring, in a weight held above your head, or in a chemical bond—are classified as potential energy. An object has **potential energy** by virtue of its position relative to other objects. Potential energy is, in essence, the “stored” energy that arises from the attractions and repulsions an object experiences in relation to other objects.

We are familiar with many instances in which potential energy is converted into kinetic energy. For example, think of a cyclist poised at the top of a hill (Figure 1.16). Because of the attractive force of gravity, the potential energy of the bicycle is greater at the top of the hill than at the bottom. As a result, the bicycle easily rolls down the hill with increasing speed. As it does so, potential energy is converted into kinetic energy. The potential energy decreases as the bicycle rolls down the hill, while at the same time its kinetic energy increases as it picks up speed (Equation 1.2). This example illustrates that kinetic and potential energy are interconvertible.

Gravitational forces play a negligible role in the ways that atoms and molecules interact with one another. Forces that arise from electrical charges are more important when dealing with atoms and molecules. One of the most important forms of potential energy in chemistry is *electrostatic potential energy*, which arises from the interactions between charged particles. You are probably familiar with the fact that opposite charges attract each other and like charges repel. The strength of this interaction increases as the magnitude of the charges increase, and decreases as the distance between charges increases. We will return to electrostatic energy several times throughout the book.

One of our goals in chemistry is to relate the energy changes seen in the macroscopic world to the kinetic or potential energy of substances at the molecular level. Many substances, fuels for example, release energy when they react. The *chemical energy* of a fuel is due to the potential energy stored in the arrangements of its atoms. As we will learn in later chapters, *chemical energy is released when bonds between atoms are formed, and consumed when bonds between atoms are broken*. When a fuel burns, some bonds are broken and others are formed, but the net effect is to convert chemical potential energy to thermal energy, the energy associated with temperature. The increase in thermal energy arises from increased molecular motion and hence increased kinetic energy at the molecular level.

### Give It Some Thought

What happens to the chemical energy of a lithium-ion battery as it is discharged to power a laptop computer? Does it increase, decrease, or remain unchanged?

## 1.5 | Units of Measurement

Many properties of matter are *quantitative*, that is, associated with numbers. When a number represents a measured quantity, the units of that quantity must be specified. To say that the length of a pencil is 17.5 is meaningless. Expressing the number with its units, 17.5 centimeters (cm), properly specifies the length. The units used for scientific measurements are those of the **metric system**.

The metric system, developed in France during the late eighteenth century, is used as the system of measurement in most countries. The United States has traditionally used the English system, although use of the metric system has become more common (Figure 1.17).

### SI Units

In 1960, an international agreement was reached specifying a particular choice of metric units for use in scientific measurements. These preferred units are called **SI units**, after the French *Système International d'Unités*. This system has seven *base units* from which all other units are derived (Table 1.3). In this chapter we will consider the base units for length, mass, and temperature.

TABLE 1.3 SI Base Units

| Physical Quantity   | Name of Unit | Abbreviation |
|---------------------|--------------|--------------|
| Length              | Meter        | m            |
| Mass                | Kilogram     | kg           |
| Temperature         | Kelvin       | K            |
| Time                | Second       | s or sec     |
| Amount of substance | Mole         | mol          |
| Electric current    | Ampere       | A or amp     |
| Luminous intensity  | Candela      | cd           |

### Give It Some Thought

The package of a fluorescent bulb for a table lamp lists the light output in terms of lumens, lm. Which of the seven SI units would you expect to be part of the definition of a lumen?

▲ Figure 1.17 Metric units. Metric measurements are increasingly common in the United States, as exemplified by the volume printed on this soda can in both English units (fluid ounces, fl oz) and metric units (milliliters, mL).

## A CLOSER LOOK The Scientific Method

Where does scientific knowledge come from? How is it acquired? How do we know it is reliable? How do scientists add to it, or modify it?

There is nothing mysterious about how scientists work. The first idea to keep in mind is that scientific knowledge is gained through observations of the natural world. A principal aim of the scientist is to organize these observations by identifying patterns and regularity, making measurements, and associating one set of observations with another. The next step is to ask *why* nature behaves in the manner we observe. To answer this question, the scientist constructs a model, known as a **hypothesis**, to explain the observations. Initially, the hypothesis is likely to be pretty tentative. There could be more than one reasonable hypothesis. If a hypothesis is correct, then certain results and observations should follow from it. In this way, hypotheses can stimulate the design of experiments to learn more about the system being studied. Scientific creativity comes into play in thinking of hypotheses that are fruitful in suggesting good experiments to do, ones that will shed new light on the nature of the system.

As more information is gathered, the initial hypotheses get winnowed down. Eventually, just one may stand out as most consistent with a body of accumulated evidence. We then begin to call this hypothesis a **theory**, a model that has predictive powers and that accounts for all the available observations. A theory also generally is consistent with other, perhaps larger and more general theories. For example, a theory of what goes on inside a volcano has to be consistent with more general theories regarding heat transfer, chemistry at high temperature, and so forth.

We will be encountering many theories as we proceed through this book. Some of them have been found over and over again to be consistent with observations. However, no theory can be proven to be absolutely true. We can treat it as though it is, but there always remains a possibility that there is some respect in which a theory is wrong. A famous example is Isaac Newton's theory of mechanics, which yielded such precise results for the mechanical behavior of matter that no exceptions to it were found before the twentieth century. But Albert Einstein showed that Newton's theory of the nature of space and time is incorrect.

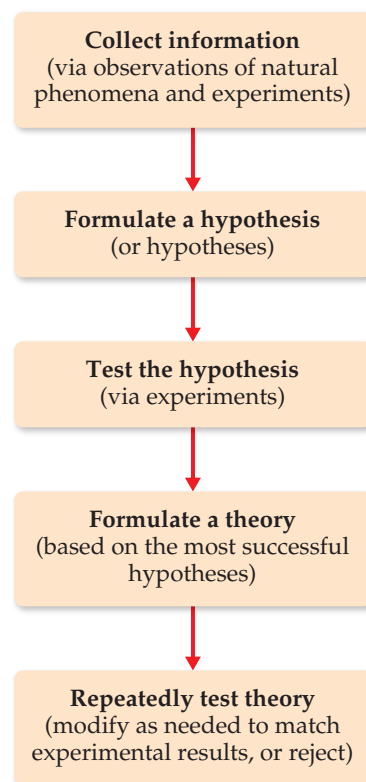

*Continued*

Einstein's theory of relativity represented a fundamental shift in how we think of space and time. He predicted where the exceptions to predictions based on Newton's theory might be found. Although only small departures from Newton's theory were predicted, they *were* observed. Einstein's theory of relativity became accepted as the correct model. However, for most uses, Newton's laws of motion are quite accurate enough.

The overall process we have just considered, illustrated in **Figure 1.18**, is often referred to as *the scientific method*. But there is no single scientific method. Many factors play a role in advancing scientific knowledge. The one unvarying requirement is that our explanations be consistent with observations and that they depend solely on natural phenomena.

When nature behaves in a certain way over and over again, under all sorts of different conditions, we can summarize that behavior in a **scientific law**. For example, it has been repeatedly observed that in a chemical reaction there is no change in the total mass of the materials reacting as compared with the materials that are formed; we call this observation the *law of conservation of mass*. It is important to make a distinction between a theory and a scientific law. On the one hand, a scientific law is a statement of what always happens, to the best of our knowledge. A theory, on the other hand, is an *explanation* for what happens. If we discover some law fails to hold true, then we must assume the theory underlying that law is wrong in some way.

**Related Exercises: 1.66, 1.88**

▲ **Figure 1.18** The scientific method.

With SI units, prefixes are used to indicate decimal fractions or multiples of various units. For example, the prefix *milli-* represents a  $10^{-3}$  fraction, one-thousandth, of a unit: A milligram (mg) is  $10^{-3}$  gram (g), a millimeter (mm) is  $10^{-3}$  meter (m), and so forth. **Table 1.4** presents the prefixes commonly encountered in chemistry. In using SI units and in working problems throughout this text, you must be comfortable using exponential notation. If you are unfamiliar with exponential notation or want to review it, refer to Appendix A.1.

**TABLE 1.4** Prefixes Used in the Metric System and with SI Units

| Prefix | Abbreviation | Meaning    | Example   |
|--------|--------------|------------|---|
| Peta   | P            | $10^{15}$  | 1 petawatt (PW) = $1 \times 10^{15}$ watts <sup>a</sup> |
| Tera   | T            | $10^{12}$  | 1 terawatt (TW) = $1 \times 10^{12}$ watts              |
| Giga   | G            | $10^9$     | 1 gigawatt (GW) = $1 \times 10^9$ watts                 |
| Mega   | M            | $10^6$     | 1 megawatt (MW) = $1 \times 10^6$ watts                 |
| Kilo   | k            | $10^3$     | 1 kilowatt (kW) = $1 \times 10^3$ watts                 |
| Deci   | d            | $10^{-1}$  | 1 deciwatt (dW) = $1 \times 10^{-1}$ watt               |
| Centi  | c            | $10^{-2}$  | 1 centiwatt (cW) = $1 \times 10^{-2}$ watt              |
| Milli  | m            | $10^{-3}$  | 1 milliwatt (mW) = $1 \times 10^{-3}$ watt              |
| Micro  | $\mu^b$      | $10^{-6}$  | 1 microwatt ( $\mu W$ ) = $1 \times 10^{-6}$ watt       |
| Nano   | n            | $10^{-9}$  | 1 nanowatt (nW) = $1 \times 10^{-9}$ watt               |
| Pico   | p            | $10^{-12}$ | 1 picowatt (pW) = $1 \times 10^{-12}$ watt              |
| Femto  | f            | $10^{-15}$ | 1 femtowatt (fW) = $1 \times 10^{-15}$ watt             |
| Atto   | a            | $10^{-18}$ | 1 attowatt (aW) = $1 \times 10^{-18}$ watt              |
| Zepto  | z            | $10^{-21}$ | 1 zeptowatt (zW) = $1 \times 10^{-21}$ watt             |

<sup>a</sup>The watt (W) is the SI unit of power, which is the rate at which energy is either generated or consumed. The SI unit of energy is the joule (J);  $1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$  and  $1 \text{ W} = 1 \text{ J/s}$ .

<sup>b</sup>Greek letter mu, pronounced "mew."

Although non-SI units are being phased out, some are still commonly used by scientists. Whenever we first encounter a non-SI unit in the text, the SI unit will also be given. The relations between the non-SI and SI units we will use most frequently in this text appear on the back inside cover. We will discuss how to convert from one to the other in Section 1.7.

### Give It Some Thought

How many  $\mu\text{g}$  are there in 1 mg?

## Length and Mass

The SI base unit of *length* is the meter, a distance slightly longer than a yard. **Mass\*** is a measure of the amount of material in an object. The SI base unit of mass is the kilogram (kg), which is equal to about 2.2 pounds (lb). This base unit is unusual because it uses a prefix, *kilo-*, instead of the word *gram* alone. We obtain other units for mass by adding prefixes to the word *gram*.

### Sample Exercise 1.2

#### Using SI Prefixes

What is the name of the unit that equals (a)  $10^{-9}$  gram, (b)  $10^{-6}$  second, (c)  $10^{-3}$  meter?

#### SOLUTION

We can find the prefix related to each power of ten in Table 1.4:  
(a) nanogram, ng; (b) microsecond,  $\mu\text{s}$ ; (c) millimeter, mm.

#### ► Practice Exercise 1

Which of the following weights would you expect to be suitable for weighing on an ordinary bathroom scale?

- (a)  $2.0 \times 10^7$  mg (b) 2500  $\mu\text{g}$  (c)  $5 \times 10^{-4}$  kg (d)  $4 \times 10^6$  cg  
(e)  $5.5 \times 10^8$  dg

#### ► Practice Exercise 2

- (a) How many picometers are there in 1 m? (b) Express  $6.0 \times 10^3$  m using a prefix to replace the power of ten.  
(c) Use exponential notation to express 4.22 mg in grams.  
(d) Use decimal notation to express 4.22 mg in grams.

## Temperature

**Temperature**, a measure of the hotness or coldness of an object, is a physical property that determines the direction of heat flow. Heat always flows spontaneously from a substance at higher temperature to one at lower temperature. Thus, the influx of heat we feel when we touch a hot object tells us that the object is at a higher temperature than our hand.

The temperature scales commonly employed in science are the Celsius and Kelvin scales. The **Celsius scale** was originally based on the assignment of  $0^\circ\text{C}$  to the freezing point of water and  $100^\circ\text{C}$  to its boiling point at sea level (Figure 1.19).

The **Kelvin scale** is the SI temperature scale, and the SI unit of temperature is the *kelvin* (K). Zero on the Kelvin scale is the temperature at which all thermal motion ceases, a temperature referred to as **absolute zero**. On the Celsius scale, absolute zero has the value  $-273.15^\circ\text{C}$ . The Celsius and Kelvin scales have equal-sized units—that is, a kelvin is the same size as a degree Celsius. Thus, the Kelvin and Celsius scales are related according to

$$\text{K} = ^\circ\text{C} + 273.15 \quad [1.3]$$

The freezing point of water,  $0^\circ\text{C}$ , is 273.15 K (Figure 1.19). Notice that we do not use a degree sign ( $^\circ$ ) with temperatures on the Kelvin scale.

The common temperature scale in the United States is the *Fahrenheit scale*, which is not generally used in science. Water freezes at  $32^\circ\text{F}$  and boils at  $212^\circ\text{F}$ . The Fahrenheit and Celsius scales are related according to

$$^\circ\text{C} = \frac{5}{9} (^\circ\text{F} - 32) \quad \text{or} \quad ^\circ\text{F} = \frac{9}{5} (^\circ\text{C}) + 32 \quad [1.4]$$

\*Mass and weight are not the same. Mass is a measure of the amount of matter; weight is the force exerted on this mass by gravity. For example, an astronaut weighs less on the Moon than on Earth because the Moon's gravitational force is less than Earth's. The astronaut's mass on the Moon, however, is the same as it is on Earth.

### Go Figure

How many 1-L bottles are required to contain 1 m<sup>3</sup> of liquid?

▲ **Figure 1.20** Volume relationships. The volume occupied by a cube 1 m on each edge is one cubic meter, 1 m<sup>3</sup>. Each cubic meter contains 1000 dm<sup>3</sup>, 1 m<sup>3</sup> = 1000 dm<sup>3</sup>. One liter is the same volume as one cubic decimeter, 1 L = 1 dm<sup>3</sup>. Each cubic decimeter contains 1000 cubic centimeters, 1 dm<sup>3</sup> = 1000 cm<sup>3</sup>. One cubic centimeter equals one milliliter, 1 cm<sup>3</sup> = 1 mL.

### Go Figure

True or false: The “size” of a degree on the Celsius scale is the same as the “size” of a degree on the Kelvin scale.

▲ **Figure 1.19** Comparison of the Kelvin, Celsius, and Fahrenheit temperature scales.

## Derived SI Units

The SI base units are used to formulate *derived units*. A **derived unit** is obtained by multiplication or division of one or more of the base units. We begin with the defining equation for a quantity and, then substitute the appropriate base units. For example, *speed* is defined as the ratio of distance traveled to elapsed time. Thus, the derived SI unit for speed is the SI unit for distance (length), m, divided by the SI unit for time, s, which gives m/s, read “meters per second.” Two common derived units in chemistry are those for volume and density.

## Volume

The *volume* of a cube is its length cubed, length<sup>3</sup>. Thus, the derived SI unit of volume is the SI unit of length, m, raised to the third power. The cubic meter, m<sup>3</sup>, is the volume of a cube that is 1 m on each edge (Figure 1.20). Smaller units, such as cubic centimeters, cm<sup>3</sup> (sometimes written cc), are frequently used in chemistry. Another volume unit used in chemistry is the *liter* (L), which equals a cubic decimeter, dm<sup>3</sup>, and is slightly larger than a quart. (The liter is the first metric unit we have encountered that is *not* an SI unit.) There are 1000 milliliters (mL) in a liter, and 1 mL is the same volume as 1 cm<sup>3</sup>: 1 mL = 1 cm<sup>3</sup>.

## Sample Exercise 1.3

### Converting Units of Temperature

A weather forecaster predicts the temperature will reach 31 °C. What is this temperature (a) in K, (b) in °F?

### SOLUTION

(a) Equation 1.3, we have  $K = 31 + 273 = 304 \text{ K}$ .

(b) Using Equation 1.4, we have

$$^{\circ}\text{F} = \frac{9}{5}(31) + 32 = 56 + 32 = 88^{\circ}\text{F}.$$

### Practice Exercise 1

Using Wolfram Alpha (<http://www.wolframalpha.com/>) or some other reference, determine which of these elements

would be liquid at 525 K (assume samples are protected from air): (a) bismuth, Bi; (b) platinum, Pt; (c) selenium, Se; (d) calcium, Ca; (e) copper, Cu.

### Practice Exercise 2

Ethylene glycol, the major ingredient in antifreeze, freezes at  $-11.5^{\circ}\text{C}$ . What is the freezing point in (a) K, (b) °F?

▲ **Figure 1.21** Common volumetric glassware.

In the lab, you will likely use the devices in **Figure 1.21** to measure and deliver volumes of liquids. Syringes, burettes, and pipettes deliver amounts of liquids with more precision than graduated cylinders. Volumetric flasks are used to contain specific volumes of liquid.

### Give It Some Thought

Which of the following quantities represents a volume measurement:  
 $15 \text{ m}^2$ ;  $2.5 \times 10^2 \text{ m}^3$ ;  $5.77 \text{ L/s}$ ?

## Density

**Density** is defined as the amount of mass in a unit volume of a substance:

$$\text{density} = \frac{\text{mass}}{\text{volume}} \quad [1.5]$$

The densities of solids and liquids are commonly expressed in either grams per cubic centimeter ( $\text{g/cm}^3$ ) or grams per milliliter ( $\text{g/mL}$ ). The densities of some common substances are listed in **Table 1.5**. It is no coincidence that the density of water is  $1.00 \text{ g/mL}$ ; the gram was originally defined as the mass of  $1 \text{ mL}$  of water at a specific temperature. Because most substances change volume when they are heated or cooled, densities are temperature dependent, and so temperature should be specified when reporting densities. If no temperature is reported, we assume  $25^\circ\text{C}$ , close to normal room temperature.

The terms *density* and *weight* are sometimes confused. A person who says that iron weighs more than air generally means that iron has a higher density than air— $1 \text{ kg}$  of air has the same mass as  $1 \text{ kg}$  of iron, but the iron occupies a smaller volume, thereby giving it a higher density. If we combine two liquids that do not mix, the less dense liquid will float on the denser liquid.

## Units of Energy

The SI unit for energy is the **joule** (pronounced “jool”),  $\text{J}$ , in honor of James Joule (1818–1889), a British scientist who investigated work and heat. If we return to Equation 1.2 where kinetic energy was defined, we immediately see that joules are a derived unit,  $1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ . Numerically, a  $2\text{-kg}$  mass moving at a velocity of  $1 \text{ m/s}$  possesses a kinetic energy of  $1 \text{ J}$ :

$$E_k = \frac{1}{2}mv^2 = \frac{1}{2}(2 \text{ kg})(1 \text{ m/s})^2 = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2 = 1 \text{ J}$$

**TABLE 1.5** Densities of Selected Substances at  $25^\circ\text{C}$

| Substance       | Density ( $\text{g/cm}^3$ ) |
|-----------------|-----------------------------|
| Air             | 0.001                       |
| Balsa wood      | 0.16                        |
| Ethanol         | 0.79                        |
| Water           | 1.00                        |
| Ethylene glycol | 1.09                        |
| Table sugar     | 1.59                        |
| Table salt      | 2.16                        |
| Iron            | 7.9                         |
| Gold            | 19.32                       |

## Sample Exercise 1.4

### Determining Density and Using Density to Determine Volume or Mass

- (a) Calculate the density of mercury if  $1.00 \times 10^2$  g occupies a volume of  $7.36 \text{ cm}^3$ .  
 (b) Calculate the volume of 65.0 g of liquid methanol (wood alcohol) if its density is  $0.791 \text{ g/mL}$ .  
 (c) What is the mass in grams of a cube of gold (density =  $19.32 \text{ g/cm}^3$ ) if the length of the cube is  $2.00 \text{ cm}$ ?

### SOLUTION

- (a) We are given mass and volume, so Equation 1.3 yields

$$\text{Density} = \frac{\text{mass}}{\text{volume}} = \frac{1.00 \times 10^2 \text{ g}}{7.36 \text{ cm}^3} = 13.6 \text{ g/cm}^3$$

- (b) Solving Equation 1.3 for volume and then using the given mass and density gives

$$\text{Volume} = \frac{\text{mass}}{\text{density}} = \frac{65.0 \text{ g}}{0.791 \text{ g/mL}} = 82.2 \text{ mL}$$

- (c) We can calculate the mass from the volume of the cube and its density. The volume of a cube is given by its length cubed:

$$\text{Volume} = (2.00 \text{ cm})^3 = (2.00)^3 \text{ cm}^3 = 8.00 \text{ cm}^3$$

Solving Equation 1.3 for mass and substituting the volume and density of the cube, we have

$$\text{Mass} = \text{volume} \times \text{density} = (8.00 \text{ cm}^3)(19.32 \text{ g/cm}^3) = 155 \text{ g}$$

### Practice Exercise 1

Platinum, Pt, is one of the rarest of the metals. Worldwide annual production is only about 130 tons. Platinum has a density of  $21.4 \text{ g/cm}^3$ . If thieves were to steal platinum from a bank using a small truck with a maximum payload capacity of 900 lb, how many 1 L bars of the metal could they take?

- (a) 19 bars (b) 2 bars (c) 42 bars (d) 1 bar (e) 47 bars

### Practice Exercise 2

(a) Calculate the density of a 374.5-g sample of copper if it has a volume of  $41.8 \text{ cm}^3$ . (b) A student needs 15.0 g of ethanol for an experiment. If the density of ethanol is  $0.789 \text{ g/mL}$ , how many milliliters of ethanol are needed? (c) What is the mass, in grams, of 25.0 mL of mercury (density =  $13.6 \text{ g/mL}$ )?

Because a joule is not a very large amount of energy, we often use *kilojoules* (kJ) in discussing the energies associated with chemical reactions. For example, the amount of heat released when hydrogen and oxygen react to form 1 g of water is 16 kJ.

It is still quite common in chemistry, biology, and biochemistry to find energy changes associated with chemical reactions expressed in the non-SI unit of calories. A **calorie** (cal) was originally defined as the amount of energy required to raise the temperature of 1 g of water from  $14.5$  to  $15.5^\circ\text{C}$ . It has since been defined in terms of a joule:

$$1 \text{ cal} = 4.184 \text{ J (exactly)}$$

A related energy unit that is familiar to anyone who has read a food label is the nutritional *Calorie* (note the capital C), which is 1000 times larger than calorie with a lowercase c:  $1 \text{ Cal} = 1000 \text{ cal} = 1 \text{ kcal}$ .

## Sample Exercise 1.5

### Identifying and Calculating Energy Changes

A standard propane ( $\text{C}_3\text{H}_8$ ) tank used in an outdoor grill holds approximately 9.0 kg of propane. When the grill is operating, propane reacts with oxygen to form carbon dioxide and water. For every gram of propane that reacts with oxygen in this way, 46 kJ of energy is released as heat. (a) How much energy is released if the entire contents of the propane tank react with oxygen? (b) As the propane reacts, does the potential energy stored in chemical bonds increase or decrease? (c) If you were to store an equivalent amount of potential energy by pumping water to an elevation of 75 m above the ground, what mass of water would be needed? (Note: The force due to gravity acting on the water, which is the water's weight, is  $F = m \times g$ , where  $m$  is the mass of the object and  $g$  is the gravitational constant,  $g = 9.8 \text{ m/s}^2$ .)

### SOLUTION

- (a) We can calculate the amount of energy released from the propane as heat by converting the mass of propane from kg to g and then using the fact that 46 kJ of heat are released per gram:

$$E = 9.0 \text{ kg} \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{46 \text{ kJ}}{1 \text{ g}} = 4.1 \times 10^5 \text{ kJ} = 4.1 \times 10^8 \text{ J}$$

- (b) When propane reacts with oxygen, the potential energy stored in the chemical bonds is converted to an alternate form of energy, heat. Therefore, the potential energy stored as chemical energy must decrease.  
 (c) The amount of work done to pump the water to a height of 75 m can be calculated using Equation 1.1:

$$w = F \times d = (m \times g) \times d$$

rearranging to solve for the mass of water:

$$m = \frac{w}{g \times d} = \frac{4.1 \times 10^8 \text{ J}}{(9.8 \text{ m/s}^2)(75 \text{ m})} = \frac{4.1 \times 10^8 \text{ kg} \cdot \text{m}^2/\text{s}^2}{(9.8 \text{ m/s}^2)(75 \text{ m})}$$

$$= 5.6 \times 10^5 \text{ kg}$$

At 25 °C, this mass of water would have a volume of 560,000 L, or roughly 150,000 gallons. Thus, we see that large amounts of potential energy can be stored as chemical energy.

### Practice Exercise 1

Which of the following objects has the greatest kinetic energy?

(a) a 500-kg motorcycle moving at 100 km/h (b) a 1,000-kg car moving at 50 km/h (c) a 1500-kg car moving at 30 km/h (d) a 5000 kg truck moving at 10 km/h (e) a 10,000-kg truck moving at 5 km/h

### Practice Exercise 2

A 12-oz vanilla milkshake at a fast-food restaurant contains 547 Calories. What quantity of energy is this in joules?

## CHEMISTRY PUT TO WORK Chemistry in the News

**Solar Energy Steps Up.** Given the challenges society faces in trying to mitigate the effects of climate change, the need for affordable clean energy has never been greater. Given the massive amount of energy our planet receives from the Sun, solar energy has long been touted as a technology of the future. The problem for decades has been the relatively high cost of solar power compared to energy generated from burning fossil fuels. However, in recent years the cost of solar energy has decreased more rapidly than most people thought possible, decreasing more than 50% in just the past five years (Figure 1.22).

Not surprisingly, over the last six years the number of solar panel installations worldwide has increased sixfold. Over the same period, the number of coal plants operating in the United States has decreased by 38%, from 523 to 323. China is on track to install plants capable of generating more than 18 gigawatts of solar energy in 2015, nearly equal to the entire solar energy capacity of the United States. Furthermore, with the price of solar energy dropping rapidly, there is reason to believe that developing nations may forgo building fossil fuel power plants and skip straight to green energy technologies like solar and wind.

Recently, chemists have discovered a new class of materials called halide perovskites that have the potential to bring the cost of solar energy down even further. Solar cells made with halide perovskites have been shown to be nearly as efficient as single crystal silicon solar cells, but can be prepared from inexpensive solution methods that differ from the more costly and energy-intensive methods used to produce silicon solar cells. There are still many challenges to be overcome before halide perovskite solar cells are produced commercially, but their future looks very promising.

**Slowing a Progressive Disease.** Proteins are very large molecules that play an essential role in biology and the functioning of living organisms. Out of the myriad different types of proteins, scientists have identified one class of proteins called *prions* that play an important role in certain neurological diseases. We all have prion proteins in our brains, and for nearly all of us, they cause no harmful effects. For a small fraction of people, though, something causes the prions to change form and to adopt an incorrectly folded molecular shape. This process, once begun, is cumulative, propagating throughout the brain; the misfolded proteins somehow trigger the same misfolding in other prion proteins. Eventually, the misfolded proteins aggregate into clusters that can destroy neurons, producing symptoms such as those seen in Alzheimer's and Parkinson's diseases.

**▲ Figure 1.22** The cost of energy generated by photovoltaic modules. The median price per watt of electricity generated has dropped by two-thirds since 1998. The cost figures here include the cost for fully installed residential solar panels.

Currently, no therapies have been developed to stop the progression of prion diseases. However, there are encouraging signs that certain small molecules could disrupt propagation of the disease. They might be able to do this by blocking the interaction between one prion protein and another that causes the misfolding to propagate. So far, the experimental work has involved studies of mice infected with prions. One such molecule, called Anle-138b, is shown in Figure 1.23. Administration of this compound more than doubled the life spans of treated mice.

Compounds such as this one are not suitable for use in treating prion disease in humans, but studies conducted thus far point the way toward discovery of molecules that might in the future provide

*Continued*

▲ **Figure 1.23** Anle-138b, a promising molecule for the treatment of degenerative brain diseases.

effective therapies. This work illustrates the complex and sometimes tortuous path that takes the scientist from promising beginnings to a much desired goal.

**Chemical Approaches to Art Restoration.** Works of art are made from materials that over time can undergo chemical reactions that alter their appearance or undermine their mechanical stability. Layers of dirt and pollutants can build up on the surface, discoloring statues, murals, and paintings. Plasters that serve as the base for frescoes react with gases in the atmosphere. One approach to art restoration is to use selected chemical reactions to undo or reverse the effects of detrimental reactions that have occurred over time.

One such example involves murals at the ancient Mayan ruins of Mayapan in Mexico's Yucatán peninsula. In the 1960s, polymer coatings were applied to these murals in an attempt to preserve them, but within a decade it became clear that the polymer coatings were doing more harm than good. Unfortunately, years of oxidation and cross-linking reactions had rendered the polymer coatings insoluble to nearly every type of organic solvent. In 2008, a team of Italian chemists found a way to remove the polymer coatings without damaging the underlying fresco. They treated the murals with a microemulsion, a special type of mixture where molecules called surfactants encapsulate and carry nanometer-sized droplets of organic solvents through an aqueous solution to the surface of the fresco. Once the droplets reach the surface, they can dissolve and carry away the unwanted polymer coating.

## 1.6 | Uncertainty in Measurement

Two kinds of numbers are encountered in scientific work: *exact numbers* (those whose values are known exactly) and *inexact numbers* (those whose values have some uncertainty). Most of the exact numbers we will encounter in this book have defined values. For example, there are exactly 12 eggs in a dozen, exactly 1000 g in a kilogram, and exactly 2.54 cm in an inch. The number 1 in any conversion factor, such as  $1 \text{ m} = 100 \text{ cm}$  or  $1 \text{ kg} = 2.2046 \text{ lb}$ , is an exact number. Exact numbers can also result from counting objects. For example, we can count the exact number of marbles in a jar or the exact number of people in a classroom.

Numbers obtained by measurement are always *inexact*. The equipment used to measure quantities always has inherent limitations (equipment errors), and there are differences in how different people make the same measurement (human errors). Suppose ten students with ten balances are to determine the mass of the same dime. The ten measurements will probably vary slightly for various reasons. The balances might be calibrated slightly differently, and there might be differences in how each student reads the mass from the balance. Remember: *Uncertainties always exist in measured quantities.*

### Give It Some Thought

Which of the following is an inexact quantity?

- (a) the number of people in your chemistry class
- (b) the mass of a penny
- (c) the number of grams in a kilogram

High precision can be achieved on a scale like this one, which has 0.1 mg accuracy.

### Precision and Accuracy

The terms *precision* and *accuracy* are often used in discussing the uncertainties of measured values. **Precision** is a measure of how closely individual measurements agree with one another. **Accuracy** refers to how closely individual measurements agree with the correct, or “true,” value. The dart analogy in **Figure 1.24** illustrates the difference between these two concepts.

In the laboratory, we often perform several “trials” of an experiment and average the results. The precision of the measurements is often expressed in terms of the *standard deviation* (Appendix A.5), which reflects how much the individual measurements differ from the average. We gain confidence in our measurements if we obtain nearly the same value each time—that is, when the standard deviation is small. Figure 1.24 reminds us,

however, that precise measurements can be inaccurate. For example, if a very sensitive balance is poorly calibrated, the masses we measure will be consistently either high or low. They will be inaccurate even if they are precise.

## Significant Figures

Suppose you determine the mass of a dime on a balance capable of measuring to the nearest 0.0001 g. You could report the mass as  $2.2405 \pm 0.0001$  g. The  $\pm$  notation (read “plus or minus”) expresses the magnitude of the uncertainty of your measurement. In much scientific work, we drop the  $\pm$  notation with the understanding that *there is always some uncertainty in the last digit reported for any measured quantity*.

**Figure 1.25** shows a thermometer with its liquid column between two scale marks. We can read the certain digits from the scale and estimate the uncertain one. Seeing that the liquid is between the 25 °C and 30 °C marks, we estimate the temperature to be 27 °C, being uncertain of the second digit of our measurement. By *uncertain* we mean that the temperature is reliably 27 °C and not 28 °C or 26 °C, but we can’t say that it is *exactly* 27 °C.

All digits of a measured quantity, including the uncertain one, are called **significant figures**. A measured mass reported as 2.2 g has two significant figures, whereas one reported as 2.2405 g has five significant figures. The greater the number of significant figures, the greater the precision implied for the measurement.

### Give It Some Thought

A sample that has a mass of about 25 g is weighed on a balance that has a precision of 0.001 g. How many significant figures should be reported for this measurement?

To determine the number of significant figures in a reported measurement, read the number from left to right, counting the digits starting with the first digit that is not zero. *In any measurement that is properly reported, all nonzero digits are significant.* Because zeros can be used either as part of the measured value or merely to locate the decimal point, they may or may not be significant:

- Zeros *between* nonzero digits are always significant—1005 kg (four significant figures); 7.03 cm (three significant figures).
- Zeros *at the beginning* of a number are never significant; they merely indicate the position of the decimal point—0.02 g (one significant figure); 0.0026 cm (two significant figures).
- Zeros *at the end* of a number are significant if the number contains a decimal point—0.0200 g (three significant figures); 3.0 cm (two significant figures).

▲ **Figure 1.25** Uncertainty and significant figures in a measurement.

### Go Figure

How would the darts be positioned on the target for the case of “good accuracy, poor precision”?

Good accuracy  
Good precision

Poor accuracy  
Good precision

Poor accuracy  
Poor precision

▲ **Figure 1.24** Precision and accuracy.

A problem arises when a number ends with zeros but contains no decimal point. In such cases, it is normally assumed that the zeros are not significant. Exponential notation (Appendix A.1) can be used to indicate whether end zeros are significant. For example, a mass of 10,300 g can be written to show three, four, or five significant figures depending on how the measurement is obtained:

|                                |                             |
|--------------------------------|-----------------------------|
| $1.03 \times 10^4 \text{ g}$   | (three significant figures) |
| $1.030 \times 10^4 \text{ g}$  | (four significant figures)  |
| $1.0300 \times 10^4 \text{ g}$ | (five significant figures)  |

In these numbers, all the zeros to the right of the decimal point are significant (rules 1 and 3). (The exponential term  $10^4$  does not add to the number of significant figures.)

## Sample Exercise 1.6

### Assigning Appropriate Significant Figures

The state of Colorado is listed in a road atlas as having a population of 5,546,574 and an area of 104,091 square miles. Do the numbers of significant figures in these two quantities seem reasonable? If not, what seems to be wrong with them?

#### SOLUTION

The population of Colorado must vary from day to day as people move in or out, are born, or die. Thus, the reported number suggests a much higher degree of *accuracy* than is possible. Moreover, it would not be feasible to actually count every individual resident in the state at any given time. Thus, the reported number suggests far greater *precision* than is possible. A reported number of 5,500,000 would better reflect the actual state of knowledge.

The area of Colorado does not normally vary from time to time, so the question here is whether the accuracy of the measurements is good to six significant figures. It would be possible to achieve such

accuracy using satellite technology, provided the legal boundaries are known with sufficient accuracy.

#### Practice Exercise 1

Which of the following numbers in your personal life are exact numbers?

- (a) Your cell phone number (b) your weight (c) your IQ  
(d) your driver's license number (e) the distance you walked yesterday

#### Practice Exercise 2

The back inside cover of the book tells us that there are 5280 ft in 1 mile. Does this make the mile an exact distance?

## Sample Exercise 1.7

### Determining the Number of Significant Figures in a Measurement

How many significant figures are in each of the following numbers (assume that each number is a measured quantity)?

- (a) 4.003, (b)  $6.023 \times 10^{23}$ , (c) 5000.

#### SOLUTION

(a) Four; the zeros are significant figures. (b) Four; the exponential term does not add to the number of significant figures. (c) One; we assume that the zeros are not significant when there is no decimal point shown. If the number has more significant figures, a decimal point should be employed or the number written in exponential notation. Thus, 5000. has four significant figures, whereas  $5.00 \times 10^3$  has three.

#### Practice Exercise 1

An object is determined to have a mass of 0.01080 g. How many significant figures are there in this measurement?

- (a) 2 (b) 3 (c) 4 (d) 5 (e) 6

#### Practice Exercise 2

How many significant figures are in each of the following measurements? (a) 3.549 g, (b)  $2.3 \times 10^4 \text{ cm}$ , (c) 0.00134  $\text{m}^3$ .

## Significant Figures in Calculations

Apply the following rule when carrying measured quantities through calculations.

*The least certain measurement limits the certainty of the calculated quantity and thereby determines the number of significant figures in the final answer.*

The final answer should be reported with only one uncertain digit. To keep track of significant figures in calculations, we will make frequent use of two rules: one for addition and subtraction, and another for multiplication and division.

1. *For addition and subtraction*, the result has the same number of decimal places as the measurement with the *fewest decimal places*. When the result contains more than

the correct number of significant figures, it must be rounded off. Consider the following example in which the uncertain digits appear in color:

|  |         |  |
|--|---------|--|
| This number limits the number of the significant figures in the result | 20.42   | ← two decimal places                     |
|  | 1.322   | ← three decimal places                   |
|  | 83.1    | ← one decimal places                     |
|  | 104.842 | ← round off to one decimal place (104.8) |

We report the result as 104.8 because 83.1 has only one decimal place.

2. For *multiplication and division*, the result contains the same number of significant figures as the measurement with the *fewest significant figures*. When the result contains more than the correct number of significant figures, it must be rounded off. For example, the area of a rectangle whose measured edge lengths are 6.221 and 5.2 cm should be reported with two significant figures, 32 cm<sup>2</sup>, even though a calculator shows the product to have more digits:

$$\text{Area} = (6.221 \text{ cm})(5.2 \text{ cm}) = 32.3492 \text{ cm}^2 \Rightarrow \text{round off to } 32 \text{ cm}^2$$

because 5.2 has two significant figures.

In determining the final answer for a calculated quantity, *exact numbers* are assumed to have an infinite number of significant figures. Thus, when we say, “There are 12 inches in 1 foot,” the number 12 is exact, and we need not worry about the number of significant figures in it.

When *rounding off numbers* look at the leftmost digit to be removed:

- If the leftmost digit removed is less than 5, the preceding number is left unchanged. Thus, rounding off 7.248 to two significant figures gives 7.2.
- If the leftmost digit removed is 5 or greater, the preceding number is increased by 1. Rounding off 4.735 to three significant figures gives 4.74, and rounding 2.376 to two significant figures gives 2.4.\*

### Give It Some Thought

The mass of a glass beaker is known to be 25.1 g. Approximately 5 mL of water are added, and the mass of the beaker and water is measured on an analytical balance to be 30.625 g. How many significant figures are there in the mass of the water?

## Sample Exercise 1.8

### Determining the Number of Significant Figures in a Calculated Quantity

The width, length, and height of a small box are 15.5, 27.3, and 5.4 cm, respectively. Calculate the volume of the box, using the correct number of significant figures in your answer.

### SOLUTION

In reporting the volume, we can show only as many significant figures as given in the dimension with the fewest significant figures, which is that for the height (two significant figures):

$$\begin{aligned}\text{Volume} &= \text{width} \times \text{length} \times \text{height} \\ &= (15.5 \text{ cm})(27.3 \text{ cm})(5.4 \text{ cm}) \\ &= 2285.01 \text{ cm}^3 \Rightarrow 2.3 \times 10^3 \text{ cm}^3\end{aligned}$$

A calculator used for this calculation shows 2285.01, which we must round off to two significant figures. Because the resulting number is 2300, it is best reported in exponential notation,  $2.3 \times 10^3$ , to clearly indicate two significant figures.

### Practice Exercise 1

Ellen recently purchased a new hybrid car and wants to check her gas mileage. At an odometer setting of 651.1 mi, she fills the tank. At 1314.4 mi, she requires 16.1 gal to refill the tank. Assuming that the tank is filled to the same level both times, how is the gas mileage best expressed?

(a) 40 mi/gal (b) 41 mi/gal (c) 41.2 mi/gal (d) 41.20 mi/gal

### Practice Exercise 2

It takes 10.5 s for a sprinter to run 100.00 m. Calculate her average speed in meters per second and express the result to the correct number of significant figures.

\*Your instructor may want you to use a slight variation on the rule when the leftmost digit to be removed is exactly 5, with no following digits or only zeros following. One common practice is to round up to the next higher number if that number will be even and down to the next lower number otherwise. Thus, 4.7350 would be rounded to 4.74, and 4.7450 would also be rounded to 4.74.

## Sample Exercise 1.9

### Determining the Number of Significant Figures in a Calculated Quantity

A vessel containing a gas at 25 °C is weighed, emptied, and then reweighed as depicted in Figure 1.26. From the data provided, calculate the density of the gas at 25 °C.

#### SOLUTION

To calculate the density, we must know both the mass and the volume of the gas. The mass of the gas is just the difference in the masses of the full and empty container:

$$\begin{array}{r} 837.63 \text{ g} \\ -836.25 \text{ g} \\ \hline 1.38 \text{ g} \end{array}$$

In subtracting numbers, we determine the number of significant figures in our result by counting decimal places in each quantity.

Pump out gas

▲ Figure 1.26 Uncertainty and significant figures in a measurement.

In this case each quantity has two decimal places. Thus, the mass of the gas, 1.38 g, has two decimal places.

Using the volume given in the question,  $1.05 \times 10^3 \text{ cm}^3$ , and the definition of density, we have

$$\begin{aligned} \text{Density} &= \frac{\text{mass}}{\text{volume}} = \frac{1.38 \text{ g}}{1.05 \times 10^3 \text{ cm}^3} \\ &= 1.31 \times 10^{-3} \text{ g/cm}^3 = 0.00131 \text{ g/cm}^3 \end{aligned}$$

In dividing numbers, we determine the number of significant figures our result should contain by counting the number of significant figures in each quantity. There are three significant figures in our answer, corresponding to the number of significant figures in the two numbers that form the ratio. Notice that in this example, following the rules for determining significant figures gives an answer containing only three significant figures, even though the measured masses contain five significant figures.

#### Practice Exercise 1

You are asked to determine the mass of a piece of copper using its reported density, 8.96 g/mL, and a 150-mL graduated cylinder. First, you add 105 mL of water to the graduated cylinder; then you place the piece of copper in the cylinder and record a volume of 137 mL. What is the mass of the copper reported with the correct number of significant figures? (a) 287 g (b)  $3.5 \times 10^{-3}$  g/mL (c) 286.72 g/mL (d)  $3.48 \times 10^{-3}$  g/mL (e)  $2.9 \times 10^2$  g/mL

#### Practice Exercise 2

If the mass of the container in the sample exercise (Figure 1.26) were measured to three decimal places before and after pumping out the gas, could the density of the gas then be calculated to four significant figures?

When a calculation involves two or more steps and you write answers for intermediate steps, retain at least one nonsignificant digit for the intermediate answers. This procedure ensures that small errors from rounding at each step do not combine to affect the final result. When using a calculator, you may enter the numbers one after another, rounding only the final answer. Accumulated rounding-off errors may account for small differences among results you obtain and answers given in the text for numerical problems.

## 1.7 | Dimensional Analysis

Because measured quantities have units associated with them, it is important to keep track of units as well as numerical values when using the quantities in calculations. Throughout the text we use dimensional analysis in solving problems. In **dimensional analysis**, units are multiplied together or divided into each other along with the numerical values. Equivalent units cancel each other. Using dimensional analysis helps ensure that solutions to problems yield the proper units. Moreover, it provides a systematic way of solving many numerical problems and of checking solutions for possible errors.

### Conversion Factors

The key to using dimensional analysis is the correct use of *conversion factors* to change one unit into another. A **conversion factor** is a fraction whose numerator and

denominator are the same quantity expressed in different units. For example, 2.54 cm and 1 in. are the same length:  $2.54 \text{ cm} = 1 \text{ in.}$  This relationship allows us to write two conversion factors:

$$\frac{2.54 \text{ cm}}{1 \text{ in.}} \quad \text{and} \quad \frac{1 \text{ in.}}{2.54 \text{ cm}}$$

We use the first factor to convert inches to centimeters. For example, the length in centimeters of an object that is 8.50 in. long is

$$\text{Number of centimeters} = (8.50 \text{ in.}) \frac{2.54 \text{ cm}}{1 \text{ in.}} = 21.6 \text{ cm}$$

Desired unit

Given unit

The unit inches in the denominator of the conversion factor cancels the unit inches in the given data (8.50 *inches*), so that the centimeters unit in the numerator of the conversion factor becomes the unit of the final answer. Because the numerator and denominator of a conversion factor are equal, multiplying any quantity by a conversion factor is equivalent to multiplying by the number 1 and so does not change the intrinsic value of the quantity. The length 8.50 in. is the same as the length 21.6 cm.

In general, we begin any conversion by examining the units of the given data and the units we desire. We then ask ourselves what conversion factors we have available to take us from the units of the given quantity to those of the desired one. When we multiply a quantity by a conversion factor, the units multiply and divide as follows:

$$\text{Given unit} \times \frac{\text{desired unit}}{\text{given unit}} = \text{desired unit}$$

If the desired units are not obtained in a calculation, an error must have been made somewhere. Careful inspection of units often reveals the source of the error.

### Sample Exercise 1.10

#### Converting Units

If a woman has a mass of 115 lb, what is her mass in grams? (Use the relationships between units given on the back inside cover of the text.)

#### SOLUTION

Because we want to change from pounds to grams, we look for a relationship between these units of mass. The conversion factor table found on the back inside cover tells us that  $1 \text{ lb} = 453.6 \text{ g}$ . To cancel pounds and leave grams, we write the conversion factor with grams in the numerator and pounds in the denominator:

$$\text{Mass in grams} = (115 \text{ lb}) \left( \frac{453.6 \text{ g}}{1 \text{ lb}} \right) = 5.22 \times 10^4 \text{ g}$$

The answer can be given to only three significant figures, the number of significant figures in 115 lb. The process we have used is diagrammed on the top right column.

Given:

lb

Use

$$\frac{453.6 \text{ g}}{1 \text{ lb}}$$

Find:

g

#### Practice Exercise 1

At a particular instant in time, the Earth is judged to be 92,955,000 miles from the Sun. What is the distance in kilometers to four significant figures? (See the back inside cover for the conversion factor).

- (a)  $5763 \times 10^4 \text{ km}$  (b)  $1.496 \times 10^8 \text{ km}$  (c)  $1.49596 \times 10^8 \text{ km}$   
(d)  $1.483 \times 10^4 \text{ km}$  (e) 57,759,000 km

#### Practice Exercise 2

By using a conversion factor from the back inside cover, determine the length in kilometers of a 500.0-mi automobile race.

## STRATEGIES FOR SUCCESS Estimating Answers

Calculators are wonderful devices; they enable you to get to the wrong answer very quickly. Of course, that's not the destination you want. You can take certain steps to avoid putting that wrong answer into your homework set or on an exam. One is to keep track of the units in a calculation and use the correct conversion factors. Second, you can do a quick mental check to be sure that your answer is reasonable: you can try to make a "ballpark" estimate.

A ballpark estimate involves making a rough calculation using numbers that are rounded off in such a way that the arithmetic can be done without a calculator. Even though this approach does not

give an exact answer, it gives one that is roughly the correct size. By using dimensional analysis and by estimating answers, you can readily check the reasonableness of your calculations.

You can get better at making estimates by practicing in everyday life. How far is it from your dorm room to the chemistry lecture hall? How much do your parents pay for gasoline per year? How many bikes are there on campus? If you respond "I have no idea" to these questions, you're giving up too easily. Try estimating familiar quantities and you'll get better at making estimates in science and in other aspects of your life where a misjudgment can be costly.

### Give It Some Thought

Consider the following conversion factors: (i)  $1000 \text{ m} = 1 \text{ km}$ , (ii)  $1 \text{ mL} = 1 \text{ cm}^3$ , (iii)  $1 \text{ lb} = 453.59 \text{ g}$ . Which of these conversion factors has the potential to change the number of significant figures in a calculation?

## Using Two or More Conversion Factors

It is often necessary to use several conversion factors in solving a problem. As an example, let's convert the length of an 8.00-m rod to inches. The table on the back inside cover does not give the relationship between meters and inches. It *does*, however, give the relationship between centimeters and inches ( $1 \text{ in.} = 2.54 \text{ cm}$ ). From our knowledge of SI prefixes, we know that  $1 \text{ cm} = 10^{-2} \text{ m}$ . Thus, we can convert step by step, first from meters to centimeters and then from centimeters to inches:

Combining the given quantity (8.00 m) and the two conversion factors, we have

$$\text{Number of inches} = (8.00 \text{ m}) \left( \frac{1 \text{ cm}}{10^{-2} \text{ m}} \right) \left( \frac{1 \text{ in.}}{2.54 \text{ cm}} \right) = 315 \text{ in.}$$

The first conversion factor is used to cancel meters and convert the length to centimeters. Thus, meters are written in the denominator and centimeters in the numerator. The second conversion factor is used to cancel centimeters and convert the length to inches, so it has centimeters in the denominator and inches, the desired unit, in the numerator.

Note that you could have used  $100 \text{ cm} = 1 \text{ m}$  as a conversion factor as well in the second parentheses. As long as you keep track of your given units and cancel them properly to obtain the desired units, you are likely to be successful in your calculations.

### Sample Exercise 1.11

#### Converting Units Using Two or More Conversion Factors

The average speed of a nitrogen molecule in air at  $25^\circ \text{C}$  is  $515 \text{ m/s}$ . Convert this speed to miles per hour.

#### SOLUTION

To go from the given units, m/s, to the desired units, mi/hr, we must convert meters to miles and seconds to hours. From our knowledge of SI prefixes we know that  $1 \text{ km} = 10^3 \text{ m}$ . From the relationships given on the back inside cover of the book, we find

that  $1 \text{ mi} = 1.6093 \text{ km}$ . Thus, we can convert m to km and then convert km to mi. From our knowledge of time we know that  $60 \text{ s} = 1 \text{ min}$  and  $60 \text{ min} = 1 \text{ hr}$ . Thus, we can convert s to min and then convert min to hr. The overall process is

Given:

Applying first the conversions for distance and then those for time, we can set up one long equation in which unwanted units are canceled:

$$\begin{aligned}\text{Speed in mi/hr} &= \left(515 \frac{\text{m}}{\text{s}}\right) \left(\frac{1 \text{ km}}{10^3 \text{ m}}\right) \left(\frac{1 \text{ mi}}{1.6093 \text{ km}}\right) \left(\frac{60 \text{ s}}{1 \text{ min}}\right) \left(\frac{60 \text{ min}}{1 \text{ hr}}\right) \\ &= 1.15 \times 10^3 \text{ mi/hr}\end{aligned}$$

Our answer has the desired units. We can check our calculation, using the estimating procedure described in the “Strategies in Chemistry” box. The given speed is about 500 m/s. Dividing by 1000 converts m to km, giving 0.5 km/s. Because 1 mi is about 1.6 km, this speed corresponds to  $0.5/1.6 = 0.3$  mi/s. Multiplying by 60 gives about  $0.3 \times 60 = 20$  mi/min. Multiplying again by 60 gives  $20 \times 60 = 1200$  mi/hr. The approximate solution (about 1200 mi/hr) and the detailed solution (1150 mi/hr) are reasonably close. The answer to the detailed solution has three significant figures, corresponding to the number of significant figures in the given speed in m/s.

### Practice Exercise 1

Fabiola, who lives in Mexico City, fills her car with gas, paying 357 pesos for 40.0 L. What is her fuel cost in dollars per gallon, if 1 peso = 0.0759 dollars?

(a) \$1.18/gal (b) \$3.03/gal (c) \$1.47/gal (d) \$9.68/gal (e) \$2.56/gal

### Practice Exercise 2

A car travels 28 mi per gallon of gasoline. What is the mileage in kilometers per liter?

## Conversions Involving Volume

The conversion factors previously noted convert from one unit of a given measure to another unit of the same measure, such as from length to length. We also have conversion factors that convert from one measure to a different one. The density of a substance, for example, can be treated as a conversion factor between mass and volume. Suppose we want to know the mass in grams of 2 cubic inches ( $2.00 \text{ in.}^3$ ) of gold, which has a density of  $19.3 \text{ g/cm}^3$ . The density gives us the conversion factors:

$$\frac{19.3 \text{ g}}{1 \text{ cm}^3} \quad \text{and} \quad \frac{1 \text{ cm}^3}{19.3 \text{ g}}$$

Because we want a mass in grams, we use the first factor, which has mass in grams in the numerator. To use this factor, however, we must first convert cubic inches to cubic centimeters. The relationship between  $\text{in.}^3$  and  $\text{cm}^3$  is not given on the back inside cover, but the relationship between inches and centimeters is given:  $1 \text{ in.} = 2.54 \text{ cm}$  (exactly). Cubing both sides of this equation gives  $(1 \text{ in.})^3 = (2.54 \text{ cm})^3$ , from which we write the desired conversion factor:

$$\frac{(2.54 \text{ cm})^3}{(1 \text{ in.})^3} = \frac{(2.54)^3 \text{ cm}^3}{(1)^3 \text{ in.}^3} = \frac{16.39 \text{ cm}^3}{1 \text{ in.}^3}$$

Notice that both the numbers and the units are cubed. Also, because 2.54 is an exact number, we can retain as many digits of  $(2.54)^3$  as we need. We have used four, one more than the number of digits in the density ( $19.3 \text{ g/cm}^3$ ). Applying our conversion factors, we can now solve the problem:

$$\text{Mass in grams} = (2.00 \text{ in.}^3) \left( \frac{16.39 \text{ cm}^3}{1 \text{ in.}^3} \right) \left( \frac{19.3 \text{ g}}{1 \text{ cm}^3} \right) = 633 \text{ g}$$

The procedure is diagrammed here. The final answer is reported to three significant figures, the same number of significant figures as in  $2.00 \text{ in.}^3$  and  $19.3 \text{ g}$ .

Given:

## Sample Exercise 1.12

### Converting Volume Units

Earth's oceans contain approximately  $1.36 \times 10^9 \text{ km}^3$  of water. Calculate the volume in liters.

#### SOLUTION

From the back inside cover, we find  $1 \text{ L} = 10^{-3} \text{ m}^3$ , but there is no relationship listed involving  $\text{km}^3$ . From our knowledge of SI prefixes, however, we know  $1 \text{ km} = 10^3 \text{ m}$  and we can use this relationship between lengths to write the desired conversion factor between volumes:

$$\left(\frac{10^3 \text{ m}}{1 \text{ km}}\right)^3 = \frac{10^9 \text{ m}^3}{1 \text{ km}^3}$$

Thus, converting from  $\text{km}^3$  to  $\text{m}^3$  to L, we have

$$\begin{aligned}\text{Volume in liters} &= (1.36 \times 10^9 \text{ km}^3) \left(\frac{10^9 \text{ m}^3}{1 \text{ km}^3}\right) \left(\frac{1 \text{ L}}{10^{-3} \text{ m}^3}\right) \\ &= 1.36 \times 10^{21} \text{ L}\end{aligned}$$

How many liters of water do Earth's oceans contain?

#### Practice Exercise 1

A barrel of oil as measured on the oil market is equal to 1.333 U.S. barrels. A U.S. barrel is equal to 31.5 gal. If oil is on the market at \$94.0 per barrel, what is the price in dollars per gallon?

(a) \$2.24/gal (b) \$3.98/gal (c) \$2.98/gal (d) \$1.05/gal  
(e) \$8.42/gal

#### Practice Exercise 2

The surface area of Earth is  $510 \times 10^6 \text{ km}^2$ , and 71% of this is ocean. Using the data from the sample exercise, calculate the average depth of the world's oceans in feet.

## STRATEGIES FOR SUCCESS The Importance of Practice

If you have ever played a musical instrument or participated in athletics, you know that the keys to success are practice and discipline. You cannot learn to play a piano merely by listening to music, and you cannot learn how to play basketball merely by watching games on television. Likewise, you cannot learn chemistry by merely watching your instructor give lectures. Simply reading this book, listening to lectures, or reviewing notes will not usually be sufficient when exam time comes around. Your task is to master chemical concepts to a degree that you can put them to use in solving problems and answering questions. Solving problems correctly takes practice—actually, a fair amount of it. You will do well in your chemistry course if you embrace the idea that you need to master the materials presented and then learn how to apply them in solving problems. Even if you're a brilliant student, this will take time; it's what being a student is all about. Almost no one fully absorbs new material on a first reading, especially when new concepts are being presented. You are sure to master the content of the chapters more fully by reading

them through at least twice, even more for passages that present you with difficulties in understanding.

Throughout the book, we have provided sample exercises in which the solutions are shown in detail. For practice exercises, we supply only the answer, at the back of the book. It is important that you use these exercises to test yourself.

The practice exercises in this text and the homework assignments given by your instructor provide the minimal practice that you will need to succeed in your chemistry course. Only by working all the assigned problems will you face the full range of difficulty and coverage that your instructor expects you to master for exams. There is no substitute for a determined and perhaps lengthy effort to work problems on your own. If you are stuck on a problem, however, ask for help from your instructor, a teaching assistant, a tutor, or a fellow student. Spending an inordinate amount of time on a single exercise is rarely effective unless you know that it is particularly challenging and is expected to require extensive thought and effort.

## STRATEGIES FOR SUCCESS The Features of This Book

If, like most students, you haven't yet read the part of the Preface to this text entitled TO THE STUDENT, *you should do it now*. In less than two pages of reading you will encounter valuable advice on how to navigate your way through this book and through the course. We're serious! This is advice you can use.

The TO THE STUDENT section describes how text features such as "What's Ahead," Key Terms, Learning Outcomes, and Key Equations will help you remember what you have learned. We also describe how to take advantage of the text's website, where many types of online study tools are available. If you have registered for MasteringChemistry®, you will have access to many helpful animations,

tutorials, and additional problems correlated to specific topics and sections of each chapter. An interactive eBook is also available online.

As previously mentioned, working exercises is very important—in fact, essential. You will find a large variety of exercises at the end of each chapter that are designed to test your problem-solving skills in chemistry. Your instructor will very likely assign some of these end-of-chapter exercises as homework.

- The first few exercises called "Visualizing Concepts" are meant to test how well you understand a concept without plugging a lot of numbers into a formula.

- Exercises for each section of a chapter are grouped in pairs, with answers given at the back of the book for the odd-numbered (red) ones.
- An exercise with a [bracket] around its number is designed to be more challenging.
- Additional Exercises appear after the regular exercises; the chapter sections that they cover are not identified, and they are not paired.
- Integrative Exercises, which start appearing in Chapter 3, are problems that require skills learned in previous chapters.
- Also first appearing in Chapter 3 are Design an Experiment exercises consisting of problem scenarios that challenge you to design experiments to test hypotheses.

Many chemical databases are available, usually on the Web.

- The *CRC Handbook of Chemistry and Physics* is the standard reference for many types of data and is available in libraries.
- The *Merck Index* is a standard reference for the properties of many organic compounds, especially those of biological interest.
- WebElements (<http://www.webelements.com/>) is a good website for looking up the properties of the elements.
- Wolfram Alpha (<http://www.wolframalpha.com/>) can also be a source of useful information on substances, numerical values, and other data.

## Sample Exercise 1.13

### Conversions Involving Density

What is the mass in grams of 1.00 gal of water? The density of water is 1.00 g/mL.

### SOLUTION

Before we begin solving this exercise, we note the following:

- We are given 1.00 gal of water (the known, or given, quantity) and asked to calculate its mass in grams (the unknown).
- We have the following conversion factors either given, commonly known, or available on the back inside cover of the text:

$$\frac{1.00 \text{ g water}}{1 \text{ mL water}} \quad \frac{1 \text{ L}}{1000 \text{ mL}} \quad \frac{1 \text{ L}}{1.057 \text{ qt}} \quad \frac{1 \text{ gal}}{4 \text{ qt}}$$

The first of these conversion factors must be used as written (with grams in the numerator) to give the desired result, whereas the last conversion factor must be inverted in order to cancel gallons:

$$\begin{aligned} \text{Mass in grams} &= (1.00 \text{ gal}) \left( \frac{4 \text{ qt}}{1 \text{ gal}} \right) \left( \frac{1 \text{ L}}{1.057 \text{ qt}} \right) \left( \frac{1000 \text{ mL}}{1 \text{ L}} \right) \left( \frac{1.00 \text{ g}}{1 \text{ mL}} \right) \\ &= 3.78 \times 10^3 \text{ g water} \end{aligned}$$

The unit of our final answer is appropriate, and we have taken care of our significant figures. We can further check our calculation by estimating. We can round 1.057 off to 1. Then focusing on the numbers that do not equal 1 gives  $4 \times 1000 = 4000 \text{ g}$ , in agreement with the detailed calculation.

You should also use common sense to assess the reasonableness of your answer. In this case we know that most

A composite deck.

people can lift a gallon of milk with one hand, although it would be tiring to carry it around all day. Milk is mostly water and will have a density not too different from that of water. Therefore, we might estimate that a gallon of water has mass that is more than 5 lb but less than 50 lb. The mass we have calculated,  $3.78 \text{ kg} \times 2.2 \text{ lb/kg} = 8.3 \text{ lb}$ , is thus reasonable.

### Practice Exercise 1

Composite decking is a manufactured substitute for wood compounded from post-consumer plastic and wood. It is frequently used in outdoor decks. The density of a particular composite decking is reported as  $60.0 \text{ lb/ft}^3$ . What is the density in  $\text{kg/L}$ ?

- (a)  $138 \text{ kg/L}$  (b)  $0.961 \text{ kg/L}$  (c)  $259 \text{ kg/L}$  (d)  $15.8 \text{ kg/L}$   
(e)  $11.5 \text{ kg/L}$

### Practice Exercise 2

The density of the organic compound benzene is  $0.879 \text{ g/mL}$ . Calculate the mass in grams of  $1.00 \text{ qt}$  of benzene.

## Chapter Summary and Key Terms

**THE STUDY OF CHEMISTRY (SECTION 1.1)** Chemistry is the study of the composition, structure, properties, and changes of **matter**. The composition of matter relates to the kinds of **elements** it contains. The structure of matter relates to the ways the **atoms** of these elements are arranged. A **property** is any characteristic that gives a sample of matter its unique identity. A **molecule** is an entity composed of two or more atoms, with the atoms attached to one another in a specific way.

The **scientific method** is a dynamic process used to answer questions about the physical world. Observations and experiments lead to tentative explanations or **hypotheses**. As a hypothesis is tested and refined, a **theory** may be developed that can predict the results of future observations and experiments. When observations repeatedly lead to the same consistent results, we speak of a **scientific law**, a general rule that summarizes how nature behaves.

**CLASSIFICATIONS OF MATTER (SECTION 1.2)** Matter exists in three physical states, **gas**, **liquid**, and **solid**, which are known as the **states of matter**. There are two kinds of **pure substances**: **elements** and **compounds**. Each element has a single kind of atom and is represented by a chemical symbol consisting of one or two letters, with the first letter capitalized. Compounds are composed of two or more elements joined chemically. The **law of constant composition**, also called the **law of definite proportions**, states that the elemental composition of a pure compound is always the same. Most matter consists of a mixture of substances. **Mixtures** have variable compositions and can be either homogeneous or heterogeneous; homogeneous mixtures are called **solutions**.

**PROPERTIES OF MATTER (SECTION 1.3)** Each substance has a unique set of **physical properties** and **chemical properties** that can be used to identify it. During a **physical change**, matter does not change its composition. **Changes of state** are physical changes. In a **chemical change (chemical reaction)**, a substance is transformed into a chemically different substance. **Intensive properties** are independent of the amount of matter examined and are used to identify substances. **Extensive properties** relate to the amount of substance present. Differences in physical and chemical properties are used to separate substances.

**THE NATURE OF ENERGY (SECTION 1.4)** **Energy** is defined as the capacity to do work or transfer heat. **Work** is the energy transferred when a force exerted on an object causes a displacement of that object, and **heat** is the energy used to cause the temperature of an object to increase. An object can possess energy in two forms: **kinetic energy**, which is the energy associated with the motion of an object, and **potential energy**, which is the energy that an object possesses by virtue of its position relative to other objects. Important forms of potential energy include gravitational energy and electrostatic energy.

**UNITS OF MEASUREMENT (SECTION 1.5)** Measurements in chemistry are made using the **metric system**. Special emphasis is placed on **SI units**, which are based on the meter, the kilogram, and the second as the basic units of length, **mass**, and time, respectively. SI units use prefixes to indicate fractions or multiples of base units. The SI **temperature** scale is the **Kelvin scale**, although the **Celsius scale** is frequently used as well. **Absolute zero** is the lowest temperature attainable. It has the value 0 K. A **derived unit** is obtained by multiplication or division of SI base units. Derived units are needed for defined quantities such as speed or volume. **Density** is an important derived unit that equals mass divided by volume.

**UNCERTAINTY IN MEASUREMENT (SECTION 1.6)** All measured quantities are inexact to some extent. The **precision** of a measurement indicates how closely different measurements of a quantity agree with one another. The **accuracy** of a measurement indicates how well a measurement agrees with the accepted or “true” value. The **significant figures** in a measured quantity include one estimated digit, the last digit of the measurement. The significant figures indicate the extent of the uncertainty of the measurement. Certain rules must be followed so that a calculation involving measured quantities is reported with the appropriate number of significant figures.

**DIMENSIONAL ANALYSIS (SECTION 1.7)** In the **dimensional analysis** approach to problem solving, we keep track of units as we carry measurements through calculations. The units are multiplied together, divided into each other, or canceled like algebraic quantities. Obtaining the proper units for the final result is an important means of checking the method of calculation. When converting units and when carrying out several other types of problems, **conversion factors** can be used. These factors are ratios constructed from valid relations between equivalent quantities.

## Learning Outcomes After studying this chapter, you should be able to:

- Distinguish among elements, compounds, and mixtures. (Section 1.2) *Related Exercises: 1.13, 1.14, 1.17*
- Identify symbols of common elements. (Section 1.2) *Related Exercises: 1.15, 1.16*
- Distinguish between chemical and physical changes. (Section 1.3) *Related Exercises: 1.19, 1.20, 1.21, 1.22*
- Distinguish between kinetic and potential energy. (Section 1.4) *Related Exercises: 1.27, 1.28*
- Calculate the kinetic energy of an object. (Section 1.4) *Related Exercises: 1.25, 1.26, 1.29, 1.30*
- Identify common metric prefixes. (Section 1.5) *Related Exercises: 1.31, 1.32*
- Demonstrate the use of significant figures, scientific notation, and SI units in calculations. (Section 1.6) *Related Exercises: 1.45, 1.46, 1.49, 1.50*
- Use appropriate SI units for defined quantities, and employ dimensional analysis in calculations. (Sections 1.5 and 1.7) *Related Exercises: 1.55, 1.56, 1.59, 1.60*

## Key Equations

- $w = F \times d$  [1.1] Work done by a force in the direction of displacement
- $E_k = \frac{1}{2}mv^2$  [1.2] Kinetic energy
- $K = ^\circ\text{C} + 273.15$  [1.3] Converting between Celsius ( $^\circ\text{C}$ ) and Kelvin (K) temperature scales
- $^\circ\text{C} = \frac{5}{9}(^\circ\text{F} - 32)$  or  $^\circ\text{F} = \frac{9}{5}(^\circ\text{C}) + 32$  [1.4] Converting between Celsius ( $^\circ\text{C}$ ) and Fahrenheit ( $^\circ\text{F}$ ) temperature scales
- $\text{Density} = \frac{\text{mass}}{\text{volume}}$  [1.5] Definition of density

## Exercises

### Visualizing Concepts

- 1.1** Which of the following figures represents (a) a pure element, (b) a mixture of two elements, (c) a pure compound, (d) a mixture of an element and a compound? (More than one picture might fit each description.) [Section 1.2]

- 1.2** Which of the following diagrams represents a chemical change? [Section 1.3]

- 1.3** Musical instruments like trumpets and trombones are made from an alloy called brass. Brass is composed of copper and zinc atoms and appears homogeneous under an optical microscope. The approximate composition of most brass objects is a 2:1 ratio of copper to zinc atoms, but the exact ratio varies somewhat from one piece of brass to another. (a) Would

you classify brass as an element, a compound, a homogeneous mixture, or a heterogeneous mixture? (b) Would it be correct to say that brass is a solution? [Section 1.2]

- 1.4** Consider the two spheres shown here, one made of silver and the other of aluminum. (a) What is the mass of each sphere in kg? (b) The force of gravity acting on an object is  $F = mg$ , where  $m$  is the mass of an object and  $g$  is the acceleration of gravity ( $9.8 \text{ m/s}^2$ ). How much work do you do on each sphere if you raise it from the floor to a height of 2.2 m? (c) Does the act of lifting the sphere off the ground increase the potential energy of the aluminum sphere by a larger, smaller, or same amount as the silver sphere? (d) If you release the spheres simultaneously, they will have the same velocity when they hit the ground. Will they have the same kinetic energy? If not, which sphere will have more kinetic energy? [Section 1.4]

- 1.5** Is the separation method used in brewing a cup of coffee best described as distillation, filtration, or chromatography? [Section 1.3]

- 1.6** Identify each of the following as measurements of length, area, volume, mass, density, time, or temperature: **(a)** 25 ps, **(b)** 374.2 mg, **(c)** 77 K, **(d)** 100,000 km<sup>2</sup>, **(e)** 1.06  $\mu$ m, **(f)** 16 nm<sup>2</sup>, **(g)** -78 °C, **(h)** 2.56 g/cm<sup>3</sup>, **(i)** 28 cm<sup>3</sup>. [Section 1.5]
- 1.7** **(a)** Three spheres of equal size are composed of aluminum (density = 2.70 g/cm<sup>3</sup>), silver (density = 10.49 g/cm<sup>3</sup>), and nickel (density = 8.90 g/cm<sup>3</sup>). List the spheres from lightest to heaviest. **(b)** Three cubes of equal mass are composed of gold (density = 19.32 g/cm<sup>3</sup>), platinum (density = 21.45 g/cm<sup>3</sup>), and lead (density = 11.35 g/cm<sup>3</sup>). List the cubes from smallest to largest. [Section 1.5]
- 1.8** The three targets from a rifle range shown below were produced by: **(A)** the instructor firing a newly acquired target rifle; **(B)** the instructor firing his personal target rifle; and **(C)** a student who has fired his target rifle only a few times. **(a)** Comment on the accuracy and precision for each of these three sets of results. **(b)** For the A and C results in the future to look like those in B, what needs to happen? [Section 1.6]

- 1.9** **(a)** What is the length of the pencil in the following figure if the ruler reads in centimeters? How many significant figures are there in this measurement? **(b)** An automobile speedometer with circular scales reading both miles per hour and kilometers per hour is shown. What speed is indicated, in both units? How many significant figures are in the measurements? [Section 1.6]

- 1.10** **(a)** How many significant figures should be reported for the volume of the metal bar shown here? **(b)** If the mass of the bar is 104.72 g, how many significant figures should be reported when its density is determined using the calculated volume? [Section 1.6]

- 1.11** Consider the jar of jelly beans in the photo. To get an estimate of the number of beans in the jar you weigh six beans and obtain masses of 3.15, 3.12, 2.98, 3.14, 3.02, and 3.09 g. Then you weigh the jar with all the beans in it, and obtain a mass of 2082 g. The empty jar has a mass of 653 g. Based on these data, estimate the number of beans in the jar. Justify the number of significant figures you use in your estimate. [Section 1.6]

- 1.12** The photo below shows a picture of an agate stone. Jack, who picked up the stone on the Lake Superior shoreline and polished it, insists that agate is a chemical compound. Ellen argues that it cannot be a compound. Discuss the relative merits of their positions. [Section 1.2]

## Classification and Properties of Matter (Sections 1.2 and 1.3)

- 1.13** Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: **(a)** rice pudding, **(b)** seawater, **(c)** magnesium, **(d)** crushed ice.
- 1.14** Classify each of the following as a pure substance or a mixture. If a mixture, indicate whether it is homogeneous or heterogeneous: **(a)** air, **(b)** tomato juice, **(c)** iodine crystals, **(d)** sand.
- 1.15** Give the chemical symbol or name for the following elements, as appropriate: **(a)** sulfur, **(b)** gold, **(c)** potassium, **(d)** chlorine, **(e)** copper, **(f)** U, **(g)** Ni, **(h)** Na, **(i)** Al, **(j)** Si.

- 1.16** Give the chemical symbol or name for each of the following elements, as appropriate: **(a)** carbon, **(b)** nitrogen, **(c)** titanium, **(d)** zinc, **(e)** iron, **(f)** P, **(g)** Ca, **(h)** He, **(i)** Pb, **(j)** Ag.
- 1.17** A solid white substance A is heated strongly in the absence of air. It decomposes to form a new white substance B and a gas C. The gas has exactly the same properties as the product obtained when carbon is burned in an excess of oxygen. Based on these observations, can we determine whether solids A and B and gas C are elements or compounds?
- 1.18** You are hiking in the mountains and find a shiny gold nugget. It might be the element gold, or it might be “fool’s gold,” which is a nickname for iron pyrite,  $\text{FeS}_2$ . Which of the following physical properties do you think would help determine if the shiny nugget is really gold—appearance, melting point, density, or physical state?
- 1.19** In the process of attempting to characterize a substance, a chemist makes the following observations: The substance is a silvery white, lustrous metal. It melts at  $649^\circ\text{C}$  and boils at  $1105^\circ\text{C}$ . Its density at  $20^\circ\text{C}$  is  $1.738\text{ g/cm}^3$ . The substance burns in air, producing an intense white light. It reacts with chlorine to give a brittle white solid. The substance can be pounded into thin sheets or drawn into wires. It is a good conductor of electricity. Which of these characteristics are physical properties, and which are chemical properties?
- 1.20** **(a)** Read the following description of the element zinc and indicate which are physical properties and which are chemical properties.

Zinc melts at  $420^\circ\text{C}$ . When zinc granules are added to dilute sulfuric acid, hydrogen is given off and the metal dissolves. Zinc has a hardness on the Mohs scale of 2.5 and a density of  $7.13\text{ g/cm}^3$  at  $25^\circ\text{C}$ . It reacts slowly with oxygen gas at elevated temperatures to form zinc oxide,  $\text{ZnO}$ .

**(b)** Which properties of zinc can you describe from the photo? Are these physical or chemical properties?

- 1.21** Label each of the following as either a physical process or a chemical process: **(a)** rusting of a metal can, **(b)** boiling a cup of water, **(c)** pulverizing an aspirin, **(d)** digesting a candy bar, **(e)** exploding of nitroglycerin.
- 1.22** A match is lit and held under a cold piece of metal. The following observations are made: **(a)** The match burns. **(b)** The metal gets warmer. **(c)** Water condenses on the metal. **(d)** Soot (carbon) is deposited on the metal. Which of these occurrences are due to physical changes, and which are due to chemical changes?
- 1.23** Which separation method is better suited for separating a solution of sugar and water into pure substances, filtration or distillation?
- 1.24** Two beakers contain clear, colorless liquids. When the contents of the beakers are mixed a white solid is formed. **(a)** Is this an example of a chemical or a physical change? **(b)** What would be the most convenient way to separate the newly formed white solid from the liquid mixture—filtration, distillation, or chromatography?

## The Nature of Energy (Section 1.4)

- 1.25** **(a)** Calculate the kinetic energy, in joules of a 1200-kg automobile moving at 18 m/s. **(b)** Convert this energy to calories.
- (c)** When the automobile brakes to a stop is the “lost” kinetic energy converted mostly to heat or to some form of potential energy?
- 1.26** **(a)** A baseball weighs 5.13 oz. What is the kinetic energy, in joules, of this baseball when it is thrown by a major league pitcher at 95.0 mi/h? **(b)** By what factor will the kinetic energy change if the speed of the baseball is decreased to 55.0 mi/h? **(c)** What happens to the kinetic energy when the baseball is caught by the catcher? Is it converted mostly to heat or to some form of potential energy?
- 1.27** Two positively charged particles are first brought close together and then released. Once released, the repulsion between particles causes them to move away from each other. **(a)** This is an example of potential energy being converted into what form of energy? **(b)** Does the potential energy of the two particles prior to release increase or decrease as the distance between them is increased.
- 1.28** For each of the following processes, does the potential energy of the object(s) increase or decrease? **(a)** The distance between two oppositely charged particles is increased. **(b)** Water is pumped from ground level to the reservoir of a water tower 30 m above the ground. **(c)** The bond in a chlorine molecule,  $\text{Cl}_2$ , is broken to form two chlorine atoms.
- 1.29** What is the kinetic energy and velocity of the aluminum sphere in Problem 1.4 at the moment it hits the ground? (Assume that energy is conserved during the fall and that 100% of the sphere’s initial potential energy is converted to kinetic energy by the time impact occurs.)
- 1.30** What is the kinetic energy and velocity of the silver sphere in Problem 1.4 at the moment it hits the ground? (Assume that energy is conserved during the fall and that 100% of the sphere’s initial potential energy is converted to kinetic energy by the time impact occurs.)

## Units of Measurement (Section 1.5)

- 1.31** What exponential notation do the following abbreviations represent? **(a)** d, **(b)** c, **(c)** f, **(d)**  $\mu$ , **(e)** M, **(f)** k, **(g)** n, **(h)** m, **(i)** p.
- 1.32** Use appropriate metric prefixes to write the following measurements without use of exponents: **(a)**  $2.3 \times 10^{-10}\text{ L}$ , **(b)**  $4.7 \times 10^{-6}\text{ g}$ , **(c)**  $1.85 \times 10^{-12}\text{ m}$ , **(d)**  $16.7 \times 10^6\text{ s}$ , **(e)**  $15.7 \times 10^3\text{ g}$ , **(f)**  $1.34 \times 10^{-3}\text{ m}$ , **(g)**  $1.84 \times 10^2\text{ cm}$ .
- 1.33** Make the following conversions: **(a)**  $72^\circ\text{F}$  to  $^\circ\text{C}$ , **(b)**  $216.7^\circ\text{C}$  to  $^\circ\text{F}$ , **(c)**  $233^\circ\text{C}$  to K, **(d)** 315 K to  $^\circ\text{F}$ , **(e)**  $2500^\circ\text{F}$  to K, **(f)** 0 K to  $^\circ\text{F}$ .
- 1.34** **(a)** The temperature on a warm summer day is  $87^\circ\text{F}$ . What is the temperature in  $^\circ\text{C}$ ? **(b)** Many scientific data are reported at  $25^\circ\text{C}$ . What is this temperature in kelvins and in degrees Fahrenheit? **(c)** Suppose that a recipe calls for an oven temperature of  $400^\circ\text{F}$ . Convert this temperature to degrees Celsius and to kelvins. **(d)** Liquid nitrogen boils at 77 K. Convert this temperature to degrees Fahrenheit and to degrees Celsius.
- 1.35** **(a)** A sample of tetrachloroethylene, a liquid used in dry cleaning that is being phased out because of its potential to cause cancer, has a mass of 40.55 g and a volume of 25.0 mL at  $25^\circ\text{C}$ . What is its density at this temperature? Will tetrachloroethylene float on water? (Materials that are less dense than water will float.) **(b)** Carbon dioxide ( $\text{CO}_2$ ) is a gas at room temperature and pressure. However, carbon dioxide can be put under pressure to become a “supercritical fluid” that is a much safer dry-cleaning agent than tetrachloroethylene. At a certain pressure, the density of supercritical  $\text{CO}_2$  is  $0.469\text{ g/cm}^3$ . What is the mass of a 25.0-mL sample of supercritical  $\text{CO}_2$  at this pressure?
- 1.36** **(a)** A cube of osmium metal 1.500 cm on a side has a mass of 76.31 g at  $25^\circ\text{C}$ . What is its density in  $\text{g/cm}^3$  at this temperature? **(b)** The density of titanium metal is  $4.51\text{ g/cm}^3$  at  $25^\circ\text{C}$ . What mass of titanium displaces 125.0 mL of water at  $25^\circ\text{C}$ ?

(c) The density of benzene at 15 °C is 0.8787 g/mL. Calculate the mass of 0.1500 L of benzene at this temperature.

- 1.37** (a) To identify a liquid substance, a student determined its density. Using a graduated cylinder, she measured out a 45-mL sample of the substance. She then measured the mass of the sample, finding that it weighed 38.5 g. She knew that the substance had to be either isopropyl alcohol (density 0.785 g/mL) or toluene (density 0.866 g/mL). What are the calculated density and the probable identity of the substance? (b) An experiment requires 45.0 g of ethylene glycol, a liquid whose density is 1.114 g/mL. Rather than weigh the sample on a balance, a chemist chooses to dispense the liquid using a graduated cylinder. What volume of the liquid should he use? (c) Is a graduated cylinder such as that shown in Figure 1.21 likely to afford the accuracy of measurement needed? (d) A cubic piece of metal measures 5.00 cm on each edge. If the metal is nickel, whose density is 8.90 g/cm<sup>3</sup>, what is the mass of the cube?
- 1.38** (a) After the label fell off a bottle containing a clear liquid believed to be benzene, a chemist measured the density of the liquid to verify its identity. A 25.0-mL portion of the liquid had a mass of 21.95 g. A chemistry handbook lists the density of benzene at 15 °C as 0.8787 g/mL. Is the calculated density in agreement with the tabulated value? (b) An experiment requires 15.0 g of cyclohexane, whose density at 25 °C is 0.7781 g/mL. What volume of cyclohexane should be used? (c) A spherical ball of lead has a diameter of 5.0 cm. What is the mass of the sphere if lead has a density of 11.34 g/cm<sup>3</sup>? (The volume of a sphere is  $(4/3)\pi r^3$ , where  $r$  is the radius.)
- 1.39** In the year 2013, an estimated amount of 36 billion metric tons (1 metric ton = 1000 kg) of carbon dioxide (CO<sub>2</sub>) was emitted worldwide due to fossil fuel combustion and cement production. Express this mass of CO<sub>2</sub> in grams without exponential notation, using an appropriate metric prefix.
- 1.40** Silicon for computer chips is grown in large cylinders called “boules” that are 300 mm in diameter and 2 m in length, as shown. The density of silicon is 2.33 g/cm<sup>3</sup>. Silicon wafers for making integrated circuits are sliced from a 2.0-m boule and are typically 0.75 mm thick and 300 mm in diameter. (a) How many wafers can be cut from a single boule? (b) What is the mass of a silicon wafer? (The volume of a cylinder is given by  $\pi r^2 h$ , where  $r$  is the radius and  $h$  is its height.)

- 1.41** Use of the British thermal unit (Btu) is common in some types of engineering work. A Btu is the amount of heat required to raise the temperature of 1 lb of water by 1 °F. Calculate the number of joules in a Btu.
- 1.42** A watt is a measure of power (the rate of energy change) equal to 1 J/s. (a) Calculate the number of joules in a kilowatt-hour. (b) An adult person radiates heat to the surroundings at about the same rate as a 100-watt electric incandescent light bulb. What is the total amount of energy in kcal radiated to the surroundings by an adult over a 24 h period?

### Uncertainty in Measurement (Section 1.6)

- 1.43** Indicate which of the following are exact numbers: (a) the mass of a 3- by 5-in. index card, (b) the number of ounces

in a pound, (c) the volume of a cup of Seattle’s Best coffee, (d) the number of inches in a mile, (e) the number of micro-seconds in a week, (f) the number of pages in this book.

- 1.44** Indicate which of the following are exact numbers: (a) the mass of a 32-oz can of coffee, (b) the number of students in your chemistry class, (c) the temperature of the surface of the Sun, (d) the mass of a postage stamp, (e) the number of milliliters in a cubic meter of water, (f) the average height of NBA basketball players.
- 1.45** What is the number of significant figures in each of the following measured quantities? (a) 601 kg, (b) 0.054 s, (c) 6.3050 cm, (d) 0.0105 L, (e)  $7.0500 \times 10^{-3} \text{ m}^3$ , (f) 400 g.
- 1.46** Indicate the number of significant figures in each of the following measured quantities: (a) 3.774 km, (b) 205 m<sup>2</sup>, (c) 1.700 cm, (d) 350.00 K, (e) 307.080 g, (f)  $1.3 \times 10^3 \text{ m/s}$ .
- 1.47** Round each of the following numbers to four significant figures and express the result in standard exponential notation: (a) 102.53070, (b) 656.980, (c) 0.008543210, (d) 0.000257870, (e) -0.0357202.
- 1.48** (a) The diameter of Earth at the equator is 7926.381 mi. Round this number to three significant figures and express it in standard exponential notation. (b) The circumference of Earth through the poles is 40,008 km. Round this number to four significant figures and express it in standard exponential notation.
- 1.49** Carry out the following operations and express the answers with the appropriate number of significant figures.  
(a)  $14.3505 + 2.65$  (b)  $952.7 - 140.7389$   
(c)  $(3.29 \times 10^4)(0.2501)$  (d)  $0.0588/0.677$
- 1.50** Carry out the following operations and express the answer with the appropriate number of significant figures.  
(a)  $320.5 - (6104.5/2.3)$   
(b)  $[(285.3 \times 10^5) - (1.200 \times 10^3)] \times 2.8954$   
(c)  $(0.0045 \times 20,000.0) + (2813 \times 12)$   
(d)  $863 \times [1255 - (3.45 \times 108)]$
- 1.51** You weigh an object on a balance and read the mass in grams according to the picture. How many significant figures are in this measurement?

- 1.52** You have a graduated cylinder that contains a liquid (see photograph). Write the volume of the liquid, in milliliters, using the proper number of significant figures.

## Dimensional Analysis (Section 1.7)

- 1.53** Using your knowledge of metric units, English units, and the information on the back inside cover, write down the conversion factors needed to convert (a) mm to nm, (b) mg to kg, (c) km to ft, (d) in.<sup>3</sup> to cm<sup>3</sup>.
- 1.54** Using your knowledge of metric units, English units, and the information on the back inside cover, write down the conversion factors needed to convert (a)  $\mu\text{m}$  to mm, (b) ms to ns, (c) mi to km, (d) ft<sup>3</sup> to L.
- 1.55** (a) A bumblebee flies with a ground speed of 15.2 m/s. Calculate its speed in km/hr. (b) The lung capacity of the blue whale is  $5.0 \times 10^3$  L. Convert this volume into gallons. (c) The Statue of Liberty is 151 ft tall. Calculate its height in meters. (d) Bamboo can grow up to 60.0 cm/day. Convert this growth rate into inches per hour.
- 1.56** (a) The speed of light in a vacuum is  $2.998 \times 10^8$  m/s. Calculate its speed in miles per hour. (b) The Sears Tower in Chicago is 1454 ft tall. Calculate its height in meters. (c) The Vehicle Assembly Building at the Kennedy Space Center in Florida has a volume of 3,666,500 m<sup>3</sup>. Convert this volume to liters and express the result in standard exponential notation. (d) An individual suffering from a high cholesterol level in her blood has 242 mg of cholesterol per 100 mL of blood. If the total blood volume of the individual is 5.2 L, how many grams of total blood cholesterol does the individual's body contain?
- 1.57** Perform the following conversions: (a) 5.00 days to s, (b) 0.0550 mi to m, (c) \$1.89/gal to dollars per liter, (d) 0.510 in./ms to km/hr, (e) 22.50 gal/min to L/s, (f) 0.02500 ft<sup>3</sup> to cm<sup>3</sup>.
- 1.58** Carry out the following conversions: (a) 0.105 in. to mm, (b) 0.650 qt to mL, (c) 8.75  $\mu\text{m/s}$  to km/hr, (d) 1.955 m<sup>3</sup> to yd<sup>3</sup> (e) \$3.99/lb to dollars per kg, (f) 8.75 lb/ft<sup>3</sup> to g/mL.
- 1.59** (a) How many liters of wine can be held in a wine barrel whose capacity is 31 gal? (b) The recommended adult dose of Elixophyllin®, a drug used to treat asthma, is 6 mg/kg of body mass. Calculate the dose in milligrams for a 185-lb person. (c) If an automobile is able to travel 400 km on 47.3 L of gasoline, what is the gas mileage in miles per gallon? (d) When the coffee is brewed according to directions, a pound of coffee beans yields 50 cups of coffee (4 cups = 1 qt). How many kg of coffee are required to produce 200 cups of coffee?
- 1.60** (a) If an electric car is capable of going 225 km on a single charge, how many charges will it need to travel from Seattle, Washington, to San Diego, California, a distance of 1257 mi, assuming that the trip begins with a full charge? (b) If a migrating loon flies at an average speed of 14 m/s, what is its average speed in mi/hr? (c) What is the engine piston displacement in liters of an engine whose displacement is listed as 450 in.<sup>3</sup>? (d) In March 1989, the *Exxon Valdez* ran aground and spilled 240,000 barrels of crude petroleum off the coast of Alaska. One barrel of petroleum is equal to 42 gal. How many liters of petroleum were spilled?
- 1.61** The density of air at ordinary atmospheric pressure and 25 °C is 1.19 g/L. What is the mass, in kilograms, of the air in a room that measures 14.5 ft  $\times$  16.5 ft  $\times$  8.0 ft?
- 1.62** The concentration of carbon monoxide in an urban apartment is 48  $\mu\text{g}/\text{m}^3$ . What mass of carbon monoxide in grams is present in a room measuring 10.6 ft  $\times$  14.8 ft  $\times$  20.5 ft?
- 1.63** Gold can be hammered into extremely thin sheets called gold leaf. An architect wants to cover a 100 ft  $\times$  82 ft ceiling with gold leaf that is five-millionths of an inch thick. The density of gold is 19.32 g/cm<sup>3</sup>, and gold costs \$1654 per troy ounce (1 troy ounce = 31.1034768 g). How much will it cost the architect to buy the necessary gold?
- 1.64** A copper refinery produces a copper ingot weighing 150 lb. If the copper is drawn into wire whose diameter is 7.50 mm, how many feet of copper can be obtained from the ingot? The density of copper is 8.94 g/cm<sup>3</sup>. (Assume that the wire is a cylinder whose volume  $V = \pi r^2 h$ , where  $r$  is its radius and  $h$  is its height or length.)

## Additional Exercises

- 1.65** Classify each of the following as a pure substance, a solution, or a heterogeneous mixture: (a) a gold ingot, (b) a cup of coffee, (c) a wood plank.
- 1.66** (a) Which is more likely to eventually be shown to be incorrect: an hypothesis or a theory? (b) A(n) \_\_\_\_\_ reliably predicts the behavior of matter, while a(n) \_\_\_\_\_ provides an explanation for that behavior.
- 1.67** A sample of ascorbic acid (vitamin C) is synthesized in the laboratory. It contains 1.50 g of carbon and 2.00 g of oxygen. Another sample of ascorbic acid isolated from citrus fruits contains 6.35 g of carbon. According to the law of constant composition, how many grams of oxygen does it contain?
- 1.68** Ethyl chloride is sold as a liquid (see photo) under pressure for use as a local skin anesthetic. Ethyl chloride boils at 12 °C at atmospheric pressure. When the liquid is sprayed onto the skin, it boils off, cooling and numbing the skin as it vaporizes. (a) What changes of state are involved in this use of ethyl chloride? (b) What is the boiling point of ethyl chloride in degrees Fahrenheit? (c) The bottle shown contains 103.5 mL of ethyl chloride. The density of ethyl chloride at 25 °C is 0.765 g/cm<sup>3</sup>. What is the mass of ethyl chloride in the bottle?

**1.69** Two students determine the percentage of lead in a sample as a laboratory exercise. The true percentage is 22.52%. The students' results for three determinations are as follows:

(1) 22.52, 22.48, 22.54

(2) 22.64, 22.58, 22.62

(a) Calculate the average percentage for each set of data and state which set is the more accurate based on the average.

(b) Precision can be judged by examining the average of the deviations from the average value for that data set. (Calculate the average value for each data set; then calculate the average value of the absolute deviations of each measurement from the average.) Which set is more precise?

**1.70** Is the use of significant figures in each of the following statements appropriate? (a) The 2005 circulation of *National Geographic* was 7,812,564. (b) On July 1, 2005, the population of Cook County, Illinois, was 5,303,683. (c) In the United States, 0.621% of the population has the surname Brown. (d) You calculate your grade point average to be 3.87562.

**1.71** What type of quantity (for example, length, volume, density) do the following units indicate? (a) mL, (b)  $\text{cm}^2$ , (c)  $\text{mm}^3$ , (d) mg/L, (e) ps, (f) nm, (g) K.

**1.72** Give the derived SI units for each of the following quantities in base SI units:

(a) acceleration = distance/time<sup>2</sup>

(b) force = mass  $\times$  acceleration

(c) work = force  $\times$  distance

(d) pressure = force/area

(e) power = work/time

(f) velocity = distance/time

(g) energy = mass  $\times$  (velocity)<sup>2</sup>

**1.73** The distance from Earth to the Moon is approximately 240,000 mi. (a) What is this distance in meters? (b) The peregrine falcon has been measured as traveling up to 350 km/hr in a dive. If this falcon could fly to the Moon at this speed, how many seconds would it take? (c) The speed of light is  $3.00 \times 10^8$  m/s. How long does it take for light to travel from Earth to the Moon and back again? (d) Earth travels around the Sun at an average speed of 29.783 km/s. Convert this speed to miles per hour.

**1.74** Which of the following would you characterize as a pure or nearly pure substance? (a) baking powder; (b) lemon juice; (c) propane gas, used in outdoor gas grills; (d) aluminum foil; (e) ibuprofen; (f) bourbon whiskey; (g) helium gas; (h) clear water pumped from a deep aquifer.

**1.75** The U.S. quarter has a mass of 5.67 g and is approximately 1.55 mm thick. (a) How many quarters would have to be stacked to reach 575 ft, the height of the Washington Monument? (b) How much would this stack weigh? (c) How much money would this stack contain? (d) The U.S. National Debt Clock showed the outstanding public debt to be \$16,213,166,914,811 on October 28, 2012. How many stacks like the one described would be necessary to pay off this debt?

**1.76** In the United States, water used for irrigation is measured in acre-feet. An acre-foot of water covers an acre to a depth of exactly 1 ft. An acre is 4840 yd<sup>2</sup>. An acre-foot is enough water to supply two typical households for 1.00 yr. (a) If desalinated water costs \$1950 per acre-foot, how much does desalinated water cost per liter? (b) How much would it cost one household per day if it were the only source of water?

**1.77** By using estimation techniques, determine which of the following is the heaviest and which is the lightest: a 5-lb bag of potatoes, a 5-kg bag of sugar, or 1 gal of water (density = 1.0 g/mL).

**1.78** Suppose you decide to define your own temperature scale with units of O, using the freezing point (13 °C) and boiling point (360 °C) of oleic acid, the main component of olive oil. If you set the freezing point of oleic acid as 0 °O and the boiling point as 100 °O, what is the freezing point of water on this new scale?

**1.79** The liquid substances mercury (density = 13.6 g/mL), water (1.00 g/mL), and cyclohexane (0.778 g/mL) do not form a solution when mixed but separate in distinct layers. Sketch how the liquids would position themselves in a test tube.

**1.80** Two spheres of equal volume are placed on the scales as shown. Which one is more dense?

**1.81** Water has a density of 0.997 g/cm<sup>3</sup> at 25 °C; ice has a density of 0.917 g/cm<sup>3</sup> at -10 °C. (a) If a soft-drink bottle whose volume is 1.50 L is completely filled with water and then frozen to -10 °C, what volume does the ice occupy? (b) Can the ice be contained within the bottle?

**1.82** A 32.65-g sample of a solid is placed in a flask. Toluene, in which the solid is insoluble, is added to the flask so that the total volume of solid and liquid together is 50.00 mL. The solid and toluene together weigh 58.58 g. The density of toluene at the temperature of the experiment is 0.864 g/mL. What is the density of the solid?

**1.83** A thief plans to steal a gold sphere with a radius of 28.9 cm from a museum. If the gold has a density of 19.3 g/cm<sup>3</sup>, what is the mass of the sphere in pounds? [The volume of a sphere is  $V = (4/3)\pi r^3$ .] Is the thief likely to be able to walk off with the gold sphere unassisted?

**1.84** Automobile batteries contain sulfuric acid, which is commonly referred to as "battery acid." Calculate the number of grams of sulfuric acid in 1.00 gal of battery acid if the solution has a density of 1.28 g/mL and is 38.1% sulfuric acid by mass.

**1.85** A 40-lb container of peat moss measures 14  $\times$  20  $\times$  30 in. A 40-lb container of topsoil has a volume of 1.9 gal. (a) Calculate the average densities of peat moss and topsoil in units of g/cm<sup>3</sup>. Would it be correct to say that peat moss is "lighter" than topsoil? (b) How many bags of peat moss are needed to cover an area measuring 15.0 ft  $\times$  20.0 ft to a depth of 3.0 in.?

**1.86** A package of aluminum foil contains 50 ft<sup>2</sup> of foil, which weighs approximately 8.0 oz. Aluminum has a density of 2.70 g/cm<sup>3</sup>. What is the approximate thickness of the foil in millimeters?

**1.87** The total rate at which power is used by humans worldwide is approximately 15 TW (terawatts). The solar flux averaged over the sunlit half of Earth is 680 W/m<sup>2</sup> (assuming no clouds). The area of Earth's disc as seen from the Sun is  $1.28 \times 10^{14}$  m<sup>2</sup>. The surface area of Earth is approximately 197,000,000 square miles. How much of Earth's surface would we need to cover with solar energy collectors to power the planet for use by all humans? Assume that the solar energy collectors can convert only 10% of the available sunlight into useful power.

- 1.88** In 2005, J. Robin Warren and Barry J. Marshall shared the Nobel Prize in Medicine for discovering the bacterium *Helicobacter pylori* and for establishing experimental proof that it plays a major role in gastritis and peptic ulcer disease. The story began when Warren, a pathologist, noticed that bacilli were associated with the tissues taken from patients suffering from ulcers. Look up the history of this case and describe Warren's first hypothesis. What sorts of evidence did it take to create a credible theory based on it?
- 1.89** A 25.0-cm-long cylindrical glass tube, sealed at one end, is filled with ethanol. The mass of ethanol needed to fill the tube is found to be 45.23 g. The density of ethanol is 0.789 g/mL. Calculate the inner diameter of the tube in centimeters.
- 1.90** Gold is alloyed (mixed) with other metals to increase its hardness in making jewelry. **(a)** Consider a piece of gold jewelry that weighs 9.85 g and has a volume of 0.675 cm<sup>3</sup>. The jewelry contains only gold and silver, which have densities of 19.3 and 10.5 g/cm<sup>3</sup>, respectively. If the total volume of the jewelry is the sum of the volumes of the gold and silver that it contains, calculate the percentage of gold (by mass) in the jewelry. **(b)** The relative amount of gold in an alloy is commonly expressed in units of carats. Pure gold is 24 carat, and the percentage of gold in an alloy is given as a percentage of this value. For example, an alloy that is 50% gold is 12 carat. State the purity of the gold jewelry in carats.
- 1.91** Paper chromatography is a simple but reliable method for separating a mixture into its constituent substances. You have a mixture of two vegetable dyes, one red and one blue, that you are trying to separate. You try two different chromatography procedures and achieve the separations shown in the figure. Which procedure worked better? Can you suggest a method to quantify how good or poor the separation was?

- 1.92** Judge the following statements as true or false. If you believe a statement to be false, provide a corrected version.
- (a)** Air and water are both elements.
  - (b)** All mixtures contain at least one element and one compound.
  - (c)** Compounds can be decomposed into two or more other substances; elements cannot.
  - (d)** Elements can exist in any of the three states of matter.
  - (e)** When yellow stains in a kitchen sink are treated with bleach water, the disappearance of the stains is due to a physical change.
  - (f)** A hypothesis is more weakly supported by experimental evidence than a theory.
  - (g)** The number 0.0033 has more significant figures than 0.033.
  - (h)** Conversion factors used in converting units always have a numerical value of one.
  - (i)** Compounds always contain at least two different elements.
- 1.93** You are assigned the task of separating a desired granular material with a density of 3.62 g/cm<sup>3</sup> from an undesired granular material that has a density of 2.04 g/cm<sup>3</sup>. You want to do this by shaking the mixture in a liquid in which the heavier material will fall to the bottom and the lighter material will float. A solid will float on any liquid that is more dense. Using an Internet-based source or a handbook of chemistry, find the densities of the following substances: carbon tetrachloride, hexane, benzene, and diiodomethane. Which of these liquids will serve your purpose, assuming no chemical interaction takes place between the liquid and the solids?
- 1.94** In 2009, a team from Northwestern University and Western Washington University reported the preparation of a new "spongy" material composed of nickel, molybdenum, and sulfur that excels at removing mercury from water. The density of this new material is 0.20 g/cm<sup>3</sup>, and its surface area is 1242 m<sup>2</sup> per gram of material. **(a)** Calculate the volume of a 10.0-mg sample of this material. **(b)** Calculate the surface area for a 10.0-mg sample of this material. **(c)** A 10.0-mL sample of contaminated water had 7.748 mg of mercury in it. After treatment with 10.0 mg of the new spongy material, 0.001 mg of mercury remained in the contaminated water. What percentage of the mercury was removed from the water? **(d)** What is the final mass of the spongy material after the exposure to mercury?

A photograph of a garden path covered in a dense carpet of small blue grape hyacinths. The path leads into the distance, flanked by lush green foliage. On the left side of the path, there are clumps of yellow daffodils and orange tulips. On the right side, there are more orange tulips. A large green triangle is overlaid on the top left corner of the image, containing a white number 2.

2

# ATOMS, MOLECULES, AND IONS

Take a moment to appreciate the great variety of colors, textures, and other properties in the materials that surround you—the array of colors in a flower garden like the one shown to the left, the texture of the fabric in your clothes, or the solubility of sugar in a cup of coffee. How can we explain the striking and seemingly infinite variety of properties of the materials that make up our world? Both carbon and sodium chloride can form transparent, colorless crystals, but table salt (NaCl) readily dissolves in water while diamonds (C) do not. Aluminum conducts electricity, but aluminum oxide does not. Paper burns in the presence of oxygen gas but not in the presence of nitrogen gas. What accounts for these differences? The answers to all such questions lie in the structures of atoms, which determine the physical and chemical properties of matter.

Although materials vary greatly in their properties, everything is formed from only about 100 different kinds of atoms. In a sense, these different atoms are like the 26 letters of the English alphabet that join in different combinations to form the immense number of words in our language. But what rules govern the ways in which atoms combine? How do the properties of a substance relate to the kinds of atoms it contains? Indeed, what is an atom like, and what makes the atoms of one element different from those of another?

In this chapter, we introduce the basic structure of atoms and discuss the formation of molecules and ions. This knowledge provides you with the foundation you need to understand the chapters that follow.

◀ **A FLOWER GARDEN.** A staggering diversity of form and function can be achieved in plants and animals despite the fact that only a half dozen or so elements account for the vast majority of molecules found in living organisms.

## WHAT'S AHEAD

- 2.1 ▶ The Atomic Theory of Matter** Learn how scientists were able to postulate that atoms are the smallest building block of matter, long before they could be seen directly.
- 2.2 ▶ The Discovery of Atomic Structure** Examine key experiments that led to the discovery of *electrons* and to the *nuclear model* of the atom.
- 2.3 ▶ The Modern View of Atomic Structure** Learn how *atomic number* and *mass number* can be used to express the number of each subatomic particle—protons, neutrons, and electrons—in a given atom.
- 2.4 ▶ Atomic Weights** Learn about the concept of *atomic weights* and how they are derived from the masses and abundances of individual atoms.
- 2.5 ▶ The Periodic Table** Examine the organization of the *periodic table*, in which elements are put in order of increasing atomic number and grouped by chemical similarity.
- 2.6 ▶ Molecules and Molecular Compounds** Explore the assemblies of atoms called *molecules* and learn how their compositions are represented by *empirical* and *molecular formulas*.
- 2.7 ▶ Ions and Ionic Compounds** Realize that atoms can gain or lose electrons to form *ions* and learn how to use the periodic table to predict the charges on ions as well as the empirical formulas of *ionic* compounds.
- 2.8 ▶ Naming Inorganic Compounds** Consider the systematic way in which substances are named, called *nomenclature*, and how this nomenclature is applied to inorganic compounds.
- 2.9 ▶ Some Simple Organic Compounds** Become familiar with simple families of organic compounds, compounds containing carbon and hydrogen, and the very basic nomenclature of these compounds.

## 2.1 | The Atomic Theory of Matter

Philosophers from the earliest times speculated about the nature of the fundamental “stuff” from which the world is made. Democritus (460–370 BCE) and other early Greek philosophers described the material world as made up of tiny indivisible particles that they called *atomos*, meaning “indivisible” or “uncuttable.” Later, however, Plato and Aristotle formulated the notion that there can be no ultimately indivisible particles, and the “atomic” view of matter faded for many centuries during which Aristotelean philosophy dominated Western culture.

The notion of **atoms** reemerged in Europe during the seventeenth century. As chemists learned to measure the amounts of elements that reacted with one another to form new substances, the ground was laid for an atomic theory that linked the idea of elements with the idea of atoms. That theory came from the work of John Dalton during the period from 1803 to 1807. Dalton’s atomic theory was based on four postulates (see [Figure 2.1](#)).

### Dalton’s Atomic Theory

1. Each element is composed of extremely small particles called atoms.

An atom of the element oxygen

An atom of the element nitrogen

2. All atoms of a given element are identical, but the atoms of one element are different from the atoms of all other elements.

Oxygen

Nitrogen

3. Atoms of one element cannot be changed into atoms of a different element by chemical reactions; atoms are neither created nor destroyed in chemical reactions.

Oxygen  Nitrogen

4. Compounds are formed when atoms of more than one element combine; a given compound always has the same relative number and kind of atoms.

► **Figure 2.1 Dalton’s atomic theory.**\* John Dalton (1766–1844), the son of a poor English weaver, began teaching at age 12. He spent most of his years in Manchester, where he taught both grammar school and college. His lifelong interest in meteorology led him to study gases, then chemistry, and eventually atomic theory. Despite his humble beginnings, Dalton gained a strong scientific reputation during his lifetime.

A good theory explains known facts; Dalton’s theory explained several laws of chemical combination known at the time.

- The *law of constant composition* [\(Section 1.2\)](#),\*\* based on postulate 4:

In a given compound, the relative numbers and kinds of atoms are constant.

- The **law of conservation of mass**, based on postulate 3:

The total mass of materials present after a chemical reaction is the same as the total mass present before the reaction.

\*Dalton, “Atomic Theory” 1844.

\*\*The short chainlike symbol ([\(Section 1.2\)](#)) that precedes the section reference indicates a link to ideas presented earlier in the text.

A good theory also predicts new facts; Dalton used his theory to deduce

- The **law of multiple proportions**:

If two elements A and B combine to form more than one compound, the masses of B that can combine with a given mass of A are in the ratio of small whole numbers.

We can illustrate this law by considering water and hydrogen peroxide, both of which consist of the elements hydrogen and oxygen. In forming water, 8.0 g of oxygen combines with 1.0 g of hydrogen. In forming hydrogen peroxide, 16.0 g of oxygen combines with 1.0 g of hydrogen. Thus, the ratio of the masses of oxygen per gram of hydrogen in the two compounds is 2:1. Using Dalton's atomic theory, we conclude that hydrogen peroxide contains twice as many atoms of oxygen per hydrogen atom than does water.

### Give It Some Thought

When carbon and oxygen react, two different compounds can form depending on the conditions. Compound A contains 1.333 g of oxygen per gram of carbon, whereas compound B contains 2.666 g of oxygen per gram of carbon.

- Does this observation illustrate the law of conservation of mass or the law of multiple proportions?
- If compound A has an equal number of oxygen and carbon atoms, what can we conclude about the composition of compound B?

## 2.2 | The Discovery of Atomic Structure

Dalton based his conclusions about atoms on chemical observations made in the laboratory. By assuming the existence of atoms, he was able to account for the laws of constant composition and of multiple proportions. But neither Dalton nor those who followed him during the century after his work was published had any direct evidence for the existence of atoms. Today, however, we can measure the properties of individual atoms and even provide images of them (Figure 2.2).

As scientists developed methods for probing the nature of matter, the supposedly indivisible atom began to show signs of a more complex structure, and today we know that the atom is composed of **subatomic particles**. Before we summarize the current model, we briefly consider a few of the landmark discoveries that led to that model. We will see that the atom is composed in part of electrically charged particles, some with a positive charge and some with a negative charge. As we discuss the development of our current model of the atom, keep in mind this fact: *Particles with the same charge repel one another, whereas particles with opposite charges attract one another.*

### Cathode Rays and Electrons

During the mid-1800s, scientists began to study electrical discharge through a glass tube pumped almost empty of air (Figure 2.3). When a high voltage was applied to the electrodes in the tube, radiation was produced between the electrodes. This radiation, called **cathode rays**, originated at the negative electrode and traveled to the positive electrode. Although the rays could not be seen, their presence was detected because they cause certain materials to *fluoresce*, or to give off light.

Experiments showed that cathode rays are deflected by electric or magnetic fields in a way consistent with there being a stream of negative electrical charge. The British scientist J. J. Thomson (1856–1940) observed that cathode rays are the same regardless of the identity of the cathode material. In a paper published in 1897, Thomson described cathode rays as streams of negatively charged particles that we now call **electrons**.

▲ **Figure 2.2** An image of the surface of silicon. The image was obtained by a technique called scanning tunneling microscopy. The color was added to the image by computer to help distinguish its features. Each gold sphere is a silicon atom.

## Go Figure

If the fluorescent screen were removed from the tube, would cathode rays still be generated? Would you be able to see them?

▲ Figure 2.3 Cathode-ray tube.

Thomson constructed a cathode-ray tube having a hole in the anode through which the cathode rays could pass. Electrically charged plates and a magnet were positioned perpendicular to the beam, and a fluorescent screen that would give off light when struck with a cathode ray was located at one end (Figure 2.4). Because the electron is a negatively charged particle, the electric field deflected the rays in one direction, and the magnetic field deflected them in the opposite direction. Thomson adjusted the strengths of the fields so that the effects balanced each other, allowing the electrons to travel in a straight path to the screen. Knowing the strengths that resulted in the straight path made it possible to calculate a value of  $1.76 \times 10^8$  coulombs\* per gram for the ratio of the electron's electrical charge to its mass.

## Go Figure

If no magnetic field were applied, would you expect the electron beam to be deflected upward or downward by the electric field?

▲ Figure 2.4 Cathode-ray tube with perpendicular magnetic and electric fields. The cathode rays (electrons) originate at the cathode and are accelerated toward the anode, which has a hole in its center. A narrow beam of electrons passes through the hole and travels to the fluorescent screen that glows when struck by a cathode ray.

\*The coulomb (C) is the SI unit for electrical charge.

### Give It Some Thought

Which of the following is an implication of Thomson's observation that the type of metal used to make the cathode does not matter? (a) The cathode rays do not originate in the cathode. (b) The particles that make up cathode rays must be present in all metals.

### Go Figure

Are the masses of the oil drops changed significantly when electrons accumulate on them?

▲ **Figure 2.5** Millikan's oil-drop experiment to measure the charge of the electron. Small drops of oil are allowed to fall between electrically charged plates. Millikan measured how varying the voltage between the plates affected the rate of fall. From these data he calculated the negative charge on the drops. Because the charge on any drop was always some integral multiple of  $1.602 \times 10^{-19} \text{ C}$ , Millikan deduced this value to be the charge of a single electron.

Once the charge-to-mass ratio of the electron was known, measuring either quantity allowed scientists to calculate the other. In 1909, Robert Millikan (1868–1953) of the University of Chicago succeeded in measuring the charge of an electron by performing the experiment described in **Figure 2.5**. He then calculated the mass of the electron by using his experimental value for the charge,  $1.602 \times 10^{-19} \text{ C}$ , and Thomson's charge-to-mass ratio,  $1.76 \times 10^8 \text{ C/g}$ :

$$\text{Electron mass} = \frac{1.602 \times 10^{-19} \text{ C}}{1.76 \times 10^8 \text{ C/g}} = 9.10 \times 10^{-28} \text{ g}$$

This result agrees well with the currently accepted value for the electron mass,  $9.10938 \times 10^{-28} \text{ g}$ . This mass is about 2000 times smaller than that of hydrogen, the lightest atom.

## Radioactivity

In 1896 the French scientist Henri Becquerel (1852–1908) discovered that a compound of uranium spontaneously emits high-energy radiation. This spontaneous emission of radiation is called **radioactivity**. At Becquerel's suggestion, Marie Curie (**Figure 2.6**) and her husband, Pierre, began experiments to identify and isolate the source of radioactivity in the compound. They concluded that it was the uranium atoms.

Further study of radioactivity, principally by the British scientist Ernest Rutherford, revealed three types of radiation: alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ). Rutherford (1871–1937) was a very important figure in this period of atomic science. After working at Cambridge University with J. J. Thomson, he moved to McGill University in Montreal, where he did research on radioactivity that led to his 1908 Nobel Prize in Chemistry. In 1907

▲ **Figure 2.6** Marie Skłodowska Curie (1867–1934). In 1903, Henri Becquerel, Marie Curie, and her husband, Pierre, were jointly awarded the Nobel Prize in Physics for their pioneering work on radioactivity (a term she introduced). In 1911, Marie Curie won a second Nobel Prize, this time in chemistry for her discovery of the elements polonium and radium.

## Go Figure

Which subatomic particle—proton, neutron, or electron—is equivalent to a  $\beta$  ray?  
 $\beta$  rays are deflected to a greater extent than  $\alpha$  rays because (a) they are lighter, or (b) they are more highly charged.

▲ Figure 2.7 Behavior of alpha ( $\alpha$ ), beta ( $\beta$ ), and gamma ( $\gamma$ ) rays in an electric field.

he returned to England as a faculty member at Manchester University, where he did his famous  $\alpha$ -particle scattering experiments, described below.

Rutherford showed that the paths of  $\alpha$  and  $\beta$  radiation are bent by an electric field, although in opposite directions; while  $\gamma$  radiation is unaffected by the field (Figure 2.7). From this finding he concluded that  $\alpha$  and  $\beta$  rays consist of fast-moving electrically charged particles. In fact,  $\beta$  particles are nothing more than high-speed electrons that can be considered the radioactive equivalent of cathode rays. Because of their negative charge, they are attracted to a positively charged plate. The  $\alpha$  particles have a positive charge and are attracted to a negative plate. In units of the charge of the electron,  $\beta$  particles have a charge of  $1^-$  and  $\alpha$  particles a charge of  $2^+$ . Each  $\alpha$  particle has a mass about 7400 times that of an electron. Gamma radiation is high-energy electromagnetic radiation similar to X rays; it does not consist of particles and it carries no charge.

## The Nuclear Model of the Atom

With growing evidence that the atom is composed of smaller particles, scientists gave attention to how the particles fit together. During the early 1900s, Thomson reasoned that because electrons contribute only a very small fraction of an atom's mass, they probably are responsible for an equally small fraction of the atom's size. He proposed that the atom consists of a uniform positive sphere of matter in which the mass is evenly distributed and in which the electrons are embedded like raisins in a pudding or seeds in a watermelon (Figure 2.8). This *plum-pudding model*, named after a traditional English dessert, was very short-lived.

In 1910, Rutherford was studying the angles at which  $\alpha$  particles were deflected, or *scattered*, as they passed through a thin sheet of gold foil (Figure 2.9). He discovered that almost all the particles passed directly through the foil without deflection, with a few particles deflected about  $1^\circ$ , consistent with Thomson's plum-pudding model. For the sake of completeness, Rutherford suggested that Ernest Marsden (1889–1970), an undergraduate student working in the laboratory, look for scattering at large angles. To everyone's surprise, a small amount of scattering was observed at large angles, with some particles scattered back in the direction from which they had come. The explanation for these results was not immediately obvious, but they were clearly inconsistent with Thomson's plum-pudding model.

Rutherford explained the results by postulating the **nuclear model** of the atom, in which most of the mass of each gold atom and all of its positive charge reside in a very small, extremely dense region that he called the **nucleus**. He postulated further that most of the volume of an atom is empty space in which electrons move around the nucleus. In the  $\alpha$ -scattering experiment, most of the particles passed through the foil unscattered because they did not encounter the minute nucleus of any gold atom. Occasionally, however, an  $\alpha$  particle came close to a gold nucleus. In such encounters, the

▲ Figure 2.8 J. J. Thomson's plum-pudding model of the atom. Ernest Rutherford and Ernest Marsden proved this model wrong.

▲ **Figure 2.9** Rutherford's  $\alpha$ -scattering experiment. When  $\alpha$  particles pass through a gold foil, most pass through undeflected but some are scattered, a few at very large angles. According to the plum-pudding model of the atom, the particles should experience only very minor deflections. The nuclear model of the atom explains why a few  $\alpha$  particles are deflected at large angles. Although the nuclear atom has been depicted here as a yellow sphere, it is important to realize that most of the space around the nucleus contains only the low-mass electrons.

repulsion between the highly positive charge of the gold nucleus and the positive charge of the  $\alpha$  particle was strong enough to deflect the particle, as shown in Figure 2.9.

Subsequent experiments led to the discovery of positive particles (**protons**) and neutral particles (**neutrons**) in the nucleus. Protons were discovered in 1919 by Rutherford and neutrons in 1932 by British scientist James Chadwick (1891–1972). Thus, the atom is composed of electrons, protons, and neutrons.

### Give It Some Thought

Would you expect the number of  $\alpha$  particles scattered at large angles in Rutherford's experiment to increase, decrease, or stay the same as the thickness of the gold foil increases?

## 2.3 | The Modern View of Atomic Structure

Since Rutherford's time, as physicists have learned more and more about atomic nuclei, the list of particles that make up nuclei has grown and continues to increase. You may have come across the names of some subatomic particles, such as quarks, leptons, and

### Go Figure

What is the approximate diameter of the nucleus in units of pm?

▲ **Figure 2.10** The structure of the atom. A cloud of rapidly moving electrons occupies most of the volume of the atom. The nucleus occupies a tiny region at the center of the atom and is composed of the protons and neutrons. The nucleus contains virtually all the mass of the atom.

bosons.\* As chemists, however, we can take a simple view of the atom because only three subatomic particles—the proton, neutron, and electron—have a bearing on chemical behavior.

As noted earlier, the charge of an electron is  $-1.602 \times 10^{-19}$  C. The charge of a proton is opposite in sign but equal in magnitude to that of an electron:  $+1.602 \times 10^{-19}$  C. The quantity  $1.602 \times 10^{-19}$  C is called the **electronic charge**. For convenience, the charges of atomic and subatomic particles are usually expressed as multiples of this charge rather than as coulombs. Thus, the charge of an electron is  $1-$  and that of a proton is  $1+$ . Neutrons are electrically neutral (which is how they received their name). *Every atom has an equal number of electrons and protons, so atoms have no net electrical charge.*

Protons and neutrons reside in the tiny nucleus of the atom. The vast majority of an atom's volume is the space in which the electrons reside (Figure 2.10). Most atoms have diameters between  $1 \times 10^{-10}$  m (100 pm) and  $5 \times 10^{-10}$  m (500 pm). A convenient non-SI unit of length used for atomic dimensions is the **angstrom** (Å), where  $1 \text{ Å} = 1 \times 10^{-10} \text{ m} = 100 \text{ pm}$ . Thus, atoms have diameters of approximately  $1 - 5 \text{ Å}$ . The diameter of a chlorine atom, for example, is 200 pm, or 2.0 Å.

Electrons are attracted to the protons in the nucleus by the electrostatic force that exists between particles of opposite electrical charge. In later chapters, we will see that the strength of the attractive forces between electrons and nuclei can be used to explain many of the differences among different elements.

### Give It Some Thought

- If an atom has 15 protons, how many electrons does it have?
- Where do the protons reside in an atom?

Atoms have extremely small masses. The mass of the heaviest known atom, for example, is approximately  $4 \times 10^{-22}$  g. Because it would be cumbersome to express such small masses in grams, we use the **atomic mass unit** (amu),\*\* where  $1 \text{ amu} = 1.66054 \times 10^{-24}$  g. A proton has a mass of 1.0073 amu, a neutron 1.0087 amu, and an electron  $5.486 \times 10^{-4}$  amu (Table 2.1). Because it takes 1836 electrons to equal the mass of one proton, and 1839 electrons to equal the mass of a single neutron, the nucleus accounts for nearly the entire mass of an atom.

**TABLE 2.1** Comparison of the Proton, Neutron, and Electron

| Particle | Charge            | Mass (amu)             |
|----------|-------------------|------------------------|
| Proton   | Positive ( $1+$ ) | 1.0073                 |
| Neutron  | None (neutral)    | 1.0087                 |
| Electron | Negative ( $1-$ ) | $5.486 \times 10^{-4}$ |

The diameter of an atomic nucleus is approximately  $10^{-4}$  Å, only a small fraction of the diameter of the atom as a whole. You can appreciate the relative sizes of the atom and its nucleus by imagining that if the hydrogen atom were as large as a football stadium, the nucleus would be the size of a small marble. Because the tiny nucleus carries most of the mass of the atom in such a small volume, it has an incredibly high density—on the order of  $10^{13}$ – $10^{14}$  g/cm<sup>3</sup>. A matchbox full of material of such density would weigh over 2.5 billion tons!

Figure 2.10 incorporates the features we have just discussed. Electrons play the major role in chemical reactions. The significance of representing the region containing

\*The electron is an elementary particle that cannot be divided into smaller particles, whereas protons and neutrons are made up of smaller particles called quarks.

\*\*The SI abbreviation for the atomic mass unit is u. We will use the more common abbreviation amu.

electrons as an indistinct cloud will become clear in later chapters when we consider the energies and spatial arrangements of the electrons. For now, however, we have all the information we need to discuss many topics that form the basis of everyday uses of chemistry.

## Atomic Numbers, Mass Numbers, and Isotopes

What makes an atom of one element different from an atom of another element? The atoms of each element have a *characteristic number of protons*. The number of protons in an atom of any particular element is called that element's **atomic number**. Because an atom has no net electrical charge, the number of electrons it contains must equal the number of protons. All atoms of carbon, for example, have six protons and six electrons, whereas all atoms of oxygen have eight protons and eight electrons. Thus, carbon has atomic number 6, and oxygen has atomic number 8. The atomic number of each element is listed with the name and symbol of the element on the front inside cover of the text.

Atoms of a given element can differ in the number of neutrons they contain and, consequently, in mass. For example, while most atoms of carbon have six neutrons, some have more and some have less. The symbol  $^{12}_6\text{C}$  (read “carbon twelve,” carbon-12) represents the carbon atom containing six protons and six neutrons, whereas carbon atoms that contain six protons and eight neutrons have mass number 14, are represented as  $^{14}_6\text{C}$  and are referred to as carbon-14.

### Sample Exercise 2.1

#### Atomic Size

The diameter of a U.S. dime is 17.9 mm, and the diameter of a silver atom is 2.88 Å. How many silver atoms could be arranged side by side across the diameter of a dime?

#### SOLUTION

The unknown is the number of silver (Ag) atoms. Using the relationship 1 Ag atom = 2.88 Å as a conversion factor relating number of atoms and distance, we start with the diameter of the dime, first converting this distance into angstroms and then using the diameter of the Ag atom to convert distance to number of Ag atoms:

$$\begin{aligned}\text{Ag atoms} &= (17.9 \text{ mm}) \left( \frac{10^{-3} \text{ m}}{1 \text{ mm}} \right) \left( \frac{1 \text{ Å}}{10^{-10} \text{ m}} \right) \left( \frac{1 \text{ Ag atom}}{2.88 \text{ Å}} \right) \\ &= 6.22 \times 10^7 \text{ Ag atoms}\end{aligned}$$

That is, 62.2 million silver atoms could sit side by side across a dime!

#### Practice Exercise 1

Which of the following factors determines the size of an atom? (a) the volume of the nucleus (b) the volume of space occupied by the electrons of the atom (c) the volume of a single electron, multiplied by the number of electrons in the atom (d) the total nuclear charge (e) the total mass of the electrons surrounding the nucleus

#### Practice Exercise 2

The diameter of a carbon atom is 1.54 Å. (a) Express this diameter in picometers. (b) How many carbon atoms could be aligned side by side across the width of a pencil line that is 0.20 mm wide?

## A CLOSER LOOK Basic Forces

Four basic forces are known in nature: (1) gravitational, (2) electromagnetic, (3) strong nuclear, and (4) weak nuclear. *Gravitational forces* are attractive forces that act between all objects in proportion to their masses. Gravitational forces between atoms or between subatomic particles are so small that they are of no chemical significance.

*Electromagnetic forces* are attractive or repulsive forces that act between either electrically charged or magnetic objects. The magnitude of the electric force between two charged particles is given by *Coulomb's law*:  $F = kQ_1Q_2/d^2$ , where  $Q_1$  and  $Q_2$  are the magnitudes of the charges on the two particles,  $d$  is the distance between their centers, and  $k$  is a constant determined by the units for  $Q$  and  $d$ .  (Section 1.4) A negative value for the force indicates attraction, whereas a positive value indicates repulsion. Electric forces are of primary importance in determining the chemical properties of elements.

All nuclei except those of hydrogen atoms contain two or more protons. Because like charges repel, electrical repulsion would cause the protons to fly apart if the *strong nuclear force* did not keep them together. As the name implies, this force can be quite strong but only when particles are extremely close together, as are the protons and neutrons in a nucleus. At this distance, the attractive strong nuclear force is stronger than the positive-positive repulsive electric force and holds the nucleus together.

The *weak nuclear force* is weaker than the electric force and the strong nuclear force but stronger than the gravitational force. We are aware of its existence only because it shows itself in certain types of radioactivity.

**Related Exercise: 2.114**

The atomic number is indicated by the subscript; the superscript, called the **mass number**, is the number of protons plus neutrons in the atom:

Because all atoms of a given element have the same atomic number, the subscript is redundant and is often omitted. Thus, the symbol for carbon-12 can be represented simply as  $^{12}\text{C}$ .

Atoms with identical atomic numbers but different mass numbers (that is, the same number of protons but different numbers of neutrons) are called **isotopes** of one another. Several isotopes of carbon are listed in Table 2.2. We will generally use the notation with superscripts only when referring to a particular isotope of an element. It is important to keep in mind that the isotopes of any given element are all alike chemically. A carbon dioxide molecule that contains a  $^{13}\text{C}$  atom behaves for all practical purposes identically to one that contains a  $^{12}\text{C}$  atom.

TABLE 2.2 Some Isotopes of Carbon<sup>a</sup>

| Symbol          | Number of Protons | Number of Electrons | Number of Neutrons |
|-----------------|-------------------|---------------------|--------------------|
| $^{11}\text{C}$ | 6                 | 6                   | 5                  |
| $^{12}\text{C}$ | 6                 | 6                   | 6                  |
| $^{13}\text{C}$ | 6                 | 6                   | 7                  |
| $^{14}\text{C}$ | 6                 | 6                   | 8                  |

<sup>a</sup> Almost 99% of the carbon found in nature is  $^{12}\text{C}$ .

## Sample Exercise 2.2

### Determining the Number of Subatomic Particles in Atoms

How many protons, neutrons, and electrons are in an atom of (a)  $^{197}\text{Au}$ , (b) strontium-90?

#### SOLUTION

(a) The superscript 197 is the mass number (protons + neutrons). According to the list of elements given on the front inside cover, gold has atomic number 79. Consequently, an atom of  $^{197}\text{Au}$  has 79 protons, 79 electrons, and  $197 - 79 = 118$  neutrons. (b) The atomic number of strontium is 38. Thus, all atoms of this element have 38 protons and 38 electrons. The strontium-90 isotope has  $90 - 38 = 52$  neutrons.

#### Practice Exercise 1

Which of these atoms has the largest number of neutrons? (a)  $^{148}\text{Eu}$  (b)  $^{157}\text{Dy}$  (c)  $^{149}\text{Nd}$  (d)  $^{162}\text{Ho}$  (e)  $^{159}\text{Gd}$

#### Practice Exercise 2

How many protons, neutrons, and electrons are in an atom of (a)  $^{138}\text{Ba}$ , (b) phosphorus-31?

## Sample Exercise 2.3

### Writing Symbols for Atoms

Magnesium has three isotopes with mass numbers 24, 25, and 26. (a) Write the complete chemical symbol (superscript and subscript) for each. (b) How many neutrons are in an atom of each isotope?

#### SOLUTION

(a) Magnesium has atomic number 12, so all atoms of magnesium contain 12 protons and 12 electrons. The three isotopes are therefore represented by  $^{24}_{12}\text{Mg}$ ,  $^{25}_{12}\text{Mg}$ , and  $^{26}_{12}\text{Mg}$ . (b) The number of neutrons in each isotope is the mass number minus the number of protons. The numbers of neutrons in an atom of each isotope are therefore 12, 13, and 14, respectively.

#### Practice Exercise 1

Which of the following is an incorrect representation for a neutral atom? (a)  $^6_3\text{Li}$  (b)  $^{13}_6\text{C}$  (c)  $^{63}_{30}\text{Cu}$  (d)  $^{30}_{13}\text{P}$  (e)  $^{108}_{47}\text{Ag}$

#### Practice Exercise 2

Give the complete chemical symbol for the atom that contains 82 protons, 82 electrons, and 126 neutrons.

## 2.4 | Atomic Weights

Atoms are small pieces of matter, so they have mass. In this section, we discuss the mass scale used for atoms and introduce the concept of *atomic weights*.

### The Atomic Mass Scale

Scientists of the nineteenth century were aware that atoms of different elements have different masses. They found, for example, that each 100.0 g of water contains 11.1 g of hydrogen and 88.9 g of oxygen. Thus, water contains  $88.9/11.1 = 8$  times as much oxygen, by mass, as hydrogen. Once scientists understood that water contains two hydrogen atoms for each oxygen atom, they concluded that an oxygen atom must have  $2 \times 8 = 16$  times as much mass as a hydrogen atom. Hydrogen, the lightest atom, was arbitrarily assigned a relative mass of 1 (no units). Atomic masses of other elements were at first determined relative to this value. Thus, oxygen was assigned an atomic mass of 16.

Today we can determine the masses of individual atoms with a high degree of accuracy. For example, we know that the  $^1\text{H}$  atom has a mass of  $1.6735 \times 10^{-24}$  g and the  $^{16}\text{O}$  atom has a mass of  $2.6560 \times 10^{-23}$  g. As we noted in Section 2.3, it is convenient to use the **atomic mass unit** when dealing with these extremely small masses:

$$1 \text{ amu} = 1.66054 \times 10^{-24} \text{ g} \quad \text{and} \quad 1 \text{ g} = 6.02214 \times 10^{23} \text{ amu}$$

The atomic mass unit is presently defined by assigning a mass of exactly 12 amu to a chemically unbound atom of the  $^{12}\text{C}$  isotope of carbon. In these units, an  $^1\text{H}$  atom has a mass of 1.0078 amu and an  $^{16}\text{O}$  atom has a mass of 15.9949 amu.

#### Give It Some Thought

To how many significant figures would you need to express the mass of an oxygen-16 atom in amu to notice the change in mass that occurs when it gains an electron?

### Atomic Weight

Most elements occur in nature as mixtures of isotopes. We can determine the *average atomic mass* of an element, usually called the element's **atomic weight**, by summing (indicated by the Greek sigma,  $\Sigma$ ) over the masses of its isotopes multiplied by their relative abundances:

$$\text{Atomic weight} = \sum_{\substack{\text{over all} \\ \text{isotopes of} \\ \text{the element}}} [(\text{isotope mass}) \times (\text{fractional isotope abundance})] \quad [2.1]$$

Naturally occurring carbon, for example, is composed of 98.93%  $^{12}\text{C}$  and 1.07%  $^{13}\text{C}$ . The masses of these isotopes are 12 amu (exactly) and 13.00335 amu, respectively, making the atomic weight of carbon

$$(0.9893)(12 \text{ amu}) + (0.0107)(13.00335 \text{ amu}) = 12.01 \text{ amu}$$

The atomic weights of the elements are listed in both the periodic table and the table of elements on the front inside cover of this text.

#### Give It Some Thought

Two isotopes of boron are found in nature:  $^{10}\text{B}$  has a mass of 10.01 amu, and  $^{11}\text{B}$  has a mass of 11.01 amu. Use the atomic weight of boron found in the periodic table to determine which isotope is more abundant,  $^{10}\text{B}$  or  $^{11}\text{B}$ .

## Sample Exercise 2.4

### Calculating the Atomic Weight of an Element from Isotopic Abundances

Naturally occurring chlorine is 75.78%  $^{35}\text{Cl}$  (atomic mass 34.969 amu) and 24.22%  $^{37}\text{Cl}$  (atomic mass 36.966 amu). Calculate the atomic weight of chlorine.

#### SOLUTION

We can calculate the atomic weight by multiplying the abundance of each isotope by its mass and summing these products. Because  $75.78\% = 0.7578$  and  $24.22\% = 0.2422$ , we have

$$\begin{aligned}\text{Atomic weight} &= (0.7578)(34.969 \text{ amu}) + (0.2422)(36.966 \text{ amu}) \\ &= 26.50 \text{ amu} + 8.953 \text{ amu} \\ &= 35.45 \text{ amu}\end{aligned}$$

This answer makes sense: The atomic weight, which is actually the average atomic mass, is between the masses of the two isotopes and is closer to the value of  $^{35}\text{Cl}$ , the more abundant isotope.

#### Practice Exercise 1

There are two stable isotopes of copper found in nature,  $^{63}\text{Cu}$  and  $^{65}\text{Cu}$ . If the atomic weight of copper Cu is 63.546 amu, which of the following statements are true?

- (a)  $^{65}\text{Cu}$  contains two more protons than  $^{63}\text{Cu}$ .
- (b)  $^{63}\text{Cu}$  must be more abundant than  $^{65}\text{Cu}$ .
- (c) All copper atoms have a mass of 63.546 amu.

#### Practice Exercise 2

Three isotopes of silicon occur in nature:  $^{28}\text{Si}$  (92.23%), atomic mass 27.97693 amu;  $^{29}\text{Si}$  (4.68%), atomic mass 28.97649 amu; and  $^{30}\text{Si}$  (3.09%), atomic mass 29.97377 amu. Calculate the atomic weight of silicon.

## A CLOSER LOOK The Mass Spectrometer

The most accurate means for determining atomic weights is provided by the **mass spectrometer** (Figure 2.11). There are various designs of mass spectrometers, but they all operate on similar principles. The first step is to get atoms or molecules into the gas phase. Sometimes the sample to be analyzed is already a gas, whereas in other cases heating, application of an electric field, or a pulse of laser light may be needed to create gas-phase atoms or molecules. Next, the gas-phase species must be converted to positively charged particles called **ions**. There are many approaches to creating ions, including bombardment with beams of high-energy electrons or chemical reactions with other gas-phase molecules. Once gas-phase ions have been produced, they are accelerated toward a negatively charged grid. After the ions pass through the grid, they encounter two slits that allow only a narrow beam of ions to pass. This beam then passes between the poles of a magnet, which deflects the ions into a curved path. For ions with the same charge, the extent of deflection depends on mass—the more massive the ion, the less the deflection. The ions are thereby separated according to their masses. By changing the strength of the magnetic field or the

accelerating voltage on the grid, ions of various masses can be selected to enter the detector.

A graph of the intensity of the detector signal versus ion atomic mass is called a **mass spectrum** (Figure 2.12). Analysis of a mass spectrum gives both the masses of the ions reaching the detector and their relative abundances, which are obtained from the signal intensities. Knowing the atomic mass and the abundance of each isotope allows us to calculate the atomic weight of an element, as shown in Sample Exercise 2.4.

Mass spectrometers are used extensively today to identify chemical compounds and analyze mixtures of substances. Any molecule that loses electrons can fall apart, forming an array of positively charged fragments. The mass spectrometer measures the masses of these fragments, producing a chemical “fingerprint” of the molecule and providing clues about how the atoms were connected in the original molecule. Thus, a chemist might use this technique to determine the molecular structure of a newly synthesized compound, to analyze proteins in the human genome, or to identify a pollutant in the environment.

**Related Exercises:** 2.37, 2.38, 2.40, 2.88, 2.98, 2.99

▲ **Figure 2.11** A mass spectrometer. Cl atoms are first ionized to form  $\text{Cl}^+$  ions, accelerated with an electric field, and finally their path is directed by a magnetic field. The paths of the ions of the two Cl isotopes diverge as they pass through the field.

▲ **Figure 2.12** Mass spectrum of atomic chlorine. The fractional abundances of the isotopes  $^{35}\text{Cl}$  and  $^{37}\text{Cl}$  are indicated by the relative signal intensities of the beams reaching the detector of the mass spectrometer.

## 2.5 | The Periodic Table

As the list of known elements expanded during the early 1800s, attempts were made to find patterns in chemical behavior. These efforts culminated in the development of the periodic table in 1869. We will have much to say about the periodic table in later chapters, but it is so important and useful that you should become acquainted with it now. You will quickly learn that *the periodic table is the most significant tool that chemists use for organizing and remembering chemical facts.*

Many elements show strong similarities to one another. The elements lithium (Li), sodium (Na), and potassium (K) are all soft, very reactive metals, for example. The elements helium (He), neon (Ne), and argon (Ar) are all nonreactive gases. If the elements are arranged in order of increasing atomic number, their chemical and physical properties show a repeating, or *periodic*, pattern. For example, each of the soft, reactive metals—lithium, sodium, and potassium—comes immediately after one of the nonreactive gases—helium, neon, and argon, respectively—as shown in **Figure 2.13**.

The arrangement of elements in order of increasing atomic number, with elements having similar properties placed in vertical columns, is known as the **periodic table** (**Figure 2.14**). The table shows the atomic number and atomic symbol for each element, and the atomic weight is often given as well, as in this typical entry for potassium:

|         |                 |
|---------|-----------------|
| 19      | ← Atomic number |
| K       | ← Atomic symbol |
| 39.0983 | ← Atomic weight |

You might notice slight variations in periodic tables from one book to another or between those in the lecture hall and in the text. These are simply matters of style, or they might concern the particular information included. There are no fundamental differences.

The horizontal rows of the periodic table are called **periods**. The first period consists of only two elements, hydrogen (H) and helium (He). The second and third periods consist of eight elements each. The fourth and fifth periods contain 18 elements. The sixth and seventh periods have 32 elements each, but in order to fit on a page 14 of the elements from each period (atomic numbers 57–70 and 89–102) appear at the bottom of the table.

The vertical columns are **groups**. The way in which the groups are labeled is somewhat arbitrary. Three labeling schemes are in common use, two of which are shown in Figure 2.14.

- The top set of labels, which have A and B designations, is widely used in North America. Roman numerals, rather than Arabic ones, are often employed in this scheme. Group 7A, for example, is often labeled VIIA.
- Europeans use a similar convention that assigns the A and B labels differently.
- In an effort to eliminate confusion, the International Union of Pure and Applied Chemistry (IUPAC) has proposed a convention that numbers the groups from 1 through 18 with no A or B designations, as shown in Figure 2.14.

▲ Figure 2.14 Periodic table of elements.

We will use the traditional North American convention with Arabic numerals and the letters A and B.

Elements in a group often exhibit similarities in physical and chemical properties. For example, the “coinage metals”—copper (Cu), silver (Ag), and gold (Au)—belong to group 1B. These elements are less reactive than most metals, which is why they have been traditionally used throughout the world to make coins. Many other groups in the periodic table also have names, listed in Table 2.3.

We will learn in Chapters 6 and 7 that elements in a group have similar properties because they have the same arrangement of electrons at the periphery of their atoms. However, we need not wait until then to make good use of the periodic table; after all, the chemists who developed the table knew nothing about electrons! We can use the table, as they intended, to correlate behaviors of elements and to help us remember many facts.

The color code of Figure 2.14 shows that, except for hydrogen, all the elements on the left and in the middle of the table are **metallic elements**, or **metals**. All the metallic elements share characteristic properties, such as luster and high electrical and heat conductivity, and all of them except mercury (Hg) are solid at room temperature.\*

TABLE 2.3 Names of Some Groups in the Periodic Table

| Group | Name                  | Elements               |
|-------|-----------------------|------------------------|
| 1A    | Alkali metals         | Li, Na, K, Rb, Cs, Fr  |
| 2A    | Alkaline earth metals | Be, Mg, Ca, Sr, Ba, Ra |
| 6A    | Chalcogens            | O, S, Se, Te, Po       |
| 7A    | Halogens              | F, Cl, Br, I, At       |
| 8A    | Noble gases           | He, Ne, Ar, Kr, Xe, Rn |

\*All metals become liquids if heated sufficiently. Hg simply has the lowest melting point of any metallic element. Although sodium (Na), potassium (K), rubidium (Rb), cesium (Cs), and gallium (Ga) are solids at room temperature, they all melt at temperatures below 100 °C.

## A CLOSER LOOK What Are Coins Made Of?

Copper, silver, and gold were traditionally employed to make coins, but modern coins are typically made from other metals (Figure 2.15). To be useful for coinage, a metal, or combination of metals (called an *alloy*), must be corrosion resistant. It must also be hard enough to withstand rough usage and yet be of a consistency that permits machines to accurately stamp the coins. Some metals that might otherwise make fine coins—for example, manganese (Mn)—are ruled out because they make the coins too hard to stamp. A third criterion is that the value of the metal in the coin should not be as great as the face value of the coin.

This last criterion has led to several changes in the composition of U.S. coins over the past century. The U.S. Mint ceased producing gold coins in 1933 during the Great Depression. In 1964, a silver crisis caused the replacement of silver in quarters and dimes. Finally, in 1982, the composition of the penny was changed from nearly pure copper to copper-plated zinc. If pennies were made today from pure copper, the metal would be worth more than a penny, thus inviting smelters to melt down the coins for the value of the metal.

One of the traditional alloys for making coins is a mixture of copper and nickel. Today only the U.S. nickel is made from this alloy, called cupronickel, which consists of 75% copper and 25% nickel. The modern U.S. dollar coin, often referred to as the silver dollar,

doesn't contain any silver. It consists of copper (88.5%), zinc (6.0%), manganese (3.5%), and nickel (2.0%).

**Related Exercises: 2.103, 2.104**

▲ **Figure 2.15** The US quarter dollar is made from an alloy that is 91.67% Cu and 8.33% Ni.

The metals are separated from the **nonmetallic elements**, or **nonmetals**, by a stepped line that runs from boron (B) to astatine (At). (Note that hydrogen, although on the left side of the table, is a nonmetal.) At room temperature and pressure, some of the nonmetals are gaseous, some are solid, and one is liquid. Nonmetals generally differ from metals in appearance (Figure 2.16) and in other physical properties. Many of the elements that lie along the line that separates metals from nonmetals have properties that fall between those of metals and nonmetals. These elements are often referred to as **metalloids**.

### Go Figure

Name two ways in which the metals shown here differ in general appearance from the nonmetals.

#### Metals

#### Nonmetals

▲ **Figure 2.16** Examples of metals and nonmetals.

### Give It Some Thought

Chlorine is a halogen (Table 2.3). Locate this element in the periodic table.

- What is its symbol?
- In which period and in which group is the element located?
- What is its atomic number?
- Is it a metal or nonmetal?

**Sample Exercise 2.5****Using the Periodic Table**

Which two of these elements would you expect to show the greatest similarity in chemical and physical properties: B, Ca, F, He, Mg, P?

**SOLUTION**

Elements in the same group of the periodic table are most likely to exhibit similar properties. We therefore expect Ca and Mg to be most alike because they are in the same group (2A, the alkaline earth metals).

**Practice Exercise 1**

A biochemist who is studying the properties of certain sulfur (S)-containing compounds in the body wonders whether

trace amounts of another nonmetallic element might have similar behavior. To which element should she turn her attention? (a) F (b) As (c) Se (d) Cr (e) P

**Practice Exercise 2**

Locate Na (sodium) and Br (bromine) in the periodic table. Give the atomic number of each and classify each as metal, metalloid, or nonmetal.

## 2.6 | Molecules and Molecular Compounds

Even though the atom is the smallest representative sample of an element, only the noble-gas elements are normally found in nature as isolated atoms. Most matter is composed of molecules or ions. We examine molecules here and ions in Section 2.7.

### Molecules and Chemical Formulas

Several elements are found in nature in molecular form—two or more of the same type of atom bound together. For example, most of the oxygen in air consists of molecules that contain two oxygen atoms. As we saw in Section 1.2, we represent this molecular oxygen by the **chemical formula**  $O_2$  (read “oh two”). The subscript tells us that two oxygen atoms are present in each molecule. A molecule made up of two atoms is called a **diatomic molecule**.

Oxygen also exists in another molecular form known as *ozone*. Molecules of ozone consist of three oxygen atoms, making the chemical formula  $O_3$ . Even though “normal” oxygen ( $O_2$ ) and ozone ( $O_3$ ) are both composed only of oxygen atoms, they exhibit very different chemical and physical properties. For example,  $O_2$  is essential for life, but  $O_3$  is toxic;  $O_2$  is odorless, whereas  $O_3$  has a sharp, pungent smell.

The elements that normally occur as diatomic molecules are hydrogen, oxygen, nitrogen, and the halogens ( $H_2$ ,  $O_2$ ,  $N_2$ ,  $F_2$ ,  $Cl_2$ ,  $Br_2$ , and  $I_2$ ). Except for hydrogen, these diatomic elements are clustered on the right side of the periodic table.

Compounds composed of molecules contain more than one type of atom and are called **molecular compounds**. A molecule of the compound methane, for example, consists of one carbon atom and four hydrogen atoms and is therefore represented by the chemical formula  $CH_4$ . Lack of a subscript on the C indicates one atom of C per methane molecule. Several common molecules of both elements and compounds are shown in **Figure 2.17**. Notice how the composition of each substance is given by its chemical formula. Notice also that these substances are composed only of nonmetallic elements.

*Most of the molecular substances we will encounter contain only nonmetals.*

### Molecular and Empirical Formulas

Chemical formulas that indicate the actual numbers of atoms in a molecule are called **molecular formulas**. (The formulas in Figure 2.17 are molecular formulas.) Chemical formulas that give only the relative number of atoms of each type in a molecule are called **empirical formulas**. The subscripts in an empirical formula are always the smallest possible whole-number ratios. The molecular formula for hydrogen peroxide is  $H_2O_2$ , for example, whereas its empirical formula is HO. The molecular formula for ethylene is

**▲ Figure 2.17 Molecular models.** Notice how the chemical formulas of these simple molecules correspond to their compositions.

$\text{C}_2\text{H}_4$ , and its empirical formula is  $\text{CH}_2$ . For many substances, the molecular formula and the empirical formula are identical, as in the case of water,  $\text{H}_2\text{O}$ .

### Give It Some Thought

Consider the following four formulas:  $\text{SO}_2$ ,  $\text{B}_2\text{H}_6$ ,  $\text{CO}$ ,  $\text{C}_4\text{H}_2\text{O}_2$ . Which of these formulas could be (a) only an empirical formula, (b) only a molecular formula, (c) either a molecular or an empirical formula?

Whenever we know the molecular formula of a compound, we can determine its empirical formula. The converse is not true, however. If we know the empirical formula of a substance, we cannot determine its molecular formula unless we have more information. So why do chemists bother with empirical formulas? As we will see in Chapter 3, certain common methods of analyzing substances lead to the empirical formula only. For example, if you decomposed hydrogen peroxide  $\text{H}_2\text{O}_2$  into its elements and weighed them, you could determine that there were equal numbers of hydrogen and oxygen atoms, but you would not know if the molecular formula was  $\text{HO}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{H}_3\text{O}_3$ , or the like. Once the empirical formula is known, additional experiments can give the information needed to convert the empirical formula to the molecular one. In addition, there are many substances that do not exist as isolated molecules, one example being ionic compounds that are discussed later in this chapter. For these substances, we must rely on empirical formulas.

### Sample Exercise 2.6

#### Relating Empirical and Molecular Formulas

Write the empirical formulas for (a) glucose, a substance also known as either blood sugar or dextrose—molecular formula  $\text{C}_6\text{H}_{12}\text{O}_6$ ; (b) nitrous oxide, a substance used as an anesthetic and commonly called laughing gas—molecular formula  $\text{N}_2\text{O}$ .

#### SOLUTION

- (a) The subscripts of an empirical formula are the smallest whole-number ratios. The smallest ratios are obtained by dividing each subscript by the largest common factor, in this case 6. The resultant empirical formula for glucose is  $\text{CH}_2\text{O}$ .
- (b) Because the subscripts in  $\text{N}_2\text{O}$  are already the lowest integral numbers, the empirical formula for nitrous oxide is the same as its molecular formula,  $\text{N}_2\text{O}$ .

#### Practice Exercise 1

Tetracarbon dioxide is an unstable oxide of carbon with the following molecular structure:

What are the molecular and empirical formulas of this substance? (a)  $\text{C}_2\text{O}_2$ ,  $\text{CO}_2$  (b)  $\text{C}_4\text{O}$ ,  $\text{CO}$  (c)  $\text{CO}_2$ ,  $\text{CO}_2$  (d)  $\text{C}_4\text{O}_2$ ,  $\text{C}_2\text{O}$  (e)  $\text{C}_2\text{O}$ ,  $\text{CO}_2$

#### Practice Exercise 2

Give the empirical formula for *decaborane*, whose molecular formula is  $\text{B}_{10}\text{H}_{14}$ .

## Picturing Molecules

The molecular formula of a substance does not show how its atoms are joined together. A **structural formula** is needed to convey that information, as in the following examples:

The atoms are represented by their chemical symbols, and lines are used to represent the bonds that hold the atoms together.

## Go Figure

Which model, the ball-and-stick or the space-filling, more effectively shows the angles between bonds around a central atom?

▲ **Figure 2.18** Different representations of the methane ( $\text{CH}_4$ ) molecule. Structural formulas, perspective drawings, ball-and-stick models, and space-filling models.

A structural formula does not typically depict the actual geometry of the molecule, that is, the actual angles at which atoms are joined; for that, more sophisticated representations are needed (Figure 2.18).

- **Perspective drawings** use wedges and dashed lines to depict bonds that are not in the plane of the paper. This gives a crude sense of the three-dimensional shape of a molecule.
- **Ball-and-stick models** show atoms as spheres and bonds as sticks. This type of model has the advantage of accurately representing the angles at which the atoms are attached to one another in a molecule (Figure 2.18). Sometimes the chemical symbols of the elements are superimposed on the balls, but often the atoms are identified simply by color.
- **Space-filling models** depict what a molecule would look like if the atoms were scaled up in size (Figure 2.18). These models show the relative sizes of the atoms, but the angles between atoms, which help define their molecular geometry, are often more difficult to see than in ball-and-stick models. Because space-filling models give a good representation of the true size of a molecule, they are useful for picturing how two molecules might fit together or pack in the solid state. As with ball-and-stick models, the identities of the atoms are typically indicated by color.

## Give It Some Thought

The structural formula for ethane is

- What is the molecular formula for ethane?
- What is its empirical formula?
- Can we infer from this drawing that the  $\text{H}-\text{C}-\text{H}$  bond angles are 90 degrees?

## 2.7 | Ions and Ionic Compounds

If electrons are removed from or added to an atom, a charged particle called an **ion** is formed. An ion with a positive charge is a **cation** (pronounced CAT-ion); a negatively charged ion is an **anion** (AN-ion).

To see how ions form, consider the sodium atom, which has 11 protons and 11 electrons. This atom easily loses one electron. The resulting cation has 11 protons and 10 electrons, which means it has a net charge of  $1+$ .

The net charge on an ion is represented by a superscript. The superscripts  $+$ ,  $2+$ , and  $3+$ , for instance, mean a net charge resulting from the *loss* of one, two, and three electrons, respectively. The superscripts  $-$ ,  $2-$ , and  $3-$  represent net charges resulting from the *gain* of one, two, and three electrons, respectively. Chlorine, with 17 protons and 17 electrons, for example, can gain an electron in chemical reactions, producing the  $\text{Cl}^-$  ion:

*In general, metal atoms tend to lose electrons to form cations and nonmetal atoms tend to gain electrons to form anions. Thus, ionic compounds tend to be composed of both metal cations and nonmetal anions, as in NaCl.*

### Sample Exercise 2.7

#### Writing Chemical Symbols for Ions

Give the chemical symbol, including superscript indicating mass number, for (a) the ion with 22 protons, 26 neutrons, and 19 electrons; and (b) the ion of sulfur that has 16 neutrons and 18 electrons.

#### SOLUTION

- (a) The number of protons is the atomic number of the element. A periodic table or list of elements tells us that the element with atomic number 22 is titanium (Ti). The mass number (protons plus neutrons) of this isotope of titanium is  $22 + 26 = 48$ . Because the ion has three more protons than electrons, it has a net charge of  $3+$  and is designated  $^{48}\text{Ti}^{3+}$ .
- (b) The periodic table tells us that sulfur (S) has an atomic number of 16. Thus, each atom or ion of sulfur contains 16 protons. We are told that the ion also has 16 neutrons, meaning the mass number is  $16 + 16 = 32$ . Because the ion has 16 protons and 18 electrons, its net charge is  $2-$  and the ion symbol is  $^{32}\text{S}^{2-}$ .

In general, we will focus on the net charges of ions and ignore their mass numbers unless the circumstances dictate that we specify a certain isotope.

#### Practice Exercise 1

In which of the following species is the difference between the number of protons and the number of electrons largest? (a)  $\text{Ti}^{2+}$  (b)  $\text{P}^{3-}$  (c) Mn (d)  $\text{Se}^{2-}$  (e)  $\text{Ce}^{4+}$

#### Practice Exercise 2

How many protons, neutrons, and electrons does the  $^{79}\text{Se}^{2-}$  ion possess?

In addition to simple ions such as  $\text{Na}^+$  and  $\text{Cl}^-$ , there are **polyatomic ions**, such as  $\text{NH}_4^+$  (ammonium ion) and  $\text{SO}_4^{2-}$  (sulfate ion), which consist of atoms joined as in a molecule, but carrying a net positive or negative charge. Polyatomic ions will be discussed in Section 2.8.

It is important to realize that the chemical properties of ions are very different from the chemical properties of the atoms from which the ions are derived. The addition or removal of one or more electrons produces a charged species with behavior very different from that of its associated atom or group of atoms. For example, sodium metal reacts violently with water, but an ionic compound containing sodium ions, such as NaCl, does not.

### Predicting Ionic Charges

As noted in Table 2.3, the elements of group 8A are called the noble-gas elements. The noble gases are chemically nonreactive elements that form very few compounds. Many atoms gain or lose electrons to end up with the same number of electrons as the noble

gas closest to them in the periodic table. We might deduce that atoms tend to acquire the electron arrangements of the noble gases because these electron arrangements are very stable. Nearby elements can obtain these same stable arrangements by losing or gaining electrons. For example, the loss of one electron from an atom of sodium leaves it with the same number of electrons as in a neon atom (10). Similarly, when chlorine gains an electron, it ends up with 18, the same number of electrons as in argon. This simple observation will be helpful for now to account for the formation of ions. A deeper explanation awaits us in Chapter 8, where we discuss chemical bonding.

### Sample Exercise 2.8

#### Predicting Ionic Charge

Predict the charge expected for the most stable ion of barium and the most stable ion of oxygen.

#### SOLUTION

We will assume that barium and oxygen form ions that have the same number of electrons as the nearest noble-gas atom. From the periodic table, we see that barium has atomic number 56. The nearest noble gas is xenon, atomic number 54. Barium can attain a stable arrangement of 54 electrons by losing two electrons, forming the  $\text{Ba}^{2+}$  cation.

Oxygen has atomic number 8. The nearest noble gas is neon, atomic number 10. Oxygen can attain this stable electron arrangement by gaining two electrons, forming the  $\text{O}^{2-}$  anion.

#### Practice Exercise 1

Although it is helpful to know that many ions have the electron arrangement of a noble gas, many elements, especially among the metals, form ions that do not have a noble-gas electron arrangement. Use the periodic table, Figure 2.14, to determine which of the following ions has a noble-gas electron arrangement, and which do not. For those that do, indicate the noble-gas arrangement they match: (a)  $\text{Ti}^{4+}$ , (b)  $\text{Mn}^{2+}$ , (c)  $\text{Pb}^{2+}$ , (d)  $\text{Te}^{2-}$ , (e)  $\text{Zn}^{2+}$ .

#### Practice Exercise 2

Predict the charge expected for the most stable ion of (a) aluminum and (b) fluorine.

The periodic table is very useful for remembering ionic charges, especially those of elements on the left and right sides of the table. As Figure 2.19 shows, the charges of these ions relate in a simple way to their positions in the table: The group 1A elements (alkali metals) form 1+ ions, the group 2A elements (alkaline earths) form 2+ ions, the group 7A elements (halogens) form 1− ions, and the group 6A elements form 2− ions. As noted in Practice Exercise 1 of Sample Exercise 2.8, many of the other groups do not lend themselves to such simple rules.

#### Go Figure

The most common ions for silver, zinc, and scandium are  $\text{Ag}^+$ ,  $\text{Zn}^{2+}$ , and  $\text{Sc}^{3+}$ . Locate the boxes in which you would place these ions in this table. Which of these ions has the same number of electrons as a noble-gas element?

| 1A            | 2A               | Transition metals |  |  |  |  |  |  |  |  |  | 3A               | 4A | 5A | 6A              | 7A               | 8A            |

| $\text{Na}^+$ | $\text{Mg}^{2+}$ |                   |  |  |  |  |  |  |  |  |  |                  |    |    |                 | $\text{Se}^{2-}$ | $\text{Br}^-$ |
| $\text{K}^+$  | $\text{Ca}^{2+}$ |                   |  |  |  |  |  |  |  |  |  |                  |    |    |                 | $\text{Te}^{2-}$ | $\text{I}^-$  |
| $\text{Rb}^+$ | $\text{Sr}^{2+}$ |                   |  |  |  |  |  |  |  |  |  |                  |    |    |                 |                  |               |
| $\text{Cs}^+$ | $\text{Ba}^{2+}$ |                   |  |  |  |  |  |  |  |  |  |                  |    |    |                 |                  |               |

▲ **Figure 2.19** Predictable charges of some common ions. Notice that the red stepped line that divides metals from nonmetals also separates cations from anions. Hydrogen forms both 1+ and 1− ions.

## Ionic Compounds

A great deal of chemical activity involves the transfer of electrons from one substance to another. Figure 2.20 shows that when elemental sodium is allowed to react with elemental chlorine, an electron transfers from a sodium atom to a chlorine atom, forming a  $\text{Na}^+$  ion and a  $\text{Cl}^-$  ion. Because objects of opposite charges attract, the  $\text{Na}^+$  and the  $\text{Cl}^-$  ions bind together to form the compound sodium chloride ( $\text{NaCl}$ ). Sodium chloride,

which we know better as common table salt, is an example of an **ionic compound**, a compound made up of cations and anions.

**▲ Figure 2.20 Formation of an ionic compound.** The transfer of an electron from a sodium atom to a chlorine atom leads to the formation of a Na<sup>+</sup> ion and a Cl<sup>-</sup> ion. These ions are arranged in a lattice in solid sodium chloride, NaCl.

We can often tell whether a compound is ionic (consisting of ions) or molecular (consisting of molecules) from its composition. As a general rule, cations are metal ions and anions are nonmetal ions. Consequently,

*Ionic compounds are generally combinations of metals and nonmetals, as in NaCl.*

### Sample Exercise 2.9

#### Identifying Ionic and Molecular Compounds

Which of these compounds would you expect to be ionic: N<sub>2</sub>O, Na<sub>2</sub>O, CaCl<sub>2</sub>, SF<sub>4</sub>?

#### SOLUTION

We predict that Na<sub>2</sub>O and CaCl<sub>2</sub> are ionic compounds because they are composed of a metal combined with a nonmetal. We predict (correctly) that N<sub>2</sub>O and SF<sub>4</sub> are molecular compounds because they are composed entirely of nonmetals.

#### Practice Exercise 1

Which of these compounds are molecular: CBr<sub>4</sub>, FeS, P<sub>4</sub>O<sub>6</sub>, PbF<sub>2</sub>?

#### Practice Exercise 2

Give a reason why each of the following statements is a safe prediction:

- Every compound of Rb with a nonmetal is ionic in character.
- Every compound of nitrogen with a halogen element is a molecular compound.
- The compound MgKr<sub>2</sub> does not exist.
- Na and K are very similar in the compounds they form with nonmetals.
- If contained in an ionic compound, calcium (Ca) will be in the form of the doubly charged ion, Ca<sup>2+</sup>.

The ions in ionic compounds are arranged in three-dimensional structures, as Figure 2.20 shows for NaCl. Because there is no discrete “molecule” of NaCl, we are able to write only an empirical formula for this substance. This is true for most other ionic compounds.

We can write the empirical formula for an ionic compound if we know the charges of the ions. Because chemical compounds are always electrically neutral, the ions in an ionic compound always occur in such a ratio that the total positive charge equals the total negative charge. Thus, there is one Na<sup>+</sup> to one Cl<sup>-</sup> in NaCl, one Ba<sup>2+</sup> to two Cl<sup>-</sup> in BaCl<sub>2</sub>, and so forth.

As you consider these and other examples, you will see that if the charges on the cation and anion are equal, the subscript on each ion is 1. If the charges are not equal, the charge on one ion (without its sign) will become the subscript on the other ion. For

example, the ionic compound formed from Mg (which forms  $\text{Mg}^{2+}$  ions) and N (which forms  $\text{N}^{3-}$  ions) is  $\text{Mg}_3\text{N}_2$ :

There is one caveat to using this approach. Remember that the empirical formula should be the smallest possible whole-number ratio of the two elements. So the empirical formula for the ionic compound formed between  $\text{Ti}^{4+}$  and  $\text{O}^{2-}$  is  $\text{TiO}_2$  rather than  $\text{Ti}_2\text{O}_4$ .

### Give It Some Thought

What is the empirical formula of the compound formed between  $\text{W}^{6+}$  and  $\text{O}^{2-}$ ?

## CHEMISTRY AND LIFE Elements Required by Living Organisms

The elements essential to life are highlighted in color in **Figure 2.21**. More than 97% of the mass of most organisms is made up of just six of these elements—oxygen, carbon, hydrogen, nitrogen, phosphorus, and sulfur. Water is the most common compound in living organisms, accounting for at least 70% of the mass of most cells. In the solid components of cells, carbon is the most prevalent element by mass. Carbon atoms are found in a vast variety of organic molecules, bonded either to other carbon atoms or to atoms of other elements. Nearly all proteins, for example, contain the carbon-based group

which occurs repeatedly in the molecules.

In addition, 23 other elements have been found in various living organisms. Five are ions required by all organisms:  $\text{Ca}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{Mg}^{2+}$ ,  $\text{K}^+$ , and  $\text{Na}^+$ . Calcium ions, for example, are necessary for the formation of bone and transmission of nervous system signals. Many

other elements are needed in only very small quantities and consequently are called *trace* elements. For example, trace quantities of copper are required in the diet of humans to aid in the synthesis of hemoglobin.

## Sample Exercise 2.10

### Using Ionic Charge to Write Empirical Formulas for Ionic Compounds

Write the empirical formula of the compound formed by (a)  $\text{Al}^{3+}$  and  $\text{Cl}^-$  ions, (b)  $\text{Al}^{3+}$  and  $\text{O}^{2-}$  ions, (c)  $\text{Mg}^{2+}$  and  $\text{NO}_3^-$  ions.

### SOLUTION

- (a) Three  $\text{Cl}^-$  ions are required to balance the charge of one  $\text{Al}^{3+}$  ion, making the empirical formula  $\text{AlCl}_3$ .
- (b) Two  $\text{Al}^{3+}$  ions are required to balance the charge of three  $\text{O}^{2-}$  ions. A 2:3 ratio is needed to balance the total positive charge of  $6+$  and the total negative charge of  $6-$ . The empirical formula is  $\text{Al}_2\text{O}_3$ .
- (c) Two  $\text{NO}_3^-$  ions are needed to balance the charge of one  $\text{Mg}^{2+}$ , yielding  $\text{Mg}(\text{NO}_3)_2$ . Note that the formula for the polyatomic ion,  $\text{NO}_3^-$ , must be enclosed in parentheses so that it is clear that the subscript 2 applies to all the atoms of that ion.

### Practice Exercise 1

Which of the following nonmetals will form an ionic compound with  $\text{Sc}^{3+}$  that has a 1:1 ratio of cations to anions?

- (a) Ne (b) F (c) O (d) N

### Practice Exercise 2

Write the empirical formula for the compound formed by (a)  $\text{Na}^+$  and  $\text{PO}_4^{3-}$ , (b)  $\text{Zn}^{2+}$  and  $\text{SO}_4^{2-}$ , (c)  $\text{Fe}^{3+}$  and  $\text{CO}_3^{2-}$ .

## 2.8 | Naming Inorganic Compounds

The names and chemical formulas of compounds are essential vocabulary in chemistry. The system used in naming substances is called **chemical nomenclature**, from the Latin words *nomen* (name) and *calare* (to call).

There are more than 50 million known chemical substances. Naming them all would be a hopelessly complicated task if each had a name independent of all others. Many important substances that have been known for a long time, such as water ( $\text{H}_2\text{O}$ ) and ammonia ( $\text{NH}_3$ ), do have traditional names (called *common names*). For most substances, however, we rely on a set of rules that leads to an informative and unique name that conveys the composition of the substance.

The rules for chemical nomenclature are based on the division of substances into categories. The major division is between organic and inorganic compounds. *Organic compounds* contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements. All others are *inorganic compounds*. Early chemists associated organic compounds with plants and animals and inorganic compounds with the nonliving portion of our world. Although this distinction is no longer pertinent, the classification between organic and inorganic compounds continues to be useful. In this section, we consider the basic rules for naming three categories of inorganic compounds: ionic compounds, acids, and molecular compounds.

### Names and Formulas of Ionic Compounds

Recall from Section 2.7 that ionic compounds usually consist of metal ions combined with nonmetal ions. The metals form the cations, and the nonmetals form the anions.

#### 1. Cations

a. Cations formed from metal atoms have the same name as the metal:

|               |            |                  |          |                  |              |
|---------------|------------|------------------|----------|------------------|--------------|
| $\text{Na}^+$ | sodium ion | $\text{Zn}^{2+}$ | zinc ion | $\text{Al}^{3+}$ | aluminum ion |
|---------------|------------|------------------|----------|------------------|--------------|

b. If a metal can form cations with different charges, the positive charge is indicated by a Roman numeral in parentheses following the name of the metal:

|                  |               |                  |                |
|------------------|---------------|------------------|----------------|
| $\text{Fe}^{2+}$ | iron(II) ion  | $\text{Cu}^+$    | copper(I) ion  |
| $\text{Fe}^{3+}$ | iron(III) ion | $\text{Cu}^{2+}$ | copper(II) ion |

Ions of the same element that have different charges have different chemical and physical properties, such as color (Figure 2.22).

Most metals that form cations with different charges are *transition metals*, elements that occur in the middle of the periodic table, from group 3B to group 2B (as indicated on the periodic table on the front inside cover of this book). The metals that form only one cation (only one possible charge) are those of group 1A and group 2A, as well as  $\text{Al}^{3+}$  (group 3A) and two transition-metal ions:  $\text{Ag}^+$  (group 1B) and  $\text{Zn}^{2+}$  (group 2B). Charges are not expressed when naming these ions. However, if there is any doubt in your mind whether a metal forms more than one cation, use a Roman numeral to indicate the charge. It is never wrong to do so, even though it may be unnecessary.

An older method still widely used for distinguishing between differently charged ions of a metal uses the endings *-ous* and *-ic* added to the root of the element's Latin name:

|                  |             |                  |             |
|------------------|-------------|------------------|-------------|
| $\text{Fe}^{2+}$ | ferrous ion | $\text{Cu}^+$    | cuprous ion |
| $\text{Fe}^{3+}$ | ferric ion  | $\text{Cu}^{2+}$ | cupric ion  |

Although we will only rarely use these older names in this text, you might encounter them elsewhere.

▲ **Figure 2.22** Different ions of the same element have different properties. Both substances shown are compounds of iron. The grey substance on the left is  $\text{Fe}_3\text{O}_4$ , which contains  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  ions. The red substance on the right is  $\text{Fe}_2\text{O}_3$ , which contains  $\text{Fe}^{3+}$  ions.

- c. Cations formed from molecules composed of nonmetal atoms have names that end in -ium:

|                 |              |                        |               |
|-----------------|--------------|------------------------|---------------|
| $\text{NH}_4^+$ | ammonium ion | $\text{H}_3\text{O}^+$ | hydronium ion |
|-----------------|--------------|------------------------|---------------|

These two ions are the only ions of this kind that we will encounter frequently in the text.

The names and formulas of some common cations are shown in Table 2.4 and on the back inside cover of the text. The ions on the left side in Table 2.4 are the monatomic ions that do not have more than one possible charge. Those on the right side are either polyatomic cations or cations with more than one possible charge. The  $\text{Hg}_2^{2+}$  ion is unusual because, even though it is a metal ion, it is not monatomic. It is called the mercury(I) ion because it can be thought of as two  $\text{Hg}^+$  ions bound together. The cations that you will encounter most frequently in this text are shown in boldface. You should learn these cations first.

TABLE 2.4 Common Cations<sup>a</sup>

| Charge | Formula                | Name                 | Formula                           | Name                            |

|        | Sr <sup>2+</sup>       | strontium ion        | <b>Fe<sup>2+</sup></b>            | <b>iron(II)</b> or ferrous ion  |
|        | Ba <sup>2+</sup>       | barium ion           | Mn <sup>2+</sup>                  | manganese(II) or manganous ion  |
|        | <b>Zn<sup>2+</sup></b> | <b>zinc ion</b>      | Hg <sub>2</sub> <sup>2+</sup>     | mercury(I) or mercurous ion     |
|        | Cd <sup>2+</sup>       | cadmium ion          | Hg <sup>2+</sup>                  | mercury(II) or mercuric ion     |
|        |                        |                      | Ni <sup>2+</sup>                  | nickel(II) or nickelous ion     |
|        |                        |                      | <b>Pb<sup>2+</sup></b>            | <b>lead(II)</b> or plumbous ion |
| 3+     |                        |                      | Sn <sup>2+</sup>                  | tin(II) or stannous ion         |
|        | <b>Al<sup>3+</sup></b> | <b>aluminum ion</b>  | Cr <sup>3+</sup>                  | chromium(III) or chromic ion    |
|        |                        |                      | <b>Fe<sup>3+</sup></b>            | <b>iron(III)</b> or ferric ion  |

<sup>a</sup>The ions we use most often in this course are in boldface. Learn them first.

### Give It Some Thought

What is the empirical formula for manganese(II) oxide— $\text{Mn}_2\text{O}$ ,  $\text{MnO}$ , or  $\text{MnO}_2$ ?

## 2. Anions

- a. The names of monatomic anions are formed by replacing the ending of the name of the element with -ide:

|                |             |                 |           |                 |             |
|----------------|-------------|-----------------|-----------|-----------------|-------------|
| H <sup>-</sup> | hydride ion | O <sup>2-</sup> | oxide ion | N <sup>3-</sup> | nitride ion |
|----------------|-------------|-----------------|-----------|-----------------|-------------|

A few polyatomic anions also have names ending in -ide:

|                 |               |                 |             |                              |              |
|-----------------|---------------|-----------------|-------------|------------------------------|--------------|
| OH <sup>-</sup> | hydroxide ion | CN <sup>-</sup> | cyanide ion | O <sub>2</sub> <sup>2-</sup> | peroxide ion |
|-----------------|---------------|-----------------|-------------|------------------------------|--------------|

- b. Polyatomic anions containing oxygen have names ending in either -ate or -ite and are called **oxyanions**. The -ate is used for the most common or representative

oxyanion of an element, and *-ite* is used for an oxyanion that has the same charge but one O atom fewer:

|                 |             |                    |             |
|-----------------|-------------|--------------------|-------------|
| $\text{NO}_3^-$ | nitrate ion | $\text{SO}_4^{2-}$ | sulfate ion |
| $\text{NO}_2^-$ | nitrite ion | $\text{SO}_3^{2-}$ | sulfite ion |

Prefixes are used when the series of oxyanions of an element extends to four members, as with the halogens. The prefix *per-* indicates one more O atom than the oxyanion ending in *-ate*; *hypo-* indicates one O atom fewer than the oxyanion ending in *-ite*:

|                  |   |
|------------------|---|
| $\text{ClO}_4^-$ | perchlorate ion (one more O atom than chlorate)   |
| $\text{ClO}_3^-$ | chlorate ion                                      |
| $\text{ClO}_2^-$ | chlorite ion (one O atom fewer than chlorate)     |
| $\text{ClO}^-$   | hypochlorite ion (one O atom fewer than chlorite) |

These rules are summarized in Figure 2.23.

**Give It Some Thought**

What information is conveyed by the endings *-ide*, *-ate*, and *-ite* in the name of an anion?

Figure 2.24 can help you remember the charge and number of oxygen atoms in the various oxyanions. Notice that C and N, both period 2 elements, have only three O atoms each, whereas the period 3 elements P, S, and Cl have four O atoms each. Beginning at the lower right in Figure 2.24, note that ionic charge increases from right to left, from  $1^-$  for  $\text{ClO}_4^-$  to  $3^-$  for  $\text{PO}_4^{3-}$ . In the second period the charges also increase from right to left, from  $1^-$  for  $\text{NO}_3^-$  to  $2^-$  for  $\text{CO}_3^{2-}$ . Notice also that although each of the anions in Figure 2.24 ends in *-ate*, the  $\text{ClO}_4^-$  ion also has a *per-* prefix.

|          |                                     |                                     |                                   |                                     |  |
|----------|-------------------------------------|-------------------------------------|-----------------------------------|-------------------------------------|--|
|          | Group 4A                            | Group 5A                            | Group 6A                          | Group 7A                            |  |
| Period 2 | $\text{CO}_3^{2-}$<br>Carbonate ion | $\text{NO}_3^-$<br>Nitrate ion      |                                   |                                     |  |
| Period 3 |                                     | $\text{PO}_4^{3-}$<br>Phosphate ion | $\text{SO}_4^{2-}$<br>Sulfate ion | $\text{ClO}_4^-$<br>Perchlorate ion |  |

Maximum of three O atoms in period 2.

Maximum of four O atoms in period 3.

Charges increase right to left.

▲ **Figure 2.24 Common oxyanions.** The composition and charges of common oxyanions are related to their location in the periodic table.

## Sample Exercise 2.11

### Determining the Formula of an Oxyanion from Its Name

Based on the formula for the sulfate ion, predict the formula for (a) the selenate ion and (b) the selenite ion. (Sulfur and selenium are both in group 6A and form analogous oxyanions.)

#### SOLUTION

(a) The sulfate ion is  $\text{SO}_4^{2-}$ . The analogous selenate ion is therefore  $\text{SeO}_4^{2-}$ .

(b) The ending *-ite* indicates an oxyanion with the same charge but one O atom fewer than the corresponding oxyanion that ends in *-ate*. Thus, the formula for the selenite ion is  $\text{SeO}_3^{2-}$ .

#### Practice Exercise 1

Which of the following oxyanions is incorrectly named?

- (a)  $\text{ClO}_2^-$ , chlorate (b)  $\text{IO}_4^-$ , periodate (c)  $\text{SO}_3^{2-}$ , sulfite (d)  $\text{IO}_3^-$ , iodate (e)  $\text{NO}_2^-$ , nitrite

#### Practice Exercise 2

The formula for the bromate ion is analogous to that for the chlorate ion. Write the formula for the hypobromite and bromite ions.

- c. Anions derived by adding  $\text{H}^+$  to an oxyanion are named by adding as a prefix the word hydrogen or dihydrogen, as appropriate:

|                    |                        |                           |                          |
|--------------------|------------------------|---------------------------|--------------------------|
| $\text{CO}_3^{2-}$ | carbonate ion          | $\text{PO}_4^{3-}$        | phosphate ion            |
| $\text{HCO}_3^-$   | hydrogen carbonate ion | $\text{H}_2\text{PO}_4^-$ | dihydrogen phosphate ion |

Notice that each  $\text{H}^+$  added reduces the negative charge of the parent anion by one. An older method for naming some of these ions uses the prefix *bi-*. Thus, the  $\text{HCO}_3^-$  ion is commonly called the bicarbonate ion, and  $\text{HSO}_4^-$  is sometimes called the bisulfate ion.

The names and formulas of the common anions are listed in Table 2.5 and on the back inside cover of the text. Those anions whose names end in *-ide* are listed on the left portion of Table 2.5, and those whose names end in *-ate* are listed on the right. The most common of these ions are shown in boldface. You should learn the names and formulas of these anions first. The formulas of the ions whose names end with *-ite* can be derived from those ending in *-ate* by removing an O atom. Notice the location of the monatomic ions in the periodic table. Those of group 7A always have a 1 $-$  charge ( $\text{F}^-$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ , and  $\text{I}^-$ ), and those of group 6A have a 2 $-$  charge ( $\text{O}^{2-}$  and  $\text{S}^{2-}$ ).

TABLE 2.5 Common Anions<sup>a</sup>

| Charge | Formula                           | Name                 | Formula  | Name                   |
|--------|-----------------------------------|----------------------|--|------------------------|
| 1 $-$  | $\text{H}^-$                      | hydride ion          | <b><math>\text{CH}_3\text{COO}^-</math></b> (or $\text{C}_2\text{H}_3\text{O}_2^-$ ) | <b>acetate ion</b>     |
|        | <b><math>\text{F}^-</math></b>    | <b>fluoride ion</b>  | $\text{ClO}_3^-$   | chlorate ion           |
|        | <b><math>\text{Cl}^-</math></b>   | <b>chloride ion</b>  | <b><math>\text{ClO}_4^-</math></b>   | <b>perchlorate ion</b> |
|        | <b><math>\text{Br}^-</math></b>   | <b>bromide ion</b>   | <b><math>\text{NO}_3^-</math></b>  | <b>nitrate ion</b>     |
|        | <b><math>\text{I}^-</math></b>    | <b>iodide ion</b>    | $\text{MnO}_4^-$   | permanganate ion       |
|        | $\text{CN}^-$                     | cyanide ion          |  |                        |
|        | <b><math>\text{OH}^-</math></b>   | <b>hydroxide ion</b> |  |                        |
| 2 $-$  | <b><math>\text{O}^{2-}</math></b> | <b>oxide ion</b>     | <b><math>\text{CO}_3^{2-}</math></b>   | <b>carbonate ion</b>   |
|        | $\text{O}_2^{2-}$                 | peroxide ion         | $\text{CrO}_4^{2-}$  | chromate ion           |
|        | <b><math>\text{S}^{2-}</math></b> | <b>sulfide ion</b>   | $\text{Cr}_2\text{O}_7^{2-}$   | dichromate ion         |
|        |                                   |                      | <b><math>\text{SO}_4^{2-}</math></b>   | <b>sulfate ion</b>     |
| 3 $-$  | $\text{N}^{3-}$                   | nitride ion          | <b><math>\text{PO}_4^{3-}</math></b>   | <b>phosphate ion</b>   |

<sup>a</sup>The ions we use most often are in boldface. Learn them first.

### 3. Ionic Compounds

Names of ionic compounds consist of the cation name followed by the anion name:

|                             |  |
|-----------------------------|--|
| $\text{CaCl}_2$             | calcium chloride                               |
| $\text{Al}(\text{NO}_3)_3$  | aluminum nitrate                               |
| $\text{Cu}(\text{ClO}_4)_2$ | copper(II) perchlorate (or cupric perchlorate) |

In the chemical formulas for aluminum nitrate and copper(II) perchlorate, parentheses followed by the appropriate subscript are used because the compounds contain two or more polyatomic ions.

### Sample Exercise 2.12

#### Determining the Names of Ionic Compounds from Their Formulas

Name the ionic compounds (a)  $\text{K}_2\text{SO}_4$ , (b)  $\text{Ba}(\text{OH})_2$ , (c)  $\text{FeCl}_3$ .

#### SOLUTION

In naming ionic compounds, it is important to recognize polyatomic ions and to determine the charge of cations with variable charge.

- (a) The cation is  $\text{K}^+$ , the potassium ion, and the anion is  $\text{SO}_4^{2-}$ , the sulfate ion, making the name potassium sulfate. (If you thought the compound contained  $\text{S}^{2-}$  and  $\text{O}^{2-}$  ions, you failed to recognize the polyatomic sulfate ion.)
- (b) The cation is  $\text{Ba}^{2+}$ , the barium ion, and the anion is  $\text{OH}^-$ , the hydroxide ion: barium hydroxide.
- (c) You must determine the charge of Fe in this compound because an iron atom can form more than one cation.

Because the compound contains three chloride ions,  $\text{Cl}^-$ , the cation must be  $\text{Fe}^{3+}$ , the iron(III), or ferric, ion. Thus, the compound is iron(III) chloride or ferric chloride.

#### Practice Exercise 1

Which of the following ionic compounds is incorrectly named? (a)  $\text{Zn}(\text{NO}_3)_2$ , zinc nitrate (b)  $\text{TeCl}_4$ , tellurium(IV) chloride (c)  $\text{Fe}_2\text{O}_3$ , diiron oxide (d)  $\text{BaO}$ , barium oxide (e)  $\text{Mn}_3(\text{PO}_4)_2$ , manganese(II) phosphate

#### Practice Exercise 2

Name the ionic compounds (a)  $\text{NH}_4\text{Br}$ , (b)  $\text{Cr}_2\text{O}_3$ , (c)  $\text{Co}(\text{NO}_3)_2$ .

### Give It Some Thought

Calcium bicarbonate is also called calcium hydrogen carbonate. (a) Write the formula for this compound, (b) predict the formulas for potassium bisulfate and lithium dihydrogen phosphate.

## Names and Formulas of Acids

Acids are an important class of hydrogen-containing compounds, and they are named in a special way. For our present purposes, an *acid* is a substance whose molecules yield hydrogen ions ( $\text{H}^+$ ) when dissolved in water. When we encounter the chemical formula for an acid at this stage of the course, it will be written with H as the first element, as in  $\text{HCl}$  and  $\text{H}_2\text{SO}_4$ .

An acid is composed of an anion connected to enough  $\text{H}^+$  ions to neutralize, or balance, the anion's charge. Thus, the  $\text{SO}_4^{2-}$  ion requires two  $\text{H}^+$  ions, forming  $\text{H}_2\text{SO}_4$ . The name of an acid is related to the name of its anion, as summarized in Figure 2.25.

#### How to Name Acids

1. Acids containing anions whose names end in -ide are named by changing the -ide ending to -ic, adding the prefix hydro- to this anion name, and then following with the word acid:

| Anion                     | Corresponding Acid                        |
|---------------------------|---|
| $\text{Cl}^-$ (chloride)  | $\text{HCl}$ (hydrochloric acid)          |
| $\text{S}^{2-}$ (sulfide) | $\text{H}_2\text{S}$ (hydrosulfuric acid) |

2. Acids containing anions whose names end in -ate or -ite are named by changing -ate to -ic and -ite to -ous and then adding the word acid. Prefixes in the anion name are retained in the name of the acid:

| Anion                          | Corresponding Acid                |
|--------------------------------|-----------------------------------|
| $\text{ClO}_4^-$ (perchlorate) | $\text{HClO}_4$ (perchloric acid) |
| $\text{ClO}_3^-$ (chlorate)    | $\text{HClO}_3$ (chloric acid)    |
| $\text{ClO}_2^-$ (chlorite)    | $\text{HClO}_2$ (chlorous acid)   |
| $\text{ClO}^-$ (hypochlorite)  | $\text{HClO}$ (hypochlorous acid) |

▲ **Figure 2.25 Procedure for naming acids.** Here acids containing chlorine are used as an example. Prefixes used for oxyanions, such as, *per-* and *hypo-*, are retained in the acids derived from those anions.

### Give It Some Thought

Name the acid obtained by adding  $\text{H}^+$  to the iodate ion,  $\text{IO}_3^-$ .

## Sample Exercise 2.13

### Relating the Names and Formulas of Acids

Name the acids (a)  $\text{HCN}$ , (b)  $\text{HNO}_3$ , (c)  $\text{H}_2\text{SO}_4$ , (d)  $\text{H}_2\text{SO}_3$ .

### SOLUTION

- (a) The anion from which this acid is derived is  $\text{CN}^-$ , the cyanide ion. Because this ion has an *-ide* ending, the acid is given a *hydro-* prefix and an *-ic* ending: hydrocyanic acid. Only water solutions of  $\text{HCN}$  are referred to as hydrocyanic acid. The pure compound, which is a gas under normal conditions, is called hydrogen cyanide. Both hydrocyanic acid and hydrogen cyanide are *extremely* toxic.
- (b) Because  $\text{NO}_3^-$  is the nitrate ion,  $\text{HNO}_3$  is called nitric acid (the *-ate* ending of the anion is replaced with an *-ic* ending in naming the acid).
- (c) Because  $\text{SO}_4^{2-}$  is the sulfate ion,  $\text{H}_2\text{SO}_4$  is called sulfuric acid.

- (d) Because  $\text{SO}_3^{2-}$  is the sulfite ion,  $\text{H}_2\text{SO}_3$  is sulfurous acid (the *-ite* ending of the anion is replaced with an *-ous* ending).

#### Practice Exercise 1

Which of the following acids are incorrectly named? For those that are, provide a correct name or formula.

- (a) hydrofluoric acid,  $\text{HF}$  (b) nitrous acid,  $\text{HNO}_3$  (c) perbromic acid,  $\text{HBrO}_4$  (d) iodic acid,  $\text{HI}$  (e) selenic acid,  $\text{H}_2\text{SeO}_4$

#### Practice Exercise 2

Give the chemical formulas for (a) hydrobromic acid, (b) carbonic acid.

## Names and Formulas of Binary Molecular Compounds

The procedures used for naming *binary* (two-element) molecular compounds are similar to those used for naming ionic compounds:

### How to Name Binary Molecular Compounds

1. The name of the element farther to the left in the periodic table (closest to the metals) is usually written first. An exception occurs when the compound contains oxygen and chlorine, bromine, or iodine (any halogen except fluorine), in which case oxygen is written last.
2. If both elements are in the same group, the one closer to the bottom of the table is named first.
3. The name of the second element is given an *-ide* ending.
4. Greek prefixes (Table 2.6) indicate the number of atoms of each element. (Exception: The prefix *mono-* is never used with the first element.) When the prefix ends in *a* or *o* and the name of the second element begins with a vowel, the *a* or *o* of the prefix is often dropped.

The following examples illustrate these rules:

|                        |                             |                           |                                     |
|------------------------|-----------------------------|---------------------------|-------------------------------------|
| $\text{Cl}_2\text{O}$  | dichlorine <b>monoxide</b>  | $\text{NF}_3$             | nitrogen <b>trifluoride</b>         |
| $\text{N}_2\text{O}_4$ | dinitrogen <b>tetroxide</b> | $\text{P}_4\text{S}_{10}$ | tetraphosphorus <b>deca</b> sulfide |

Rule 4 is necessary because we cannot predict formulas for most molecular substances the way we can for ionic compounds. Molecular compounds that contain hydrogen and one other element are an important exception, however. These compounds can be treated as if they were neutral substances containing  $\text{H}^+$  ions and anions. Thus, you can predict that the substance named hydrogen chloride has the formula  $\text{HCl}$ , containing one  $\text{H}^+$  to balance the charge of one  $\text{Cl}^-$ . (The name *hydrogen chloride* is used only for the pure compound; water solutions of  $\text{HCl}$  are called hydrochloric acid. The distinction, which is important, will be explained in Section 4.1.) Similarly, the formula for hydrogen sulfide is  $\text{H}_2\text{S}$  because two  $\text{H}^+$  ions are needed to balance the charge on  $\text{S}^{2-}$ .

### Give It Some Thought

Is  $\text{SOCl}_2$  a binary compound?

**TABLE 2.6** Prefixes Used in Naming Binary Compounds Formed between Nonmetals

| Prefix        | Meaning |
|---------------|---------|
| <i>mono-</i>  | 1       |
| <i>di-</i>    | 2       |
| <i>tri-</i>   | 3       |
| <i>tetra-</i> | 4       |
| <i>penta-</i> | 5       |
| <i>hexa-</i>  | 6       |
| <i>hepta-</i> | 7       |
| <i>octa-</i>  | 8       |
| <i>nona-</i>  | 9       |
| <i>deca-</i>  | 10      |

### Sample Exercise 2.14

#### Relating the Names and Formulas of Binary Molecular Compounds

Name the compounds (a)  $\text{SO}_2$ , (b)  $\text{PCl}_5$ , (c)  $\text{Cl}_2\text{O}_3$ .

#### SOLUTION

The compounds consist entirely of nonmetals, so they are molecular rather than ionic. Using the prefixes in Table 2.6, we have (a) sulfur dioxide, (b) phosphorus pentachloride, (c) dichlorine trioxide.

#### Practice Exercise 1

Give the name for each of the following binary compounds of carbon: (a)  $\text{CS}_2$ , (b)  $\text{CO}$ , (c)  $\text{C}_3\text{O}_2$ , (d)  $\text{CBr}_4$ , (e)  $\text{CF}$ .

#### Practice Exercise 2

Give the chemical formulas for (a) silicon tetrabromide, (b) disulfur dichloride, (c) diphosphorus hexaoxide.

## 2.9 | Some Simple Organic Compounds

The study of compounds of carbon is called **organic chemistry**, and as noted earlier, compounds that contain carbon and hydrogen, often in combination with oxygen, nitrogen, or other elements, are called *organic compounds*. Organic compounds are a very important part of chemistry, far outnumbering all other types of chemical substances. We will examine organic compounds in a systematic way in Chapter 24, but you will encounter many examples of them throughout the text. Here we present a brief introduction to some of the simplest organic compounds and the ways in which they are named.

### Alkanes

Compounds that contain only carbon and hydrogen are called **hydrocarbons**. In the simplest class of hydrocarbons, **alkanes**, each carbon is bonded to four other atoms. The three smallest alkanes are methane ( $\text{CH}_4$ ), ethane ( $\text{C}_2\text{H}_6$ ), and propane ( $\text{C}_3\text{H}_8$ ). The structural formulas of these three alkanes are as follows:

Although hydrocarbons are binary molecular compounds, they are not named like the binary inorganic compounds discussed in Section 2.8. Instead, each alkane has a

▲ Figure 2.26 The two forms (isomers) of propanol.

name that ends in *-ane*. The alkane with four carbons is called *butane*. For alkanes with five or more carbons, the names are derived from prefixes like those in Table 2.6. An alkane with eight carbon atoms, for example, is *octane* ( $C_8H_{18}$ ), where the *octa-* prefix for eight is combined with the *-ane* ending for an alkane.

## Some Derivatives of Alkanes

Other classes of organic compounds are obtained when one or more hydrogen atoms in an alkane are replaced with *functional groups*, which are specific groups of atoms. An **alcohol**, for example, is obtained by replacing an H atom of an alkane with an  $-OH$  group. The name of the alcohol is derived from that of the alkane by adding an *-ol* ending:

Alcohols have properties that are very different from those of the alkanes from which the alcohols are obtained. For example, methane, ethane, and propane are all colorless gases under normal conditions, whereas methanol, ethanol, and propanol are colorless liquids. We will discuss the reasons for these differences in Chapter 11.

The prefix “1” in the name 1-propanol indicates that the replacement of H with OH has occurred at one of the “outer” carbon atoms rather than the “middle” carbon atom. A different compound, called either 2-propanol or isopropyl alcohol, is obtained when the OH functional group is attached to the middle carbon atom (Figure 2.26).

Compounds with the same molecular formula but different arrangements of atoms are called **isomers**. For example, 1-propanol and 2-propanol are *structural isomers*, compounds that have the same molecular formula but different structural formulas. There are many different kinds of isomers, as we will discover later in this book.

### Give It Some Thought

Draw the structural formulas of the two isomers of butane,  $C_4H_{10}$ .

As already noted, many different functional groups can replace one or more of the hydrogens on an alkane—for example, one or more of the halogens, or a special grouping of carbon and oxygen atoms, such as the carboxylic acid group,  $-COOH$ . Here are a few examples of functional groups you will be encountering in the chapters that lie ahead (the functional group is outlined in blue):

Much of the richness of organic chemistry is possible because organic compounds can form long chains of carbon-carbon bonds. The series of alkanes that begins with methane, ethane, and propane and the series of alcohols that begins with methanol, ethanol, and propanol can both be extended for as long as we desire, in principle. The

properties of alkanes and alcohols change as the chains get longer. Octanes, which are alkanes with eight carbon atoms, are liquids under normal conditions. If the alkane series is extended to tens of thousands of carbon atoms, we obtain *polyethylene*, a solid substance that is used to make thousands of plastic products, such as plastic bags, food containers, and laboratory equipment.

### Sample Exercise 2.15

#### Writing Structural and Molecular Formulas for Hydrocarbons

Assuming the carbon atoms in *pentane* are in a linear chain, write (a) the structural formula and (b) the molecular formula for this alkane.

#### SOLUTION

- (a) Alkanes contain only carbon and hydrogen, and each carbon is attached to four other atoms. The name *pentane* contains the prefix *penta-* for five (Table 2.6), and we are told that the carbons are in a linear chain. If we then add enough hydrogen atoms to make four bonds to each carbon, we obtain the structural formula

This form of pentane is often called *n*-pentane, where the *n*- stands for “normal” because all five carbon atoms are in one line in the structural formula.

- (b) Once the structural formula is written, we determine the molecular formula by counting the atoms present. Thus, *n*-pentane has the molecular formula  $\text{C}_5\text{H}_{12}$ .

#### Practice Exercise 1

(a) What is the molecular formula of hexane, the alkane with six carbons? (b) What are the name and molecular formula of an alcohol derived from hexane?

#### Practice Exercise 2

These two compounds have “butane” in their name. Are they isomers?

Butane

Cyclobutane

## STRATEGIES FOR SUCCESS

### How to Take a Test

At about this time in your study of chemistry, you are likely to face your first examination. The best way to prepare is to study, do homework diligently, and get help from the instructor on any material that is unclear or confusing. (See the advice for learning and studying chemistry presented in the preface of the book.) We present here some general guidelines for taking tests.

Depending on the nature of your course, the exam could consist of a variety of different types of questions.

- Multiple-choice questions** In large-enrollment courses, the most common kind of test question is the multiple-choice question. Many of the practice exercise problems in this book are written in this format to give you practice at this style of question. When faced with this type of problem, the first thing to realize is that the instructor has written the question so that at first glance all the answers appear to be correct. Thus, you should not jump to the conclusion that because one of the choices looks correct, it must be correct.

If a multiple-choice question involves a calculation, do the calculation, check your work, and *only then* compare your answer with the choices. Keep in mind, though, that your instructor has anticipated the most common errors you might make in solving a given problem and has probably listed the incorrect answers resulting from those errors. Always double-check your reasoning and use dimensional analysis to arrive at the correct numeric answer and the correct units.

In multiple-choice questions that do not involve calculations, if you are not sure of the correct choice, eliminate all the

choices you know for sure to be incorrect. The reasoning you use in eliminating incorrect choices may offer insight into which of the remaining choices is correct.

- Calculations in which you must show your work** In questions of this kind, you may receive partial credit even if you do not arrive at the correct answer, depending on whether the instructor can follow your line of reasoning. It is important, therefore, to be neat and organized in your calculations. Pay particular attention to what information is given and to what your unknown is. Think about how you can get from the given information to your unknown.

You may want to write a few words or a diagram on the test paper to indicate your approach. Then write out your calculations as neatly as you can. Show the units for every number you write down, and use dimensional analysis as much as you can, showing how units cancel.

- Questions requiring drawings** Questions of this kind will come later in the course, but it is useful to talk about them here. (You should review this box before each exam to remind yourself of good exam-taking practices.) Be sure to label your drawing as completely as possible.

Finally, if you find that you simply do not understand how to arrive at a reasoned response to a question, do not linger over the question. Put a check next to it and go on to the next one. If time permits, you can come back to the unanswered questions, but lingering over a question when nothing is coming to mind is wasting time you may need to finish the exam.

## Chapter Summary and Key Terms

**THE ATOMIC THEORY OF MATTER; THE DISCOVERY OF ATOMIC STRUCTURE (SECTION 2.1 AND 2.2)** Atoms are the basic building blocks of matter. They are the smallest units of an element that can combine with other elements. Atoms are composed of even smaller particles, called **subatomic particles**. Some of these subatomic particles are charged and follow the usual behavior of charged particles: Particles with the same charge repel one another, whereas particles with opposite charges are attracted to one another.

We considered some of the important experiments that led to the discovery and characterization of subatomic particles. Thomson's experiments on the behavior of **cathode rays** in magnetic and electric fields led to the discovery of the electron and allowed its charge-to-mass ratio to be measured. Millikan's oil-drop experiment determined the charge of the electron. Becquerel's discovery of **radioactivity**, the spontaneous emission of radiation by atoms, gave further evidence that the atom has a substructure. Rutherford's studies of how  $\alpha$  particles scatter when passing through thin metal foils led to the **nuclear model** of the atom, showing that the atom has a dense, positively charged **nucleus**.

**THE MODERN VIEW OF ATOMIC STRUCTURE (SECTION 2.3)** Atoms have a nucleus that contains **protons** and **neutrons**; **electrons** move in the space around the nucleus. The magnitude of the charge of the electron,  $1.602 \times 10^{-19}$  C, is called the **electronic charge**. The charges of particles are usually represented as multiples of this charge—an electron has a  $1-$  charge, and a proton has a  $1+$  charge. The masses of atoms are usually expressed in terms of **atomic mass units** ( $1 \text{ amu} = 1.66054 \times 10^{-24}$  g). The dimensions of atoms are often expressed in units of **angstroms** ( $1 \text{ \AA} = 10^{-10}$  m).

Elements can be classified by **atomic number**, the number of protons in the nucleus of an atom. All atoms of a given element have the same atomic number. The **mass number** of an atom is the sum of the numbers of protons and neutrons. Atoms of the same element that differ in mass number are known as **isotopes**.

**ATOMIC WEIGHTS (SECTION 2.4)** The atomic mass scale is defined by assigning a mass of exactly 12 amu to a  $^{12}\text{C}$  atom. The **atomic weight** (average atomic mass) of an element can be calculated from the relative abundances and masses of that element's isotopes. The **mass spectrometer** provides the most direct and accurate means of experimentally measuring atomic (and molecular) weights.

**THE PERIODIC TABLE (SECTION 2.5)** The **periodic table** is an arrangement of the elements in order of increasing atomic number. Elements with similar properties are placed in vertical columns. The elements in a column are known as a **group**. The elements in a horizontal row are known as a **period**. The **metallic elements (metals)**, which comprise the majority of the elements, dominate the left side and the middle of the table; the **nonmetallic elements (nonmetals)** are located on the upper right side. Many of the elements that lie along the line that separates metals from nonmetals are **metalloids**.

### MOLECULES AND MOLECULAR COMPOUNDS (SECTION 2.6)

Atoms can combine to form **molecules**. Compounds composed of molecules (**molecular compounds**) usually contain only nonmetallic elements. A molecule that contains two atoms is called a **diatomic molecule**. The composition of a substance is given by its **chemical formula**. A molecular substance can be represented by its **empirical formula**, which gives the relative numbers of atoms of each kind, but is usually represented by its **molecular formula**, which gives the actual numbers of each type of atom in a molecule. **Structural formulas** show the order in which the atoms in a molecule are connected. **Ball-and-stick models** and **space-filling models** convey additional information about the shapes of molecules.

**IONS AND IONIC COMPOUNDS (SECTION 2.7)** Atoms can either gain or lose electrons, forming charged particles called **ions**. Metals tend to lose electrons, becoming positively charged ions (**cations**). Nonmetals tend to gain electrons, forming negatively charged ions (**anions**). Because **ionic compounds** are electrically neutral, containing both cations and anions, they usually contain both metallic and nonmetallic elements. Atoms that are joined together, as in a molecule, but carry a net charge are called **polyatomic ions**. The chemical formulas used for ionic compounds are empirical formulas, which can be written readily if the charges of the ions are known. The total positive charge of the cations in an ionic compound must equal the total negative charge of the anions.

**NAMING INORGANIC COMPOUNDS (SECTION 2.8)** The set of rules for naming chemical compounds is called **chemical nomenclature**. We studied the systematic rules used for naming three classes of inorganic substances: ionic compounds, acids, and binary molecular compounds. In naming an ionic compound, the cation is named first and then the anion. Cations formed from metal atoms have the same name as the metal. If the metal can form cations of differing charges, the charge is given using Roman numerals. Monatomic anions have names ending in *-ide*. Polyatomic anions containing oxygen and another element (**oxyanions**) have names ending in *-ate* or *-ite*. In naming binary molecular compounds, Greek prefixes are used to denote the number of each element in the molecular formula, and the element farthest to the left in the periodic table (closest to metallic elements) is generally written first.

**SOME SIMPLE ORGANIC COMPOUNDS (SECTION 2.9)** Organic chemistry is the study of compounds that contain carbon. The simplest class of organic molecules is the **hydrocarbons**, which contain only carbon and hydrogen. Hydrocarbons in which each carbon atom is attached to four other atoms are called **alkanes**. Alkanes have names that end in *-ane*, such as methane and ethane. Other organic compounds are formed when an H atom of a hydrocarbon is replaced with a functional group. An **alcohol**, for example, is a compound in which an H atom of a hydrocarbon is replaced by an OH functional group. Alcohols have names that end in *-ol*, such as methanol and ethanol. Compounds with the same molecular formula but different bonding arrangements of their constituent atoms are called **isomers**.

## Learning Outcomes After studying this chapter, you should be able to:

- List the basic postulates of Dalton's atomic theory. (Section 2.1) *Related Exercises: 2.11–2.14*
- Describe the key experiments that led to the discovery of electrons and to the nuclear model of the atom. (Section 2.2) *Related Exercises: 2.15–2.18*
- Describe the structure of the atom in terms of protons, neutrons, and electrons and express the relative electrical charges and masses of these subatomic particles. (Section 2.3) *Related Exercises: 2.21, 2.22*
- Use chemical symbols together with atomic number and mass number to express the subatomic composition of isotopes. (Section 2.3) *Related Exercises: 2.23, 2.25, 2.29, 2.55*
- Calculate the atomic weight of an element from the masses of individual atoms and a knowledge of natural abundances. (Section 2.4) *Related Exercises: 2.34–2.36, 2.39*
- Describe how elements are organized in the periodic table by atomic number and by similarities in chemical behavior, giving rise to periods and groups. (Section 2.5) *Related Exercises: 2.43, 2.44*

- Identify the locations of metals and nonmetals in the periodic table. (Section 2.5) *Related Exercises: 2.41, 2.42*
- Distinguish between molecular substances and ionic substances in terms of their composition. (Section 2.6 and 2.7) *Related Exercises: 2.61, 2.63, 2.65, 2.66*
- Distinguish between empirical formulas and molecular formulas. (Section 2.6) *Related Exercises: 2.45–2.47, 2.49*
- Describe how molecular formulas and structural formulas are used to represent the compositions of molecules. (Section 2.6) *Related Exercises: 2.53, 2.54*
- Explain how ions are formed by the gain or loss of electrons and use the periodic table to predict the charges of common ions. (Section 2.7) *Related Exercises: 2.56–2.58*
- Write the empirical formulas of ionic compounds, given the charges of their component ions. (Section 2.7) *Related Exercises: 2.59, 2.61–2.63*
- Write the name of an ionic compound given its chemical formula or write the chemical formula given its name. (Section 2.8) *Related Exercises: 2.71–2.74*
- Name or write chemical formulas for binary inorganic compounds and for acids. (Section 2.8) *Related Exercises: 2.75–2.78*
- Identify organic compounds and name simple alkanes and alcohols. (Section 2.9) *Related Exercises: 2.81, 2.83–2.85*

## Key Equations

- Atomic weight =  $\sum_{\text{over all isotopes}} [(\text{isotope mass}) \times (\text{fractional isotope abundance})]$  [2.1] Calculating atomic weight as a fractionally weighted average of isotopic masses.

## Exercises

### Visualizing Concepts

These exercises are intended to probe your understanding of key concepts rather than your ability to utilize formulas and perform calculations. Exercises with red numbers have answers in the back of the book.

- 2.1** A charged particle moves between two electrically charged plates, as shown here.

- (a) What is the sign of the electrical charge on the particle?  
 (b) As the charge on the plates is increased, would you expect the bending to increase, decrease, or stay the same?  
 (c) As the mass of the particle is increased while the speed of the particles remains the same, would you expect the bending to increase, decrease, or stay the same? [Section 2.2]
- 2.2** The following diagram is a representation of 20 atoms of a fictitious element, which we will call nevadium (Nv). The red spheres are  $^{293}\text{Nv}$ , and the blue spheres are  $^{295}\text{Nv}$ . (a) Assuming that this sample is a statistically representative sample of the element, calculate the percent abundance of each element. (b) If the mass of  $^{293}\text{Nv}$  is 293.15 amu and that of  $^{295}\text{Nv}$  is 295.15 amu, what is the atomic weight of Nv? [Section 2.4]

- 2.3** Four of the boxes in the following periodic table are colored. Which of these are metals and which are nonmetals? Which one is an alkaline earth metal? Which one is a noble gas? [Section 2.5]

- 2.4** Does the following drawing represent a neutral atom or an ion? Write its complete chemical symbol, including mass number, atomic number, and net charge (if any). [Sections 2.3 and 2.7]

- 2.5** Which of the following diagrams most likely represents an ionic compound, and which represents a molecular one? Explain your choice. [Sections 2.6 and 2.7]

(i)

(ii)

- 2.6** Write the chemical formula for the following compound. Is the compound ionic or molecular? Name the compound. [Sections 2.6 and 2.8]

- 2.7** Five of the boxes in the following periodic table are colored. Predict the charge on the ion associated with each of these elements. [Section 2.7]

- 2.8** The following diagram represents an ionic compound in which the red spheres represent cations and the blue spheres represent anions. Which of the following formulas is consistent with the drawing?  $\text{KBr}$ ,  $\text{K}_2\text{SO}_4$ ,  $\text{Ca}(\text{NO}_3)_2$ ,  $\text{Fe}_2(\text{SO}_4)_3$ . Name the compound. [Sections 2.7 and 2.8]

- 2.9** Are these two compounds isomers? Explain. [Section 2.9]

- 2.10** In the Millikan oil-drop experiment (see Figure 2.5), the tiny oil drops are observed through the viewing lens as rising, stationary, or falling, as shown here. (a) What causes their rate of fall to vary from their rate in the absence of an electric field? (b) Why do some drops move upward? [Section 2.2]

The following exercises are divided into sections that deal with specific topics in the chapter. The exercises are grouped in pairs, with the answers given in the back of the book to the odd-numbered exercises, as indicated by the red exercise

numbers. Those exercises whose numbers appear in brackets are more challenging than the nonbracketed exercises.

## The Atomic Theory of Matter and the Discovery of Atomic Structure (Sections 2.1 and 2.2)

- 2.11** A 1.0-g sample of carbon dioxide ( $\text{CO}_2$ ) is fully decomposed into its elements, yielding 0.273 g of carbon and 0.727 g of oxygen. (a) What is the ratio of the mass of O to C? (b) If a sample of a different compound decomposes into 0.429 g of carbon and 0.571 g of oxygen, what is its ratio of the mass of O to C? (c) According to Dalton's atomic theory, what is the empirical formula of the second compound?
- 2.12** Hydrogen sulfide is composed of two elements: hydrogen and sulfur. In an experiment, 6.500 g of hydrogen sulfide is fully decomposed into its elements. (a) If 0.384 g of hydrogen is obtained in this experiment, how many grams of sulfur must be obtained? (b) What fundamental law does this experiment demonstrate?
- 2.13** A chemist finds that 30.82 g of nitrogen will react with 17.60, 35.20, 70.40, or 88.00 g of oxygen to form four different compounds. (a) Calculate the mass of oxygen per gram of nitrogen in each compound. (b) How do the numbers in part (a) support Dalton's atomic theory?
- 2.14** In a series of experiments, a chemist prepared three different compounds that contain only iodine and fluorine and determined the mass of each element in each compound:

| Compound | Mass of Iodine (g) | Mass of Fluorine (g) |
|----------|--------------------|----------------------|
| 1        | 4.75               | 3.56                 |
| 2        | 7.64               | 3.43                 |
| 3        | 9.41               | 9.86                 |

(a) Calculate the mass of fluorine per gram of iodine in each compound. (b) How do the numbers in part (a) support the atomic theory?

- 2.15** Which of the three subatomic particles was discovered first—the proton, neutron, or electron? Which one was discovered last?
- 2.16** An unknown particle is caused to move between two electrically charged plates, as illustrated in Figure 2.7. You hypothesize that the particle is a proton. (a) If your hypothesis is correct, would the particle be deflected in the same or opposite direction as the  $\beta$  rays? (b) Would it be deflected by a smaller or larger amount than the  $\beta$  rays?
- 2.17** What fraction of the  $\alpha$  particles in Rutherford's gold foil experiment are scattered at large angles? Assume the gold foil is two layers thick, as shown in Figure 2.9, and that the approximate diameters of a gold atom and its nucleus are  $2.7 \text{ \AA}$  and  $1.0 \times 10^{-4} \text{ \AA}$ , respectively. *Hint:* Calculate the cross sectional area occupied by the nucleus as a fraction of that occupied by the atom. Assume that the gold nuclei in each layer are offset from each other.
- 2.18** Millikan determined the charge on the electron by studying the static charges on oil drops falling in an electric field (Figure 2.5). A student carried out this experiment using several oil drops for her measurements and calculated the charges on the drops. She obtained the following data:

| Droplet | Calculated Charge (C)  |
|---------|------------------------|
| A       | $1.60 \times 10^{-19}$ |
| B       | $3.15 \times 10^{-19}$ |
| C       | $4.81 \times 10^{-19}$ |
| D       | $6.31 \times 10^{-19}$ |

(a) What is the significance of the fact that the droplets carried different charges? (b) What conclusion can the student draw from these data regarding the charge of the electron? (c) What value (and to how many significant figures) should she report for the electronic charge?

### The Modern View of Atomic Structure; Atomic Weights (Sections 2.3 and 2.4)

**2.19** The radius of an atom of gold (Au) is about 1.35 Å. (a) Express this distance in nanometers (nm) and in picometers (pm). (b) How many gold atoms would have to be lined up to span 1.0 mm? (c) If the atom is assumed to be a sphere, what is the volume in  $\text{cm}^3$  of a single Au atom?

**2.20** An atom of rhodium (Rh) has a diameter of about  $2.7 \times 10^{-8}$  cm. (a) What is the radius of a rhodium atom in angstroms (Å) and in meters (m)? (b) How many Rh atoms would have to be placed side by side to span a distance of  $6.0 \mu\text{m}$ ? (c) If you assume that the Rh atom is a sphere, what is the volume in  $\text{m}^3$  of a single atom?

**2.21** Answer the following questions without referring to Table 2.1: (a) What are the main subatomic particles that make up the atom? (b) What is the relative charge (in multiples of the electronic charge) of each of the particles? (c) Which of the particles is the most massive? (d) Which is the least massive?

**2.22** Determine whether each of the following statements is true or false. If false, correct the statement to make it true: (a) The nucleus has most of the mass and comprises most of the volume of an atom. (b) Every atom of a given element has the same number of protons. (c) The number of electrons in an atom equals the number of neutrons in the atom. (d) The protons in the nucleus of the helium atom are held together by a force called the strong nuclear force.

**2.23** Consider an atom of  $^{10}\text{B}$ . (a) How many protons, neutrons, and electrons does this atom contain? (b) What is the symbol of the atom obtained by adding one proton to  $^{10}\text{B}$ ? (c) What is the symbol of the atom obtained by adding one neutron to  $^{10}\text{B}$ ? (d) Are either of the atoms obtained in parts (b) and (c) isotopes of  $^{10}\text{B}$ ? If so which one?

**2.24** Consider an atom of  $^{63}\text{Cu}$ . (a) How many protons, neutrons, and electrons does this atom contain? (b) What is the symbol of the ion obtained by removing two electrons from  $^{63}\text{Cu}$ ? (c) What is the symbol for the isotope of  $^{63}\text{Cu}$  that possesses 36 neutrons?

**2.25** (a) Define atomic number and mass number. (b) Which of these can vary without changing the identity of the element?

**2.26** (a) Which two of the following are isotopes of the same element:  $^{31}_{16}\text{X}$ ,  $^{31}_{15}\text{X}$ ,  $^{32}_{16}\text{X}$ ? (b) What is the identity of the element whose isotopes you have selected?

**2.27** How many protons, neutrons, and electrons are in the following atoms? (a)  $^{40}\text{Ar}$ , (b)  $^{65}\text{Zn}$ , (c)  $^{70}\text{Ga}$ , (d)  $^{80}\text{Br}$ , (e)  $^{184}\text{W}$ , (f)  $^{243}\text{Am}$ .

**2.28** Each of the following isotopes is used in medicine. Indicate the number of protons and neutrons in each isotope: (a) phosphorus-32, (b) chromium-51, (c) cobalt-60, (d) technetium-99, (e) iodine-131, (f) thallium-201.

**2.29** Fill in the gaps in the following table, assuming each column represents a neutral atom.

| Symbol    | $^{79}\text{Br}$ |    |    |     |     |
|-----------|------------------|----|----|-----|-----|
| Protons   |                  | 25 |    |     | 82  |
| Neutrons  |                  | 30 | 64 |     |     |
| Electrons |                  |    | 48 | 86  |     |
| Mass no.  |                  |    |    | 222 | 207 |

**2.30** Fill in the gaps in the following table, assuming each column represents a neutral atom.

| Symbol    | $^{112}\text{Cd}$ |    |    |    |     |
|-----------|-------------------|----|----|----|-----|
| Protons   |                   | 38 |    |    | 92  |
| Neutrons  |                   | 58 | 49 |    |     |
| Electrons |                   |    | 38 | 36 |     |
| Mass no.  |                   |    |    | 81 | 235 |

**2.31** Write the correct symbol, with both superscript and subscript, for each of the following. Use the list of elements in the front inside cover as needed: (a) the isotope of platinum that contains 118 neutrons, (b) the isotope of krypton with mass number 84, (c) the isotope of arsenic with mass number 75, (d) the isotope of magnesium that has an equal number of protons and neutrons.

**2.32** One way in which Earth's evolution as a planet can be understood is by measuring the amounts of certain isotopes in rocks. One quantity recently measured is the ratio of  $^{129}\text{Xe}$  to  $^{130}\text{Xe}$  in some minerals. In what way do these two isotopes differ from one another? In what respects are they the same?

**2.33** (a) What isotope is used as the standard in establishing the atomic mass scale? (b) The atomic weight of boron is reported as 10.81, yet no atom of boron has the mass of 10.81 amu. Explain.

**2.34** (a) What is the mass in amu of a carbon-12 atom? (b) Why is the atomic weight of carbon reported as 12.011 in the table of elements and the periodic table in the front inside cover of this text?

**2.35** Only two isotopes of copper occur naturally:  $^{63}\text{Cu}$  (atomic mass = 62.9296 amu; abundance 69.17%) and  $^{65}\text{Cu}$  (atomic mass = 64.9278 amu; abundance 30.83%). Calculate the atomic weight (average atomic mass) of copper.

**2.36** Rubidium has two naturally occurring isotopes, rubidium-85 (atomic mass = 84.9118 amu; abundance = 72.15%) and rubidium-87 (atomic mass = 86.9092 amu; abundance = 27.85%). Calculate the atomic weight of rubidium.

**2.37** (a) Thomson's cathode-ray tube (Figure 2.4) and the mass spectrometer (Figure 2.11) both involve the use of electric or magnetic fields to deflect charged particles. What are the charged particles involved in each of these experiments? (b) What are the labels on the axes of a mass spectrum? (c) To measure the mass spectrum of an atom, the atom must first lose one or more electrons. Which would you expect to be deflected more by the same setting of the electric and magnetic fields, a  $\text{Cl}^+$  or a  $\text{Cl}^{2+}$  ion?

**2.38** Consider the mass spectrometer shown in Figure 2.11. Determine whether each of the following statements is true or false. If false, correct the statement to make it true: (a) The paths of neutral (uncharged) atoms are not affected by the magnet. (b) The height of each peak in the mass spectrum is inversely proportional to the mass of that isotope. (c) For a given element, the number of peaks in the spectrum is equal to the number of naturally occurring isotopes of that element.

**2.39** Naturally occurring magnesium has the following isotopic abundances:

| Isotope          | Abundance (%) | Atomic mass (amu) |
|------------------|---------------|-------------------|
| $^{24}\text{Mg}$ | 78.99         | 23.98504          |
| $^{25}\text{Mg}$ | 10.00         | 24.98584          |
| $^{26}\text{Mg}$ | 11.01         | 25.98259          |

(a) What is the average atomic mass of Mg? (b) Sketch the mass spectrum of Mg.

- 2.40** Mass spectrometry is more often applied to molecules than to atoms. We will see in Chapter 3 that the *molecular weight* of a molecule is the sum of the atomic weights of the atoms in the molecule. The mass spectrum of  $\text{H}_2$  is taken under conditions that prevent decomposition into H atoms. The two naturally occurring isotopes of hydrogen are  $^1\text{H}$  (atomic mass = 1.00783 amu; abundance 99.9885%) and  $^2\text{H}$  (atomic mass = 2.01410 amu; abundance 0.0115%). (a) How many peaks will the mass spectrum have? (b) Give the relative atomic masses of each of these peaks. (c) Which peak will be the largest, and which the smallest?

### The Periodic Table, Molecules, Molecular Compounds, Ions, and Ionic Compounds (Sections 2.5, 2.6, and 2.7)

- 2.41** For each of the following elements, write its chemical symbol, locate it in the periodic table, give its atomic number, and indicate whether it is a metal, metalloid, or nonmetal: (a) chromium, (b) helium, (c) phosphorus, (d) zinc, (e) magnesium, (f) bromine, (g) arsenic.
- 2.42** Locate each of the following elements in the periodic table; give its name and atomic number, and indicate whether it is a metal, metalloid, or nonmetal: (a) Li, (b) Sc, (c) Ge, (d) Yb, (e) Mn, (f) Sb, (g) Xe.
- 2.43** For each of the following elements, write its chemical symbol, determine the name of the group to which it belongs (Table 2.3), and indicate whether it is a metal, metalloid, or nonmetal: (a) potassium, (b) iodine, (c) magnesium, (d) argon, (e) sulfur.
- 2.44** The elements of group 4A show an interesting change in properties moving down the group. Give the name and chemical symbol of each element in the group and label it as a nonmetal, metalloid, or metal.
- 2.45** The structural formulas of the compounds *n*-butane and isobutane are shown below. (a) Determine the molecular formula of each. (b) Determine the empirical formula of each. (c) Which formulas—empirical, molecular, or structural—allow you to determine these are different compounds?

- 2.46** Ball-and-stick representations of benzene, a colorless liquid often used in organic chemistry reactions, and acetylene, a gas used as a fuel for high-temperature welding, are shown below. (a) Determine the molecular formula of each. (b) Determine the empirical formula of each.

- 2.47** What are the molecular and empirical formulas for each of the following compounds?

- 2.48** Two substances have the same molecular and empirical formulas. Does this mean that they must be the same compound?
- 2.49** Write the empirical formula corresponding to each of the following molecular formulas: (a)  $\text{Al}_2\text{Br}_6$ , (b)  $\text{C}_8\text{H}_{10}$ , (c)  $\text{C}_4\text{H}_8\text{O}_2$ , (d)  $\text{P}_4\text{O}_{10}$ , (e)  $\text{C}_6\text{H}_4\text{Cl}_2$ , (f)  $\text{B}_3\text{N}_3\text{H}_6$ .
- 2.50** Determine the molecular and empirical formulas of the following: (a) the organic solvent *benzene*, which has six carbon atoms and six hydrogen atoms; (b) the compound *silicon tetrachloride*, which has a silicon atom and four chlorine atoms and is used in the manufacture of computer chips; (c) the reactive substance *diborane*, which has two boron atoms and six hydrogen atoms; (d) the sugar called *glucose*, which has six carbon atoms, twelve hydrogen atoms, and six oxygen atoms.
- 2.51** How many hydrogen atoms are in each of the following: (a)  $\text{C}_2\text{H}_5\text{OH}$ , (b)  $\text{Ca}(\text{C}_2\text{H}_5\text{COO})_2$ , (c)  $(\text{NH}_4)_3\text{PO}_4$ ?
- 2.52** How many of the indicated atoms are represented by each chemical formula: (a) carbon atoms in  $\text{C}_4\text{H}_9\text{COOCH}_3$ , (b) oxygen atoms in  $\text{Ca}(\text{ClO}_3)_2$ , (c) hydrogen atoms in  $(\text{NH}_4)_2\text{HPO}_4$ ?
- 2.53** Write the molecular and structural formulas for the compounds represented by the following molecular models:

- 2.54** Write the molecular and structural formulas for the compounds represented by the following models:

**2.55** Fill in the gaps in the following table:

| Symbol     | $^{59}\text{Co}^{3+}$ |    |     |     |
|------------|-----------------------|----|-----|-----|
| Protons    |                       | 34 | 76  | 80  |
| Neutrons   |                       | 46 | 116 | 120 |
| Electrons  |                       | 36 |     | 78  |
| Net charge |                       |    | 2+  |     |

**2.56** Fill in the gaps in the following table:

| Symbol     | $^{31}\text{P}^{3-}$ |    |    |     |
|------------|----------------------|----|----|-----|
| Protons    |                      | 34 | 50 |     |
| Neutrons   |                      | 45 | 69 | 118 |
| Electrons  |                      |    | 46 | 76  |
| Net charge |                      | 2- |    | 3+  |

**2.57** Each of the following elements is capable of forming an ion in chemical reactions. By referring to the periodic table, predict the charge of the most stable ion of each: **(a)** Mg, **(b)** Al, **(c)** K, **(d)** S, **(e)** Fe.

**2.58** Using the periodic table, predict the charges of the ions of the following elements: **(a)** Ga, **(b)** Sr, **(c)** As, **(d)** Br, **(e)** Se.

**2.59** Using the periodic table to guide you, predict the chemical formula and name of the compound formed by the following elements: **(a)** Ga and F, **(b)** Li and H, **(c)** Al and I, **(d)** K and S.

**2.60** The most common charge associated with scandium in its compounds is 3+. Indicate the chemical formulas you would expect for compounds formed between scandium and **(a)** iodine, **(b)** sulfur, **(c)** nitrogen.

**2.61** Predict the chemical formula for the ionic compound formed by **(a)**  $\text{Ca}^{2+}$  and  $\text{Br}^-$ , **(b)**  $\text{K}^+$  and  $\text{CO}_3^{2-}$ , **(c)**  $\text{Al}^{3+}$  and  $\text{CH}_3\text{COO}^-$ , **(d)**  $\text{NH}_4^+$  and  $\text{SO}_4^{2-}$ , **(e)**  $\text{Mg}^{2+}$  and  $\text{PO}_4^{3-}$ .

**2.62** Predict the chemical formulas of the compounds formed by the following pairs of ions: **(a)**  $\text{Cr}^{3+}$  and  $\text{Br}^-$ , **(b)**  $\text{Fe}^{3+}$  and  $\text{O}^{2-}$ , **(c)**  $\text{Hg}_2^{2+}$  and  $\text{CO}_3^{2-}$ , **(d)**  $\text{Ca}^{2+}$  and  $\text{ClO}_3^-$ , **(e)**  $\text{NH}_4^+$  and  $\text{PO}_4^{3-}$ .

**2.63** Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

| Ion                | $\text{K}^+$ | $\text{NH}_4^+$ | $\text{Mg}^{2+}$ | $\text{Fe}^{3+}$ |
|--------------------|--------------|-----------------|------------------|------------------|
| $\text{Cl}^-$      | KCl          |                 |                  |                  |
| $\text{OH}^-$      |              |                 |                  |                  |
| $\text{CO}_3^{2-}$ |              |                 |                  |                  |
| $\text{PO}_4^{3-}$ |              |                 |                  |                  |

**2.64** Complete the table by filling in the formula for the ionic compound formed by each pair of cations and anions, as shown for the first pair.

| Ion                 | $\text{Na}^+$         | $\text{Ca}^{2+}$ | $\text{Fe}^{2+}$ | $\text{Al}^{3+}$ |
|---------------------|-----------------------|------------------|------------------|------------------|
| $\text{O}^{2-}$     | $\text{Na}_2\text{O}$ |                  |                  |                  |
| $\text{NO}_3^-$     |                       |                  |                  |                  |
| $\text{SO}_4^{2-}$  |                       |                  |                  |                  |
| $\text{AsO}_4^{3-}$ |                       |                  |                  |                  |

**2.65** Predict whether each of the following compounds is molecular or ionic: **(a)**  $\text{B}_2\text{H}_6$ , **(b)**  $\text{CH}_3\text{OH}$ , **(c)**  $\text{LiNO}_3$ , **(d)**  $\text{Sc}_2\text{O}_3$ , **(e)**  $\text{CsBr}$ , **(f)**  $\text{NOCl}$ , **(g)**  $\text{NF}_3$ , **(h)**  $\text{Ag}_2\text{SO}_4$ .

**2.66** Which of the following are ionic, and which are molecular? **(a)**  $\text{PF}_5$ , **(b)**  $\text{NaI}$ , **(c)**  $\text{SCl}_2$ , **(d)**  $\text{Ca}(\text{NO}_3)_2$ , **(e)**  $\text{FeCl}_3$ , **(f)**  $\text{LaP}$ , **(g)**  $\text{CoCO}_3$ , **(h)**  $\text{N}_2\text{O}_4$ .

## Naming Inorganic Compounds; Some Simple Organic Compounds (Sections 2.8 and 2.9)

**2.67** Give the chemical formula for **(a)** chlorite ion, **(b)** chloride ion, **(c)** chlorate ion, **(d)** perchlorate ion, **(e)** hypochlorite ion.

**2.68** Selenium, an element required nutritionally in trace quantities, forms compounds analogous to sulfur. Name the following ions: **(a)**  $\text{SeO}_4^{2-}$ , **(b)**  $\text{Se}^{2-}$ , **(c)**  $\text{HSe}^-$ , **(d)**  $\text{HSeO}_3^-$ .

**2.69** Give the names and charges of the cation and anion in each of the following compounds: **(a)**  $\text{CaO}$ , **(b)**  $\text{Na}_2\text{SO}_4$ , **(c)**  $\text{KClO}_4$ , **(d)**  $\text{Fe}(\text{NO}_3)_2$ , **(e)**  $\text{Cr}(\text{OH})_3$ .

**2.70** Give the names and charges of the cation and anion in each of the following compounds: **(a)**  $\text{CuS}$ , **(b)**  $\text{Ag}_2\text{SO}_4$ , **(c)**  $\text{Al}(\text{ClO}_3)_3$ , **(d)**  $\text{Co}(\text{OH})_2$ , **(e)**  $\text{PbCO}_3$ .

**2.71** Name the following ionic compounds: **(a)**  $\text{Li}_2\text{O}$ , **(b)**  $\text{FeCl}_3$ , **(c)**  $\text{NaClO}$ , **(d)**  $\text{CaSO}_3$ , **(e)**  $\text{Cu}(\text{OH})_2$ , **(f)**  $\text{Fe}(\text{NO}_3)_2$ , **(g)**  $\text{Ca}(\text{CH}_3\text{COO})_2$ , **(h)**  $\text{Cr}_2(\text{CO}_3)_3$ , **(i)**  $\text{K}_2\text{CrO}_4$ , **(j)**  $(\text{NH}_4)_2\text{SO}_4$ .

**2.72** Name the following ionic compounds: **(a)**  $\text{KCN}$ , **(b)**  $\text{NaBrO}_2$ , **(c)**  $\text{Sr}(\text{OH})_2$ , **(d)**  $\text{CoTe}$ , **(e)**  $\text{Fe}_2(\text{CO}_3)_3$ , **(f)**  $\text{Cr}(\text{NO}_3)_3$ , **(g)**  $(\text{NH}_4)_2\text{SO}_3$ , **(h)**  $\text{NaH}_2\text{PO}_4$ , **(i)**  $\text{KMnO}_4$ , **(j)**  $\text{Ag}_2\text{Cr}_2\text{O}_7$ .

**2.73** Write the chemical formulas for the following compounds: **(a)** aluminum hydroxide, **(b)** potassium sulfate, **(c)** copper(I) oxide, **(d)** zinc nitrate, **(e)** mercury(II) bromide, **(f)** iron(III) carbonate, **(g)** sodium hypobromite.

**2.74** Give the chemical formula for each of the following ionic compounds: **(a)** sodium phosphate, **(b)** zinc nitrate, **(c)** barium bromate, **(d)** iron(II) perchlorate, **(e)** cobalt(II) hydrogen carbonate, **(f)** chromium(III) acetate, **(g)** potassium dichromate.

**2.75** Give the name or chemical formula, as appropriate, for each of the following acids: **(a)**  $\text{HBrO}_3$ , **(b)**  $\text{HBr}$ , **(c)**  $\text{H}_3\text{PO}_4$ , **(d)** hypochlorous acid, **(e)** iodic acid, **(f)** sulfurous acid.

**2.76** Provide the name or chemical formula, as appropriate, for each of the following acids: **(a)** hydroiodic acid, **(b)** chloric acid, **(c)** nitrous acid, **(d)**  $\text{H}_2\text{CO}_3$ , **(e)**  $\text{HClO}_4$ , **(f)**  $\text{CH}_3\text{COOH}$ .

**2.77** Give the name or chemical formula, as appropriate, for each of the following binary molecular substances: **(a)**  $\text{SF}_6$ , **(b)**  $\text{IF}_5$ , **(c)**  $\text{XeO}_3$ , **(d)** dinitrogen tetroxide, **(e)** hydrogen cyanide, **(f)** tetraphosphorus hexasulfide.

**2.78** The oxides of nitrogen are very important components in urban air pollution. Name each of the following compounds: **(a)**  $\text{N}_2\text{O}$ , **(b)**  $\text{NO}$ , **(c)**  $\text{NO}_2$ , **(d)**  $\text{N}_2\text{O}_5$ , **(e)**  $\text{N}_2\text{O}_4$ .

**2.79** Write the chemical formula for each substance mentioned in the following word descriptions (use the front inside cover to find the symbols for the elements you do not know). **(a)** Zinc carbonate can be heated to form zinc oxide and carbon dioxide. **(b)** On treatment with hydrofluoric acid, silicon dioxide forms silicon tetrafluoride and water. **(c)** Sulfur dioxide reacts with water to form sulfurous acid. **(d)** The substance phosphorus trihydride, commonly called phosphine, is a toxic gas. **(e)** Perchloric acid reacts with cadmium to form cadmium(II) perchlorate. **(f)** Vanadium(III) bromide is a colored solid.

**2.80** Assume that you encounter the following sentences in your reading. What is the chemical formula for each substance mentioned? **(a)** Sodium hydrogen carbonate is used as a deodorant. **(b)** Calcium hypochlorite is used in some bleaching solutions. **(c)** Hydrogen cyanide is a very poisonous gas. **(d)** Magnesium hydroxide is used as a cathartic. **(e)** Tin(II) fluoride has been used as a fluoride additive in toothpastes. **(f)** When cadmium sulfide is treated with sulfuric acid, fumes of hydrogen sulfide are given off.

**2.81** **(a)** What is a hydrocarbon? **(b)** Pentane is the alkane for a chain of five carbon atoms. Write a structural formula for this compound and determine its molecular and empirical formulas.

- 2.82** (a) What is meant by the term *isomer*? (b) Among the four alkanes, ethane, propane, butane, and pentane, which is capable of existing in isomeric forms?
- 2.83** (a) What is a functional group? (b) What functional group characterizes an alcohol? (c) Write a structural formula for 1-pentanol, the alcohol derived from pentane by making a substitution on one of the carbon atoms.
- 2.84** Consider the following organic substances: ethanol, propane, hexane, and propanol. (a) Which of these molecules

contains an OH group? (b) Which of these molecules contains three carbon atoms?

- 2.85** Chloropropane is derived from propane by substituting Cl for H on one of the carbon atoms. (a) Draw the structural formulas for the two isomers of chloropropane. (b) Suggest names for these two compounds.
- 2.86** Draw the structural formulas for three isomers of pentane,  $C_5H_{12}$ .

## Additional Exercises

These exercises are not divided by category, although they are roughly in the order of the topics in the chapter. They are not paired.

- 2.87** Suppose a scientist repeats the Millikan oil-drop experiment but reports the charges on the drops using an unusual (and imaginary) unit called the *warmomb* (wa). The scientist obtains the following data for four of the drops:

| Droplet | Calculated Charge (wa) |
|---------|------------------------|
| A       | $3.84 \times 10^{-8}$  |
| B       | $4.80 \times 10^{-8}$  |
| C       | $2.88 \times 10^{-8}$  |
| D       | $8.64 \times 10^{-8}$  |

- (a) If all the droplets were the same size, which would fall most slowly through the apparatus? (b) From these data, what is the best choice for the charge of the electron in warmombs? (c) Based on your answer to part (b), how many electrons are there on each of the droplets? (d) What is the conversion factor between warmombs and coulombs?
- 2.88** The natural abundance of  $^3\text{He}$  is 0.000137%. (a) How many protons, neutrons, and electrons are in an atom of  $^3\text{He}$ ? (b) Based on the sum of the masses of their subatomic particles, which is expected to be more massive, an atom of  $^3\text{He}$  or an atom of  $^3\text{H}$  (which is also called *tritium*)? (c) Based on your answer to part (b), what would need to be the precision of a mass spectrometer that is able to differentiate between peaks that are due to  $^3\text{He}^+$  and  $^3\text{H}^+$ ?
- 2.89** A cube of gold that is 1.00 cm on a side has a mass of 19.3 g. A single gold atom has a mass of 197.0 amu. (a) How many gold atoms are in the cube? (b) From the information given, estimate the diameter in Å of a single gold atom. (c) What assumptions did you make in arriving at your answer for part (b)?
- 2.90** The diameter of a rubidium atom is 4.95 Å. We will consider two different ways of placing the atoms on a surface. In arrangement A, all the atoms are lined up with one another to form a square grid. Arrangement B is called a *close-packed* arrangement because the atoms sit in the “depressions” formed by the previous row of atoms:

- (a) Using arrangement A, how many Rb atoms could be placed on a square surface that is 1.0 cm on a side? (b) How many Rb atoms could be placed on a square surface that is 1.0 cm on a side, using arrangement B? (c) By what factor has the number of atoms on the surface increased in going to arrangement B from arrangement A? If extended to three dimensions, which arrangement would lead to a greater density for Rb metal?

- 2.91** (a) Assuming the dimensions of the nucleus and atom shown in Figure 2.10, what fraction of the *volume* of the atom is taken up by the nucleus? (b) Using the mass of the proton from Table 2.1 and assuming its diameter is  $1.0 \times 10^{-15}$  m, calculate the density of a proton in  $\text{g}/\text{cm}^3$ .
- 2.92** Identify the element represented by each of the following symbols and give the number of protons and neutrons in each: (a)  $^{74}_{33}\text{X}$ , (b)  $^{127}_{53}\text{X}$ , (c)  $^{152}_{63}\text{X}$ , (d)  $^{209}_{83}\text{X}$ .
- 2.93** The nucleus of  $^6\text{Li}$  is a powerful absorber of neutrons. It exists in the naturally occurring metal to the extent of 7.5%. In the era of nuclear deterrence, large quantities of lithium were processed to remove  $^6\text{Li}$  for use in hydrogen bomb production. The lithium metal remaining after removal of  $^6\text{Li}$  was sold on the market. (a) What are the compositions of the nuclei of  $^6\text{Li}$  and  $^7\text{Li}$ ? (b) The atomic masses of  $^6\text{Li}$  and  $^7\text{Li}$  are 6.015122 and 7.016004 amu, respectively. A sample of lithium depleted in the lighter isotope was found on analysis to contain 1.442%  $^6\text{Li}$ . What is the average atomic weight of this sample of the metal?
- 2.94** The element oxygen has three naturally occurring isotopes, with 8, 9, and 10 neutrons in the nucleus, respectively. (a) Write the full chemical symbols for these three isotopes. (b) Describe the similarities and differences between the three kinds of atoms of oxygen.
- 2.95** The element lead (Pb) consists of four naturally occurring isotopes with atomic masses 203.97302, 205.97444, 206.97587, and 207.97663 amu. The relative abundances of these four isotopes are 1.4, 24.1, 22.1, and 52.4%, respectively. From these data, calculate the atomic weight of lead.
- 2.96** Gallium (Ga) consists of two naturally occurring isotopes with masses of 68.926 and 70.925 amu. (a) How many protons and neutrons are in the nucleus of each isotope? Write the complete atomic symbol for each, showing the atomic number and mass number. (b) The average atomic mass of Ga is 69.72 amu. Calculate the abundance of each isotope.
- 2.97** Using a suitable reference such as the *CRC Handbook of Chemistry and Physics* or <http://www.webelements.com>, look up the following information for nickel: (a) the number of known isotopes, (b) the atomic masses (in amu), (c) the natural abundances of the five most abundant isotopes.
- 2.98** There are two different isotopes of bromine atoms. Under normal conditions, elemental bromine consists of  $\text{Br}_2$  molecules, and the mass of a  $\text{Br}_2$  molecule is the sum of the masses of the two atoms in the molecule. The mass spectrum of  $\text{Br}_2$  consists of three peaks:

| Mass (amu) | Relative Size |
|------------|---------------|
| 157.836    | 0.2569        |
| 159.834    | 0.4999        |
| 161.832    | 0.2431        |

- (a) What is the origin of each peak (of what isotopes does each consist)? (b) What is the mass of each isotope? (c) Determine the average molecular mass of a  $\text{Br}_2$  molecule.

(d) Determine the average atomic mass of a bromine atom.  
(e) Calculate the abundances of the two isotopes.

- 2.99** It is common in mass spectrometry to assume that the mass of a cation is the same as that of its parent atom. (a) Using data in Table 2.1, determine the number of significant figures that must be reported before the difference in masses of  $^1\text{H}$  and  $^1\text{H}^+$  is significant. (b) What percentage of the mass of an  $^1\text{H}$  atom does the electron represent?
- 2.100** From the following list of elements—Ar, H, Ga, Al, Ca, Br, Ge, K, O—pick the one that best fits each description. Use each element only once: (a) an alkali metal, (b) an alkaline earth metal, (c) a noble gas, (d) a halogen, (e) a metalloid, (f) a nonmetal listed in group 1A, (g) a metal that forms a  $3+$  ion, (h) a nonmetal that forms a  $2-$  ion, (i) an element that resembles aluminum.
- 2.101** The first atoms of seaborgium (Sg) were identified in 1974. The longest-lived isotope of Sg has a mass number of 266. (a) How many protons, electrons, and neutrons are in an  $^{266}\text{Sg}$  atom? (b) Atoms of Sg are very unstable, and it is therefore difficult to study this element's properties. Based on the position of Sg in the periodic table, what element should it most closely resemble in its chemical properties?
- 2.102** The explosion of an atomic bomb releases many radioactive isotopes, including strontium-90. Considering the location of strontium in the periodic table, suggest a reason for the fact that this isotope is particularly dangerous for human health.
- 2.103** A U.S. 1-cent coin (a penny) has a diameter of 19 mm and a thickness of 1.5 mm. Assume the coin is made of pure copper, whose density and approximate market price are  $8.9\text{ g/cm}^3$  and \$2.40 per pound, respectively. Calculate the value of the copper in the coin, assuming its thickness is uniform.
- 2.104** The U.S. Mint produces a dollar coin called the American Silver Eagle that is made of nearly pure silver. This coin has a diameter of 41 mm and a thickness of 2.5 mm. The density and approximate market price of silver are  $10.5\text{ g/cm}^3$  and \$0.51 per gram, respectively. Calculate the value of the silver in the coin, assuming its thickness is uniform.
- 2.105** From the molecular structures shown here, identify the one that corresponds to each of the following species: (a) chlorine gas; (b) propane; (c) nitrate ion; (d) sulfur trioxide; (e) methyl chloride,  $\text{CH}_3\text{Cl}$ .

(i)

(ii)

(iii)

(iv)

(v)

- 2.106** Name each of the following oxides. Assuming that the compounds are ionic, what charge is associated with the

metallic element in each case? (a)  $\text{NiO}$ , (b)  $\text{MnO}_2$ , (c)  $\text{Cr}_2\text{O}_3$ , (d)  $\text{MoO}_3$ .

- 2.107** Fill in the blanks in the following table:

| Cation           | Anion              | Formula                      | Name               |
|------------------|--------------------|------------------------------|--------------------|
|                  |                    |                              | Lithium oxide      |
| $\text{Fe}^{2+}$ | $\text{PO}_4^{3-}$ |                              |                    |
|                  |                    | $\text{Al}_2(\text{SO}_4)_3$ |                    |
|                  |                    |                              | Copper(II) nitrate |
| $\text{Cr}^{3+}$ | $\text{I}^-$       |                              |                    |
|                  |                    | $\text{MnClO}_2$             |                    |
|                  |                    |                              | Ammonium carbonate |
|                  |                    |                              | Zinc perchlorate   |

- 2.108** Cyclopropane is an interesting hydrocarbon. Instead of having three carbons in a row, the three carbons form a ring, as shown in this perspective drawing (see Figure 2.18 for a prior example of this kind of drawing):

Cyclopropane was at one time used as an anesthetic, but its use was discontinued, in part because it is highly flammable. (a) What is the empirical formula of cyclopropane? How does it differ from that of propane? (b) The three carbon atoms are necessarily in a plane. What do the different wedges mean? (c) What change would you make to the structure shown to illustrate chlorocyclopropane? Are there isomers of chlorocyclopropane?

- 2.109** Elements in the same group of the periodic table often form oxyanions with the same general formula. The anions are also named in a similar fashion. Based on these observations, suggest a chemical formula or name, as appropriate, for each of the following ions: (a)  $\text{BrO}_4^-$ , (b)  $\text{SeO}_3^{2-}$ , (c) arsenate ion, (d) hydrogen tellurate ion.
- 2.110** Carbonic acid occurs in carbonated beverages. When allowed to react with lithium hydroxide, it produces lithium carbonate. Lithium carbonate is used to treat depression and bipolar disorder. Write chemical formulas for carbonic acid, lithium hydroxide, and lithium carbonate.
- 2.111** Give the chemical names of each of the following familiar compounds: (a)  $\text{NaCl}$  (table salt), (b)  $\text{NaHCO}_3$  (baking soda), (c)  $\text{NaOCl}$  (in many bleaches), (d)  $\text{NaOH}$  (caustic soda), (e)  $(\text{NH}_4)_2\text{CO}_3$  (smelling salts), (f)  $\text{CaSO}_4$  (plaster of Paris).
- 2.112** Many familiar substances have common, unsystematic names. For each of the following, give the correct systematic name: (a) saltpeter,  $\text{KNO}_3$ ; (b) soda ash,  $\text{Na}_2\text{CO}_3$ ; (c) lime,  $\text{CaO}$ ; (d) muriatic acid,  $\text{HCl}$ ; (e) Epsom salts,  $\text{MgSO}_4$ ; (f) milk of magnesia,  $\text{Mg}(\text{OH})_2$ .
- 2.113** Because many ions and compounds have very similar names, there is great potential for confusing them. Write the correct chemical formulas to distinguish between (a) calcium sulfide and calcium hydrogen sulfide, (b) hydrobromic acid and bromic acid, (c) aluminum nitride and aluminum nitrite, (d) iron(II) oxide and iron(III) oxide, (e) ammonia and ammonium ion, (f) potassium sulfite and potassium bisulfite, (g) mercurous chloride and mercuric chloride, (h) chloric acid and perchloric acid.
- 2.114** In what part of the atom does the strong nuclear force operate?

3

# CHEMICAL REACTIONS AND REACTION STOICHIOMETRY

Have you ever mixed vinegar with baking soda? If so, you know the result is an immediate and effervescent cascade of bubbles. The bubbles contain carbon dioxide gas that is produced by the chemical reaction between sodium bicarbonate in the baking soda and acetic acid in the vinegar.

The bubbles released when baking soda reacts with an acid play an important role in baking, where the release of gaseous  $\text{CO}_2$  causes the dough in your biscuits or the batter in your pancakes to rise. An alternative way to produce  $\text{CO}_2$  in cooking is to use yeasts that rely on chemical reactions to convert sugar into  $\text{CO}_2$ , ethanol, and other organic compounds. These types of chemical reactions have been used for thousands of years in the baking of breads as well as in the production of alcoholic beverages like beer and wine. Chemical reactions that produce  $\text{CO}_2$  are not limited to cooking, though—they occur in places as diverse as the cells in your body and the engine of your car.

In this chapter we begin exploring chemical reactions. Our focus will be on the use of chemical formulas to represent reactions and on the quantitative information we can obtain about the amounts of substances involved in those reactions. **Stoichiometry** (pronounced stoy-key-OM-uh-tree) is the area of study that examines the quantities of substances consumed and produced in chemical reactions. Stoichiometry (Greek *stoicheion*, “element,” and *metron*, “measure”) provides an essential set of tools widely used in chemistry.

◀ **THESE STAINLESS STEEL REACTORS** are where the chemistry happens to make the carbonated alcoholic beverage known as beer.

## WHAT'S AHEAD

- 3.1 ▶ Chemical Equations** Use chemical formulas to write equations representing chemical reactions.
- 3.2 ▶ Simple Patterns of Chemical Reactivity** Examine some simple chemical reactions: *combination reactions*, *decomposition reactions*, and *combustion reactions*.
- 3.3 ▶ Formula Weights** Learn to obtain quantitative information from chemical formulas by using *formula weights*.
- 3.4 ▶ Avogadro's Number and the Mole** Use chemical formulas to relate the masses of substances to the numbers of atoms, molecules, or ions contained in the substances, a relationship that leads to the crucially important concept of the *mole*, defined as  $6.022 \times 10^{23}$  objects (atoms, molecules, ions, and so on).
- 3.5 ▶ Empirical Formulas from Analyses** Apply the mole concept to determine chemical formulas from the masses of each element in a given quantity of a compound.
- 3.6 ▶ Quantitative Information from Balanced Equations** Use the quantitative information inherent in chemical formulas and equations together with the mole concept to predict the amounts of substances consumed or produced in chemical reactions.
- 3.7 ▶ Limiting Reactants** Recognize that one reactant may be used up before others in a chemical reaction. This is the *limiting reactant*. Once the limiting reactant is used up, the reaction stops, leaving some excess of the other starting materials.

▲ **Figure 3.1** Antoine Lavoisier (1734–1794). The science career of Lavoisier, who conducted many important studies on combustion reactions, was cut short by the French Revolution. Guillotined in 1794 during the Reign of Terror, he is generally considered the father of modern chemistry because he conducted carefully controlled experiments and used quantitative measurements.

Stoichiometry is built on an understanding of atomic masses (Section 2.4), chemical formulas, and the **law of conservation of mass**. (Section 2.1) The French nobleman and scientist Antoine Lavoisier (Figure 3.1) discovered this important chemical law during the late 1700s. Lavoisier stated the law in this eloquent way: “We may lay it down as an incontestable axiom that, in all the operations of art and nature, nothing is created; an equal quantity of matter exists both before and after the experiment. Upon this principle, the whole art of performing chemical experiments depends.”\* With the advent of Dalton’s atomic theory, chemists came to understand the basis for this law: *Atoms are neither created nor destroyed during a chemical reaction*. The changes that occur during any reaction merely rearrange the atoms. The same collection of atoms is present both before and after the reaction.

## 3.1 | Chemical Equations

We represent chemical reactions by **chemical equations**. When the gas hydrogen ( $\text{H}_2$ ) burns, for example, it reacts with oxygen ( $\text{O}_2$ ) in the air to form water ( $\text{H}_2\text{O}$ ). We write the chemical equation for this reaction as

We read the + sign as “reacts with” and the arrow as “produces.” The chemical formulas to the left of the arrow represent the starting substances, called **reactants**. The chemical formulas to the right of the arrow represent substances produced in the reaction, called **products**. The numbers in front of the formulas, called coefficients, indicate the relative numbers of molecules of each kind involved in the reaction. (As in algebraic equations, *the coefficient 1 is usually not written*.)

Because atoms are neither created nor destroyed in any reaction, a *balanced* chemical equation must have an equal number of atoms of each element on each side of the arrow. On the right side of Equation 3.1, for example, there are two molecules of  $\text{H}_2\text{O}$ , each composed of two atoms of hydrogen and one atom of oxygen (Figure 3.2). Thus,  $2 \text{H}_2\text{O}$  (read “two molecules of water”) contains  $2 \times 2 = 4$  H atoms and  $2 \times 1 = 2$  O atoms. Notice that *the number of atoms is obtained by multiplying each subscript in a chemical formula by the coefficient for the formula*. Because there are four H atoms and two O atoms on each side of the equation, the equation is balanced.

### Give It Some Thought

How many atoms of Mg, O, and H are represented by the notation  $3 \text{Mg}(\text{OH})_2$ ?

## Balancing Equations

Chemists write unbalanced equations all the time in order to identify the reactants and products in a reaction. But to determine the amount of product that can be made, or the amount of a reactant that is required, the chemical equation needs to be balanced.

To construct a balanced chemical equation we start by writing the formulas for the reactants on the left-hand side of the arrow and the products on the right-hand side. Next we balance the equation by determining the coefficients that provide equal numbers of each type of atom on both sides of the equation. For most purposes, a balanced equation should contain the smallest possible whole-number coefficients.

In balancing an equation, you need to understand the difference between coefficients and subscripts. As Figure 3.3 illustrates, changing a subscript in a formula—from  $\text{H}_2\text{O}$  to  $\text{H}_2\text{O}_2$ , for example—changes the identity of the substance. The substance  $\text{H}_2\text{O}_2$ , hydrogen peroxide, is quite different from the substance  $\text{H}_2\text{O}$ , water. *Never change subscripts when balancing an equation*. In contrast, placing a coefficient in front of a formula changes only the *amount* of the substance and not its *identity*. Thus,  $2 \text{H}_2\text{O}$  means two molecules of water,  $3 \text{H}_2\text{O}$  means three molecules of water, and so forth.

▲ **Figure 3.2** A balanced chemical equation.

\*Lavoisier, Antoine. “Elements of Chemistry.” 1790.

◀ **Figure 3.3** The difference between changing subscripts and changing coefficients in chemical equations.

## A Step-by-Step Example of Balancing a Chemical Equation

To illustrate the process of balancing an equation, consider the reaction that occurs when methane ( $\text{CH}_4$ ), the principal component of natural gas, burns in air to produce carbon dioxide gas ( $\text{CO}_2$ ) and water vapor ( $\text{H}_2\text{O}$ ) (Figure 3.4). Both products contain oxygen atoms that come from  $\text{O}_2$  in the air. Thus,  $\text{O}_2$  is a reactant, and the unbalanced equation is

It is usually best to balance first those elements that occur in the fewest chemical formulas in the equation. In our example, C appears in only one reactant ( $\text{CH}_4$ ) and one product ( $\text{CO}_2$ ). The same is true for H ( $\text{CH}_4$  and  $\text{H}_2\text{O}$ ). Notice, however, that O appears in one reactant ( $\text{O}_2$ ) and two products ( $\text{CO}_2$  and  $\text{H}_2\text{O}$ ). So, let's begin with C. Because one molecule of  $\text{CH}_4$  contains the same number of C atoms as one molecule of  $\text{CO}_2$ , the coefficients for these substances *must* be the same in the balanced equation. Therefore, we start by choosing the coefficient 1 (unwritten) for both  $\text{CH}_4$  and  $\text{CO}_2$ .

Next we focus on H. On the left side of the equation we have  $\text{CH}_4$ , which has four H atoms, whereas on the right side of the equation we have  $\text{H}_2\text{O}$ , containing two H atoms. To balance the H atoms in the equation we place the coefficient **2** in front of  $\text{H}_2\text{O}$ . Now there are four H atoms on each side of the equation:

While the equation is now balanced with respect to hydrogen and carbon, it is not yet balanced for oxygen. Adding the coefficient **2** in front of  $\text{O}_2$  balances the equation by giving four O atoms on each side ( $2 \times 2$  left,  $2 + (2 \times 1)$  right):

The molecular view of the balanced equation is shown in Figure 3.5.

► **Figure 3.5** Balanced chemical equation for the combustion of  $\text{CH}_4$ .

## Sample Exercise 3.1

### Interpreting and Balancing Chemical Equations

The following diagram represents a chemical reaction in which the red spheres are oxygen atoms and the blue spheres are nitrogen atoms. **(a)** Write the chemical formulas for the reactants and products. **(b)** Write a balanced equation for the reaction. **(c)** Is the diagram consistent with the law of conservation of mass?

### SOLUTION

- (a)** The left box, which represents reactants, contains two kinds of molecules, those composed of two oxygen atoms ( $\text{O}_2$ ) and those composed of one nitrogen atom and one oxygen atom ( $\text{NO}$ ). The right box, which represents products, contains only one kind of molecule, which is composed of one nitrogen atom and two oxygen atoms ( $\text{NO}_2$ ).

- (b)** The unbalanced chemical equation is

An inventory of atoms on each side of the equation shows that there are one N and three O on the left side of the arrow and one N and two O on the right. To balance O, we must increase the number of O atoms on the right while keeping the coefficients for NO and  $\text{NO}_2$  equal. Sometimes a trial-and-error approach is required; we need to go back and forth several times from one side of an equation to the other, changing coefficients first on one side of the equation and then the other until it is balanced. In our present case, let's start by increasing the number of O atoms on the right side of the equation by placing the coefficient **2** in front of  $\text{NO}_2$ :

Now the equation gives two N atoms and four O atoms on the right, so we go back to the left side. Placing the coefficient **2** in front of NO balances both N and O:

- (c)** The reactants box contains four  $\text{O}_2$  and eight NO. Thus, the molecular ratio is one  $\text{O}_2$  for each two NO, as required by the balanced equation. The products box contains eight  $\text{NO}_2$ , which means the number of  $\text{NO}_2$  product molecules equals the number of NO reactant molecules, as the balanced equation requires.

There are eight N atoms in the eight NO molecules in the reactants box. There are also  $4 \times 2 = 8$  O atoms in the  $\text{O}_2$  molecules and 8 O atoms in the NO molecules, giving a total of 16 O atoms. In the products box, we find eight  $\text{NO}_2$  molecules, which contain eight N atoms and  $8 \times 2 = 16$  O atoms. Because there are equal numbers of N and O atoms in the two boxes, the drawing is consistent with the law of conservation of mass.

### Practice Exercise 1

In the following diagram, the white spheres represent hydrogen atoms and the blue spheres represent nitrogen atoms.

The two reactants combine to form a single product, ammonia,  $\text{NH}_3$ , which is not shown. Write a balanced chemical equation for the reaction. Based on the equation and the contents of the left (reactants) box, how many  $\text{NH}_3$  molecules should be shown in the right (products) box?

- (a)** 2 **(b)** 3 **(c)** 4 **(d)** 6 **(e)** 9

### Practice Exercise 2

In the following diagram, the white spheres represent hydrogen atoms, the black spheres carbon atoms, and the red spheres oxygen atoms.

In this reaction, there are two reactants, ethylene,  $\text{C}_2\text{H}_4$ , which is shown, and oxygen,  $\text{O}_2$ , which is not shown, and two products,  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , both of which are shown. (a) Write a balanced chemical equation for the reaction. (b) Determine the number of  $\text{O}_2$  molecules that should be shown in the left (reactants) box.

## Indicating the States of Reactants and Products

Symbols indicating the physical state of each reactant and product are often shown in chemical equations. We use the symbols (g), (l), (s), and (aq) for substances that are gases, liquids, solids, and dissolved in aqueous (water) solution, respectively. Thus, Equation 3.4 can be written

Sometimes symbols that represent the conditions under which the reaction proceeds appear above or below the reaction arrow. One example that we will encounter later in this chapter involves the symbol  $\Delta$  (Greek uppercase delta); a delta above the reaction arrow indicates the addition of heat.

### Sample Exercise 3.2

#### Balancing Chemical Equations

Balance the equation

#### SOLUTION

Begin by counting each kind of atom on the two sides of the arrow. There are one Na, one O, and two H on the left side, and one Na, one O, and three H on the right. The Na and O atoms are balanced, but the number of H atoms is not. To increase the number of H atoms on the left, let's try placing the coefficient **2** in front of  $\text{H}_2\text{O}$ :

Although beginning this way does not balance H, it does increase the number of reactant H atoms, which we need to do. (Also, adding the coefficient **2** on  $\text{H}_2\text{O}$  unbalances O, but we will take care of that after we balance H.) Now that we have  $2 \text{H}_2\text{O}$  on the left, we balance H by putting the coefficient **2** in front of NaOH:

Balancing H in this way brings O into balance, but now Na is unbalanced, with one Na on the left and two on the right. To rebalance Na, we put the coefficient **2** in front of the reactant:

We now have two Na atoms, four H atoms, and two O atoms on each side. The equation is balanced.

**Comment** Notice that we moved back and forth, placing a coefficient in front of  $\text{H}_2\text{O}$ , then NaOH, and finally Na. In balancing equations, we often find ourselves following this pattern of moving back and forth from one side of the arrow to the other, placing coefficients first in front of a formula on one side and then in front of a formula on the other side until the equation is balanced. You can always tell if you have balanced your equation correctly by checking that the number of atoms of each element is the same on the two sides of the arrow, and that you've chosen the smallest set of coefficients that balances the equation.

#### Practice Exercise 1

The unbalanced equation for the reaction between methane and bromine is

Once this equation is balanced, what is the value of the coefficient in front of bromine  $\text{Br}_2$ ?

(a) 1 (b) 2 (c) 3 (d) 4 (e) 6

#### Practice Exercise 2

Balance these equations by providing the missing coefficients:

## 3.2 | Simple Patterns of Chemical Reactivity

In this section we examine three types of reactions: combination reactions, decomposition reactions, and combustion reactions. Our first reason for examining these reactions is to become better acquainted with chemical reactions and their balanced equations. Our second reason is to consider how we might predict the products of some of these reactions knowing only their reactants. The key to predicting the products formed by a given combination of reactants is recognizing general patterns of chemical reactivity. Recognizing a pattern of reactivity for a class of substances gives you a broader understanding than merely memorizing a large number of unrelated reactions.

### Combination and Decomposition Reactions

In **combination reactions**, two or more substances react to form one product (Table 3.1). For example, magnesium metal burns brilliantly in air to produce magnesium oxide (Figure 3.6):

TABLE 3.1 Combination and Decomposition Reactions

#### Combination Reactions

Two or more reactants combine to form a single product. Many elements react with one another in this fashion to form compounds.

#### Decomposition Reactions

A single reactant breaks apart to form two or more substances. Many compounds react this way when heated.

▲ Figure 3.6 Combustion of magnesium metal in air, a combination reaction.

This reaction is used to produce the bright flame generated by flares and some fireworks.

A combination reaction between a metal and a nonmetal, as in Equation 3.6, produces an ionic solid. Recall that the formula of an ionic compound can be determined from the charges of its ions. [Section 2.7](#) When magnesium reacts with oxygen, the magnesium loses electrons and forms the magnesium ion,  $\text{Mg}^{2+}$ . The oxygen gains electrons and forms the oxide ion,  $\text{O}^{2-}$ . Thus, the reaction product is  $\text{MgO}$ .

You should be able to recognize when a reaction is a combination reaction and to predict the products when the reactants are a metal and a nonmetal.

### Give It Some Thought

When Na and S undergo a combination reaction, what is the chemical formula of the product?

In a **decomposition reaction** one substance undergoes a reaction to produce two or more other substances (Table 3.1). For example, many metal carbonates decompose to form metal oxides and carbon dioxide when heated:

Decomposition of  $\text{CaCO}_3$  is an important commercial process. Limestone or seashells, which are both primarily  $\text{CaCO}_3$ , are heated to prepare  $\text{CaO}$ , known as lime or quicklime. Tens of millions of tons of  $\text{CaO}$  are used in the United States each year in making glass, in metallurgy where it is used to isolate the metals from their ores, and in steel manufacturing where it is used to remove impurities.

The decomposition of sodium azide ( $\text{NaN}_3$ ) rapidly releases  $\text{N}_2(g)$ , so this reaction is used to inflate safety air bags in automobiles ([Figure 3.7](#)):

The system is designed so that an impact ignites a detonator cap, which in turn causes  $\text{NaN}_3$  to decompose explosively. A small quantity of  $\text{NaN}_3$  (about 100 g) forms a large quantity of gas (about 50 L).

**Figure 3.7** Decomposition of sodium azide,  $\text{NaN}_3(s)$ , produces  $\text{N}_2(g)$  that inflates air bags in automobiles.

### Sample Exercise 3.3

#### Writing Balanced Equations for Combination and Decomposition Reactions

Write a balanced equation for (a) the combination reaction between lithium metal and fluorine gas and (b) the decomposition reaction that occurs when solid barium carbonate is heated (two products form, a solid and a gas).

#### SOLUTION

- (a) With the exception of mercury, all metals are solids at room temperature. Fluorine occurs as a diatomic molecule. Thus, the reactants are  $\text{Li}(s)$  and  $\text{F}_2(g)$ . The product will be composed of a metal and a nonmetal, so we expect it to be an ionic solid. Lithium ions have a 1+ charge,  $\text{Li}^+$ , whereas fluoride ions have a 1− charge,  $\text{F}^-$ . Thus, the chemical formula for the product is  $\text{LiF}$ . The balanced chemical equation is

- (b) The chemical formula for barium carbonate is  $\text{BaCO}_3$ . As mentioned, many metal carbonates decompose to metal oxides and carbon dioxide when heated. In Equation 3.7, for example,  $\text{CaCO}_3$  decomposes to form  $\text{CaO}$  and  $\text{CO}_2$ . Thus, we expect  $\text{BaCO}_3$  to decompose to  $\text{BaO}$  and  $\text{CO}_2$ .

Barium and calcium are both in group 2A in the periodic table, which further suggests they react in the same way:

#### Practice Exercise 1

Which of the following reactions is the balanced equation that represents the decomposition reaction that occurs when silver(I) oxide is heated?

- (a)  $\text{AgO}(s) \longrightarrow \text{Ag}(s) + \text{O}(g)$  (b)  $2 \text{AgO}(s) \longrightarrow 2 \text{Ag}(s) + \text{O}_2(g)$   
 (c)  $\text{Ag}_2\text{O}(s) \longrightarrow 2 \text{Ag}(s) + \text{O}(g)$  (d)  $2 \text{Ag}_2\text{O}(s) \longrightarrow 4 \text{Ag}(s) + \text{O}_2(g)$   
 (e)  $\text{Ag}_2\text{O}(s) \longrightarrow 2 \text{Ag}(s) + \text{O}_2(g)$

#### Practice Exercise 2

Write a balanced equation for (a) solid mercury(II) sulfide decomposing into its component elements when heated and (b) aluminum metal combining with oxygen in the air.

### Go Figure

Does this reaction produce or consume thermal energy (heat)?

▲ **Figure 3.8** Propane burning in air. Liquid propane in the tank,  $\text{C}_3\text{H}_8$ , vaporizes and mixes with air as it escapes through the nozzle. The combustion reaction of  $\text{C}_3\text{H}_8$  and  $\text{O}_2$  produces a blue flame.

## Combustion Reactions

**Combustion reactions** are rapid reactions that produce a flame. Most combustion reactions we observe involve  $\text{O}_2$  from air as a reactant. The combustion of hydrocarbons (compounds that contain only carbon and hydrogen) in air, as illustrated in Equation 3.5, is a major energy-producing process in our world. [∞\(Section 2.9\)](#)

Hydrocarbons combusted in air react with  $\text{O}_2$  to form  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .\* The number of molecules of  $\text{O}_2$  required and the number of molecules of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  formed depend on the composition of the hydrocarbon, which acts as the fuel in the reaction. For example, the combustion of propane ( $\text{C}_3\text{H}_8$ , [Figure 3.8](#)), a gas used for cooking and home heating, is described by the equation

The state of the water in this reaction,  $\text{H}_2\text{O}(g)$  or  $\text{H}_2\text{O}(l)$ , depends on the reaction conditions. In this case,  $\text{H}_2\text{O}(g)$  is formed as the high-temperature flame burns in air.

Combustion of oxygen-containing derivatives of hydrocarbons, such as  $\text{CH}_3\text{OH}$ , also produces  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . The rule that hydrocarbons and their oxygen-containing derivatives form  $\text{CO}_2$  and  $\text{H}_2\text{O}$  when they burn in air summarizes the reactions of about 3 million compounds with oxygen. Many substances that our bodies use as energy sources, such as the sugar glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), react with  $\text{O}_2$  to form  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . In our bodies, however, the reactions take place in a series of intermediate steps that occur at body temperature. These reactions that involve intermediate steps are described as *oxidation reactions* instead of combustion reactions.

### Sample Exercise 3.4

#### Writing Balanced Equations for Combustion Reactions

Write the balanced equation for the reaction that occurs when methanol,  $\text{CH}_3\text{OH}(l)$ , is burned in air.

#### SOLUTION

When any compound containing C, H, and O is combusted, it reacts with the  $\text{O}_2(g)$  in air to produce  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(g)$ . Thus, the unbalanced equation is

The C atoms are balanced, one on each side of the arrow. Because  $\text{CH}_3\text{OH}$  has four H atoms, we place the coefficient **2** in front of  $\text{H}_2\text{O}$  to balance the H atoms:

Adding this coefficient balances H but gives four O atoms in the products. Because there are only three O atoms in the reactants, we are not finished. We can place the coefficient  $\frac{3}{2}$  in front of  $\text{O}_2$  to give four O atoms in the reactants ( $\frac{3}{2} \times 2 = 3$  O atoms in  $\frac{3}{2} \text{O}_2$ ):

Although this equation is balanced, it is not in its most conventional form because it contains a fractional coefficient. However,

multiplying through by 2 removes the fraction and keeps the equation balanced:

#### Practice Exercise 1

Write the balanced equation for the reaction that occurs when ethylene glycol,  $\text{C}_2\text{H}_4(\text{OH})_2$ , burns in air.

- (a)  $\text{C}_2\text{H}_4(\text{OH})_2(l) + 5 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 3 \text{H}_2\text{O}(g)$
- (b)  $2 \text{C}_2\text{H}_4(\text{OH})_2(l) + 5 \text{O}_2(g) \longrightarrow 4 \text{CO}_2(g) + 6 \text{H}_2\text{O}(g)$
- (c)  $\text{C}_2\text{H}_4(\text{OH})_2(l) + 3 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 3 \text{H}_2\text{O}(g)$
- (d)  $\text{C}_2\text{H}_4(\text{OH})_2(l) + 5 \text{O}(g) \longrightarrow 2 \text{CO}_2(g) + 3 \text{H}_2\text{O}(g)$
- (e)  $4 \text{C}_2\text{H}_4(\text{OH})_2(l) + 10 \text{O}_2(g) \longrightarrow 8 \text{CO}_2(g) + 12 \text{H}_2\text{O}(g)$

#### Practice Exercise 2

Write the balanced equation for the reaction that occurs when ethanol,  $\text{C}_2\text{H}_5\text{OH}(l)$ , burns in air.

## 3.3 | Formula Weights

Chemical formulas and chemical equations both have a *quantitative* significance in that the subscripts in formulas and the coefficients in equations represent precise quantities. The formula  $\text{H}_2\text{O}$  indicates that a molecule of this substance (water) contains exactly two

\*When there is an insufficient quantity of  $\text{O}_2$  present, carbon monoxide (CO) is produced along with  $\text{CO}_2$ ; this is called incomplete combustion. If the quantity of  $\text{O}_2$  is severely restricted, the fine particles of carbon we call soot are produced. Complete combustion produces only  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . Unless stated to the contrary, we will always take combustion to mean complete combustion.

atoms of hydrogen and one atom of oxygen. Similarly, the coefficients in a balanced chemical equation indicate the exact relative quantities of reactants and products. But how do we relate the numbers of atoms or molecules to the amounts we measure in the laboratory? If you wanted to react hydrogen and oxygen in exactly the right ratio to make  $\text{H}_2\text{O}$ , how would you make sure the reactants contain a 2:1 ratio of hydrogen atoms to oxygen atoms?

Although we cannot count individual atoms or molecules, we can indirectly determine their numbers if we know their masses. So, if we are to calculate amounts of reactants needed to obtain a given amount of product, or otherwise extrapolate quantitative information from a chemical equation or formula, we need to know more about the masses of atoms and molecules.

## Formula and Molecular Weights

The **formula weight** (FW) of a substance is the sum of the atomic weights (AW) of the atoms in the chemical formula of the substance. Using atomic weights from the periodic table, we find, for example, that the formula weight of sulfuric acid,  $\text{H}_2\text{SO}_4$ , is 98.1 amu (atomic mass units):

$$\begin{aligned}\text{FW of H}_2\text{SO}_4 &= 2(\text{AW of H}) + (\text{AW of S}) + 4(\text{AW of O}) \\ &= 2(1.0 \text{ amu}) + 32.1 \text{ amu} + 4(16.0 \text{ amu}) \\ &= 98.1 \text{ amu}\end{aligned}$$

For convenience, we have rounded off the atomic weights to one decimal place, a practice we will follow in most calculations in this book.

If the chemical formula is the chemical symbol of an element, such as Na, the formula weight equals the atomic weight of the element, in this case 23.0 amu. If the chemical formula is that of a molecule, the formula weight is also called the **molecular weight** (MW). The molecular weight of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), for example, is

$$\text{MW of C}_6\text{H}_{12}\text{O}_6 = 6(12.0 \text{ amu}) + 12(1.0 \text{ amu}) + 6(16.0 \text{ amu}) = 180.0 \text{ amu}$$

Because ionic substances exist as three-dimensional arrays of ions (see Figure 2.20), it is inappropriate to speak of *molecules* of these substances. Instead we use the empirical formula as the formula unit, and the formula weight of an ionic substance is determined by summing the atomic weights of the atoms in the empirical formula. For example, the formula unit of  $\text{CaCl}_2$  consists of one  $\text{Ca}^{2+}$  ion and two  $\text{Cl}^-$  ions. Thus, the formula weight of  $\text{CaCl}_2$  is

$$\text{FW of CaCl}_2 = 40.1 \text{ amu} + 2(35.5 \text{ amu}) = 111.1 \text{ amu}$$

### Sample Exercise 3.5

#### Calculating Formula Weights

Calculate the formula weight of (a) sucrose,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  (table sugar); and (b) calcium nitrate,  $\text{Ca}(\text{NO}_3)_2$ .

#### SOLUTION

- (a) By adding the atomic weights of the atoms in sucrose, we find the formula weight to be 342.0 amu:

$$\begin{aligned}12 \text{ C atoms} &= 12(12.0 \text{ amu}) = 144.0 \text{ amu} \\ 22 \text{ H atoms} &= 22(1.0 \text{ amu}) = 22.0 \text{ amu} \\ 11 \text{ O atoms} &= 11(16.0 \text{ amu}) = \underline{176.0 \text{ amu}} \\ &342.0 \text{ amu}\end{aligned}$$

- (b) If a chemical formula has parentheses, the subscript outside the parentheses is a multiplier for all atoms inside. Thus, for  $\text{Ca}(\text{NO}_3)_2$  we have

$$\begin{aligned}1 \text{ Ca atom} &= 1(40.1 \text{ amu}) = 40.1 \text{ amu} \\ 2 \text{ N atoms} &= 2(14.0 \text{ amu}) = 28.0 \text{ amu} \\ 6 \text{ O atoms} &= 6(16.0 \text{ amu}) = \underline{96.0 \text{ amu}} \\ &164.1 \text{ amu}\end{aligned}$$

#### Practice Exercise 1

Which of the following is the correct formula weight for calcium phosphate?

- (a) 310.2 amu  
(b) 135.1 amu  
(c) 182.2 amu  
(d) 278.2 amu  
(e) 175.1 amu

#### Practice Exercise 2

Calculate the formula weight of (a)  $\text{Al}(\text{OH})_3$ , (b)  $\text{CH}_3\text{OH}$ , and (c)  $\text{TaON}$ .

## Percentage Composition from Chemical Formulas

Chemists must sometimes calculate the *percentage composition* of a compound—that is, the percentage by mass contributed by each element in the substance. Forensic chemists, for example, can measure the percentage composition of an unknown powder and compare it with the percentage compositions of suspected substances (such as, sugar, salt, or cocaine) to identify the powder.

Calculating the percentage composition of any element in a substance (sometimes called the **elemental composition** of a substance) is straightforward if the chemical formula is known. The calculation depends on the formula weight of the substance, the atomic weight of the element of interest, and the number of atoms of that element in the chemical formula:

$$\begin{array}{c} \text{\% mass composition} \\ \text{of element} \end{array} = \frac{\left( \begin{array}{c} \text{number of atoms} \\ \text{of element} \end{array} \right) \left( \begin{array}{c} \text{atomic weight} \\ \text{of element} \end{array} \right)}{\text{formula weight of substance}} \times 100\% \quad [3.10]$$

### STRATEGIES FOR SUCCESS Problem Solving

Practice is the key to success in solving problems. As you practice, you can improve your skills by following these steps:

1. **Analyze the problem.** Read the problem carefully. What does it say? Draw a picture or diagram that will help you to visualize the problem. Write down both the data you are given and the quantity you need to obtain (the unknown).
2. **Develop a plan for solving the problem.** Consider a possible path between the given information and the unknown. What principles or equations relate the known data to the unknown? Recognize that some data may not be given explicitly in the problem; you may be expected to know certain quantities or look them up in tables (such as atomic weights). Recognize also that
3. **Solve the problem.** Use the known information and suitable equations or relationships to solve for the unknown. Dimensional analysis (Section 1.7) is a useful tool for solving a great number of problems. Be careful with significant figures, signs, and units.
4. **Check the solution.** Read the problem again to make sure you have found all the solutions asked for in the problem. Does your answer make sense? That is, is the answer outrageously large or small or is it in the ballpark? Finally, are the units and significant figures correct?

### Sample Exercise 3.6

#### Calculating Percentage Composition

Calculate the percentage of carbon, hydrogen, and oxygen (by mass) in  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ .

#### SOLUTION

We'll use the steps outlined in the Strategies For Success: Problem Solving feature to answer the question.

**Analyze** We are given a chemical formula and asked to calculate the percentage by mass of each element.

**Plan** We use Equation 3.10, obtaining our atomic weights from a periodic table. We know the denominator in Equation 3.10, the formula weight of  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ , from Sample Exercise 3.5. We must use that value in three calculations, one for each element.

#### Solve

$$\% \text{C} = \frac{(12)(12.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 42.1\%$$

$$\% \text{H} = \frac{(22)(1.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 6.4\%$$

$$\% \text{O} = \frac{(11)(16.0 \text{ amu})}{342.0 \text{ amu}} \times 100\% = 51.5\%$$

**Check** Our calculated percentages must add up to 100%, which they do. We could have used more significant figures for our atomic weights, giving more significant figures for our percentage composition, but we have adhered to our suggested guideline of rounding atomic weights to one digit beyond the decimal point.

#### Practice Exercise 1

What is the percentage of nitrogen, by mass, in calcium nitrate?

(a) 8.54% (b) 17.1% (c) 13.7% (d) 24.4% (e) 82.9%

#### Practice Exercise 2

Calculate the percentage of potassium, by mass, in  $\text{K}_2\text{PtCl}_6$ .

## 3.4 | Avogadro's Number and the Mole

Even the smallest samples we deal with in the laboratory contain enormous numbers of atoms, ions, or molecules. For example, a teaspoon of water (about 5 mL) contains  $2 \times 10^{23}$  water molecules, a number so large it almost defies comprehension. Chemists therefore have devised a counting unit for describing large numbers of atoms or molecules.

In everyday life we use such familiar counting units as dozen (12 objects) and gross (144 objects). In chemistry the counting unit for numbers of atoms, ions, or molecules in a laboratory-size sample is the *mole*, abbreviated mol. One **mole** is the amount of matter that contains as many objects (atoms, molecules, or whatever other objects we are considering) as the number of atoms in exactly 12 g of isotopically pure  $^{12}\text{C}$ . From experiments, scientists have determined this number to be  $6.0221415 \times 10^{23}$ , which we usually round to  $6.02 \times 10^{23}$ . Scientists call this value **Avogadro's number**,  $N_A$ , in honor of the Italian scientist Amedeo Avogadro (1776–1856), and it is often cited with units of reciprocal moles,  $6.02 \times 10^{23} \text{ mol}^{-1}$ .\* The unit (read as either “inverse mole” or “per mole”) reminds us that there are  $6.02 \times 10^{23}$  objects per one mole. A mole of atoms, a mole of molecules, or a mole of anything else all contain Avogadro's number of objects:

$$1 \text{ mol } ^{12}\text{C atoms} = 6.02 \times 10^{23} \text{ } ^{12}\text{C atoms}$$

$$1 \text{ mol H}_2\text{O molecules} = 6.02 \times 10^{23} \text{ H}_2\text{O molecules}$$

$$1 \text{ mol NO}_3^- \text{ ions} = 6.02 \times 10^{23} \text{ NO}_3^- \text{ ions}$$

Avogadro's number is so large that it is difficult to imagine. Spreading  $6.02 \times 10^{23}$  marbles over Earth's surface would produce a layer about 3 miles thick. Avogadro's number of pennies placed side by side in a straight line would encircle Earth 300 trillion ( $3 \times 10^{14}$ ) times.

### Sample Exercise 3.7

#### Estimating Numbers of Atoms

Without using a calculator, arrange these samples in order of increasing numbers of carbon atoms:

12 g  $^{12}\text{C}$ , 1 mol  $\text{C}_2\text{H}_2$ ,  $9 \times 10^{23}$  molecules of  $\text{CO}_2$ .

#### SOLUTION

**Analyze** We are given amounts of three substances expressed in grams, moles, and number of molecules and asked to arrange the samples in order of increasing numbers of C atoms.

**Plan** To determine the number of C atoms in each sample, we must convert 12 g  $^{12}\text{C}$ , 1 mol  $\text{C}_2\text{H}_2$ , and  $9 \times 10^{23}$  molecules  $\text{CO}_2$  to numbers of C atoms. To make these conversions, we use the definition of mole and Avogadro's number.

**Solve** One mole is defined as the amount of matter that contains as many units of the matter as there are C atoms in exactly 12 g of  $^{12}\text{C}$ . Thus, 12 g of  $^{12}\text{C}$  contains 1 mol of C atoms =  $6.02 \times 10^{23}$  C atoms.

One mol of  $\text{C}_2\text{H}_2$  contains  $6.02 \times 10^{23}$   $\text{C}_2\text{H}_2$  molecules. Because there are two C atoms in each molecule, this sample contains  $12.04 \times 10^{23}$  C atoms.

Because each  $\text{CO}_2$  molecule contains one C atom, the  $\text{CO}_2$  sample contains  $9 \times 10^{23}$  C atoms.

Hence, the order is 12 g  $^{12}\text{C}$  ( $6 \times 10^{23}$  C atoms) <  $9 \times 10^{23}$   $\text{CO}_2$  molecules ( $9 \times 10^{23}$  C atoms) < 1 mol  $\text{C}_2\text{H}_2$  ( $12 \times 10^{23}$  C atoms).

**Check** We can check our results by comparing numbers of moles of C atoms in the samples because the number of moles is proportional to the number of atoms. Thus, 12 g of  $^{12}\text{C}$  is 1 mol C, 1 mol of  $\text{C}_2\text{H}_2$  contains 2 mol C, and  $9 \times 10^{23}$  molecules of  $\text{CO}_2$  contain 1.5 mol C, giving the same order as stated previously.

#### Practice Exercise 1

Which of the following samples contains the fewest sodium atoms?  
(a) 1 mol sodium oxide (b) 45 g sodium fluoride  
(c) 50 g sodium chloride (d) 1 mol sodium nitrate

#### Practice Exercise 2

Without using a calculator, arrange these samples in order of increasing numbers of O atoms: 1 mol  $\text{H}_2\text{O}$ , 1 mol  $\text{CO}_2$ ,  $3 \times 10^{23}$  molecules of  $\text{O}_3$ .

\*Avogadro's number is also referred to as the Avogadro constant. The latter term is the name adopted by agencies such as the National Institute of Standards and Technology (NIST), but Avogadro's number remains in widespread usage and is used in most places in this book.

## Sample Exercise 3.8

### Converting Moles to Number of Atoms

Calculate the number of H atoms in 0.350 mol of  $\text{C}_6\text{H}_{12}\text{O}_6$ .

#### SOLUTION

**Analyze** We are given the amount of a substance (0.350 mol) and its chemical formula  $\text{C}_6\text{H}_{12}\text{O}_6$ . The unknown is the number of H atoms in the sample.

**Plan** Avogadro's number provides the conversion factor between moles of  $\text{C}_6\text{H}_{12}\text{O}_6$  and molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ :  $1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6 = 6.02 \times 10^{23} \text{ molecules of } \text{C}_6\text{H}_{12}\text{O}_6$ . Once we know the number

of molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ , we can use the chemical formula, which tells us that each molecule of  $\text{C}_6\text{H}_{12}\text{O}_6$  contains 12 H atoms. Thus, we convert moles of  $\text{C}_6\text{H}_{12}\text{O}_6$  to molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$  and then determine the number of atoms of H from the number of molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ :

#### Solve

$$\begin{aligned} \text{H atoms} &= (0.350 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6) \left( \frac{6.02 \times 10^{23} \text{ molecules } \text{C}_6\text{H}_{12}\text{O}_6}{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{12 \text{ H atoms}}{1 \text{ molecule } \text{C}_6\text{H}_{12}\text{O}_6} \right) \\ &= 2.53 \times 10^{24} \text{ H atoms} \end{aligned}$$

**Check** We can do a ballpark calculation, figuring that  $0.35(6 \times 10^{23})$  is about  $2 \times 10^{23}$  molecules of  $\text{C}_6\text{H}_{12}\text{O}_6$ . We know that each one of these molecules contains 12 H atoms.  $12(2 \times 10^{23})$  gives  $24 \times 10^{23} = 2.4 \times 10^{24}$  H atoms, which is close to our result. Because we were asked for the number of H atoms, the units of our answer are correct. We check, too, for significant figures. The given data had three significant figures, as does our answer.

#### Practice Exercise 1

How many sulfur atoms are in (a) 0.45 mol  $\text{BaSO}_4$  and (b) 1.10 mol of aluminum sulfide?

#### Practice Exercise 2

How many oxygen atoms are in (a) 0.25 mol  $\text{Ca}(\text{NO}_3)_2$  and (b) 1.50 mol of sodium carbonate?

## Molar Mass

A dozen is the same number, 12, whether we have a dozen eggs or a dozen elephants. Clearly, however, a dozen eggs does not have the same mass as a dozen elephants. Similarly, a mole is always the *same number* ( $6.02 \times 10^{23}$ ), but 1-mol samples of different substances have *different masses*. Compare, for example, 1 mol of  $^{12}\text{C}$  and 1 mol of  $^{24}\text{Mg}$ . A single  $^{12}\text{C}$  atom has a mass of 12 amu, whereas a single  $^{24}\text{Mg}$  atom is twice as massive, 24 amu (to two significant figures). Because a mole of anything always contains the same number of particles, a mole of  $^{24}\text{Mg}$  must be twice as massive as a mole of  $^{12}\text{C}$ . Because a mole of  $^{12}\text{C}$  has a mass of 12 g (by definition), a mole of  $^{24}\text{Mg}$  must have a mass of 24 g. This example illustrates a general rule relating the mass of an atom to the mass of Avogadro's number (1 mol) of these atoms: *The atomic weight of an element in atomic mass units is numerically equal to the mass in grams of 1 mol of that element.* For example (the symbol  $\Rightarrow$  means “therefore”),

Cl has an atomic weight of 35.5 amu  $\Rightarrow$  1 mol Cl has a mass of 35.5 g.

Au has an atomic weight of 197 amu  $\Rightarrow$  1 mol Au has a mass of 197 g.

For other kinds of substances, the same numerical relationship exists between formula weight and mass of 1 mol of a substance:

$\text{H}_2\text{O}$  has a formula weight of 18.0 amu  $\Rightarrow$  1 mol  $\text{H}_2\text{O}$  has a mass of 18.0 g (Figure 3.9).

$\text{NaCl}$  has a formula weight of 58.5 amu  $\Rightarrow$  1 mol  $\text{NaCl}$  has a mass of 58.5 g.

### Give It Some Thought

- Which has more mass, a mole of water ( $\text{H}_2\text{O}$ ) or a mole of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ )?
- Which contains more molecules, a mole of water or a mole of glucose?

The mass in grams of one mole, often abbreviated as 1 mol, of a substance (that is, the mass in grams per mole) is called the **molar mass** of the substance. *The molar mass in grams per mole of any substance is numerically equal to its formula weight in atomic mass units.* For NaCl, for example, the formula weight is 58.5 amu and the molar mass is 58.5 g/mol. Mole relationships for several other substances are shown in Table 3.2, and Figure 3.10 shows 1 mol quantities of three common substances.

The entries in Table 3.2 for N and N<sub>2</sub> point out the importance of stating the chemical form of a substance when using the mole concept. Suppose you read that 1 mol of nitrogen is produced in a particular reaction. You might interpret this statement to mean 1 mol of nitrogen atoms (14.0 g). Unless otherwise stated, however, what is probably meant is 1 mol of nitrogen molecules, N<sub>2</sub> (28.0 g), because N<sub>2</sub> is the most common chemical form of the element. To avoid ambiguity, it is important to state explicitly the chemical form being discussed. Using the chemical formula—N or N<sub>2</sub>, for instance—avoids any confusion.

**TABLE 3.2 Mole Relationships**

| Name of Substance                  | Formula           | Formula Weight (amu) | Molar Mass (g/mol) | Number and Kind of Particles in One Mole  |
|------------------------------------|-------------------|----------------------|--------------------|---|
| Atomic nitrogen                    | N                 | 14.0                 | 14.0               | $6.02 \times 10^{23}$ N atoms   |
| Molecular nitrogen or “dinitrogen” | N <sub>2</sub>    | 28.0                 | 28.0               | $\left\{ \begin{array}{l} 6.02 \times 10^{23} \text{ N}_2 \text{ molecules} \\ 2(6.02 \times 10^{23}) \text{ N atoms} \end{array} \right.$  |
| Silver                             | Ag                | 107.9                | 107.9              | $6.02 \times 10^{23}$ Ag atoms  |
| Silver ions                        | Ag <sup>+</sup>   | 107.9 <sup>a</sup>   | 107.9              | $6.02 \times 10^{23}$ Ag <sup>+</sup> ions  |
| Barium chloride                    | BaCl <sub>2</sub> | 208.2                | 208.2              | $\left\{ \begin{array}{l} 6.02 \times 10^{23} \text{ BaCl}_2 \text{ formula units} \\ 6.02 \times 10^{23} \text{ Ba}^{2+} \text{ ions} \\ 2(6.02 \times 10^{23}) \text{ Cl}^- \text{ ions} \end{array} \right.$ |

<sup>a</sup>Recall that the mass of an electron is more than 1800 times smaller than the masses of the proton and the neutron; thus, ions and atoms have essentially the same mass.

▲ **Figure 3.10** One mole each of a solid (NaCl), a liquid (H<sub>2</sub>O), and a gas (O<sub>2</sub>). In each case, the mass in grams of 1 mol—that is, the molar mass—is numerically equal to the formula weight in atomic mass units. Each of these samples contains  $6.02 \times 10^{23}$  formula units.

### Go Figure

What number do you get if you divide the mass of 1 mol of water by the mass of 1 molecule of water?

Single molecule

1 molecule H<sub>2</sub>O  
(18.0 amu)

Avogadro's number of water molecules in a mole of water

Laboratory-size sample

1 mol H<sub>2</sub>O  
(18.0 g)

▲ **Figure 3.9** Comparing the mass of 1 molecule and 1 mol of H<sub>2</sub>O. Both masses have the same number but different units (atomic mass units and grams). Expressing both masses in grams indicates their huge difference: 1 molecule of H<sub>2</sub>O has a mass of  $2.99 \times 10^{-23}$  g, whereas 1 mol H<sub>2</sub>O has a mass of 18.0 g.

**Sample Exercise 3.9****Calculating Molar Mass**

What is the molar mass of glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ ?

**SOLUTION**

**Analyze** We are given a chemical formula and asked to determine its molar mass.

**Plan** Because the molar mass of any substance is numerically equal to its formula weight, we first determine the formula weight of glucose by adding the atomic weights of its component atoms. The formula weight will have units of amu, whereas the molar mass has units of grams per mole (g/mol).

**Solve** Our first step is to determine the formula weight of glucose:

$$\begin{array}{rcl} 6 \text{ C atoms} & = & 6(12.0 \text{ amu}) = 72.0 \text{ amu} \\ 12 \text{ H atoms} & = & 12(1.0 \text{ amu}) = 12.0 \text{ amu} \\ 6 \text{ O atoms} & = & 6(16.0 \text{ amu}) = 96.0 \text{ amu} \\ & & \hline & & 180.0 \text{ amu} \end{array}$$

Because glucose has a formula weight of 180.0 amu, 1 mol of this substance ( $6.02 \times 10^{23}$  molecules) has a mass of 180.0 g. In other words,  $\text{C}_6\text{H}_{12}\text{O}_6$  has a molar mass of 180.0 g/mol.

**Check** A molar mass below 250 seems reasonable based on the earlier examples we have encountered, and grams per mole is the appropriate unit for the molar mass.

**Practice Exercise 1**

A sample of an ionic compound containing iron and chlorine is analyzed and found to have a molar mass of 126.8 g/mol. What is the charge of the iron in this compound?

(a) 1+ (b) 2+ (c) 3+ (d) 4+

**Practice Exercise 2**

Calculate the molar mass of  $\text{Ca}(\text{NO}_3)_2$ .

**CHEMISTRY AND LIFE Glucose Monitoring**

Our body converts most of the food we eat into glucose. After digestion, glucose is delivered to cells via the blood. Cells need glucose to live, and the hormone insulin must be present in order for glucose to enter the cells. Normally, the body adjusts the concentration of insulin automatically, in concert with the glucose concentration after eating, so that normal blood glucose levels are 70–120 mg/dL. However, in a diabetic person, either little or no insulin is produced (Type 1 diabetes) or insulin is produced but the cells cannot take it up properly (Type 2 diabetes). In either case the blood glucose levels are higher than they are in a normal person. A person who has not eaten for 8 hours or more is diagnosed as diabetic if his or her glucose level is 126 mg/dL or higher.

Glucose meters work by the introduction of blood from a person, usually by a prick of the finger, onto a small strip of paper that contains chemicals that react with glucose. Insertion of the strip into a small battery-operated reader gives the glucose concentration (Figure 3.11). The mechanism of the readout varies from one monitor to another—it may be a measurement of a

small electrical current or a measurement of light produced in a chemical reaction. Depending on the reading on any given day, a diabetic person may need to receive an injection of insulin or simply limit his or her intake of sugar-rich foods for a while.

▲ Figure 3.11 Glucose meter.

**Interconverting Masses and Moles**

Conversions of mass to moles and of moles to mass are frequently encountered in calculations using the mole concept. These calculations are simplified using dimensional analysis (Section 1.7), as shown in Sample Exercises 3.10 and 3.11.

**Sample Exercise 3.10****Converting Grams to Moles**

Calculate the number of moles of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in a 5.380 g sample.

**SOLUTION**

**Analyze** We are given the number of grams of a substance and its chemical formula and asked to calculate the number of moles.

**Plan** The molar mass of a substance provides the factor for converting grams to moles. The molar mass of  $\text{C}_6\text{H}_{12}\text{O}_6$  is 180.0 g/mol (Sample Exercise 3.9).

**Solve** Using  $1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6 = 180.0 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6$  to write the appropriate conversion factor, we have

$$\begin{aligned} \text{Moles } \text{C}_6\text{H}_{12}\text{O}_6 &= (5.380 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6} \right) \\ &= 0.02989 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6 \end{aligned}$$

**Check** Because 5.380 g is less than the molar mass, an answer less than 1 mol is reasonable. The unit mol is appropriate. The original data had four significant figures, so our answer has four significant figures.

► **Practice Exercise 1**

A 508-g sample of sodium bicarbonate ( $\text{NaHCO}_3$ ) contains how many moles of sodium bicarbonate?

► **Practice Exercise 2**

How many moles of water are in 1.00 L of water, whose density is 1.00 g/mL?

### Sample Exercise 3.11

#### Converting Moles to Grams

Calculate the mass, in grams, of 0.433 mol of calcium nitrate.

#### SOLUTION

**Analyze** We are given the number of moles and the name of a substance and asked to calculate the number of grams in the substance.

**Plan** To convert moles to grams, we need the molar mass, which we can calculate using the chemical formula and atomic weights.

**Solve** Because the calcium ion is  $\text{Ca}^{2+}$  and the nitrate ion is  $\text{NO}_3^-$ , the chemical formula for calcium nitrate is  $\text{Ca}(\text{NO}_3)_2$ . Adding the atomic weights of the elements in the compound gives a formula weight of 164.1 amu. Using  $1 \text{ mol Ca}(\text{NO}_3)_2 = 164.1 \text{ g Ca}(\text{NO}_3)_2$  to write the appropriate conversion factor, we have

$$\begin{aligned}\text{Grams Ca}(\text{NO}_3)_2 &= (0.433 \text{ mol Ca}(\text{NO}_3)_2) \left( \frac{164.1 \text{ g Ca}(\text{NO}_3)_2}{1 \text{ mol Ca}(\text{NO}_3)_2} \right) \\ &= 71.1 \text{ g Ca}(\text{NO}_3)_2\end{aligned}$$

**Check** The number of moles is less than 1, so the number of grams must be less than the molar mass, 164.1 g. Using rounded numbers to estimate, we have  $0.5 \times 150 = 75 \text{ g}$ , which means the magnitude of our answer is reasonable. Both the units (g) and the number of significant figures (3) are correct.

► **Practice Exercise 1**

What is the mass, in grams, of (a) 6.33 mol of  $\text{NaHCO}_3$  and (b)  $3.0 \times 10^{-5}$  mol of sulfuric acid?

► **Practice Exercise 2**

What is the mass, in grams, of (a) 0.50 mol of diamond (C) and (b) 0.155 mol of ammonium chloride?

## Interconverting Masses and Numbers of Particles

The mole concept provides the bridge between mass and number of particles (Figure 3.12). To illustrate how this bridge works, let's calculate the number of copper atoms in an old copper penny. Such a penny has a mass of about 3 g, and for this illustration we will assume it is 100% copper:

$$\begin{aligned}\text{Cu atoms} &= (3 \text{ g Cu}) \left( \frac{1 \text{ mol Cu}}{63.5 \text{ g Cu}} \right) \left( \frac{6.02 \times 10^{23} \text{ Cu atoms}}{1 \text{ mol Cu}} \right) \\ &= 3 \times 10^{22} \text{ Cu atoms}\end{aligned}$$

We have rounded our answer to one significant figure because we used only one significant figure for the mass of the penny. Notice how dimensional analysis provides a straightforward route from grams to numbers of atoms. The molar mass and Avogadro's number are used as conversion factors to convert grams to moles and then moles to atoms. Notice also that our answer is a very large number. Any time you calculate the number of atoms, molecules, or ions in an ordinary sample of matter, you can expect the answer to be very large. In contrast, the number of moles in a sample will usually be small, often less than 1.

#### Go Figure

What units would you put under "molar mass" and "Avogadro's number" on this diagram?

▲ **Figure 3.12** Procedure for interconverting mass and number of formula units. The number of moles of the substance is central to the calculation. Thus, the mole concept can be thought of as the bridge between the mass of a sample in grams and the number of formula units contained in the sample.

### Sample Exercise 3.12

#### Calculating Numbers of Molecules and Atoms from Mass

- (a) How many glucose molecules are in 5.23 g of  $\text{C}_6\text{H}_{12}\text{O}_6$ ?  
 (b) How many oxygen atoms are in this sample?

#### SOLUTION

**Analyze** We are given the number of grams and the chemical formula of a substance and asked to calculate (a) the number of molecules and (b) the number of O atoms in the substance.

**Plan** (a) The strategy for determining the number of molecules in a given quantity of a substance is summarized in Figure 3.12. We must convert 5.23 g to moles of  $\text{C}_6\text{H}_{12}\text{O}_6$  and then convert moles to molecules

of  $\text{C}_6\text{H}_{12}\text{O}_6$ . The first conversion uses the molar mass of  $\text{C}_6\text{H}_{12}\text{O}_6$ , 180.0 g/mol, and the second conversion uses Avogadro's number.

(b) To determine the number of O atoms, we use the fact that there are six O atoms in each  $\text{C}_6\text{H}_{12}\text{O}_6$  molecule. Thus, multiplying the number of molecules we calculated in (a) by the factor (6 atoms O/1 molecule  $\text{C}_6\text{H}_{12}\text{O}_6$ ) gives the number of O atoms.

#### Solve

$$\begin{aligned} \text{(a) Convert grams } \text{C}_6\text{H}_{12}\text{O}_6 \text{ to molecules } \text{C}_6\text{H}_{12}\text{O}_6. \quad & \text{Molecules } \text{C}_6\text{H}_{12}\text{O}_6 = (5.23 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g } \text{C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{6.02 \times 10^{23} \text{ molecules } \text{C}_6\text{H}_{12}\text{O}_6}{1 \text{ mol } \text{C}_6\text{H}_{12}\text{O}_6} \right) \\ & = 1.75 \times 10^{22} \text{ molecules } \text{C}_6\text{H}_{12}\text{O}_6 \end{aligned}$$

$$\begin{aligned} \text{(b) Convert molecules } \text{C}_6\text{H}_{12}\text{O}_6 \text{ to atoms O.} \quad & \text{Atoms O} = (1.75 \times 10^{22} \text{ molecules } \text{C}_6\text{H}_{12}\text{O}_6) \left( \frac{6 \text{ atoms O}}{1 \text{ molecule } \text{C}_6\text{H}_{12}\text{O}_6} \right) \\ & = 1.05 \times 10^{23} \text{ atoms O} \end{aligned}$$

#### Check

(a) Because the mass we began with is less than a mole, there should be fewer than  $6.02 \times 10^{23}$  molecules in the sample, which means the magnitude of our answer is reasonable. A ballpark estimate of the answer comes reasonably close to the answer we derived in this exercise:  $5/200 = 2.5 \times 10^{-2}$  mol;  $(2.5 \times 10^{-2})(6 \times 10^{23}) = 15 \times 10^{21} = 1.5 \times 10^{22}$  molecules. The units (molecules) and the number of significant figures (three) are appropriate.

(b) The answer is six times as large as the answer to part (a), exactly what it should be. The number of significant figures (three) and the units (atoms O) are correct.

#### Practice Exercise 1

How many chlorine atoms are in 12.2 g of  $\text{CCl}_4$ ?

- (a)  $4.77 \times 10^{22}$   
 (b)  $7.34 \times 10^{24}$   
 (c)  $1.91 \times 10^{23}$   
 (d)  $2.07 \times 10^{23}$

#### Practice Exercise 2

- (a) How many nitric acid molecules are in 4.20 g of  $\text{HNO}_3$ ?  
 (b) How many O atoms are in this sample?

## 3.5 | Empirical Formulas from Analyses

The empirical formula for a substance tells us the relative number of atoms of each element in the substance. [Section 2.6](#) The empirical formula  $\text{H}_2\text{O}$  shows that water contains two H atoms for each O atom. This ratio also applies on the molar level: 1 mol of  $\text{H}_2\text{O}$  contains 2 mol of H atoms and 1 mol of O atoms. Conversely, *the ratio of the numbers of moles of all elements in a compound gives the subscripts in the compound's empirical formula*. Thus, the mole concept provides a way of calculating empirical formulas.

Mercury and chlorine, for example, combine to form a compound that is measured to be 74.0% mercury and 26.0% chlorine by mass. Thus, if we had a 100.0-g sample of the compound, it would contain 74.0 g of mercury and 26.0 g of chlorine. (Samples of any size can be used in problems of this type, but we will generally use 100.0 g to simplify the calculation of mass from percentage.) Using atomic weights to get molar masses, we calculate the number of moles of each element in the sample:

$$(74.0 \text{ g Hg}) \left( \frac{1 \text{ mol Hg}}{200.6 \text{ g Hg}} \right) = 0.369 \text{ mol Hg}$$

$$(26.0 \text{ g Cl}) \left( \frac{1 \text{ mol Cl}}{35.5 \text{ g Cl}} \right) = 0.732 \text{ mol Cl}$$

▲ **Figure 3.13** Procedure for calculating an empirical formula from percentage composition.

We then divide the larger number of moles by the smaller number to obtain the Cl:Hg mole ratio:

$$\frac{\text{moles of Cl}}{\text{moles of Hg}} = \frac{0.732 \text{ mol Cl}}{0.369 \text{ mol Hg}} = \frac{1.98 \text{ mol Cl}}{1 \text{ mol Hg}}$$

Because of experimental errors, calculated values for a mole ratio may not be whole numbers, as in the calculation here. The number 1.98 is very close to 2, however, and so we can confidently conclude that the empirical formula for the compound is  $\text{HgCl}_2$ . The empirical formula is correct because its subscripts are the smallest integers that express the *ratio* of atoms present in the compound.

The general procedure for determining empirical formulas is outlined in **Figure 3.13**.

### Give It Some Thought

Could the empirical formula determined from chemical analysis be used to tell the difference between acetylene,  $\text{C}_2\text{H}_2$ , and benzene,  $\text{C}_6\text{H}_6$ ?

### Sample Exercise 3.13

#### Calculating an Empirical Formula

Ascorbic acid (vitamin C) contains 40.92% C, 4.58% H, and 54.50% O by mass. What is the empirical formula of ascorbic acid?

#### SOLUTION

**Analyze** We are to determine the empirical formula of a compound from the mass percentages of its elements.

**Plan** The strategy for determining the empirical formula involves the three steps given in Figure 3.13.

#### Solve

(1) For simplicity we assume we have exactly 100 g of material, although any other mass could also be used.

In 100.00 g of ascorbic acid we have 40.92 g C, 4.58 g H, and 54.50 g O.

(2) Next we calculate the number of moles of each element. We use atomic masses with four significant figures to match the precision of our experimental masses.

$$\text{Moles C} = (40.92 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 3.407 \text{ mol C}$$

$$\text{Moles H} = (4.58 \text{ g H}) \left( \frac{1 \text{ mol H}}{1.008 \text{ g H}} \right) = 4.54 \text{ mol H}$$

$$\text{Moles O} = (54.50 \text{ g O}) \left( \frac{1 \text{ mol O}}{16.00 \text{ g O}} \right) = 3.406 \text{ mol O}$$

Continued

(3) We determine the simplest whole-number ratio of moles by dividing each number of moles by the smallest number of moles.

$$\text{C: } \frac{3.407}{3.406} = 1.000 \quad \text{H: } \frac{4.54}{3.406} = 1.33 \quad \text{O: } \frac{3.406}{3.406} = 1.000$$

The ratio for H is too far from 1 to attribute the difference to experimental error; in fact, it is quite close to  $1\frac{1}{3}$ . This suggests we should multiply the ratios by 3 to obtain whole numbers:

$$\text{C : H : O} = (3 \times 1 : 3 \times 1.33 : 3 \times 1) = (3 : 4 : 3)$$

Thus, the empirical formula is  $\text{C}_3\text{H}_4\text{O}_3$ .

**Check** It is reassuring that the subscripts are moderate-size whole numbers. Also, calculating the percentage composition of  $\text{C}_3\text{H}_4\text{O}_3$  gives values very close to the original percentages.

#### Practice Exercise 1

A 2.144-g sample of phosgene, a compound used as a chemical warfare agent during World War I, contains 0.260 g of carbon, 0.347 g of oxygen, and 1.537 g of chlorine. What is the

empirical formula of this substance?

(a)  $\text{CO}_2\text{Cl}_6$  (b)  $\text{COCl}_2$  (c)  $\text{C}_{0.022}\text{O}_{0.022}\text{Cl}_{0.044}$  (d)  $\text{C}_2\text{OCl}_2$

#### Practice Exercise 2

A 5.325-g sample of methyl benzoate, a compound used in the manufacture of perfumes, contains 3.758 g of carbon, 0.316 g of hydrogen, and 1.251 g of oxygen. What is the empirical formula of this substance?

## Molecular Formulas from Empirical Formulas

We can obtain the molecular formula for any compound from its empirical formula if we know either the molecular weight or the molar mass of the compound. *The subscripts in the molecular formula of a substance are always whole-number multiples of the subscripts in its empirical formula.* (Section 2.6) This multiple can be found by dividing the molecular weight by the empirical formula weight:

$$\text{Whole-number multiple} = \frac{\text{molecular weight}}{\text{empirical formula weight}} \quad [3.11]$$

In Sample Exercise 3.13, for example, the empirical formula of ascorbic acid was determined to be  $\text{C}_3\text{H}_4\text{O}_3$ . This means the empirical formula weight is  $3(12.0 \text{ amu}) + 4(1.0 \text{ amu}) + 3(16.0 \text{ amu}) = 88.0 \text{ amu}$ . The experimentally determined molecular weight is 176 amu. Thus, we find the whole-number multiple that converts the empirical formula to the molecular formula by dividing

$$\text{Whole-number multiple} = \frac{\text{molecular weight}}{\text{empirical formula weight}} = \frac{176 \text{ amu}}{88.0 \text{ amu}} = 2$$

Consequently, we multiply the subscripts in the empirical formula by this multiple, giving the molecular formula:  $\text{C}_6\text{H}_8\text{O}_6$ .

## Sample Exercise 3.14

### Determining a Molecular Formula

Mesitylene, a hydrocarbon found in crude oil, has an empirical formula of  $\text{C}_3\text{H}_4$  and an experimentally determined molecular weight of 121 amu. What is its molecular formula?

#### SOLUTION

**Analyze** We are given an empirical formula and a molecular weight of a compound and asked to determine its molecular formula.

**Plan** The subscripts in a compound's molecular formula are whole-number multiples of the subscripts in its empirical formula. We find the appropriate multiple by using Equation 3.11.

**Solve** The formula weight of the empirical formula  $\text{C}_3\text{H}_4$  is

$$3(12.0 \text{ amu}) + 4(1.0 \text{ amu}) = 40.0 \text{ amu}$$

Next, we use this value in Equation 3.11:

$$\begin{aligned} \text{Whole-number multiple} &= \frac{\text{molecular weight}}{\text{empirical formula weight}} \\ &= \frac{121}{40.0} = 3.03 \end{aligned}$$

Only whole-number ratios make physical sense because molecules contain whole atoms. The 3.03 in this case could result from a small experimental error in the molecular weight. We therefore multiply each subscript in the empirical formula by 3 to give the molecular formula:  $\text{C}_9\text{H}_{12}$ .

**Check** We can have confidence in the result because dividing molecular weight by empirical formula weight yields nearly a whole number.

### Practice Exercise 1

Cyclohexane, a commonly used organic solvent, is 85.6% C and 14.4% H by mass with a molar mass of 84.2 g/mol.

What is its molecular formula?

(a)  $C_6H$  (b)  $CH_2$  (c)  $C_5H_{24}$  (d)  $C_6H_{12}$  (e)  $C_4H_8$

### Practice Exercise 2

Ethylene glycol, used in automobile antifreeze, is 38.7% C, 9.7% H, and 51.6% O by mass. Its molar mass is 62.1 g/mol.

(a) What is the empirical formula of ethylene glycol? (b) What is its molecular formula?

## Combustion Analysis

One technique for determining empirical formulas in the laboratory is *combustion analysis*, commonly used for compounds containing principally carbon and hydrogen.

When a compound containing carbon and hydrogen is completely combusted in an apparatus such as that shown in Figure 3.14, the carbon is converted to  $CO_2$  and the hydrogen is converted to  $H_2O$ . (Section 3.2). From the masses of  $CO_2$  and  $H_2O$  we can calculate the number of moles of C and H in the original sample and thereby the empirical formula. If a third element is present in the compound, its mass can be determined by subtracting the measured masses of C and H from the original sample mass.

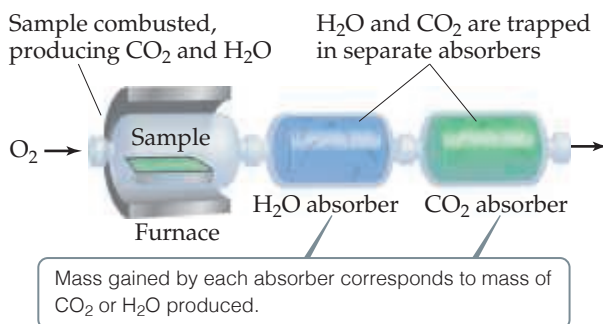

Figure 3.14 Apparatus for combustion analysis.

### Sample Exercise 3.15

#### Determining an Empirical Formula by Combustion Analysis

Isopropyl alcohol, sold as rubbing alcohol, is composed of C, H, and O. Combustion of 0.255 g of isopropyl alcohol produces 0.561 g of  $CO_2$  and 0.306 g of  $H_2O$ . Determine the empirical formula of isopropyl alcohol.

#### SOLUTION

**Analyze** We are told that isopropyl alcohol contains C, H, and O atoms and are given the quantities of  $CO_2$  and  $H_2O$  produced when a given quantity of the alcohol is combusted. We must determine the empirical formula for isopropyl alcohol, a task that requires us to calculate the number of moles of C, H, and O in the sample.

**Plan** We can use the mole concept to calculate grams of C in the  $CO_2$  and grams of H in the  $H_2O$ —the masses of C and H in the alcohol before combustion. The mass of O in the compound equals the mass of the original sample minus the sum of the C and H masses. Once we have the C, H, and O masses, we can proceed as in Sample Exercise 3.13.

**Solve** Because all of the carbon in the sample is converted to  $CO_2$ , we can use dimensional analysis and the following steps to calculate the mass C in the sample.

Using the values given in this example, the mass of C is

$$\begin{aligned} \text{Grams C} &= (0.561 \text{ g } CO_2) \left( \frac{1 \text{ mol } CO_2}{44.0 \text{ g } CO_2} \right) \left( \frac{1 \text{ mol C}}{1 \text{ mol } CO_2} \right) \left( \frac{12.0 \text{ g C}}{1 \text{ mol C}} \right) \\ &= 0.153 \text{ g C} \end{aligned}$$

Continued

Because all of the hydrogen in the sample is converted to  $\text{H}_2\text{O}$ , we can use dimensional analysis and the following steps to calculate the mass H in the sample. We use three significant figures for the atomic mass of H to match the significant figures in the mass of  $\text{H}_2\text{O}$  produced.

Using the values given in this example, we find that the mass of H is

$$\text{Grams H} = (0.306 \text{ g H}_2\text{O}) \left( \frac{1 \text{ mol H}_2\text{O}}{18.0 \text{ g H}_2\text{O}} \right) \left( \frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}} \right) \left( \frac{1.01 \text{ g H}}{1 \text{ mol H}} \right) = 0.0343 \text{ g H}$$

The mass of the sample, 0.255 g, is the sum of the masses of C, H, and O. Thus, the O mass is

$$\text{Mass of O} = \text{mass of sample} - (\text{mass of C} + \text{mass of H}) = 0.255 \text{ g} - (0.153 \text{ g} + 0.0343 \text{ g}) = 0.068 \text{ g O}$$

The number of moles of C, H, and O in the sample is therefore

$$\text{Moles C} = (0.153 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.0 \text{ g C}} \right) = 0.0128 \text{ mol C}$$

$$\text{Moles H} = (0.0343 \text{ g H}) \left( \frac{1 \text{ mol H}}{1.01 \text{ g H}} \right) = 0.0340 \text{ mol H}$$

$$\text{Moles O} = (0.068 \text{ g O}) \left( \frac{1 \text{ mol O}}{16.0 \text{ g O}} \right) = 0.0043 \text{ mol O}$$

To find the empirical formula, we must compare the relative number of moles of each element in the sample, as illustrated in Sample Exercise 3.13.

$$\text{C: } \frac{0.0128}{0.0043} = 3.0 \quad \text{H: } \frac{0.0340}{0.0043} = 7.9 \quad \text{O: } \frac{0.0043}{0.0043} = 1.0$$

The first two numbers are very close to the whole numbers 3 and 8, giving the empirical formula  $\text{C}_3\text{H}_8\text{O}$ .

### ► Practice Exercise 1

The compound dioxane, which is used as a solvent in various industrial processes, is composed of C, H, and O atoms. Combustion of a 2.203-g sample of this compound produces 4.401 g  $\text{CO}_2$  and 1.802 g  $\text{H}_2\text{O}$ . A separate experiment shows that it has a molar mass of 88.1 g/mol. Which of the following is the correct molecular formula for dioxane?

(a)  $\text{C}_2\text{H}_4\text{O}$  (b)  $\text{C}_4\text{H}_4\text{O}_2$  (c)  $\text{CH}_2$  (d)  $\text{C}_4\text{H}_8\text{O}_2$

### ► Practice Exercise 2

(a) Caproic acid, responsible for the odor of dirty socks, is composed of C, H, and O atoms. Combustion of a 0.225-g sample of this compound produces 0.512 g  $\text{CO}_2$  and 0.209 g  $\text{H}_2\text{O}$ . What is the empirical formula of caproic acid? (b) Caproic acid has a molar mass of 116 g/mol. What is its molecular formula?

## 3.6 | Quantitative Information from Balanced Equations

The coefficients in a chemical equation represent the relative numbers of molecules in a reaction. The mole concept allows us to convert this information to the masses of the substances in the reaction. For instance, the coefficients in the balanced equation

indicate that two molecules of  $\text{H}_2$  react with one molecule of  $\text{O}_2$  to form two molecules of  $\text{H}_2\text{O}$ . It follows that the relative numbers of moles are identical to the relative numbers of molecules:

We can generalize this observation to all balanced chemical equations: *The coefficients in a balanced chemical equation indicate both the relative numbers of molecules (or formula units) in the reaction and the relative numbers of moles.* Figure 3.15 shows how this result corresponds to the law of conservation of mass.

◀ **Figure 3.15** Interpreting a balanced chemical equation quantitatively.

The quantities 2 mol  $\text{H}_2$ , 1 mol  $\text{O}_2$ , and 2 mol  $\text{H}_2\text{O}$  given by the coefficients in Equation 3.12 are called *stoichiometrically equivalent quantities*. The relationship between these quantities can be represented as

where the  $\simeq$  symbol means “is stoichiometrically equivalent to.” Stoichiometric relations such as these can be used to convert between quantities of reactants and products in a chemical reaction. For example, the number of moles of  $\text{H}_2\text{O}$  produced from 1.57 mol of  $\text{O}_2$  is

$$\text{Moles H}_2\text{O} = (1.57 \text{ mol } \cancel{\text{O}_2}) \left( \frac{2 \text{ mol H}_2\text{O}}{1 \text{ mol } \cancel{\text{O}_2}} \right) = 3.14 \text{ mol H}_2\text{O}$$

### Give It Some Thought

When 1.57 mol  $\text{O}_2$  reacts with  $\text{H}_2$  to form  $\text{H}_2\text{O}$ , how many moles of  $\text{H}_2$  are consumed in the process?

As an additional example, consider the combustion of butane ( $\text{C}_4\text{H}_{10}$ ), the fuel in disposable lighters:

Let's calculate the mass of  $\text{CO}_2$  produced when 1.00 g of  $\text{C}_4\text{H}_{10}$  is burned. The coefficients in Equation 3.13 tell us how the amount of  $\text{C}_4\text{H}_{10}$  consumed is related to the amount of  $\text{CO}_2$  produced: 2 mol  $\text{C}_4\text{H}_{10} \simeq 8 \text{ mol CO}_2$ . To use this stoichiometric relationship, we must convert grams of  $\text{C}_4\text{H}_{10}$  to moles using the molar mass of  $\text{C}_4\text{H}_{10}$ , 58.0 g/mol:

$$\begin{aligned} \text{Moles C}_4\text{H}_{10} &= (1.00 \text{ g } \cancel{\text{C}_4\text{H}_{10}}) \left( \frac{1 \text{ mol C}_4\text{H}_{10}}{58.0 \text{ g } \cancel{\text{C}_4\text{H}_{10}}} \right) \\ &= 1.72 \times 10^{-2} \text{ mol C}_4\text{H}_{10} \end{aligned}$$

We then use the stoichiometric factor from the balanced equation to calculate moles of  $\text{CO}_2$ :

$$\begin{aligned} \text{Moles CO}_2 &= (1.72 \times 10^{-2} \text{ mol } \cancel{\text{C}_4\text{H}_{10}}) \left( \frac{8 \text{ mol CO}_2}{2 \text{ mol } \cancel{\text{C}_4\text{H}_{10}}} \right) \\ &= 6.88 \times 10^{-2} \text{ mol CO}_2 \end{aligned}$$

Finally, we use the molar mass of  $\text{CO}_2$ , 44.0 g/mol, to calculate the  $\text{CO}_2$  mass in grams:

$$\begin{aligned} \text{Grams CO}_2 &= (6.88 \times 10^{-2} \text{ mol } \cancel{\text{CO}_2}) \left( \frac{44.0 \text{ g CO}_2}{1 \text{ mol } \cancel{\text{CO}_2}} \right) \\ &= 3.03 \text{ g CO}_2 \end{aligned}$$

This conversion sequence involves three steps, as illustrated in Figure 3.16. These three conversions can be combined in a single equation:

$$\begin{aligned}\text{Grams CO}_2 &= (1.00 \text{ g C}_4\text{H}_{10}) \left( \frac{1 \text{ mol C}_4\text{H}_{10}}{58.0 \text{ g C}_4\text{H}_{10}} \right) \left( \frac{8 \text{ mol CO}_2}{2 \text{ mol C}_4\text{H}_{10}} \right) \left( \frac{44.0 \text{ g CO}_2}{1 \text{ mol CO}_2} \right) \\ &= 3.03 \text{ g CO}_2\end{aligned}$$

To calculate the amount of O<sub>2</sub> consumed in the reaction of Equation 3.13, we again rely on the coefficients in the balanced equation for our stoichiometric factor, 2 mol C<sub>4</sub>H<sub>10</sub> ≈ 13 mol O<sub>2</sub>:

$$\begin{aligned}\text{Grams O}_2 &= (1.00 \text{ g C}_4\text{H}_{10}) \left( \frac{1 \text{ mol C}_4\text{H}_{10}}{58.0 \text{ g C}_4\text{H}_{10}} \right) \left( \frac{13 \text{ mol O}_2}{2 \text{ mol C}_4\text{H}_{10}} \right) \left( \frac{32.0 \text{ g O}_2}{1 \text{ mol O}_2} \right) \\ &= 3.59 \text{ g O}_2\end{aligned}$$

▲ **Figure 3.16** Procedure for calculating amounts of reactants consumed or products formed in a reaction. The number of grams of a reactant consumed or product formed can be calculated in three steps, starting with the number of grams of any reactant or product.

### Give It Some Thought

In the previous example, 1.00 g of C<sub>4</sub>H<sub>10</sub> reacts with 3.59 g of O<sub>2</sub> to form 3.03 g of CO<sub>2</sub>. Using only addition and subtraction, calculate the amount of H<sub>2</sub>O produced.

## Sample Exercise 3.16

### Calculating Amounts of Reactants and Products

Determine how many grams of water are produced in the oxidation of 1.00 g of glucose, C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>:

### SOLUTION

**Analyze** We are given the mass of a reactant and must determine the mass of a product in the given reaction.

**Plan** We follow the general strategy outlined in Figure 3.16:

- (1) Convert grams of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> to moles using the molar mass of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>.
- (2) Convert moles of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> to moles of H<sub>2</sub>O using the stoichiometric relationship 1 mol C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> ≈ 6 mol H<sub>2</sub>O.
- (3) Convert moles of H<sub>2</sub>O to grams using the molar mass of H<sub>2</sub>O.

### Solve

(1) First we convert grams of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> to moles using the molar mass of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>.

$$\text{Moles C}_6\text{H}_{12}\text{O}_6 = (1.00 \text{ g C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g C}_6\text{H}_{12}\text{O}_6} \right)$$

(2) Next we convert moles of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> to moles of H<sub>2</sub>O using the stoichiometric relationship 1 mol C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> ≈ 6 mol H<sub>2</sub>O.

$$\text{Moles H}_2\text{O} = (1.00 \text{ g C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{6 \text{ mol H}_2\text{O}}{1 \text{ mol C}_6\text{H}_{12}\text{O}_6} \right)$$

(3) Finally, we convert moles of  $\text{H}_2\text{O}$  to grams using the molar mass of  $\text{H}_2\text{O}$ .

$$\begin{aligned}\text{Grams H}_2\text{O} &= (1.00 \text{ g C}_6\text{H}_{12}\text{O}_6) \left( \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.0 \text{ g C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{6 \text{ mol H}_2\text{O}}{1 \text{ mol C}_6\text{H}_{12}\text{O}_6} \right) \left( \frac{18.0 \text{ g H}_2\text{O}}{1 \text{ mol H}_2\text{O}} \right) \\ &= 0.600 \text{ g H}_2\text{O}\end{aligned}$$

**Check** We can check how reasonable our result is by doing a ballpark estimate of the mass of  $\text{H}_2\text{O}$ . Because the molar mass of glucose is 180 g/mol, 1 g of glucose equals 1/180 mol. Because 1 mol of glucose yields 6 mol  $\text{H}_2\text{O}$ , we would have 6/180 = 1/30 mol  $\text{H}_2\text{O}$ . The molar mass of water is 18 g/mol, so we have 1/30  $\times$  18 = 6/10 = 0.6 g of  $\text{H}_2\text{O}$ , which agrees with the full calculation. The units, grams  $\text{H}_2\text{O}$ , are correct. The initial data had three significant figures, so three significant figures for the answer is correct.

#### Practice Exercise 1

Sodium hydroxide reacts with carbon dioxide to form sodium carbonate and water:

How many grams of  $\text{Na}_2\text{CO}_3$  can be prepared from 2.40 g of  $\text{NaOH}$ ? (a) 3.18 g (b) 6.36 g (c) 1.20 g (d) 0.0300 g

#### Practice Exercise 2

Decomposition of  $\text{KClO}_3$  is sometimes used to prepare small amounts of  $\text{O}_2$  in the laboratory:  $2 \text{KClO}_3(s) \longrightarrow 2 \text{KCl}(s) + 3 \text{O}_2(g)$ . How many grams of  $\text{O}_2$  can be prepared from 4.50 g of  $\text{KClO}_3$ ?

### Sample Exercise 3.17

#### Calculating Amounts of Reactants and Products

Solid lithium hydroxide is used in space vehicles to remove the carbon dioxide gas exhaled by astronauts. The hydroxide reacts with the carbon dioxide to form solid lithium carbonate and liquid water. How many grams of carbon dioxide can be absorbed by 1.00 g of lithium hydroxide?

#### SOLUTION

**Analyze** We are given a verbal description of a reaction and asked to calculate the number of grams of one reactant that reacts with 1.00 g of another.

**Plan** The verbal description of the reaction can be used to write a balanced equation:

We are given the mass in grams of  $\text{LiOH}$  and asked to calculate the mass in grams of  $\text{CO}_2$ . We can accomplish this with the three conversion steps in Figure 3.16. The conversion of Step 1 requires the molar mass of  $\text{LiOH}$  ( $6.94 + 16.00 + 1.01 = 23.95 \text{ g/mol}$ ). The conversion of Step 2 is based on a stoichiometric relationship from the balanced chemical equation:  $2 \text{ mol LiOH} \approx 1 \text{ mol CO}_2$ . For the Step 3 conversion, we use the molar mass of  $\text{CO}_2$ :  $12.01 + 2(16.00) = 44.01 \text{ g/mol}$ .

#### Solve

$$\begin{aligned}(1.00 \text{ g LiOH}) &\left( \frac{1 \text{ mol LiOH}}{23.95 \text{ g LiOH}} \right) \left( \frac{1 \text{ mol CO}_2}{2 \text{ mol LiOH}} \right) \left( \frac{44.01 \text{ g CO}_2}{1 \text{ mol CO}_2} \right) \\ &= 0.919 \text{ g CO}_2\end{aligned}$$

**Check** Notice that  $23.95 \text{ g LiOH/mol} \approx 24 \text{ g LiOH/mol}$ ,  $24 \text{ g LiOH/mol} \times 2 \text{ mol LiOH} = 48 \text{ g LiOH}$ , and  $(44 \text{ g CO}_2/\text{mol}) / (48 \text{ g LiOH})$  is slightly less than 1. Thus, the magnitude of our answer, 0.919 g  $\text{CO}_2$ , is reasonable based on the amount of starting  $\text{LiOH}$ . The number of significant figures and units are also appropriate.

#### Practice Exercise 1

Propane,  $\text{C}_3\text{H}_8$  (Figure 3.8), is a common fuel used for cooking and home heating. What mass of  $\text{O}_2$  is consumed in the combustion of 1.00 g of propane?

(a) 5.00 g (b) 0.726 g (c) 2.18 g (d) 3.63 g

#### Practice Exercise 2

Methanol,  $\text{CH}_3\text{OH}$ , reacts with oxygen from air in a combustion reaction to form water and carbon dioxide. What mass of water is produced in the combustion of 23.6 g of methanol?

Many chemical reactions either consume or produce heat (Figure 3.8). This heat is also a stoichiometric quantity. For instance, if a given reaction of a given number of reactant moles produces 100 J of energy in the form of heat, performing the reaction with twice the number of moles of reactants will produce 200 J of heat. We will explore these ideas further in Chapter 5.

## 3.7 Limiting Reactants

Suppose you wish to make several sandwiches using one slice of cheese and two slices of bread for each. Using Bd = bread, Ch = cheese, and Bd<sub>2</sub>Ch = sandwich, we can represent the recipe for making a sandwich like a chemical equation:

If you have ten slices of bread and seven slices of cheese, you can make only five sandwiches and will have two slices of cheese left over. The amount of bread available limits the number of sandwiches.

An analogous situation occurs in chemical reactions when one reactant is used up before the others. The reaction stops as soon as any reactant is totally consumed, leaving the excess reactants as leftovers. Suppose, for example, we have a mixture of 10 mol H<sub>2</sub> and 7 mol O<sub>2</sub>, which react to form water:

Because 2 mol H<sub>2</sub>  $\approx$  1 mol O<sub>2</sub>, the number of moles of O<sub>2</sub> needed to react with all the H<sub>2</sub> is

$$\text{Moles O}_2 = (10 \text{ mol H}_2) \left( \frac{1 \text{ mol O}_2}{2 \text{ mol H}_2} \right) = 5 \text{ mol O}_2$$

Because 7 mol O<sub>2</sub> is available at the start of the reaction, 7 mol O<sub>2</sub> – 5 mol O<sub>2</sub> = 2 mol O<sub>2</sub> is still present when all the H<sub>2</sub> is consumed.

The reactant that is completely consumed in a reaction is called the **limiting reactant** because it determines, or limits, the amount of product formed. The other reactants are sometimes called *excess reactants*. In our example, shown in Figure 3.17, H<sub>2</sub> is the limiting reactant, which means that once all the H<sub>2</sub> has been consumed, the reaction stops. At that point some of the excess reactant O<sub>2</sub> is left over.

There are no restrictions on the starting amounts of reactants in any reaction. Indeed, many reactions are carried out using an excess of one reactant. The quantities of reactants consumed and products formed, however, are restricted by the quantity of the limiting reactant. For example, when a combustion reaction takes place in the open air, oxygen is plentiful and is therefore the excess reactant. If you run out of gasoline while driving, the car stops because the gasoline is the limiting reactant in the combustion reaction that moves the car.

Before we leave the example illustrated in Figure 3.17, let's summarize the data:

|                    | 2 H <sub>2</sub> (g) | + O <sub>2</sub> (g) | → 2 H <sub>2</sub> O(g) |
|--------------------|----------------------|----------------------|-------------------------|
| Before reaction:   | 10 mol               | 7 mol                | 0 mol                   |
| Change (reaction): | –10 mol              | –5 mol               | +10 mol                 |
| After reaction:    | 0 mol                | 2 mol                | 10 mol                  |

### Go Figure

If the amount of H<sub>2</sub> is doubled, how many moles of H<sub>2</sub>O would have formed?

▲ **Figure 3.17 Limiting reactant.** Because H<sub>2</sub> is completely consumed, it is the limiting reactant. Because some O<sub>2</sub> is left over after the reaction is complete, it is the excess reactant. The amount of H<sub>2</sub>O formed depends on the amount of limiting reactant, H<sub>2</sub>.

The second line in the table (Change) summarizes the amounts of reactants consumed (where this consumption is indicated by the minus signs) and the amount of the product formed (indicated by the plus sign). These quantities are restricted by the quantity of the limiting reactant and depend on the coefficients in the balanced equation. The mole ratio  $\text{H}_2:\text{O}_2:\text{H}_2\text{O} = 10:5:10$  is a multiple of the ratio of the coefficients in the balanced equation,  $2:1:2$ . The after quantities, which depend on the before quantities and their changes, are found by adding the before quantity and change quantity for each column. The amount of the limiting reactant ( $\text{H}_2$ ) must be zero at the end of the reaction. What remains is 2 mol  $\text{O}_2$  (excess reactant) and 10 mol  $\text{H}_2\text{O}$  (product).

### Sample Exercise 3.18

#### Calculating the Amount of Product Formed from a Limiting Reactant

The most important commercial process for converting  $\text{N}_2$  from the air into nitrogen-containing compounds is based on the reaction of  $\text{N}_2$  and  $\text{H}_2$  to form ammonia ( $\text{NH}_3$ ):

How many moles of  $\text{NH}_3$  can be formed from 3.0 mol of  $\text{N}_2$  and 6.0 mol of  $\text{H}_2$ ?

#### SOLUTION

**Analyze** We are asked to calculate the number of moles of product,  $\text{NH}_3$ , given the quantities of each reactant,  $\text{N}_2$  and  $\text{H}_2$ , available in a reaction. This is a limiting reactant problem.

**Plan** If we assume one reactant is completely consumed, we can calculate how much of the second reactant is needed. By comparing the calculated quantity of the second reactant with the amount available, we can determine which reactant is limiting. We then proceed with the calculation, using the quantity of the limiting reactant.

#### Solve

The number of moles of  $\text{H}_2$  needed for complete consumption of 3.0 mol of  $\text{N}_2$  is

$$\text{Moles H}_2 = (3.0 \text{ mol } \cancel{\text{N}_2}) \left( \frac{3 \text{ mol H}_2}{1 \text{ mol } \cancel{\text{N}_2}} \right) = 9.0 \text{ mol H}_2$$

Because only 6.0 mol  $\text{H}_2$  is available, we will run out of  $\text{H}_2$  before the  $\text{N}_2$  is gone, which tells us that  $\text{H}_2$  is the limiting reactant. Therefore, we use the quantity of  $\text{H}_2$  to calculate the quantity of  $\text{NH}_3$  produced:

$$\text{Moles NH}_3 = (6.0 \text{ mol } \cancel{\text{H}_2}) \left( \frac{2 \text{ mol NH}_3}{3 \text{ mol } \cancel{\text{H}_2}} \right) = 4.0 \text{ mol NH}_3$$

Notice that we can calculate not only the number of moles of  $\text{NH}_3$  formed but also the number of moles of each reactant remaining after the reaction. Notice also that although the initial (before) number of moles of  $\text{H}_2$  is greater than the final (after) number of moles of  $\text{N}_2$ ,  $\text{H}_2$  is nevertheless the limiting reactant because of its larger coefficient in the balanced equation.

**Check** Examine the change row of the summary table to see that the mole ratio of reactants consumed and product formed,  $2:6:4$ , is a multiple of the coefficients in the balanced equation,  $1:3:2$ . We confirm that  $\text{H}_2$  is the limiting reactant because it is completely consumed in the reaction, leaving 0 mol at the end. Because 6.0 mol  $\text{H}_2$  has two significant figures, our answer has two significant figures.

**Comment** It is useful to summarize the reaction data in a table:

|                    | $\text{N}_2(g)$ | + | $3 \text{H}_2(g)$ | $\longrightarrow$ | $2 \text{NH}_3(g)$ |
|--------------------|-----------------|---|-------------------|-------------------|--------------------|
| Before reaction:   | 3.0 mol         |   | 6.0 mol           |                   | 0 mol              |
| Change (reaction): | -2.0 mol        |   | -6.0 mol          |                   | +4.0 mol           |
| After reaction:    | 1.0 mol         |   | 0 mol             |                   | 4.0 mol            |

#### Practice Exercise 1

When 24 mol of methanol and 15 mol of oxygen combine in the combustion reaction  $2 \text{CH}_3\text{OH}(l) + 3 \text{O}_2(g) \longrightarrow 2 \text{CO}_2(g) + 4 \text{H}_2\text{O}(g)$ , what is the excess reactant and how many moles of it remains at the end of the reaction?

(a) 9 mol  $\text{CH}_3\text{OH}(l)$  (b) 10 mol  $\text{CO}_2(g)$  (c) 10 mol  $\text{CH}_3\text{OH}(l)$  (d) 14 mol  $\text{CH}_3\text{OH}(l)$  (e) 1 mol  $\text{O}_2(g)$

#### Practice Exercise 2

(a) When 1.50 mol of  $\text{Al}$  and 3.00 mol of  $\text{Cl}_2$  combine in the reaction  $2 \text{Al}(s) + 3 \text{Cl}_2(g) \longrightarrow 2 \text{AlCl}_3(s)$ , which is the limiting reactant? (b) How many moles of  $\text{AlCl}_3$  are formed? (c) How many moles of the excess reactant remain at the end of the reaction?

### Sample Exercise 3.19

#### Calculating the Amount of Product Formed from a Limiting Reactant

The reaction

is used to produce electricity in a hydrogen fuel cell. Suppose a fuel cell contains 150 g of  $\text{H}_2(g)$  and 1500 g of  $\text{O}_2(g)$  (each measured to two significant figures). How many grams of water can form?

*Continued*

**SOLUTION**

**Analyze** We are asked to calculate the amount of a product, given the amounts of two reactants, so this is a limiting reactant problem.

**Plan** To identify the limiting reactant, we can calculate the number of moles of each reactant and compare their ratio with the ratio of coefficients in the balanced equation. We then use the quantity of the limiting reactant to calculate the mass of water that forms.

**Solve** From the balanced equation, we have the stoichiometric relations

Using the molar mass of each substance, we calculate the number of moles of each reactant:

$$\text{Moles H}_2 = (150 \text{ g H}_2) \left( \frac{1 \text{ mol H}_2}{2.02 \text{ g H}_2} \right) = 74 \text{ mol H}_2$$

$$\text{Moles O}_2 = (1500 \text{ g O}_2) \left( \frac{1 \text{ mol O}_2}{32.0 \text{ g O}_2} \right) = 47 \text{ mol O}_2$$

The coefficients in the balanced equation indicate that the reaction requires 2 mol of H<sub>2</sub> for every 1 mol of O<sub>2</sub>. Therefore, for all the O<sub>2</sub> to completely react, we would need  $2 \times 47 = 94 \text{ mol of H}_2$ . Since there are only 74 mol of H<sub>2</sub>, all of the O<sub>2</sub> cannot react, so it is the excess reactant, and H<sub>2</sub> must be the limiting reactant. (Notice that the limiting reactant is not necessarily the one present in the lowest amount.)

We use the given quantity of H<sub>2</sub> (the limiting reactant) to calculate the quantity of water formed. We could begin this calculation with the given H<sub>2</sub> mass, 150 g, but we can save a step by starting with the moles of H<sub>2</sub>, 74 mol, we just calculated:

$$\begin{aligned} \text{Grams H}_2\text{O} &= (74 \text{ mol H}_2) \left( \frac{2 \text{ mol H}_2\text{O}}{2 \text{ mol H}_2} \right) \left( \frac{18.0 \text{ g H}_2\text{O}}{1 \text{ mol H}_2\text{O}} \right) \\ &= 1.3 \times 10^2 \text{ g H}_2\text{O} \end{aligned}$$

**Check** The magnitude of the answer seems reasonable based on the amounts of the reactants. The units are correct, and the number of significant figures (two) corresponds to those in the values given in the problem statement.

**Comment** The quantity of the limiting reactant, H<sub>2</sub>, can also be used to determine the quantity of O<sub>2</sub> used:

$$\begin{aligned} \text{Grams O}_2 &= (74 \text{ mol H}_2) \left( \frac{1 \text{ mol O}_2}{2 \text{ mol H}_2} \right) \left( \frac{32.0 \text{ g O}_2}{1 \text{ mol O}_2} \right) \\ &= 1.2 \times 10^3 \text{ g O}_2 \end{aligned}$$

The mass of O<sub>2</sub> remaining at the end of the reaction equals the starting amount minus the amount consumed:

$$1500 \text{ g} - 1200 \text{ g} = 300 \text{ g}.$$

**Practice Exercise 1**

Molten gallium reacts with arsenic to form the semiconductor, gallium arsenide, GaAs, used in light-emitting diodes and solar cells:

If 4.00 g of gallium is reacted with 5.50 g of arsenic, how many grams of the excess reactant are left at the end of the reaction?

(a) 1.20 g As (b) 1.50 g As (c) 4.30 g As (d) 8.30 g Ga

**Practice Exercise 2**

When a 2.00-g strip of zinc metal is placed in an aqueous solution containing 2.50 g of silver nitrate, the reaction is

(a) Which reactant is limiting? (b) How many grams of Ag form? (c) How many grams of Zn(NO<sub>3</sub>)<sub>2</sub> form? (d) How many grams of the excess reactant are left at the end of the reaction?

**Theoretical and Percent Yields**

The quantity of product calculated to form when all of a limiting reactant is consumed is called the **theoretical yield**. The amount of product actually obtained, called the *actual yield*, is almost always less than (and can never be greater than) the theoretical yield. There are many reasons for this difference. Some of the reactants may not react, for example, or they may react in a way different from that desired (side reactions). In addition, it is not always possible to recover all of the product from the reaction mixture. The **percent yield** of a reaction relates actual and theoretical yields:

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \quad [3.14]$$

**Sample Exercise 3.20****Calculating Theoretical Yield and Percent Yield**

Adipic acid, H<sub>2</sub>C<sub>6</sub>H<sub>8</sub>O<sub>4</sub>, used to produce nylon, is made commercially by a reaction between cyclohexane (C<sub>6</sub>H<sub>12</sub>) and O<sub>2</sub>:

(a) Assume that you carry out this reaction with 25.0 g of cyclohexane and that cyclohexane is the limiting reactant. What is the theoretical yield of adipic acid? (b) If you obtain 33.5 g of adipic acid, what is the percent yield for the reaction?

## SOLUTION

**Analyze** We are given a chemical equation and the quantity of the limiting reactant (25.0 g of  $\text{C}_6\text{H}_{12}$ ). We are asked to calculate the theoretical yield of a product  $\text{H}_2\text{C}_6\text{H}_8\text{O}_4$  and the percent yield if only 33.5 g of product is obtained.

## Solve

(a) The theoretical yield is:

$$\text{Grams H}_2\text{C}_6\text{H}_8\text{O}_4 = (25.0 \text{ g C}_6\text{H}_{12}) \left( \frac{1 \text{ mol C}_6\text{H}_{12}}{84.0 \text{ g C}_6\text{H}_{12}} \right) \left( \frac{2 \text{ mol H}_2\text{C}_6\text{H}_8\text{O}_4}{2 \text{ mol C}_6\text{H}_{12}} \right) \left( \frac{146.0 \text{ g H}_2\text{C}_6\text{H}_8\text{O}_4}{1 \text{ mol H}_2\text{C}_6\text{H}_8\text{O}_4} \right) = 43.5 \text{ g H}_2\text{C}_6\text{H}_8\text{O}_4$$

(b) The percent yield is:

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% = \frac{33.5 \text{ g}}{43.5 \text{ g}} \times 100\% = 77.0\%$$

**Check** We can check our answer in (a) by doing a ballpark calculation. From the balanced equation we know that each mole of cyclohexane gives 1 mol adipic acid. We have  $25/84 \approx 25/75 = 0.3$  mol hexane, so we expect 0.3 mol adipic acid, which equals about  $0.3 \times 150 = 45$  g, about the same magnitude as the 43.5 g obtained in the more detailed calculation given previously. In addition, our answer has the appropriate units and number of significant figures. In (b) the answer is less than 100%, as it must be from the definition of percent yield.

## ► Practice Exercise 1

If 3.00 g of titanium metal is reacted with 6.00 g of chlorine gas,  $\text{Cl}_2$ , to form 7.7 g of titanium(IV) chloride in a

## Plan

- The theoretical yield, which is the calculated quantity of adipic acid formed, can be calculated using the sequence of conversions shown in Figure 3.16.
- The percent yield is calculated by using Equation 3.14 to compare the given actual yield (33.5 g) with the theoretical yield.

combination reaction, what is the percent yield of the product?

- (a) 65% (b) 96% (c) 48% (d) 86%

## ► Practice Exercise 2

Imagine you are working on ways to improve the process by which iron ore containing  $\text{Fe}_2\text{O}_3$  is converted into iron:

- If you start with 150 g of  $\text{Fe}_2\text{O}_3$  as the limiting reactant, what is the theoretical yield of Fe?
- If your actual yield is 87.9 g, what is the percent yield?

## STRATEGIES FOR SUCCESS Design an Experiment

One of the most important skills you can learn in school is how to think like a scientist. Questions such as: “What experiment might test this hypothesis?”, “How do I interpret these data?”, and “Do these data support the hypothesis?” are asked every day by chemists and other scientists as they go about their work.

We want you to become a good critical thinker as well as an active, logical, and curious learner. For this purpose, starting in this chapter, we include at the end of each chapter a special exercise called “Design an Experiment.” Here is an example:

*Is milk a pure liquid or a mixture of chemical components in water? Design an experiment to distinguish between these two possibilities.*

You might already know the answer—milk is indeed a mixture of components in water—but the goal is to think of how to demonstrate this in practice. Upon thinking about it, you will likely realize that the key idea for this experiment is separation: You can prove that milk is a mixture of chemical components if you can figure out how to separate these components.

Testing a hypothesis is a creative endeavor. While some experiments may be more efficient than others, there is often more than one good way to test a hypothesis. Our question about milk, for example, might be explored by an experiment in which you boil a known quantity of milk until it is dry. Does a solid residue form in the bottom of the pan? If so, you could weigh it and calculate the percentage of solids in milk, which would offer good evidence that milk is a mixture. If there is no residue after boiling, then you still cannot distinguish between the two possibilities.

What other experiments might you do to demonstrate that milk is a mixture? You could put a sample of milk in a centrifuge, which

you might have used in a biology lab, spin your sample, and observe if any solids collect at the bottom of the centrifuge tube; large molecules can be separated in this way from a mixture. Measurement of the mass of the solid at the bottom of the tube is a way to obtain a value for the % solids in milk and also tells you that milk is indeed a mixture.

Keep an open mind: Lacking a centrifuge, how else might you separate solids in the milk? You could consider using a filter with really tiny holes in it or perhaps even a fine strainer. You could propose that if milk were poured through this filter, some (large) solid components should stay on the top of the filter, while water (and really small molecules or ions) would pass through the filter. That result would be evidence that milk is a mixture. Does such a filter exist? Yes! But for our purposes, the existence of such a filter is not the point: The point is, can you use your imagination and your knowledge of chemistry to design a reasonable experiment? Don't worry too much about the exact apparatus you need for the Design an Experiment exercises. The goal is to imagine what you would need to do, or what kind of data you would need to collect, in order to answer the question. If your instructor allows it, you can collaborate with others in your class to develop ideas. Scientists discuss their ideas with other scientists all the time. We find that discussing ideas, and refining them, makes us better scientists and helps us collectively answer important questions.

The design and interpretation of scientific experiments is at the heart of the scientific method. Think of the Design an Experiment exercises as puzzles that can be solved in various ways, and enjoy your explorations!

## Chapter Summary and Key Terms

### CHEMICAL EQUATIONS (INTRODUCTION AND SECTION 3.1)

The study of the quantitative relationships between chemical formulas and chemical equations is known as **stoichiometry**. One of the important concepts of stoichiometry is the **law of conservation of mass**, which states that the total mass of the products of a chemical reaction is the same as the total mass of the reactants. The same numbers of atoms of each type are present before and after a chemical reaction. A balanced **chemical equation** shows equal numbers of atoms of each element on each side of the equation. Equations are balanced by placing coefficients in front of the chemical formulas for the **reactants** and **products** of a reaction, *not* by changing the subscripts in chemical formulas.

### SIMPLE PATTERNS OF CHEMICAL REACTIVITY (SECTION 3.2)

Among the reaction types described in this chapter are (1) **combination reactions**, in which two reactants combine to form one product; (2) **decomposition reactions**, in which a single reactant forms two or more products; and (3) **combustion reactions** in oxygen, in which a substance, typically a hydrocarbon, reacts rapidly with  $O_2$  to form  $CO_2$  and  $H_2O$ .

**FORMULA WEIGHTS (SECTION 3.3)** Much quantitative information can be determined from chemical formulas and balanced chemical equations by using atomic weights. The **formula weight** of a compound equals the sum of the atomic weights of the atoms in its formula. If the formula is a molecular formula, the formula weight is also called the **molecular weight**. Atomic weights and formula weights can be used to determine the **elemental composition** of a compound.

**AVOGADRO'S NUMBER AND THE MOLE (SECTION 3.4)** A mole of any substance contains **Avogadro's number** ( $6.02 \times 10^{23}$ ) of formula

units of that substance. The mass of a **mole** of atoms, molecules, or ions (the **molar mass**) equals the formula weight of that material expressed in grams. The mass of 1 molecule of  $H_2O$ , for example, is 18.0 amu, so the mass of 1 mol of  $H_2O$  is 18.0 g. That is, the molar mass of  $H_2O$  is 18.0 g/mol.

**EMPIRICAL FORMULAS FROM ANALYSIS (SECTION 3.5)** The empirical formula of any substance can be determined from its percent composition by calculating the relative number of moles of each atom in 100 g of the substance. If the substance is molecular in nature, its molecular formula can be determined from the empirical formula if the molecular weight is also known. Combustion analysis is a special technique for determining the empirical formulas of compounds containing only carbon, hydrogen, and/or oxygen.

### QUANTITATIVE INFORMATION FROM BALANCED EQUATIONS AND LIMITING REACTANTS (SECTIONS 3.6 AND 3.7)

The mole concept can be used to calculate the relative quantities of reactants and products in chemical reactions. The coefficients in a balanced equation give the relative numbers of moles of the reactants and products. To calculate the number of grams of a product from the number of grams of a reactant, first convert grams of reactant to moles of reactant. Then use the coefficients in the balanced equation to convert the number of moles of reactant to moles of product. Finally, convert moles of product to grams of product.

A **limiting reactant** is completely consumed in a reaction. When it is used up, the reaction stops, thus limiting the quantities of products formed. The **theoretical yield** of a reaction is the quantity of product calculated to form when all of the limiting reactant reacts. The actual yield of a reaction is always less than the theoretical yield. The **percent yield** compares the actual and theoretical yields.

## Learning Outcomes After studying this chapter, you should be able to:

- Balance chemical equations. (Section 3.1)  
*Related Exercises: 3.11, 3.12*
- Predict the products of simple combination, decomposition, and combustion reactions. (Section 3.2) *Related Exercises: 3.19, 3.20*
- Calculate formula weights. (Section 3.3) *Related Exercises: 3.23, 3.24*
- Convert grams to moles and vice versa using molar masses. (Section 3.4) *Related Exercises: 3.35, 3.36*
- Convert number of molecules to moles and vice versa using Avogadro's number. (Section 3.4) *Related Exercises: 3.39, 3.40*
- Calculate the empirical and molecular formulas of a compound from percentage composition and molecular weight. (Section 3.5) *Related Exercises: 3.53, 3.54*
- Identify limiting reactants and calculate amounts, in grams or moles, of reactants consumed and products formed for a reaction. (Section 3.6) *Related Exercises: 3.65, 3.66*
- Calculate the percent yield of a reaction. (Section 3.7) *Related Exercises: 3.83, 3.84*

## Key Equations

$$\% \text{ mass composition of element} = \frac{\left( \frac{\text{number of atoms of element}}{\text{formula weight of compound}} \right) \left( \text{atomic weight of element} \right)}{\text{formula weight of compound}} \times 100\% \quad [3.10]$$

This is the formula to calculate the mass percentage of each element in a compound. The sum of all the percentages of all the elements in a compound should add up to 100%.

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \quad [3.14]$$

This is the formula to calculate the percent yield of a reaction. The percent yield can never be more than 100%.

## Exercises

### Visualizing Concepts

- 3.1** The reaction between reactant A (blue spheres) and reactant B (red spheres) is shown in the following diagram:

Based on this diagram, which equation best describes the reaction? [Section 3.1]

- (a)  $A_2 + B \longrightarrow A_2B$   
 (b)  $A_2 + 4B \longrightarrow 2AB_2$   
 (c)  $2A + B_4 \longrightarrow 2AB_2$   
 (d)  $A + B_2 \longrightarrow AB_2$
- 3.2** The following diagram shows the combination reaction between hydrogen,  $H_2$ , and carbon monoxide,  $CO$ , to produce methanol,  $CH_3OH$  (white spheres are H, black spheres are C, red spheres are O). The correct number of  $CO$  molecules involved in this reaction is not shown. [Section 3.1]
- (a) Determine the number of  $CO$  molecules that should be shown in the left (reactants) box.  
 (b) Write a balanced chemical equation for the reaction.

- 3.3** The following diagram represents the collection of elements formed by a decomposition reaction. (a) If the blue spheres represent N atoms and the red ones represent O atoms, what was the empirical formula of the original compound? (b) Could you draw a diagram representing the molecules of the compound that had been decomposed? Why or why not? [Section 3.2]

- 3.4** The following diagram represents the collection of  $CO_2$  and  $H_2O$  molecules formed by complete combustion of a hydrocarbon. What is the empirical formula of the hydrocarbon? [Section 3.2]

- 3.5** Glycine, an amino acid used by organisms to make proteins, is represented by the following molecular model.

- (a) Write its molecular formula.  
 (b) Determine its molar mass.  
 (c) Calculate how many moles of glycine are in a 100.0-g sample of glycine.  
 (d) Calculate the percent nitrogen by mass in glycine. [Sections 3.3 and 3.5]

- 3.6** The following diagram represents a high-temperature reaction between  $CH_4$  and  $H_2O$ . Based on this reaction, find how many moles of each product can be obtained starting with 4.0 mol  $CH_4$ . [Section 3.6]

- 3.7** Nitrogen ( $N_2$ ) and hydrogen ( $H_2$ ) react to form ammonia ( $NH_3$ ). Consider the mixture of  $N_2$  and  $H_2$  shown in the accompanying diagram. The blue spheres represent N, and the white ones represent H. (a) Write the balanced chemical equation for the reaction. (b) What is the limiting reactant? (c) How many molecules of ammonia can be made, assuming the reaction goes to completion, based on the diagram? (d) Are any reactant molecules left over, based on the diagram? If so, how many of which type are left over? [Section 3.7]

- 3.8** Nitrogen monoxide and oxygen react to form nitrogen dioxide. Consider the mixture of NO and O<sub>2</sub> shown in the accompanying diagram. The blue spheres represent N, and the red ones represent O. **(a)** How many molecules of NO<sub>2</sub> can be formed, assuming the reaction goes to completion? **(b)** What is the limiting reactant? **(c)** If the actual yield of the reaction was 75% instead of 100%, how many molecules of each kind would be present after the reaction was over?

### Chemical Equations and Simple Patterns of Chemical Reactivity (Sections 3.1 and 3.2)

- 3.9** Write “true” or “false” for each statement. **(a)** We balance chemical equations as we do because energy must be conserved. **(b)** If the reaction  $2\text{O}_3(g) \rightarrow 3\text{O}_2(g)$  goes to completion and all O<sub>3</sub> is converted to O<sub>2</sub>, then the mass of O<sub>3</sub> at the beginning of the reaction must be the same as the mass of O<sub>2</sub> at the end of the reaction. **(c)** You can balance the “water-splitting” reaction  $\text{H}_2\text{O}(l) \rightarrow \text{H}_2(g) + \text{O}_2(g)$  by writing it this way:  $\text{H}_2\text{O}_2(l) \rightarrow \text{H}_2(g) + \text{O}_2(g)$ .
- 3.10** A key step in balancing chemical equations is correctly identifying the formulas of the reactants and products. For example, consider the reaction between calcium oxide, CaO(s), and H<sub>2</sub>O(l) to form aqueous calcium hydroxide. **(a)** Write a balanced chemical equation for this combination reaction, having correctly identified the product as Ca(OH)<sub>2</sub>(aq). **(b)** Is it possible to balance the equation if you incorrectly identify the product as CaOH(aq), and if so, what is the equation?
- 3.11** Balance the following equations:
- $\text{CO}(g) + \text{O}_2(g) \rightarrow \text{CO}_2(g)$
  - $\text{N}_2\text{O}_5(g) + \text{H}_2\text{O}(l) \rightarrow \text{HNO}_3(aq)$
  - $\text{CH}_4(g) + \text{Cl}_2(g) \rightarrow \text{CCl}_4(l) + \text{HCl}(g)$
  - $\text{Zn}(\text{OH})_2(s) + \text{HNO}_3(aq) \rightarrow \text{Zn}(\text{NO}_3)_2(aq) + \text{H}_2\text{O}(l)$
- 3.12** Balance the following equations:
- $\text{Li}(s) + \text{N}_2(g) \rightarrow \text{Li}_3\text{N}(s)$
  - $\text{TiCl}_4(l) + \text{H}_2\text{O}(l) \rightarrow \text{TiO}_2(s) + \text{HCl}(aq)$
  - $\text{NH}_4\text{NO}_3(s) \rightarrow \text{N}_2(g) + \text{O}_2(g) + \text{H}_2\text{O}(g)$
  - $\text{AlCl}_3(s) + \text{Ca}_3\text{N}_2(s) \rightarrow \text{AlN}(s) + \text{CaCl}_2(s)$
- 3.13** Balance the following equations:
- $\text{Al}_4\text{C}_3(s) + \text{H}_2\text{O}(l) \rightarrow \text{Al}(\text{OH})_3(s) + \text{CH}_4(g)$
  - $\text{C}_5\text{H}_{10}\text{O}_2(l) + \text{O}_2(g) \rightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$
  - $\text{Fe}(\text{OH})_3(s) + \text{H}_2\text{SO}_4(aq) \rightarrow \text{Fe}_2(\text{SO}_4)_3(aq) + \text{H}_2\text{O}(l)$
  - $\text{Mg}_3\text{N}_2(s) + \text{H}_2\text{SO}_4(aq) \rightarrow \text{MgSO}_4(aq) + (\text{NH}_4)_2\text{SO}_4(aq)$
- 3.14** Balance the following equations:
- $\text{Ca}_3\text{P}_2(s) + \text{H}_2\text{O}(l) \rightarrow \text{Ca}(\text{OH})_2(aq) + \text{PH}_3(g)$
  - $\text{Al}(\text{OH})_3(s) + \text{H}_2\text{SO}_4(aq) \rightarrow \text{Al}_2(\text{SO}_4)_3(aq) + \text{H}_2\text{O}(l)$
  - $\text{AgNO}_3(aq) + \text{Na}_2\text{CO}_3(aq) \rightarrow \text{Ag}_2\text{CO}_3(s) + \text{NaNO}_3(aq)$
  - $\text{C}_2\text{H}_5\text{NH}_2(g) + \text{O}_2(g) \rightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g) + \text{N}_2(g)$
- 3.15** Write balanced chemical equations corresponding to each of the following descriptions: **(a)** Solid calcium carbide, CaC<sub>2</sub>, reacts with water to form an aqueous solution of calcium hydroxide and acetylene gas, C<sub>2</sub>H<sub>2</sub>. **(b)** When solid potassium chlorate is heated, it decomposes to form solid potassium chloride and oxygen gas. **(c)** Solid zinc metal reacts with

sulfuric acid to form hydrogen gas and an aqueous solution of zinc sulfate. **(d)** When liquid phosphorus trichloride is added to water, it reacts to form aqueous phosphorous acid, H<sub>3</sub>PO<sub>3</sub>(aq), and aqueous hydrochloric acid. **(e)** When hydrogen sulfide gas is passed over solid hot iron(III) hydroxide, the resulting reaction produces solid iron(III) sulfide and gaseous water.

- 3.16** Write balanced chemical equations to correspond to each of the following descriptions: **(a)** When sulfur trioxide gas reacts with water, a solution of sulfuric acid forms. **(b)** Boron sulfide, B<sub>2</sub>S<sub>3</sub>(s), reacts violently with water to form dissolved boric acid, H<sub>3</sub>BO<sub>3</sub>, and hydrogen sulfide gas. **(c)** Phosphine, PH<sub>3</sub>(g), combusts in oxygen gas to form water vapor and solid tetraphosphorus decoxide. **(d)** When solid mercury(II) nitrate is heated, it decomposes to form solid mercury(II) oxide, gaseous nitrogen dioxide, and oxygen. **(e)** Copper metal reacts with hot concentrated sulfuric acid solution to form aqueous copper(II) sulfate, sulfur dioxide gas, and water.

### Patterns of Chemical Reactivity (Section 3.2)

- 3.17** **(a)** When the metallic element sodium combines with the nonmetallic element bromine, Br<sub>2</sub>(l), what is the chemical formula of the product? **(b)** Is the product a solid, liquid, or gas at room temperature? **(c)** In the balanced chemical equation for this reaction, what is the coefficient in front of the product if the coefficient in front of Br<sub>2</sub>(l) is 1?
- 3.18** **(a)** When a compound containing C, H, and O is completely combusted in air, what reactant besides the hydrocarbon is involved in the reaction? **(b)** What products form in this reaction? **(c)** What is the sum of the coefficients in the balanced chemical equation for the combustion of one mole of acetone, C<sub>3</sub>H<sub>6</sub>O(l), in air?
- 3.19** Write a balanced chemical equation for the reaction that occurs when **(a)** Mg(s) reacts with Cl<sub>2</sub>(g); **(b)** barium carbonate decomposes into barium oxide and carbon dioxide gas when heated; **(c)** the hydrocarbon styrene, C<sub>8</sub>H<sub>8</sub>(l), is combusted in air; **(d)** dimethylether, CH<sub>3</sub>OCH<sub>3</sub>(g), is combusted in air.
- 3.20** Write a balanced chemical equation for the reaction that occurs when **(a)** titanium metal reacts with O<sub>2</sub>(g); **(b)** silver(I) oxide decomposes into silver metal and oxygen gas when heated; **(c)** propanol, C<sub>3</sub>H<sub>7</sub>OH(l) burns in air; **(d)** methyl *tert*-butyl ether, C<sub>5</sub>H<sub>12</sub>O(l), burns in air.
- 3.21** Balance the following equations and indicate whether they are combination, decomposition, or combustion reactions:
- $\text{C}_3\text{H}_6(g) + \text{O}_2(g) \rightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$
  - $\text{NH}_4\text{NO}_3(s) \rightarrow \text{N}_2\text{O}(g) + \text{H}_2\text{O}(g)$
  - $\text{C}_5\text{H}_6\text{O}(l) + \text{O}_2(g) \rightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$
  - $\text{N}_2(g) + \text{H}_2(g) \rightarrow \text{NH}_3(g)$
  - $\text{K}_2\text{O}(s) + \text{H}_2\text{O}(l) \rightarrow \text{KOH}(aq)$
- 3.22** Balance the following equations and indicate whether they are combination, decomposition, or combustion reactions:
- $\text{PbCO}_3(s) \rightarrow \text{PbO}(s) + \text{CO}_2(g)$
  - $\text{C}_2\text{H}_4(g) + \text{O}_2(g) \rightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$
  - $\text{Mg}(s) + \text{N}_2(g) \rightarrow \text{Mg}_3\text{N}_2(s)$
  - $\text{C}_7\text{H}_8\text{O}_2(l) + \text{O}_2(g) \rightarrow \text{CO}_2(g) + \text{H}_2\text{O}(g)$
  - $\text{Al}(s) + \text{Cl}_2(g) \rightarrow \text{AlCl}_3(s)$

### Formula Weights (Section 3.3)

- 3.23** Determine the formula weights of each of the following compounds: **(a)** nitric acid, HNO<sub>3</sub>; **(b)** KMnO<sub>4</sub>; **(c)** Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>; **(d)** quartz, SiO<sub>2</sub>; **(e)** gallium sulfide, **(f)** chromium(III) sulfate, **(g)** phosphorus trichloride.

- 3.24** Determine the formula weights of each of the following compounds: **(a)** nitrous oxide,  $\text{N}_2\text{O}$ , known as laughing gas and used as an anesthetic in dentistry; **(b)** benzoic acid,  $\text{C}_6\text{H}_5\text{COOH}$ , a substance used as a food preservative; **(c)**  $\text{Mg}(\text{OH})_2$ , the active ingredient in milk of magnesia; **(d)** urea,  $(\text{NH}_2)_2\text{CO}$ , a compound used as a nitrogen fertilizer; **(e)** isopentyl acetate,  $\text{CH}_3\text{CO}_2\text{C}_5\text{H}_{11}$ , responsible for the odor of bananas.
- 3.25** Calculate the percentage by mass of oxygen in the following compounds: **(a)** morphine,  $\text{C}_{17}\text{H}_{19}\text{NO}_3$ ; **(b)** codeine,  $\text{C}_{18}\text{H}_{21}\text{NO}_3$ ; **(c)** cocaine,  $\text{C}_{17}\text{H}_{21}\text{NO}_4$ ; **(d)** tetracycline,  $\text{C}_{22}\text{H}_{24}\text{N}_2\text{O}_8$ ; **(e)** digoxin,  $\text{C}_{41}\text{H}_{64}\text{O}_{13}$ ; **(f)** vancomycin,  $\text{C}_{66}\text{H}_{75}\text{Cl}_2\text{N}_9\text{O}_{24}$ .
- 3.26** Calculate the percentage by mass of the indicated element in the following compounds: **(a)** carbon in acetylene,  $\text{C}_2\text{H}_2$ , a gas used in welding; **(b)** hydrogen in ascorbic acid,  $\text{C}_6\text{H}_8\text{O}_6$ , also known as vitamin C; **(c)** hydrogen in ammonium sulfate,  $(\text{NH}_4)_2\text{SO}_4$ , a substance used as a nitrogen fertilizer; **(d)** platinum in  $\text{PtCl}_2(\text{NH}_3)_2$ , a chemotherapy agent called cisplatin; **(e)** oxygen in the female sex hormone estradiol,  $\text{C}_{18}\text{H}_{24}\text{O}_2$ ; **(f)** carbon in capsaicin,  $\text{C}_{18}\text{H}_{27}\text{NO}_3$ , the compound that gives the hot taste to chili peppers.
- 3.27** Based on the following structural formulas, calculate the percentage of carbon by mass present in each compound:

- 3.28** Calculate the percentage of carbon by mass in each of the compounds represented by the following models:

## Avogadro's Number and the Mole (Section 3.4)

- 3.29** **(a)** Write “true” or “false” for each statement. **(a)** A mole of horses contain a mole of horse legs. **(b)** A mole of water has a mass of 18.0 g. **(c)** The mass of 1 molecule of water is 18.0 g. **(d)** A mole of  $\text{NaCl}(\text{s})$  contains 2 moles of ions.
- 3.30** **(a)** What is the mass, in grams, of one mole of  $^{12}\text{C}$ ? **(b)** How many carbon atoms are present in one mole of  $^{12}\text{C}$ ?
- 3.31** Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing numbers of atoms: 0.50 mol  $\text{H}_2\text{O}$ , 23 g Na,  $6.0 \times 10^{23}$   $\text{N}_2$  molecules.
- 3.32** Without doing any detailed calculations (but using a periodic table to give atomic weights), rank the following samples in order of increasing numbers of atoms: 42 g of  $\text{NaHCO}_3$ , 1.5 mol  $\text{CO}_2$ ,  $6.0 \times 10^{24}$  Ne atoms.
- 3.33** What is the mass, in kilograms, of an Avogadro's number of people, if the average mass of a person is 160 lb? How does this compare with the mass of Earth,  $5.98 \times 10^{24}$  kg?
- 3.34** If Avogadro's number of pennies is divided equally among the 321 million men, women, and children in the United States, how many dollars would each receive? How does this compare with the gross domestic product (GDP) of the United States, which was \$17.419 trillion in 2015? (The GDP is the total market value of the nation's goods and services.)
- 3.35** Calculate the following quantities:
- (a)** mass, in grams, of 0.105 mol sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ )  
**(b)** moles of  $\text{Zn}(\text{NO}_3)_2$  in 143.50 g of this substance  
**(c)** number of molecules in  $1.0 \times 10^{-6}$  mol  $\text{CH}_3\text{CH}_2\text{OH}$   
**(d)** number of N atoms in 0.410 mol  $\text{NH}_3$
- 3.36** Calculate the following quantities:
- (a)** mass, in grams, of  $1.50 \times 10^{-2}$  mol CdS  
**(b)** number of moles of  $\text{NH}_4\text{Cl}$  in 86.6 g of this substance  
**(c)** number of molecules in  $8.447 \times 10^{-2}$  mol  $\text{C}_6\text{H}_6$   
**(d)** number of O atoms in  $6.25 \times 10^{-3}$  mol  $\text{Al}(\text{NO}_3)_3$
- 3.37** **(a)** What is the mass, in grams, of  $2.50 \times 10^{-3}$  mol of ammonium phosphate?  
**(b)** How many moles of chloride ions are in 0.2550 g of aluminum chloride?  
**(c)** What is the mass, in grams, of  $7.70 \times 10^{20}$  molecules of caffeine,  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ ?  
**(d)** What is the molar mass of cholesterol if 0.00105 mol has a mass of 0.406 g?
- 3.38** **(a)** What is the mass, in grams, of 1.223 mol of iron(III) sulfate?  
**(b)** How many moles of ammonium ions are in 6.955 g of ammonium carbonate?  
**(c)** What is the mass, in grams, of  $1.50 \times 10^{21}$  molecules of aspirin,  $\text{C}_9\text{H}_8\text{O}_4$ ?  
**(d)** What is the molar mass of diazepam (Valium®) if 0.05570 mol has a mass of 15.86 g?
- 3.39** The molecular formula of allicin, the compound responsible for the characteristic smell of garlic, is  $\text{C}_6\text{H}_{10}\text{OS}_2$ . **(a)** What is the molar mass of allicin? **(b)** How many moles of allicin are present in 5.00 mg of this substance? **(c)** How many molecules of allicin are in 5.00 mg of this substance? **(d)** How many S atoms are present in 5.00 mg of allicin?
- 3.40** The molecular formula of aspartame, the artificial sweetener marketed as NutraSweet®, is  $\text{C}_{14}\text{H}_{18}\text{N}_2\text{O}_5$ . **(a)** What is the molar mass of aspartame? **(b)** How many moles of aspartame are present in 1.00 mg of aspartame? **(c)** How many molecules of aspartame are present in 1.00 mg of aspartame? **(d)** How many hydrogen atoms are present in 1.00 mg of aspartame?

- 3.41** A sample of glucose,  $C_6H_{12}O_6$ , contains  $1.250 \times 10^{21}$  carbon atoms. (a) How many atoms of hydrogen does it contain? (b) How many molecules of glucose does it contain? (c) How many moles of glucose does it contain? (d) What is the mass of this sample in grams?
- 3.42** A sample of the male sex hormone testosterone,  $C_{19}H_{28}O_2$ , contains  $3.88 \times 10^{21}$  hydrogen atoms. (a) How many atoms of carbon does it contain? (b) How many molecules of testosterone does it contain? (c) How many moles of testosterone does it contain? (d) What is the mass of this sample in grams?
- 3.43** The allowable concentration level of vinyl chloride,  $C_2H_3Cl$ , in the atmosphere in a chemical plant is  $2.0 \times 10^{-6}$  g/L. How many moles of vinyl chloride in each liter does this represent? How many molecules per liter?
- 3.44** At least 25  $\mu\text{g}$  of tetrahydrocannabinol (THC), the active ingredient in marijuana, is required to produce intoxication. The molecular formula of THC is  $C_{21}H_{30}O_2$ . How many moles of THC does this 25  $\mu\text{g}$  represent? How many molecules?

### Empirical Formulas from Analyses (Section 3.5)

- 3.45** Give the empirical formula of each of the following compounds if a sample contains (a) 0.0130 mol C, 0.0390 mol H, and 0.0065 mol O; (b) 11.66 g iron and 5.01 g oxygen; (c) 40.0% C, 6.7% H, and 53.3% O by mass.
- 3.46** Determine the empirical formula of each of the following compounds if a sample contains (a) 0.104 mol K, 0.052 mol C, and 0.156 mol O; (b) 5.28 g Sn and 3.37 g F; (c) 87.5% N and 12.5% H by mass.
- 3.47** Determine the empirical formulas of the compounds with the following compositions by mass:
- (a) 10.4% C, 27.8% S, and 61.7% Cl
  - (b) 21.7% C, 9.6% O, and 68.7% F
  - (c) 32.79% Na, 13.02% Al, and the remainder F
- 3.48** Determine the empirical formulas of the compounds with the following compositions by mass:
- (a) 55.3% K, 14.6% P, and 30.1% O
  - (b) 24.5% Na, 14.9% Si, and 60.6% F
  - (c) 62.1% C, 5.21% H, 12.1% N, and the remainder O
- 3.49** A compound whose empirical formula is  $XF_3$  consists of 65% F by mass. What is the atomic mass of X?
- 3.50** The compound  $XCl_4$  contains 75.0% Cl by mass. What is the element X?
- 3.51** What is the molecular formula of each of the following compounds?
- (a) empirical formula  $CH_2$ , molar mass = 84.0 g/mol
  - (b) empirical formula  $NH_2Cl$ , molar mass = 51.5 g/mol
- 3.52** What is the molecular formula of each of the following compounds?
- (a) empirical formula  $HCO_2$ , molar mass = 90.0 g/mol
  - (b) empirical formula  $C_2H_4O$ , molar mass = 88.0 g/mol
- 3.53** Determine the empirical and molecular formulas of each of the following substances:
- (a) Styrene, a compound used to make Styrofoam® cups and insulation, contains 92.3% C and 7.7% H by mass and has a molar mass of 104 g/mol.
  - (b) Caffeine, a stimulant found in coffee, contains 49.5% C, 5.15% H, 28.9% N, and 16.5% O by mass and has a molar mass of 195 g/mol.
  - (c) Monosodium glutamate (MSG), a flavor enhancer in certain foods, contains 35.51% C, 4.77% H, 37.85% O, 8.29% N, and 13.60% Na, and has a molar mass of 169 g/mol.
- 3.54** Determine the empirical and molecular formulas of each of the following substances:
- (a) Ibuprofen, a headache remedy, contains 75.69% C, 8.80% H, and 15.51% O by mass and has a molar mass of 206 g/mol.
  - (b) Cadaverine, a foul-smelling substance produced by the action of bacteria on meat, contains 58.55% C, 13.81% H, and 27.40% N by mass; its molar mass is 102.2 g/mol.
  - (c) Epinephrine (adrenaline), a hormone secreted into the bloodstream in times of danger or stress, contains 59.0% C, 7.1% H, 26.2% O, and 7.7% N by mass; its molar mass is about 180 amu.
- 3.55** (a) Combustion analysis of toluene, a common organic solvent, gives 5.86 mg of  $CO_2$  and 1.37 mg of  $H_2O$ . If the compound contains only carbon and hydrogen, what is its empirical formula? (b) Menthol, the substance we can smell in mentholated cough drops, is composed of C, H, and O. A 0.1005-g sample of menthol is combusted, producing 0.2829 g of  $CO_2$  and 0.1159 g of  $H_2O$ . What is the empirical formula for menthol? If menthol has a molar mass of 156 g/mol, what is its molecular formula?
- 3.56** (a) The characteristic odor of pineapple is due to ethyl butyrate, a compound containing carbon, hydrogen, and oxygen. Combustion of 2.78 mg of ethyl butyrate produces 6.32 mg of  $CO_2$  and 2.58 mg of  $H_2O$ . What is the empirical formula of the compound? (b) Nicotine, a component of tobacco, is composed of C, H, and N. A 5.250-mg sample of nicotine was combusted, producing 14.242 mg of  $CO_2$  and 4.083 mg of  $H_2O$ . What is the empirical formula for nicotine? If nicotine has a molar mass of  $160 \pm 5$  g/mol, what is its molecular formula?
- 3.57** Valproic acid, used to treat seizures and bipolar disorder, is composed of C, H, and O. A 0.165-g sample is combusted to produce 0.166 g of water and 0.403 g of carbon dioxide. What is the empirical formula for valproic acid? If the molar mass is 144 g/mol, what is the molecular formula?
- 3.58** Propenoic acid,  $C_3H_4O_2$ , is a reactive organic liquid that is used in the manufacturing of plastics, coatings, and adhesives. An unlabeled container is thought to contain this liquid. A 0.275-g sample of the liquid is combusted to produce 0.102 g of water and 0.374 g carbon dioxide. Is the unknown liquid propenoic acid? Support your reasoning with calculations.
- 3.59** Washing soda, a compound used to prepare hard water for washing laundry, is a hydrate, which means that a certain number of water molecules are included in the solid structure. Its formula can be written as  $Na_2CO_3 \cdot xH_2O$ , where  $x$  is the number of moles of  $H_2O$  per mole of  $Na_2CO_3$ . When a 2.558-g sample of washing soda is heated at 125 °C, all the water of hydration is lost, leaving 0.948 g of  $Na_2CO_3$ . What is the value of  $x$ ?
- 3.60** Epsom salts, a strong laxative used in veterinary medicine, is a hydrate, which means that a certain number of water molecules are included in the solid structure. The formula for Epsom salts can be written as  $MgSO_4 \cdot xH_2O$ , where  $x$  indicates the number of moles of  $H_2O$  per mole of  $MgSO_4$ . When 5.061 g of this hydrate is heated to 250 °C, all the water of hydration is lost, leaving 2.472 g of  $MgSO_4$ . What is the value of  $x$ ?

## Quantitative Information from Balanced Equations (Section 3.6)

- 3.61** Hydrofluoric acid,  $\text{HF}(aq)$ , cannot be stored in glass bottles because compounds called silicates in the glass are attacked by the  $\text{HF}(aq)$ . Sodium silicate ( $\text{Na}_2\text{SiO}_3$ ), for example, reacts as follows:

- (a) How many moles of  $\text{HF}$  are needed to react with 0.300 mol of  $\text{Na}_2\text{SiO}_3$ ?  
 (b) How many grams of  $\text{NaF}$  form when 0.500 mol of  $\text{HF}$  reacts with excess  $\text{Na}_2\text{SiO}_3$ ?  
 (c) How many grams of  $\text{Na}_2\text{SiO}_3$  can react with 0.800 g of  $\text{HF}$ ?
- 3.62** The reaction between potassium superoxide,  $\text{KO}_2$ , and  $\text{CO}_2$ ,

is used as a source of  $\text{O}_2$  and absorber of  $\text{CO}_2$  in self-contained breathing equipment used by rescue workers.

- (a) How many moles of  $\text{O}_2$  are produced when 0.400 mol of  $\text{KO}_2$  reacts in this fashion?  
 (b) How many grams of  $\text{KO}_2$  are needed to form 7.50 g of  $\text{O}_2$ ?

- (c) How many grams of  $\text{CO}_2$  are used when 7.50 g of  $\text{O}_2$  are produced?

- 3.63** Several brands of antacids use  $\text{Al}(\text{OH})_3$  to react with stomach acid, which contains primarily  $\text{HCl}$ :

- (a) Balance this equation.  
 (b) Calculate the number of grams of  $\text{HCl}$  that can react with 0.500 g of  $\text{Al}(\text{OH})_3$ .  
 (c) Calculate the number of grams of  $\text{AlCl}_3$  and the number of grams of  $\text{H}_2\text{O}$  formed when 0.500 g of  $\text{Al}(\text{OH})_3$  reacts.  
 (d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.
- 3.64** An iron ore sample contains  $\text{Fe}_2\text{O}_3$  together with other substances. Reaction of the ore with  $\text{CO}$  produces iron metal:

- (a) Balance this equation.  
 (b) Calculate the number of grams of  $\text{CO}$  that can react with 0.350 kg of  $\text{Fe}_2\text{O}_3$ .  
 (c) Calculate the number of grams of  $\text{Fe}$  and the number of grams of  $\text{CO}_2$  formed when 0.350 kg of  $\text{Fe}_2\text{O}_3$  reacts.  
 (d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.
- 3.65** Aluminum sulfide reacts with water to form aluminum hydroxide and hydrogen sulfide. (a) Write the balanced chemical equation for this reaction. (b) How many grams of aluminum hydroxide are obtained from 14.2 g of aluminum sulfide?

- 3.66** Calcium hydride reacts with water to form calcium hydroxide and hydrogen gas. (a) Write a balanced chemical equation for the reaction. (b) How many grams of calcium hydride are needed to form 4.500 g of hydrogen?

- 3.67** Automotive air bags inflate when sodium azide,  $\text{NaN}_3$ , rapidly decomposes to its component elements:

- (a) How many moles of  $\text{N}_2$  are produced by the decomposition of 1.50 mol of  $\text{NaN}_3$ ?  
 (b) How many grams of  $\text{NaN}_3$  are required to form 10.0 g of nitrogen gas?  
 (c) How many grams of  $\text{NaN}_3$  are required to produce 10.0  $\text{ft}^3$  of nitrogen gas, about the size of an automotive air bag, if the gas has a density of 1.25 g/L?
- 3.68** The complete combustion of octane,  $\text{C}_8\text{H}_{18}$ , a component of gasoline, proceeds as follows:
- $$2 \text{C}_8\text{H}_{18}(l) + 25 \text{O}_2(g) \longrightarrow 16 \text{CO}_2(g) + 18 \text{H}_2\text{O}(g)$$
- (a) How many moles of  $\text{O}_2$  are needed to burn 1.50 mol of  $\text{C}_8\text{H}_{18}$ ?  
 (b) How many grams of  $\text{O}_2$  are needed to burn 10.0 g of  $\text{C}_8\text{H}_{18}$ ?  
 (c) Octane has a density of 0.692 g/mL at 20 °C. How many grams of  $\text{O}_2$  are required to burn 15.0 gal of  $\text{C}_8\text{H}_{18}$  (the capacity of an average fuel tank)?  
 (d) How many grams of  $\text{CO}_2$  are produced when 15.0 gal of  $\text{C}_8\text{H}_{18}$  are combusted?

- 3.69** A piece of aluminum foil 1.00  $\text{cm}^2$  and 0.550-mm thick is allowed to react with bromine to form aluminum bromide.

- (a) How many moles of aluminum were used? (The density of aluminum is 2.699 g/ $\text{cm}^3$ .) (b) How many grams of aluminum bromide form, assuming the aluminum reacts completely?
- 3.70** Detonation of nitroglycerin proceeds as follows:
- $$4 \text{C}_3\text{H}_5\text{N}_3\text{O}_9(l) \longrightarrow 12 \text{CO}_2(g) + 6 \text{N}_2(g) + \text{O}_2(g) + 10 \text{H}_2\text{O}(g)$$
- (a) If a sample containing 2.00 mL of nitroglycerin (density = 1.592 g/mL) is detonated, how many moles of gas are produced? (b) If each mole of gas occupies 55 L under the conditions of the explosion, how many liters of gas are produced? (c) How many grams of  $\text{N}_2$  are produced in the detonation?
- 3.71** The combustion of one mole of liquid ethanol,  $\text{CH}_3\text{CH}_2\text{OH}$ , produces 1367 kJ of heat. Calculate how much heat is produced when 235.0 g of ethanol are combusted.
- 3.72** The combustion of one mole of liquid octane,  $\text{CH}_3(\text{CH}_2)_6\text{CH}_3$ , produces 5470 kJ of heat. Calculate how much heat is produced if 1.000 gallon of octane is combusted. See Exercise 3.68 for necessary information about octane.

## Limiting Reactants (Section 3.7)

**3.73** (a) Define the terms *limiting reactant* and *excess reactant*. (b) Why are the amounts of products formed in a reaction determined only by the amount of the limiting reactant? (c) Why should you base your choice of which compound is the limiting reactant on its number of initial moles, not on its initial mass in grams?

**3.74** Define the terms *theoretical yield*, *actual yield*, and *percent yield*. (b) Why is the actual yield in a reaction almost always less than the theoretical yield? (c) Can a reaction ever have 110% actual yield?

**3.75** Consider the mixture of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , and  $\text{O}_2$  shown in the accompanying diagram. (a) Write a balanced equation for the combustion reaction that occurs between ethanol and oxygen. (b) Which reactant is the limiting reactant? (c) How many molecules of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{C}_2\text{H}_5\text{OH}$ , and  $\text{O}_2$  will be present if the reaction goes to completion?

**3.76** Consider the mixture of propane,  $\text{C}_3\text{H}_8$ , and  $\text{O}_2$  shown here. (a) Write a balanced equation for the combustion reaction that occurs between propane and oxygen. (b) Which reactant is the limiting reactant? (c) How many molecules of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{C}_3\text{H}_8$ , and  $\text{O}_2$  will be present if the reaction goes to completion?

**3.77** Sodium hydroxide reacts with carbon dioxide as follows:

Which is the limiting reactant when 1.85 mol NaOH and 1.00 mol  $\text{CO}_2$  are allowed to react? How many moles of  $\text{Na}_2\text{CO}_3$  can be produced? How many moles of the excess reactant remain after the completion of the reaction?

**3.78** Aluminum hydroxide reacts with sulfuric acid as follows:

Which is the limiting reactant when 0.500 mol  $\text{Al}(\text{OH})_3$  and 0.500 mol  $\text{H}_2\text{SO}_4$  are allowed to react? How many moles of  $\text{Al}_2(\text{SO}_4)_3$  can form under these conditions? How many moles of the excess reactant remain after the completion of the reaction?

**3.79** The fizz produced when an Alka-Seltzer tablet is dissolved in water is due to the reaction between sodium bicarbonate ( $\text{NaHCO}_3$ ) and citric acid ( $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$ ):

In a certain experiment 1.00 g of sodium bicarbonate and 1.00 g of citric acid are allowed to react. (a) Which is the limiting reactant? (b) How many grams of carbon dioxide form? (c) How many grams of the excess reactant remain after the limiting reactant is completely consumed?

**3.80** One of the steps in the commercial process for converting ammonia to nitric acid is the conversion of  $\text{NH}_3$  to  $\text{NO}$ :

In a certain experiment, 2.00 g of  $\text{NH}_3$  reacts with 2.50 g of  $\text{O}_2$ . (a) Which is the limiting reactant? (b) How many grams of  $\text{NO}$  and  $\text{H}_2\text{O}$  form? (c) How many grams of the excess reactant remain after the limiting reactant is completely consumed? (d) Show that your calculations in parts (b) and (c) are consistent with the law of conservation of mass.

**3.81** Solutions of sodium carbonate and silver nitrate react to form solid silver carbonate and a solution of sodium nitrate. A solution containing 3.50 g of sodium carbonate is mixed with one containing 5.00 g of silver nitrate. How many grams of sodium carbonate, silver nitrate, silver carbonate, and sodium nitrate are present after the reaction is complete?

**3.82** Solutions of sulfuric acid and lead(II) acetate react to form solid lead(II) sulfate and a solution of acetic acid. If 5.00 g of sulfuric acid and 5.00 g of lead(II) acetate are mixed, calculate the number of grams of sulfuric acid, lead(II) acetate, lead(II) sulfate, and acetic acid present in the mixture after the reaction is complete.

**3.83** When benzene ( $\text{C}_6\text{H}_6$ ) reacts with bromine ( $\text{Br}_2$ ), bromobenzene ( $\text{C}_6\text{H}_5\text{Br}$ ) is obtained:

(a) When 30.0 g of benzene reacts with 65.0 g of bromine, what is the theoretical yield of bromobenzene? (b) If the actual yield of bromobenzene is 42.3 g, what is the percentage yield?

**3.84** When ethane ( $\text{C}_2\text{H}_6$ ) reacts with chlorine ( $\text{Cl}_2$ ), the main product is  $\text{C}_2\text{H}_5\text{Cl}$ , but other products containing Cl, such as  $\text{C}_2\text{H}_4\text{Cl}_2$ , are also obtained in small quantities. The formation of these other products reduces the yield of  $\text{C}_2\text{H}_5\text{Cl}$ . (a) Calculate the theoretical yield of  $\text{C}_2\text{H}_5\text{Cl}$  when 125 g of  $\text{C}_2\text{H}_6$  reacts with 255 g of  $\text{Cl}_2$ , assuming that  $\text{C}_2\text{H}_6$  and  $\text{Cl}_2$  react only to form  $\text{C}_2\text{H}_5\text{Cl}$  and  $\text{HCl}$ . (b) Calculate the percent yield of  $\text{C}_2\text{H}_5\text{Cl}$  if the reaction produces 206 g of  $\text{C}_2\text{H}_5\text{Cl}$ .

**3.85** Hydrogen sulfide is an impurity in natural gas that must be removed. One common removal method is called the Claus process, which relies on the reaction:

Under optimal conditions the Claus process gives 98% yield of  $\text{S}_8$  from  $\text{H}_2\text{S}$ . If you started with 30.0 g of  $\text{H}_2\text{S}$  and 50.0 g of  $\text{O}_2$ , how many grams of  $\text{S}_8$  would be produced, assuming 98% yield?

**3.86** When hydrogen sulfide gas is bubbled into a solution of sodium hydroxide, the reaction forms sodium sulfide and water. How many grams of sodium sulfide are formed if 1.25 g of hydrogen sulfide is bubbled into a solution containing 2.00 g of sodium hydroxide, assuming that the sodium sulfide is made in 92.0% yield?

## Additional Exercises

- 3.87** Write the balanced chemical equations for (a) the complete combustion of acetic acid ( $\text{CH}_3\text{COOH}$ ), the main ingredient in vinegar; (b) the decomposition of solid calcium hydroxide into solid calcium oxide (lime) and water vapor; (c) the combination reaction between nickel metal and chlorine gas.
- 3.88** If 1.5 mol  $\text{C}_2\text{H}_5\text{OH}$ , 1.5 mol  $\text{C}_3\text{H}_8$ , and 1.5 mol  $\text{CH}_3\text{CH}_2\text{COCH}_3$  are completely combusted in oxygen, which produces the largest number of moles of  $\text{H}_2\text{O}$ ? Which produces the least? Explain.
- 3.89** The effectiveness of nitrogen fertilizers depends on both their ability to deliver nitrogen to plants and the amount of nitrogen they can deliver. Four common nitrogen-containing fertilizers are ammonia, ammonium nitrate, ammonium sulfate, and urea  $[(\text{NH}_2)_2\text{CO}]$ . Rank these fertilizers in terms of the mass percentage nitrogen they contain.
- 3.90** (a) The molecular formula of acetylsalicylic acid (aspirin), one of the most common pain relievers, is  $\text{C}_9\text{H}_8\text{O}_4$ . How many moles of  $\text{C}_9\text{H}_8\text{O}_4$  are in a 0.500-g tablet of aspirin? Assume the tablet is composed entirely of aspirin. (b) How many molecules of  $\text{C}_9\text{H}_8\text{O}_4$  are in this tablet? (c) How many carbon atoms are in the tablet?
- 3.91** Very small semiconductor crystals, composed of approximately 1000 to 10,000 atoms, are called quantum dots. Quantum dots made of the semiconductor  $\text{CdSe}$  are now being used in electronic reader and tablet displays because they emit light efficiently and in multiple colors, depending on dot size. The density of  $\text{CdSe}$  is  $5.82 \text{ g/cm}^3$ .
- (a) What is the mass of one 2.5-nm  $\text{CdSe}$  quantum dot?
- (b)  $\text{CdSe}$  quantum dots that are 2.5 nm in diameter emit blue light upon stimulation. Assuming that the dot is a perfect sphere and that the empty space in the dot can be neglected, calculate how many Cd atoms are in one quantum dot of this size.
- (c) What is the mass of one 6.5-nm  $\text{CdSe}$  quantum dot?
- (d)  $\text{CdSe}$  quantum dots that are 6.5 nm in diameter emit red light upon stimulation. Assuming that the dot is a perfect sphere, calculate how many Cd atoms are in one quantum dot of this size.
- (e) If you wanted to make one 6.5-nm dot from multiple 2.5-nm dots, how many 2.5-nm dots would you need, and how many  $\text{CdSe}$  formula units would be left over, if any?
- 3.92** (a) One molecule of the antibiotic penicillin G has a mass of  $5.342 \times 10^{-21} \text{ g}$ . What is the molar mass of penicillin G? (b) Hemoglobin, the oxygen-carrying protein in red blood cells, has four iron atoms per molecule and contains 0.340% iron by mass. Calculate the molar mass of hemoglobin.
- 3.93** Serotonin is a compound that conducts nerve impulses in the brain. It contains 68.2% C, 6.86% H, 15.9% N, and 9.08% O. Its molar mass is  $176 \text{ g/mol}$ . Determine its molecular formula.
- 3.94** The koala dines exclusively on eucalyptus leaves. Its digestive system detoxifies the eucalyptus oil, a poison to other animals. The chief constituent in eucalyptus oil is a substance called eucalyptol, which contains 77.87% C, 11.76% H, and the remainder O. (a) What is the empirical formula for this substance? (b) A mass spectrum of eucalyptol shows a peak at about 154 amu. What is the molecular formula of the substance?
- 3.95** Vanillin, the dominant flavoring in vanilla, contains C, H, and O. When 1.05 g of this substance is completely combusted, 2.43 g of  $\text{CO}_2$  and 0.50 g of  $\text{H}_2\text{O}$  are produced. What is the empirical formula of vanillin?
- 3.96** An organic compound was found to contain only C, H, and Cl. When a 1.50-g sample of the compound was completely combusted in air, 3.52 g of  $\text{CO}_2$  was formed. In a separate experiment, the chlorine in a 1.00-g sample of the compound was converted to 1.27 g of  $\text{AgCl}$ . Determine the empirical formula of the compound.
- 3.97** A compound,  $\text{KBrO}_x$ , where  $x$  is unknown, is analyzed and found to contain 52.92% Br. What is the value of  $x$ ?
- 3.98** An element X forms an iodide ( $\text{XI}_3$ ) and a chloride ( $\text{XCl}_3$ ). The iodide is quantitatively converted to the chloride when it is heated in a stream of chlorine:
- $$2 \text{XI}_3 + 3 \text{Cl}_2 \longrightarrow 2 \text{XCl}_3 + 3 \text{I}_2$$
- If 0.5000 g of  $\text{XI}_3$  is treated with chlorine, 0.2360 g of  $\text{XCl}_3$  is obtained. (a) Calculate the atomic weight of the element X. (b) Identify the element X.
- 3.99** A method used by the U.S. Environmental Protection Agency (EPA) for determining the concentration of ozone in air is to pass the air sample through a "bubbler" containing sodium iodide, which removes the ozone according to the following equation:
- $$\text{O}_3(\text{g}) + 2 \text{NaI}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{O}_2(\text{g}) + \text{I}_2(\text{s}) + 2 \text{NaOH}(\text{aq})$$
- (a) How many moles of sodium iodide are needed to remove  $5.95 \times 10^{-6} \text{ mol}$  of  $\text{O}_3$ ? (b) How many grams of sodium iodide are needed to remove 1.3 mg of  $\text{O}_3$ ?
- 3.100** A chemical plant uses electrical energy to decompose aqueous solutions of  $\text{NaCl}$  to give  $\text{Cl}_2$ ,  $\text{H}_2$ , and  $\text{NaOH}$ :
- $$2 \text{NaCl}(\text{aq}) + 2 \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{NaOH}(\text{aq}) + \text{H}_2(\text{g}) + \text{Cl}_2(\text{g})$$
- If the plant produces  $1.5 \times 10^6 \text{ kg}$  (1500 metric tons) of  $\text{Cl}_2$  daily, estimate the quantities of  $\text{H}_2$  and  $\text{NaOH}$  produced.
- 3.101** The fat stored in a camel's hump is a source of both energy and water. Calculate the mass of  $\text{H}_2\text{O}$  produced by the metabolism of 1.0 kg of fat, assuming the fat consists entirely of tristearin ( $\text{C}_{57}\text{H}_{110}\text{O}_6$ ), a typical animal fat, and assuming that during metabolism, tristearin reacts with  $\text{O}_2$  to form only  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .
- 3.102** When hydrocarbons are burned in a limited amount of air, both  $\text{CO}$  and  $\text{CO}_2$  form. When 0.450 g of a particular hydrocarbon was burned in air, 0.467 g of  $\text{CO}$ , 0.733 g of  $\text{CO}_2$ , and 0.450 g of  $\text{H}_2\text{O}$  were formed. (a) What is the empirical formula of the compound? (b) How many grams of  $\text{O}_2$  were used in the reaction? (c) How many grams would have been required for complete combustion?
- 3.103** A mixture of  $\text{N}_2(\text{g})$  and  $\text{H}_2(\text{g})$  reacts in a closed container to form ammonia,  $\text{NH}_3(\text{g})$ . The reaction ceases before either reactant has been totally consumed. At this stage 3.0 mol  $\text{N}_2$ , 3.0 mol  $\text{H}_2$ , and 3.0 mol  $\text{NH}_3$  are present. How many moles of  $\text{N}_2$  and  $\text{H}_2$  were present originally?
- 3.104** A mixture containing  $\text{KClO}_3$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{KHCO}_3$ , and  $\text{KCl}$  was heated, producing  $\text{CO}_2$ ,  $\text{O}_2$ , and  $\text{H}_2\text{O}$  gases according to the following equations:
- $$2 \text{KClO}_3(\text{s}) \longrightarrow 2 \text{KCl}(\text{s}) + 3 \text{O}_2(\text{g})$$
- $$2 \text{KHCO}_3(\text{s}) \longrightarrow \text{K}_2\text{O}(\text{s}) + \text{H}_2\text{O}(\text{g}) + 2 \text{CO}_2(\text{g})$$
- $$\text{K}_2\text{CO}_3(\text{s}) \longrightarrow \text{K}_2\text{O}(\text{s}) + \text{CO}_2(\text{g})$$
- The  $\text{KCl}$  does not react under the conditions of the reaction. If 100.0 g of the mixture produces 1.80 g of  $\text{H}_2\text{O}$ , 13.20 g of  $\text{CO}_2$ , and 4.00 g of  $\text{O}_2$ , what was the composition of the original mixture? (Assume complete decomposition of the mixture.)
- 3.105** When a mixture of 10.0 g of acetylene ( $\text{C}_2\text{H}_2$ ) and 10.0 g of oxygen ( $\text{O}_2$ ) is ignited, the resulting combustion reaction produces  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . (a) Write the balanced chemical equation for this reaction. (b) Which is the limiting reactant? (c) How many grams of  $\text{C}_2\text{H}_2$ ,  $\text{O}_2$ ,  $\text{CO}_2$ , and  $\text{H}_2\text{O}$  are present after the reaction is complete?

## Integrative Exercises

These exercises require skills from earlier chapters as well as skills from the present chapter.

- 3.106** The semiconductor gallium arsenide, GaAs, is used in high-speed integrated circuits, light-emitting diodes, and solar cells. Its density is  $5.32 \text{ g/cm}^3$ . It can be made by reacting trimethylgallium,  $(\text{CH}_3)_3\text{Ga}$ , with arsine gas,  $\text{AsH}_3$ . The other product of the reaction is methane,  $\text{CH}_4$ . (a) If you reacted  $450.0 \text{ g}$  of trimethylgallium with  $300.0 \text{ g}$  of arsine, what mass of GaAs could you make? (b) Which reactant, if any, would be left over, and how many moles of the leftover reactant would remain? (c) One application of GaAs uses it as a thin film. If you take the mass of GaAs from part (a) and make a  $40\text{-nm}$  thin film from it, what area, in  $\text{cm}^2$ , would it cover? Recall that  $1 \text{ nm} = 1 \times 10^{-9} \text{ m}$ .
- 3.107** Paclitaxel,  $\text{C}_{47}\text{H}_{51}\text{NO}_{14}$ , is an anticancer compound that is difficult to make in the lab. One reported synthesis requires 11 steps, and the final yield of paclitaxel is only 5%. Assuming all steps have equivalent yields, what is the average percent yield for each step in the synthesis?
- 3.108** Consider a sample of calcium carbonate in the form of a cube measuring  $2.005 \text{ in.}$  on each edge. If the sample has a density of  $2.71 \text{ g/cm}^3$ , how many oxygen atoms does it contain?
- 3.109** (a) You are given a cube of silver metal that measures  $1.000 \text{ cm}$  on each edge. The density of silver is  $10.5 \text{ g/cm}^3$ . How many atoms are in this cube? (b) Because atoms are spherical, they cannot occupy all of the space of the cube. The silver atoms pack in the solid in such a way that 74% of the volume of the solid is actually filled with the silver atoms. Calculate the volume of a single silver atom. (c) Using the volume of a silver atom and the formula for the volume of a sphere, calculate the radius in angstroms of a silver atom.
- 3.110** (a) If an automobile travels  $225 \text{ mi}$  with a gas mileage of  $20.5 \text{ mi/gal}$ , how many kilograms of  $\text{CO}_2$  are produced? Assume that the gasoline is composed of octane,  $\text{C}_8\text{H}_{18}(\text{l})$ , whose density is  $0.692 \text{ g/mL}$ . (b) Repeat the calculation for a truck that has a gas mileage of  $5 \text{ mi/gal}$ .
- 3.111** Section 2.9 introduced the idea of structural isomerism, with 1-propanol and 2-propanol as examples. Determine which of these properties would distinguish these two substances: (a) boiling point, (b) combustion analysis results, (c) molecular weight, (d) density at a given temperature and pressure. You can check on the properties of these two compounds in *Wolfram Alpha* (<http://www.wolframalpha.com/>) or the *CRC Handbook of Chemistry and Physics*.
- 3.112** A particular coal contains 2.5% sulfur by mass. When this coal is burned at a power plant, the sulfur is converted into sulfur dioxide gas, which is a pollutant. To reduce sulfur dioxide emissions, calcium oxide (lime) is used. The sulfur dioxide reacts with calcium oxide to form solid calcium sulfite. (a) Write the balanced chemical equation for the reaction. (b) If the coal is burned in a power plant that uses  $2000.0 \text{ tons}$  of coal per day, what mass of calcium oxide is required daily to eliminate the sulfur dioxide? (c) How many grams of calcium sulfite does this power plant produce daily?
- 3.113** Hydrogen cyanide,  $\text{HCN}$ , is a poisonous gas. The lethal dose is approximately  $300 \text{ mg HCN}$  per kilogram of air when inhaled. (a) Calculate the amount of  $\text{HCN}$  that gives the lethal dose in a small laboratory room measuring  $12 \times 15 \times 8.0 \text{ ft}$ . The density of air at  $26^\circ\text{C}$  is  $0.00118 \text{ g/cm}^3$ . (b) If the  $\text{HCN}$  is formed by reaction of  $\text{NaCN}$  with an acid such as  $\text{H}_2\text{SO}_4$ , what mass of  $\text{NaCN}$  gives the lethal dose in the room?

(c)  $\text{HCN}$  forms when synthetic fibers containing Orlon® or Acrilan® burn. Acrilan® has an empirical formula of  $\text{CH}_2\text{CHCN}$ , so  $\text{HCN}$  is 50.9% of the formula by mass. A rug measures  $12 \times 15 \text{ ft}$  and contains  $30 \text{ oz}$  of Acrilan® fibers per square yard of carpet. If the rug burns, will a lethal dose of  $\text{HCN}$  be generated in the room? Assume that the yield of  $\text{HCN}$  from the fibers is 20% and that the carpet is 50% consumed.

- 3.114** The source of oxygen that drives the internal combustion engine in an automobile is air. Air is a mixture of gases, principally  $\text{N}_2$  (~79%) and  $\text{O}_2$  (~20%). In the cylinder of an automobile engine, nitrogen can react with oxygen to produce nitric oxide gas,  $\text{NO}$ . As  $\text{NO}$  is emitted from the tailpipe of the car, it can react with more oxygen to produce nitrogen dioxide gas. (a) Write balanced chemical equations for both reactions. (b) Both nitric oxide and nitrogen dioxide are pollutants that can lead to acid rain and global warming; collectively, they are called “ $\text{NO}_x$ ” gases. In 2009, the United States emitted an estimated 19 million tons of nitrogen dioxide into the atmosphere. How many grams of nitrogen dioxide is this? (c) The production of  $\text{NO}_x$  gases is an unwanted side reaction of the main engine combustion process that turns octane,  $\text{C}_8\text{H}_{18}$ , into  $\text{CO}_2$  and water. If 85% of the oxygen in an engine is used to combust octane and the remainder used to produce nitrogen dioxide, calculate how many grams of nitrogen dioxide would be produced during the combustion of  $500 \text{ g}$  of octane.

- 3.115** The thermite reaction,

produces so much heat that the  $\text{Fe}$  product melts. This reaction is used industrially to weld metal parts under water, where a torch cannot be employed. It is also a favorite chemical demonstration in the lecture hall (on a small scale).

- (a) Balance the chemical equation for the thermite reaction, and include the proper states of matter.
- (b) Calculate how many grams of aluminum are needed to completely react with  $500.0 \text{ g}$  of  $\text{Fe}_2\text{O}_3$  in this reaction.
- (c) This reaction produces  $852 \text{ kJ}$  of heat per mole of  $\text{Fe}_2\text{O}_3$  reacted. How many grams of  $\text{Fe}_2\text{O}_3$  are needed to produce  $1.00 \times 10^4 \text{ kJ}$  of heat?
- (d) If you performed the reverse reaction—aluminum oxide plus iron makes iron oxide plus aluminum—would that reaction have heat as a reactant or a product?
- 3.116** One of the most bizarre reactions in chemistry is called the Ugi reaction:

- (a) Write out the balanced chemical equation for the Ugi reaction, for the case where  $\text{R} = \text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2$ —(this is called the *hexyl* group) for all compounds. (b) What mass of the “hexyl Ugi product” would you form if  $435.0 \text{ mg}$  of  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$  was the limiting reactant?

## Design an Experiment

You will learn later in this book that sulfur is capable of forming two common oxides,  $\text{SO}_2$  and  $\text{SO}_3$ . One question that we might ask is whether the direct reaction between sulfur and oxygen leads to the formation of  $\text{SO}_2$ ,  $\text{SO}_3$ , or a mixture of the two. This question has practical significance because  $\text{SO}_3$  can go on to react with water to form sulfuric acid,  $\text{H}_2\text{SO}_4$ , which is produced industrially on a very large scale. Consider also that the answer to this question may depend on the relative amount of each element that is present and the temperature at which the reaction is carried out. For example, on the one hand, carbon and oxygen normally react to form  $\text{CO}_2$ , but when not enough oxygen is present,  $\text{CO}$  can form. On the other hand, under normal reaction conditions  $\text{H}_2$  and  $\text{O}_2$  react to form water,  $\text{H}_2\text{O}$  (rather than hydrogen peroxide  $\text{H}_2\text{O}_2$ ), regardless of the starting ratio of hydrogen to oxygen.

Suppose you are given a bottle of sulfur, which is a yellow solid, a cylinder of  $\text{O}_2$ , a transparent reaction vessel that can be evacuated and sealed so that only sulfur, oxygen, and the product(s) of the reaction between the two are present, an analytical balance so

that you can determine the masses of the reactants and/or products, and a furnace that can be used to heat the reaction vessel to  $200^\circ\text{C}$  where the two elements react. **(a)** If you start with 0.10 mol of sulfur in the reaction vessel how many moles of oxygen would need to be added to form  $\text{SO}_2$ , assuming  $\text{SO}_2$  forms exclusively? **(b)** How many moles of oxygen would be needed to form  $\text{SO}_3$ , assuming  $\text{SO}_3$  forms exclusively? **(c)** Given the available equipment, how would you determine you had added the correct number of moles of each reactant to the reaction vessel? **(d)** What observation or experimental technique would you use to determine the identity of the reaction product(s)? Could differences in the physical properties of  $\text{SO}_2$  and  $\text{SO}_3$  be used to help identify the product(s)? Have any instruments been described in Chapters 1–3 that would allow you to identify the product(s)? **(e)** What experiments would you conduct to determine if the product(s) of this reaction (either  $\text{SO}_2$  or  $\text{SO}_3$  or a mixture of the two) can be controlled by varying the ratio of sulfur and oxygen that are added to the reaction vessel? What ratio(s) of S to  $\text{O}_2$  would you test to answer this question?

4

# REACTIONS IN AQUEOUS SOLUTION

## Water covers nearly two-thirds

of our planet, and this simple substance has been the key to much of Earth's evolutionary history. Life almost certainly originated in water, and the need for water by all forms of life has helped determine diverse biological structures. Indeed, most of the mass of our bodies is water, and the chemical reactions responsible for life occur in water. In contrast, much of the chemical industry relies on either high temperatures or other liquids for creating and purifying compounds (**Figure 4.1**).

A solution in which water is the dissolving medium is called an **aqueous solution**. In this chapter we examine chemical reactions that take place in aqueous solutions. In addition, we extend the concepts of stoichiometry learned in Chapter 3 by considering how solution concentrations are expressed and used. Although the reactions we will discuss in this chapter are relatively simple, they form the basis for understanding very complex reaction cycles in biology, geology, and oceanography.

◀ **WATER IS THE MOST ABUNDANT** liquid on our planet. The composition of seawater closely matches the composition of the body fluids of almost all life forms, suggesting that life arose in the seas.

## WHAT'S AHEAD

- 4.1 ▶ General Properties of Aqueous Solutions** Recognize that substances dissolved in water exist as ions, molecules, or a mixture of the two.
- 4.2 ▶ Precipitation Reactions** Identify reactions in which soluble reactants yield an insoluble product.
- 4.3 ▶ Acids, Bases, and Neutralization Reactions** Explore reactions in which protons,  $H^+$  ions, are transferred from one reactant to another.
- 4.4 ▶ Oxidation-Reduction Reactions** Examine reactions in which electrons are transferred from one reactant to another.
- 4.5 ▶ Concentrations of Solutions** Learn to express the amount of a compound dissolved in a given volume of a solution as a *concentration* in the unit called *molarity*: moles of compound per liter of solution.
- 4.6 ▶ Solution Stoichiometry and Chemical Analysis** Use the concepts of stoichiometry and concentration to calculate quantities involved in the process known as titration.

▲ **Figure 4.1** Big solutions. The BASF chemical plant in Ludwigshafen, Germany, produces many of the compounds used in our everyday lives.

## 4.1 | General Properties of Aqueous Solutions

A *solution* is a homogeneous mixture of two or more substances. ∞(Section 1.2) The substance present in the greatest quantity is usually called the **solvent**, and the other substances are called **solutes**; they are said to be *dissolved in* the solvent. When a small amount of sodium chloride (NaCl) is dissolved in a large quantity of water, for example, water is the solvent and sodium chloride is the solute.

### Electrolytes and Nonelectrolytes

At a young age we learn not to bring electrical devices into the bathtub so as not to electrocute ourselves. That is a useful lesson because most of the water we encounter in daily life is electrically conducting. Pure water, however, is a very poor conductor of electricity. The conductivity of bathwater originates from the substances dissolved in the water, not from the water itself.

Not all substances that dissolve in water make the resulting solution conducting. **Figure 4.2** shows a simple experiment to test the electrical conductivity of three solutions: pure water, a solution of table sugar (sucrose) in water, and a solution of table salt (NaCl) in water. A light bulb is connected to a battery-powered electrical circuit that contains two electrodes submerged in a beaker of each solution. In order for the light bulb to turn on, there must be an electrical current (that is, a flow of electrically charged particles) between the two electrodes immersed in the solution. Because the light bulb does not turn on in pure water, we conclude that there are not enough charged particles in pure water to create a circuit; water must then mostly exist as  $\text{H}_2\text{O}$  molecules. The solution containing sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) also does not turn on the light bulb; therefore, we

▲ **Figure 4.2** Completion of an electrical circuit with an electrolyte turns on the light.

conclude that the sucrose molecules in solution are uncharged. But the solution containing NaCl does provide enough charged particles to create an electrical circuit and turn on the light bulb. This is experimental evidence that  $\text{Na}^+$  and  $\text{Cl}^-$  ions are formed in aqueous solution.

A substance (such as NaCl) whose aqueous solutions contain ions is called an **electrolyte**. A substance (such as  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) that does not form ions in solution is called a **nonelectrolyte**. The different classifications of NaCl and  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  arise largely because NaCl is an ionic compound, whereas  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  is a molecular compound.

## How Compounds Dissolve in Water

Recall from Figure 2.19 that solid NaCl consists of an orderly arrangement of  $\text{Na}^+$  and  $\text{Cl}^-$  ions. When NaCl dissolves in water, each ion separates from the solid structure and disperses throughout the solution [Figure 4.3(a)]. The ionic solid *dissociates* into its component ions as it dissolves.

Water is a very effective solvent for ionic compounds. Although  $\text{H}_2\text{O}$  is an electrically neutral molecule, the O atom is rich in electrons and has a partial negative charge, while each H atom has a partial positive charge. The lowercase Greek letter delta ( $\delta$ ) is used to denote partial charge: A partial negative charge is denoted  $\delta^-$  (“delta minus”), and a partial positive charge is denoted by  $\delta^+$  (“delta plus”). Cations are attracted by the negative end of  $\text{H}_2\text{O}$ , and anions are attracted by the positive end.

As an ionic compound dissolves, the ions become surrounded by  $\text{H}_2\text{O}$  molecules, as shown in Figure 4.3(a). The ions are said to be *solvated*. In chemical equations, we denote solvated ions by writing them as  $\text{Na}^+(aq)$  and  $\text{Cl}^-(aq)$ , where *aq* is an abbreviation for “aqueous.” **Solvation** helps stabilize the ions in solution and prevents cations and anions from recombining. Furthermore, because the ions and their shells of surrounding water molecules are free to move about, the ions become dispersed uniformly throughout the solution.

We can usually predict the nature of the ions in a solution of an ionic compound from the chemical name of the substance. Sodium sulfate ( $\text{Na}_2\text{SO}_4$ ), for example, dissociates into sodium ions ( $\text{Na}^+$ ) and sulfate ions ( $\text{SO}_4^{2-}$ ). You must remember the formulas and charges of common ions (Tables 2.4 and 2.5) to understand the forms in which ionic compounds exist in aqueous solution.

### Give It Some Thought

What dissolved species are present in a solution of

- (a) KCN?
- (b)  $\text{NaClO}_4$ ?

## Go Figure

Do both, just one, or neither of the following solutions conduct electricity? If just one, which one?

(a) Ionic compounds like sodium chloride, NaCl, form ions when they dissolve.

(b) Molecular substances like methanol, CH<sub>3</sub>OH, dissolve without forming ions.

▲ **Figure 4.3 Dissolution in water.** (a) When an ionic compound, such as sodium chloride, NaCl, dissolves in water, H<sub>2</sub>O molecules separate, surround, and uniformly disperse the ions into the liquid. (b) Molecular substances that dissolve in water, such as methanol, CH<sub>3</sub>OH, usually do so without forming ions. We can think of methanol in water as a simple mixing of two molecular species. In both (a) and (b) the water molecules have been moved apart so that the solute particles can be seen clearly.

When a molecular compound such as sucrose or methanol [Figure 4.3(b)] dissolves in water, the solution usually consists of intact molecules dispersed throughout the solution. Consequently, most molecular compounds are nonelectrolytes. A few molecular substances do have aqueous solutions that contain ions. Acids are the most important of these solutions. For example, when HCl(g) dissolves in water to form HCl(aq), the molecule *ionizes*; that is, it dissociates into H<sup>+</sup>(aq) and Cl<sup>-</sup>(aq) ions.

## Strong and Weak Electrolytes

Electrolytes differ in the extent to which they conduct electricity. **Strong electrolytes** are those solutes that exist in solution completely or nearly completely as ions. Essentially all water-soluble ionic compounds (such as NaCl) and a few molecular compounds (such as HCl) are strong electrolytes. **Weak electrolytes** are those solutes that exist in solution mostly in the form of neutral molecules with only a small fraction in the form of ions. For example, in a solution of acetic acid (CH<sub>3</sub>COOH), most of the solute is present as CH<sub>3</sub>COOH(aq) molecules. Only a small fraction (about 1%) of the CH<sub>3</sub>COOH has dissociated into H<sup>+</sup>(aq) and CH<sub>3</sub>COO<sup>-</sup>(aq) ions.\*

We must be careful not to confuse the extent to which an electrolyte dissolves (its solubility) with whether it is strong or weak. For example, CH<sub>3</sub>COOH is extremely soluble in water but is a weak electrolyte. Ca(OH)<sub>2</sub>, in contrast, is not very soluble in water,

\*The chemical formula of acetic acid is sometimes written HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> so that the formula looks like that of other common acids such as HCl. The formula (CH<sub>3</sub>COOH) conforms to the molecular structure of acetic acid, with the acidic H on the O atom at the end of the formula.

but the amount that does dissolve dissociates almost completely. Thus,  $\text{Ca}(\text{OH})_2$  is a strong electrolyte.

When a weak electrolyte, such as acetic acid, ionizes in solution, we write the reaction in the form

The half-arrows pointing in opposite directions mean that the reaction is significant in both directions. At any given moment some  $\text{CH}_3\text{COOH}$  molecules are ionizing to form  $\text{H}^+$  and  $\text{CH}_3\text{COO}^-$  ions, and some of the  $\text{H}^+$  and  $\text{CH}_3\text{COO}^-$  ions are recombining to form  $\text{CH}_3\text{COOH}$ . The balance between these opposing processes determines the relative numbers of ions and neutral molecules. This balance produces a state of **chemical equilibrium** in which the relative numbers of each type of ion or molecule in the reaction are constant over time. Chemists use half-arrows pointing in opposite directions to represent reactions that go both forward and backward to achieve equilibrium, such as the ionization of weak electrolytes. In contrast, a single reaction arrow is used for reactions that largely go forward, such as the ionization of strong electrolytes. Because  $\text{HCl}$  is a strong electrolyte, we write the equation for the ionization of  $\text{HCl}$  as

The absence of a left-pointing half-arrow indicates that the  $\text{H}^+$  and  $\text{Cl}^-$  ions have no tendency to recombine to form  $\text{HCl}$  molecules.

In the following sections, we will look at how a compound's composition lets us predict whether it is a strong electrolyte, weak electrolyte, or nonelectrolyte. For the moment, you need only to remember that *water-soluble ionic compounds are strong electrolytes*. Ionic compounds can usually be identified by the presence of both metals and nonmetals [for example,  $\text{NaCl}$ ,  $\text{FeSO}_4$ , and  $\text{Al}(\text{NO}_3)_3$ ]. Ionic compounds containing the ammonium ion,  $\text{NH}_4^+$  [for example,  $\text{NH}_4\text{Br}$  and  $(\text{NH}_4)_2\text{CO}_3$ ], are exceptions to this rule of thumb.

### Give It Some Thought

Which solute will cause the light bulb in Figure 4.2 to glow most brightly,  $\text{CH}_3\text{OH}$ ,  $\text{NaOH}$ , or  $\text{CH}_3\text{COOH}$ ?

### Sample Exercise 4.1

#### Relating Relative Numbers of Anions and Cations to Chemical Formulas

The accompanying diagram represents an aqueous solution of either  $\text{MgCl}_2$ ,  $\text{KCl}$ , or  $\text{K}_2\text{SO}_4$ . Which solution does the drawing best represent?

#### SOLUTION

**Analyze** We are asked to associate the charged spheres in the diagram with ions present in a solution of an ionic substance.

**Plan** We examine each ionic substance given to determine the relative numbers and charges of its ions. We then correlate these ionic species with the ones shown in the diagram.

**Solve** The diagram shows twice as many cations as anions, consistent with the formulation  $\text{K}_2\text{SO}_4$ .

**Check** Notice that the net charge in the diagram is zero, as it must be if it is to represent an ionic substance.

#### Practice Exercise 1

If you have an aqueous solution that contains 1.5 moles of  $\text{HCl}$ , how many moles of ions are in the solution?  
(a) 1.0 (b) 1.5 (c) 2.0 (d) 2.5 (e) 3.0

#### Practice Exercise 2

If you were to draw diagrams representing aqueous solutions of (a)  $\text{NiSO}_4$ , (b)  $\text{Ca}(\text{NO}_3)_2$ , (c)  $\text{Na}_3\text{PO}_4$ , (d)  $\text{Al}_2(\text{SO}_4)_3$ , how many anions would you show if each diagram contained six cations?

## 4.2 | Precipitation Reactions

**Figure 4.4** shows two clear solutions being mixed. One solution contains potassium iodide, KI, dissolved in water, and the other contains lead nitrate,  $\text{Pb}(\text{NO}_3)_2$ , dissolved in water. The reaction between these two solutes produces a water-insoluble yellow solid. Reactions that result in the formation of an insoluble product are called **precipitation reactions**. A **precipitate** is an insoluble solid formed by a reaction in solution. In Figure 4.4 the precipitate is lead iodide ( $\text{PbI}_2$ ), a compound that has a very low solubility in water:

The other product of this reaction, potassium nitrate ( $\text{KNO}_3$ ), remains in solution.

Precipitation reactions occur when pairs of oppositely charged ions attract each other so strongly that they form an insoluble ionic solid. To predict whether certain combinations of ions form insoluble compounds, we must consider some guidelines concerning the solubilities of common ionic compounds.

### Solubility Guidelines for Ionic Compounds

The **solubility** of a substance at a given temperature is the amount of the substance that can be dissolved in a given quantity of solvent at the given temperature. Any substance

▲ **Figure 4.4** A precipitation reaction.

**TABLE 4.1 Solubility Guidelines for Common Ionic Compounds in Water**

| Soluble Ionic Compounds   |                           | Important Exceptions  |
|---------------------------|---------------------------|---|
| Compounds containing      | $\text{NO}_3^-$           | None  |
|                           | $\text{CH}_3\text{COO}^-$ | None  |
|                           | $\text{Cl}^-$             | Compounds of $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$  |
|                           | $\text{Br}^-$             | Compounds of $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$  |
|                           | $\text{I}^-$              | Compounds of $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$  |
|                           | $\text{SO}_4^{2-}$        | Compounds of $\text{Sr}^{2+}$ , $\text{Ba}^{2+}$ , $\text{Hg}_2^{2+}$ , and $\text{Pb}^{2+}$                        |
| Insoluble Ionic Compounds |                           | Important Exceptions  |
| Compounds containing      | $\text{S}^{2-}$           | Compounds of $\text{NH}_4^+$ , the alkali metal cations, $\text{Ca}^{2+}$ , $\text{Sr}^{2+}$ , and $\text{Ba}^{2+}$ |
|                           | $\text{CO}_3^{2-}$        | Compounds of $\text{NH}_4^+$ and the alkali metal cations   |
|                           | $\text{PO}_4^{3-}$        | Compounds of $\text{NH}_4^+$ and the alkali metal cations   |
|                           | $\text{OH}^-$             | Compounds of $\text{NH}_4^+$ , the alkali metal cations, $\text{Ca}^{2+}$ , $\text{Sr}^{2+}$ , and $\text{Ba}^{2+}$ |

with a solubility less than 0.01 mol/L will be considered *insoluble*. In these cases, the attraction between the oppositely charged ions in the solid is too great for the water molecules to separate the ions to any significant extent; the substance remains largely undissolved.

Unfortunately, there are no rules based on simple physical properties such as ionic charge to guide us in predicting whether a particular ionic compound will be soluble. Experimental observations, however, have led to guidelines for predicting solubility for ionic compounds. For example, experiments show that all common ionic compounds that contain the nitrate anion,  $\text{NO}_3^-$ , are soluble in water. **Table 4.1** summarizes the solubility guidelines for common ionic compounds. The table is organized according to the anion in the compound, but it also reveals many important facts about cations. Note that *all common ionic compounds of the alkali metal ions (group 1A of the periodic table) and of the ammonium ions ( $\text{NH}_4^+$ ) are soluble in water*.

#### How to Predict Whether a Precipitate Forms When Strong Electrolytes Mix

1. Note the ions present in the reactants.
2. Consider the possible cation–anion combinations.
3. Use Table 4.1 to determine if any of the combinations is insoluble.

For example, will a precipitate form when solutions of  $\text{Mg}(\text{NO}_3)_2$  and  $\text{NaOH}$  are mixed? Both substances are soluble ionic compounds and strong electrolytes. Mixing the solutions first produces a solution containing  $\text{Mg}^{2+}$ ,  $\text{NO}_3^-$ ,  $\text{Na}^+$ , and  $\text{OH}^-$  ions. Will either cation interact with either anion to form an insoluble compound? Knowing from Table 4.1 that  $\text{Mg}(\text{NO}_3)_2$  and  $\text{NaOH}$  are both soluble in water, our only possibilities are  $\text{Mg}^{2+}$  with  $\text{OH}^-$  and  $\text{Na}^+$  with  $\text{NO}_3^-$ . From Table 4.1 we see that hydroxides are generally insoluble. Because  $\text{Mg}^{2+}$  is not an exception,  $\text{Mg}(\text{OH})_2$  is insoluble and thus forms a precipitate.  $\text{NaNO}_3$ , however, is soluble, so  $\text{Na}^+$  and  $\text{NO}_3^-$  remain in solution. The balanced equation for the precipitation reaction is

## Exchange (Metathesis) Reactions

Notice in Equation 4.4 that the reactant cations exchange anions— $\text{Mg}^{2+}$  ends up with  $\text{OH}^-$ , and  $\text{Na}^+$  ends up with  $\text{NO}_3^-$ . The chemical formulas of the products are based on the charges of the ions—two  $\text{OH}^-$  ions are needed to give a neutral compound with  $\text{Mg}^{2+}$ , and one  $\text{NO}_3^-$  ion is needed to give a neutral compound with  $\text{Na}^+$ . [Section 2.7](#) The equation can be balanced only after the chemical formulas of the products have been determined.

**Sample Exercise 4.2****Using Solubility Rules**

Classify these ionic compounds as soluble or insoluble in water: (a) sodium carbonate,  $\text{Na}_2\text{CO}_3$ , (b) lead sulfate,  $\text{PbSO}_4$ .

**SOLUTION**

**Analyze** We are given the names and formulas of two ionic compounds and asked to predict whether they are soluble or insoluble in water.

**Plan** We can use Table 4.1 to answer the question. Thus, we need to focus on the anion in each compound because the table is organized by anions.

**Solve**

(a) According to Table 4.1, most carbonates are insoluble. But carbonates of the alkali metal cations (such as sodium ion) are an exception to this rule and are soluble. Thus,  $\text{Na}_2\text{CO}_3$  is soluble in water.

(b) Table 4.1 indicates that although most sulfates are water soluble, the sulfate of  $\text{Pb}^{2+}$  is an exception. Thus,  $\text{PbSO}_4$  is insoluble in water.

**Practice Exercise 1**

Which of the following compounds is insoluble in water?

(a)  $(\text{NH}_4)_2\text{S}$  (b)  $\text{CaCO}_3$  (c)  $\text{NaOH}$  (d)  $\text{Ag}_2\text{SO}_4$  (e)  $\text{Pb}(\text{CH}_3\text{COO})_2$

**Practice Exercise 2**

Classify the following compounds as soluble or insoluble in water:

(a) cobalt(II) hydroxide, (b) barium nitrate, (c) ammonium phosphate.

Reactions in which cations and anions appear to exchange partners conform to the general equation

Such reactions are called either **exchange reactions** or **metathesis reactions** (meh-TATH-eh-sis, Greek for “to transpose”). Precipitation reactions conform to this pattern, as do many neutralization reactions between acids and bases, as we will see in Section 4.3.

**How To Balance a Metathesis Reaction**

1. Use the chemical formulas of the reactants to determine which ions are present.
2. Write the chemical formulas of the products by combining the cation from one reactant with the anion of the other, using the ionic charges to determine the subscripts in the chemical formulas.
3. Check the water solubilities of the products. For a precipitation reaction to occur, at least one product must be insoluble in water.
4. Balance the equation.

**Sample Exercise 4.3****Predicting a Metathesis Reaction**

(a) Predict the identity of the precipitate that forms when aqueous solutions of  $\text{BaCl}_2$  and  $\text{K}_2\text{SO}_4$  are mixed. (b) Write the balanced chemical equation for the reaction.

**SOLUTION**

**Analyze** We are given two ionic reactants and asked to predict the insoluble product that they form.

**Plan** We need to write the ions present in the reactants and exchange the anions between the two cations. Once we have written the chemical formulas for these products, we can use Table 4.1 to determine which is insoluble in water. Knowing the products also allows us to write the equation for the reaction.

**Solve**

(a) The reactants contain  $\text{Ba}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{K}^+$ , and  $\text{SO}_4^{2-}$  ions. Exchanging the anions gives us  $\text{BaSO}_4$  and  $\text{KCl}$ . According to Table 4.1, most compounds of  $\text{SO}_4^{2-}$  are soluble but those of  $\text{Ba}^{2+}$  are not. Thus,  $\text{BaSO}_4$  is insoluble and will precipitate from solution.  $\text{KCl}$  is soluble.

(b) From part (a) we know the chemical formulas of the products,  $\text{BaSO}_4$  and  $\text{KCl}$ . The balanced equation is

**Practice Exercise 1**

Yes or No: Will a precipitate form when solutions of  $\text{Ba}(\text{NO}_3)_2$  and  $\text{KOH}$  are mixed?

**Practice Exercise 2**

(a) What compound precipitates when aqueous solutions of  $\text{Fe}_2(\text{SO}_4)_3$  and  $\text{LiOH}$  are mixed? (b) Write a balanced equation for the reaction.

## Ionic Equations and Spectator Ions

In writing equations for reactions in aqueous solution, it is often useful to indicate whether the dissolved substances are present predominantly as ions or as molecules. Let's reconsider the precipitation reaction between  $\text{Pb}(\text{NO}_3)_2$  and 2 KI (Eq. 4.3):

An equation written in this fashion, showing the complete chemical formulas of reactants and products, is called a **molecular equation** because it shows chemical formulas without indicating ionic character. Because  $\text{Pb}(\text{NO}_3)_2$ , KI, and  $\text{KNO}_3$  are all water-soluble ionic compounds and therefore strong electrolytes, we can write the equation in a form that indicates which species exist as ions in the solution:

An equation written in this form, with all soluble strong electrolytes shown as ions, is called a **complete ionic equation**.

Notice that  $\text{K}^+(aq)$  and  $\text{NO}_3^-(aq)$  appear on both sides of Equation 4.6. Ions that appear in identical forms on both sides of a complete ionic equation, called **spectator ions**, play no direct role in the reaction. Spectator ions can be canceled, like algebraic quantities, on either side of the reaction arrow, since they are not reacting with anything. Once we cancel the spectator ions, we are left with the **net ionic equation**, which is one that includes only the ions and molecules directly involved in the reaction:

Because charge is conserved in reactions, the sum of the ionic charges must be the same on both sides of a balanced net ionic equation. In this case, the 2+ charge of the cation and the two 1− charges of the anions add to zero, the charge of the electrically neutral product. *If every ion in a complete ionic equation is a spectator, no reaction occurs.*

### Give It Some Thought

Which ions, if any, are spectator ions in this reaction?

Net ionic equations illustrate the similarities between various reactions involving electrolytes. For example, Equation 4.7 expresses the essential feature of the precipitation reaction between any strong electrolyte containing  $\text{Pb}^{2+}(aq)$  and any strong electrolyte containing  $\text{I}^-(aq)$ : The ions combine to form a precipitate of  $\text{PbI}_2$ . Thus, a net ionic equation demonstrates that more than one set of reactants can lead to the same net reaction. For example, aqueous solutions of KI and  $\text{MgI}_2$  share many chemical similarities because both contain  $\text{I}^-$  ions. Either solution when mixed with a  $\text{Pb}(\text{NO}_3)_2$  solution produces  $\text{PbI}_2(s)$ . The complete ionic equation, however, identifies the actual reactants that participate in a reaction.

### How to Write a Net Ionic Equation

1. Write a balanced molecular equation for the reaction.
2. Rewrite the equation to show the ions that form in solution when each soluble strong electrolyte dissociates into its ions. *Only strong electrolytes dissolved in aqueous solution are written in ionic form.*
3. Identify and cancel spectator ions.

## Sample Exercise 4.4

## Writing a Net Ionic Equation

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of calcium chloride and sodium carbonate are mixed.

## SOLUTION

**Analyze** Our task is to write a net ionic equation for a precipitation reaction, given the names of the reactants present in solution.

**Plan** We write the chemical formulas of the reactants and products and then determine which product is insoluble. We then write and balance the molecular equation. Next, we write each soluble strong electrolyte as separated ions to obtain the complete ionic equation. Finally, we eliminate the spectator ions to obtain the net ionic equation.

**Solve** Calcium chloride is composed of calcium ions,  $\text{Ca}^{2+}$ , and chloride ions,  $\text{Cl}^-$ ; hence, an aqueous solution of the substance is  $\text{CaCl}_2(aq)$ . Sodium carbonate is composed of  $\text{Na}^+$  ions and  $\text{CO}_3^{2-}$  ions; hence, an aqueous solution of the compound is  $\text{Na}_2\text{CO}_3(aq)$ . In the molecular equations for precipitation reactions, the anions and cations appear to exchange partners. Thus, we put  $\text{Ca}^{2+}$  and  $\text{CO}_3^{2-}$  together to give  $\text{CaCO}_3$  and  $\text{Na}^+$  and  $\text{Cl}^-$  together to give  $\text{NaCl}$ . According to the solubility guidelines in Table 4.1,  $\text{CaCO}_3$  is insoluble and  $\text{NaCl}$  is soluble. The balanced molecular equation is

In a complete ionic equation, *only* dissolved strong electrolytes (such as soluble ionic compounds) are written as separate ions. As the  $(aq)$  designations remind us,  $\text{CaCl}_2$ ,  $\text{Na}_2\text{CO}_3$ , and  $\text{NaCl}$  are all dissolved in the solution. Furthermore, they are all strong electrolytes.  $\text{CaCO}_3$  is an ionic compound, but it is not soluble. We do not write the formula of any insoluble compound as its component ions. Thus, the complete ionic equation is

The spectator ions are  $\text{Na}^+$  and  $\text{Cl}^-$ . Canceling them gives the following net ionic equation:

**Check** We can check our result by confirming that both the elements and the electric charge are balanced. Each side has one Ca, one C, and three O, and the net charge on each side equals 0.

**Comment** If none of the ions in an ionic equation is removed from solution or changed in some way, all ions are spectator ions and a reaction does not occur.

## Practice Exercise 1

What happens when you mix an aqueous solution of sodium nitrate with an aqueous solution of barium chloride?

- (a) There is no reaction; all possible products are soluble.
- (b) Only barium nitrate precipitates.
- (c) Only sodium chloride precipitates.
- (d) Both barium nitrate and sodium chloride precipitate.
- (e) Nothing; barium chloride is not soluble and it stays as a precipitate.

## Practice Exercise 2

Write the net ionic equation for the precipitation reaction that occurs when aqueous solutions of silver nitrate and potassium phosphate are mixed.

▲ **Figure 4.5** Common household acids and bases. Vinegar and lemon juice are common household acids. Ammonia and baking soda (sodium bicarbonate) are common household bases.

## 4.3 | Acids, Bases, and Neutralization Reactions

Many acids and bases are industrial and household substances (Figure 4.5), and some are important components of biological fluids. Hydrochloric acid, for example, is an important industrial chemical and the main constituent of gastric juice in your stomach. Acids and bases are also common electrolytes.

## Acids

As noted in Section 2.8, **acids** are substances that ionize in aqueous solution to form hydrogen ions  $\text{H}^+(aq)$ . Because a hydrogen atom consists of a proton and an electron,  $\text{H}^+$  is simply a proton. Thus, acids are often called *proton donors*. Molecular models of four common acids are shown in Figure 4.6.

► **Figure 4.6** Molecular models of four common acids.

Protons in aqueous solution are solvated by water molecules, just as other cations are [Figure 4.3(a)]. In writing chemical equations involving protons in water, therefore, we write  $\text{H}^+(\text{aq})$ .

Molecules of different acids ionize to form different numbers of  $\text{H}^+$  ions. Both  $\text{HCl}$  and  $\text{HNO}_3$  are *monoprotic* acids, yielding one  $\text{H}^+$  per molecule of acid. Sulfuric acid,  $\text{H}_2\text{SO}_4$ , is a *diprotic* acid, one that yields two  $\text{H}^+$  per molecule of acid. The ionization of  $\text{H}_2\text{SO}_4$  and other diprotic acids occurs in two steps:

Although  $\text{H}_2\text{SO}_4$  is a strong electrolyte, only the first ionization (Equation 4.8) is complete. Thus, aqueous solutions of sulfuric acid contain a mixture of  $\text{H}^+(\text{aq})$ ,  $\text{HSO}_4^-(\text{aq})$ , and  $\text{SO}_4^{2-}(\text{aq})$ .

The molecule  $\text{CH}_3\text{COOH}$  (acetic acid) that we have mentioned frequently is the primary component in vinegar. Acetic acid has four hydrogens, as Figure 4.6 shows, but only one of them, the H that is bonded to an oxygen in the  $-\text{COOH}$  group, is ionized in water. Thus, the H in the  $\text{COOH}$  group breaks its  $\text{O}-\text{H}$  bond in water. The three other hydrogens in acetic acid are bound to carbon and do not break their  $\text{C}-\text{H}$  bonds in water. The reasons for this difference are very interesting and will be discussed in Chapter 16.

### Give It Some Thought

The structural formula of citric acid, a main component of citrus fruits, is

How many  $\text{H}^+(\text{aq})$  can be generated by each citric acid molecule dissolved in water?

## Bases

**Bases** are substances that accept (react with)  $\text{H}^+$  ions. Bases produce hydroxide ions ( $\text{OH}^-$ ) when they dissolve in water. Ionic hydroxide compounds, such as  $\text{NaOH}$ ,  $\text{KOH}$ , and  $\text{Ca}(\text{OH})_2$ , are among the most common bases. When dissolved in water, they dissociate into ions, introducing  $\text{OH}^-$  ions into the solution.

Compounds that do not contain  $\text{OH}^-$  ions can also be bases. For example, ammonia ( $\text{NH}_3$ ) is a common base. When added to water, it accepts an  $\text{H}^+$  ion from a water molecule and thereby produces an  $\text{OH}^-$  ion (Figure 4.7):

Ammonia is a weak electrolyte because only about 1% of the  $\text{NH}_3$  forms  $\text{NH}_4^+$  and  $\text{OH}^-$  ions.

◀ **Figure 4.7 Proton transfer.** An  $\text{H}_2\text{O}$  molecule acts as a proton donor (acid), and  $\text{NH}_3$  acts as a proton acceptor (base). In aqueous solutions, only a fraction of the  $\text{NH}_3$  molecules react with  $\text{H}_2\text{O}$ . Consequently,  $\text{NH}_3$  is a weak electrolyte.

**TABLE 4.2 Common Strong Acids and Bases**

| Strong Acids   | Strong Bases  |
|--|---|
| Hydrochloric acid, HCl                                       | Group 1A metal hydroxides<br>[LiOH, NaOH, KOH, RbOH, CsOH]  |
| Hydrobromic acid, HBr  | Heavy group 2A metal hydroxides<br>[Ca(OH) <sub>2</sub> , Sr(OH) <sub>2</sub> , Ba(OH) <sub>2</sub> ] |
| Hydroiodic acid, HI  |   |
| Chloric acid, HClO <sub>3</sub>                              |   |
| Perchloric acid, HClO <sub>4</sub>                           |   |
| Nitric acid, HNO <sub>3</sub>                                |   |
| Sulfuric acid (first proton), H <sub>2</sub> SO <sub>4</sub> |   |

### Strong and Weak Acids and Bases

Acids and bases that are strong electrolytes (completely ionized in solution) are **strong acids** and **strong bases**. Those that are weak electrolytes (partly ionized) are **weak acids** and **weak bases**. When reactivity depends only on  $\text{H}^+(aq)$  concentration, strong acids are more reactive than weak acids. The reactivity of an acid, however, can depend on the anion as well as on  $\text{H}^+(aq)$  concentration. For example, hydrofluoric acid (HF) is a weak acid (only partly ionized in aqueous solution), but it is very reactive and vigorously attacks many substances, including glass. This reactivity is due to the combined action of  $\text{H}^+(aq)$  and  $\text{F}^-(aq)$ .

**Table 4.2** lists the strong acids and bases we are most likely to encounter. You need to commit this information to memory in order to correctly identify strong electrolytes and write net ionic equations. The brevity of this list tells us that most acids are weak. (For  $\text{H}_2\text{SO}_4$ , as we noted earlier, only the first proton completely ionizes.) The only common strong bases are the common soluble metal hydroxides. The most common weak base is  $\text{NH}_3$ , which reacts with water to form  $\text{OH}^-$  ions (Equation 4.10).

#### Give It Some Thought

Why isn't  $\text{Al}(\text{OH})_3$  classified as a strong base?

### Identifying Strong and Weak Electrolytes

If we remember the common strong acids and bases (Table 4.2) and also remember that  $\text{NH}_3$  is a weak base, we can make reasonable predictions about the electrolytic strength of

#### Sample Exercise 4.5

##### Comparing Acid Strengths

The following diagrams represent aqueous solutions of acids HX, HY, and HZ, with water molecules omitted for clarity. Rank the acids from strongest to weakest.

**SOLUTION**

**Analyze** We are asked to rank three acids from strongest to weakest, based on schematic drawings of their solutions.

**Plan** We can determine the relative numbers of uncharged molecular species in the diagrams. The strongest acid is the one with the most  $\text{H}^+$  ions and fewest undissociated molecules in solution. The weakest acid is the one with the largest number of undissociated molecules.

**Solve** The order is  $\text{HY} > \text{HZ} > \text{HX}$ . HY is a strong acid because it is totally ionized (no HY molecules in solution), whereas both HX and HZ are weak acids, whose solutions consist of a mixture of molecules and ions. Because HZ contains more  $\text{H}^+$  ions and fewer molecules than HX, it is a stronger acid.

**Practice Exercise 1**

A set of aqueous solutions are prepared containing different acids at the same concentration: acetic acid, chloric acid, and hydrobromic acid. Which solution(s) are the most electrically conductive? (a) chloric acid (b) hydrobromic acid (c) acetic acid (d) both chloric acid and hydrobromic acid (e) all three solutions have the same electrical conductivity

**Practice Exercise 2**

Imagine a diagram showing 10  $\text{Na}^+$  ions and 10  $\text{OH}^-$  ions. If this solution were mixed with the one pictured above for HY, what species would be present in a diagram that represents the combined solutions after any possible reaction?

a great number of *water-soluble* substances. Table 4.3 summarizes our observations about electrolytes. We first ask whether the substance is ionic or molecular. If it is ionic, it is a strong electrolyte. If the substance is molecular, we ask whether it is an acid or a base. (It is an acid if it either has H first in the chemical formula or contains a COOH group.) If it is an acid, we use Table 4.2 to determine whether it is a strong or weak electrolyte: All strong acids are strong electrolytes, and all weak acids are weak electrolytes. If an acid is not listed in Table 4.2, it is probably a weak acid and therefore a weak electrolyte.

If our substance is a base, we use Table 4.2 to determine whether it is a strong base.  $\text{NH}_3$  is the only molecular base that we consider in this chapter, and it is a weak base; Table 4.3 tells us it is therefore a weak electrolyte. Finally, any molecular substance that we encounter in this chapter that is not an acid or  $\text{NH}_3$  is probably a nonelectrolyte.

**TABLE 4.3 Summary of the Electrolytic Behavior of Common Soluble Ionic and Molecular Compounds**

|                  | Strong Electrolyte           | Weak Electrolyte       | Nonelectrolyte      |
|------------------|------------------------------|------------------------|---------------------|
| <b>Ionic</b>     | All                          | None                   | None                |
| <b>Molecular</b> | Strong acids (see Table 4.2) | Weak acids, weak bases | All other compounds |

**Sample Exercise 4.6****Identifying Strong, Weak, and Nonelectrolytes**

Classify these dissolved substances as a strong electrolyte, weak electrolyte, or nonelectrolyte:  $\text{CaCl}_2$ ,  $\text{HNO}_3$ ,  $\text{C}_2\text{H}_5\text{OH}$  (ethanol),  $\text{HCOOH}$  (formic acid),  $\text{KOH}$ .

**SOLUTION**

**Analyze** We are given several chemical formulas and asked to classify each substance as a strong electrolyte, weak electrolyte, or nonelectrolyte.

**Plan** The approach we take is outlined in Table 4.3. We can predict whether a substance is ionic or molecular based on its composition. As we saw in Section 2.7, most ionic compounds we encounter in this text are composed of a metal and a nonmetal, whereas most molecular compounds are composed only of nonmetals.

**Solve** Two compounds fit the criteria for ionic compounds:  $\text{CaCl}_2$  and  $\text{KOH}$ . Because Table 4.3 tells us that all ionic compounds are strong electrolytes, that is how we classify these two substances. The three remaining compounds are molecular. Two of these molecular substances,  $\text{HNO}_3$  and  $\text{HCOOH}$ , are acids. Nitric acid,  $\text{HNO}_3$ , is a common strong acid, as shown in Table 4.2, and therefore is a strong electrolyte. Because most acids are weak acids, our best guess would be that  $\text{HCOOH}$  is a weak acid (weak electrolyte), which is in fact the case. The remaining molecular compound,  $\text{C}_2\text{H}_5\text{OH}$ , is neither an acid nor a base, so it is a nonelectrolyte.

**Comment** Although ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , has an OH group, it is not a metal hydroxide and therefore not a base. Rather, ethanol is a member of a class of organic compounds that have C—OH bonds, which are known as alcohols. [Section 2.9](#) Organic compounds containing the COOH group are called carboxylic acids (Chapter 16). Molecules that have this group are weak acids.

**Practice Exercise 1**

Which of these substances, when dissolved in water, is a strong electrolyte? (a) ammonia (b) hydrofluoric acid (c) folic acid (d) sodium nitrate (e) sucrose

**Practice Exercise 2**

Consider solutions in which 0.1 mol of each of the following compounds is dissolved in 1 L of water:  $\text{Ca}(\text{NO}_3)_2$  (calcium nitrate),  $\text{C}_6\text{H}_{12}\text{O}_6$  (glucose),  $\text{NaCH}_3\text{COO}$  (sodium acetate), and  $\text{CH}_3\text{COOH}$  (acetic acid). Rank the solutions in order of increasing electrical conductivity, knowing that the greater the number of ions in solution, the greater the conductivity.

▲ **Figure 4.8** Litmus paper. Litmus paper is coated with dyes that change color in response to exposure to either acids or bases.

## Neutralization Reactions and Salts

The properties of acidic solutions are quite different from those of basic solutions. Acids have a sour taste, whereas bases have a bitter taste.\* Acids change the colors of certain dyes in a way that differs from the way bases affect the same dyes. This is the principle behind the indicator known as litmus paper (**Figure 4.8**). Acid-base chemistry is an important theme throughout all of chemistry that we begin to explore here.

When a solution of an acid and a solution of a base are mixed, a **neutralization reaction** occurs. The products of the reaction have none of the characteristic properties of either the acidic solution or the basic solution. For example, when hydrochloric acid is mixed with a solution of sodium hydroxide, the reaction is

Water and table salt, NaCl, are the products of the reaction. By analogy to this reaction, the term **salt** has come to mean any ionic compound whose cation comes from a base (for example,  $\text{Na}^+$  from NaOH) and whose anion comes from an acid (for example,  $\text{Cl}^-$  from HCl). In general, *a neutralization reaction between an acid and a metal hydroxide produces water and a salt.*

Because HCl, NaOH, and NaCl are all water-soluble strong electrolytes, the complete ionic equation associated with Equation 4.11 is

Therefore, the net ionic equation is

Equation 4.13 summarizes the main feature of the neutralization reaction between any strong acid and any strong base:  $\text{H}^+(aq)$  and  $\text{OH}^-(aq)$  ions combine to form  $\text{H}_2\text{O}(l)$ .

**Figure 4.9** shows the neutralization reaction between hydrochloric acid and the water-insoluble base  $\text{Mg}(\text{OH})_2$ :

*Molecular equation:*

*Net ionic equation:*

Notice that the  $\text{OH}^-$  ions (this time in a solid reactant) and  $\text{H}^+$  ions combine to form  $\text{H}_2\text{O}$ . Because the ions exchange partners, neutralization reactions between acids and metal hydroxides are metathesis reactions.

### Sample Exercise 4.7

#### Writing Chemical Equations for a Neutralization Reaction

For the reaction between aqueous solutions of acetic acid ( $\text{CH}_3\text{COOH}$ ) and barium hydroxide,  $\text{Ba}(\text{OH})_2$ , write (a) the balanced molecular equation, (b) the complete ionic equation, (c) the net ionic equation.

#### SOLUTION

**Analyze** We are given the chemical formulas for an acid and a base and asked to write a balanced molecular equation, a complete ionic equation, and a net ionic equation for their neutralization reaction.

#### Solve

(a) The salt contains the cation of the base ( $\text{Ba}^{2+}$ ) and the anion of the acid ( $\text{CH}_3\text{COO}^-$ ). Thus, the salt formula is  $\text{Ba}(\text{CH}_3\text{COO})_2$ . According to Table 4.1, this compound is soluble in water. The unbalanced molecular equation for the neutralization reaction is:

**Plan** As Equation 4.11 and the italicized statement that follows it indicate, neutralization reactions form two products,  $\text{H}_2\text{O}$  and a salt. We examine the cation of the base and the anion of the acid to determine the composition of the salt.

\*Tasting chemical solutions is not a good practice. However, we have all had acids such as ascorbic acid (vitamin C), acetylsalicylic acid (aspirin), and citric acid (in citrus fruits) in our mouths, and we are familiar with their characteristic sour taste. Soaps, which are basic, have the characteristic bitter taste of bases.

To balance this equation, we must provide two molecules of  $\text{CH}_3\text{COOH}$  to furnish the two  $\text{CH}_3\text{COO}^-$  ions and to supply the two  $\text{H}^+$  ions needed to combine with the two  $\text{OH}^-$  ions of the base. The balanced molecular equation is:

- (b) To write the complete ionic equation, we identify the strong electrolytes and break them into ions. In this case  $\text{Ba}(\text{OH})_2$  and  $\text{Ba}(\text{CH}_3\text{COO})_2$  are both water-soluble ionic compounds and hence strong electrolytes. Thus, the complete ionic equation is:

- (c) Eliminating the spectator ion,  $\text{Ba}^{2+}$ , and simplifying coefficients give the net ionic equation:

**Check** We can determine whether the molecular equation is balanced by counting the number of atoms of each kind on both sides of the arrow (10 H, 6 O, 4 C, and 1 Ba on each side). However, it is often easier to check equations by counting groups: There are 2  $\text{CH}_3\text{COO}$  groups, as well as 1 Ba, and 4 additional H atoms and 2 additional O atoms on each side of the equation. The net ionic equation checks out because the numbers of each kind of element and the net charge are the same on both sides of the equation.

### Practice Exercise 1

Which is the correct net ionic equation for the reaction of aqueous ammonia with nitric acid?

- (a)  $\text{NH}_4^+(aq) + \text{H}^+(aq) \longrightarrow \text{NH}_5^{2+}(aq)$
- (b)  $\text{NH}_3(aq) + \text{NO}_3^-(aq) \longrightarrow \text{NH}_2^-(aq) + \text{HNO}_3(aq)$
- (c)  $\text{NH}_2^-(aq) + \text{H}^+(aq) \longrightarrow \text{NH}_3(aq)$
- (d)  $\text{NH}_3(aq) + \text{H}^+(aq) \longrightarrow \text{NH}_4^+(aq)$
- (e)  $\text{NH}_4^+(aq) + \text{NO}_3^-(aq) \longrightarrow \text{NH}_4\text{NO}_3(aq)$

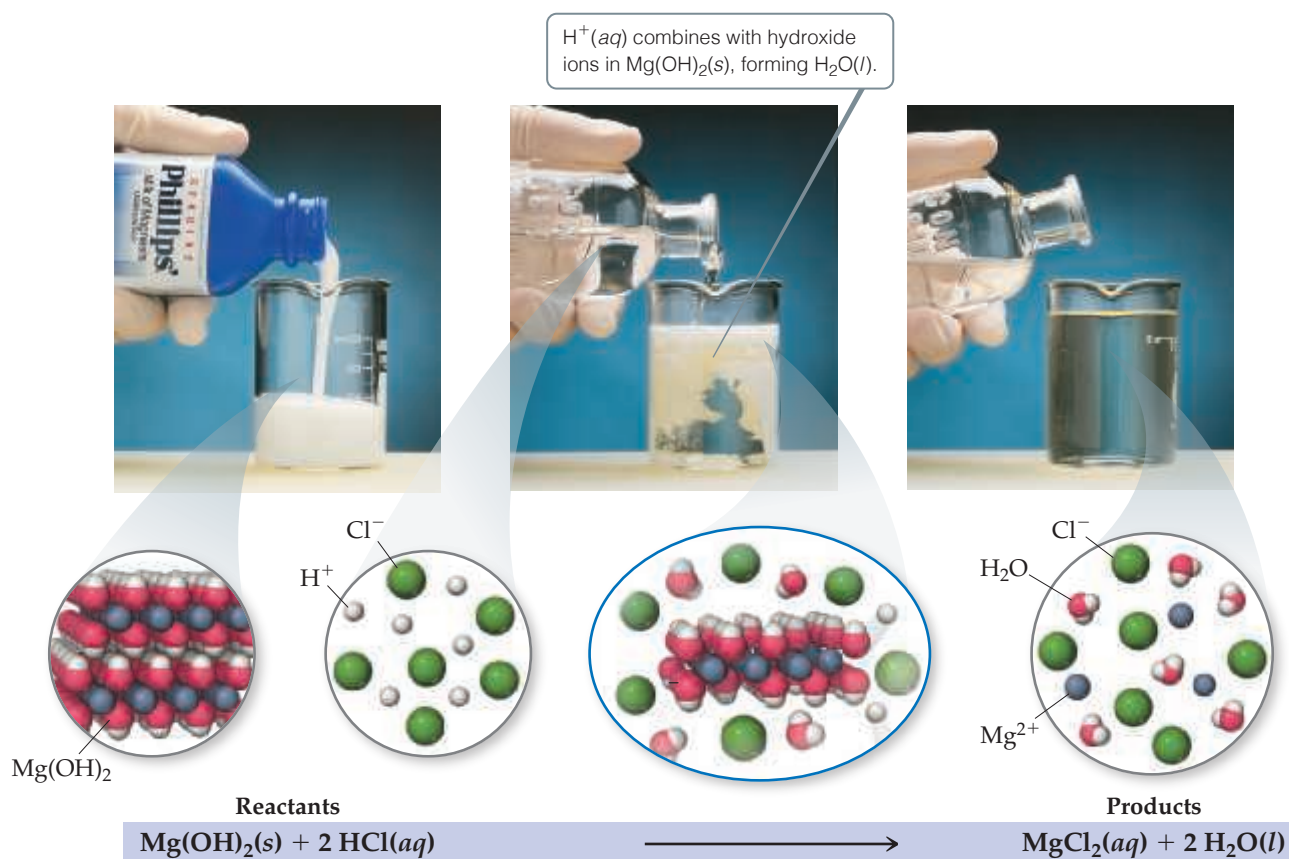

### Practice Exercise 2

For the reaction of phosphorous acid ( $\text{H}_3\text{PO}_3$ ) and potassium hydroxide (KOH), write (a) the balanced molecular equation and (b) the net ionic equation. Note that phosphorous acid is a diprotic acid.

### Go Figure

If you used nitric acid instead of hydrochloric acid in this reaction, what products would form?

▲ **Figure 4.9** Neutralization reaction between  $\text{Mg}(\text{OH})_2(s)$  and hydrochloric acid. Milk of magnesia is a suspension of water-insoluble magnesium hydroxide,  $\text{Mg}(\text{OH})_2(s)$ , in water. When sufficient hydrochloric acid,  $\text{HCl}(aq)$ , is added, a reaction ensues that leads to an aqueous solution containing  $\text{Mg}^{2+}(aq)$  and  $\text{Cl}^-(aq)$  ions.

## Neutralization Reactions with Gas Formation

Many bases besides  $\text{OH}^-$  react with  $\text{H}^+$  to form molecular compounds. Two of these that you might encounter in the laboratory are the sulfide ion and the carbonate ion. Both of these anions react with acids to form gases that have low solubilities in water.

Hydrogen sulfide ( $\text{H}_2\text{S}$ ), the substance that gives rotten eggs their foul odor, forms when an acid such as  $\text{HCl}(\text{aq})$  reacts with a metal sulfide such as  $\text{Na}_2\text{S}$ :

*Molecular equation:*

*Net ionic equation:*

Carbonates and bicarbonates react with acids to form  $\text{CO}_2(\text{g})$ . Reaction of  $\text{CO}_3^{2-}$  or  $\text{HCO}_3^-$  with an acid first gives carbonic acid ( $\text{H}_2\text{CO}_3$ ). For example, when hydrochloric acid is added to sodium bicarbonate, the reaction is

Carbonic acid is unstable. If present in solution in sufficient concentrations, it decomposes to  $\text{H}_2\text{O}$  and  $\text{CO}_2$ , which escapes from the solution as a gas:

The overall reaction is summarized by the following equations:

*Molecular equation:*

*Net ionic equation:*

Both  $\text{NaHCO}_3(\text{s})$  and  $\text{Na}_2\text{CO}_3(\text{s})$  are used as neutralizers in acid spills; either salt is added until the fizzing caused by  $\text{CO}_2(\text{g})$  formation stops. Sometimes sodium bicarbonate is used as an antacid to soothe an upset stomach. In that case the  $\text{HCO}_3^-$  reacts with stomach acid to form  $\text{CO}_2(\text{g})$ .

### Give It Some Thought

By analogy to examples given in the text, predict what gas forms when  $\text{Na}_2\text{SO}_3(\text{s})$  reacts with  $\text{HCl}(\text{aq})$ .

## CHEMISTRY PUT TO WORK Antacids

Your stomach secretes acids to help digest foods. These acids, which include hydrochloric acid, contain about 0.1 mol of  $\text{H}^+$  per liter of solution. The stomach and digestive tract are normally protected from the corrosive effects of stomach acid by a mucosal lining. Holes can develop in this lining, however, allowing the acid to attack the underlying tissue, causing painful damage. These holes, known as ulcers, can be caused by the secretion of excess acids and/or by a weakness in the digestive lining. Many peptic ulcers are caused by infection by the bacterium *Helicobacter pylori*. Between 10 and 20% of Americans suffer from ulcers at some point in their lives. Many others experience

occasional indigestion, heartburn, or reflux due to digestive acids entering the esophagus.

The problem of excess stomach acid can be addressed by (1) removing the excess acid or (2) decreasing the production of acid. Substances that remove excess acid are called *antacids*, whereas those that decrease acid production are called *acid inhibitors*. Figure 4.10 shows several common over-the-counter antacids, which usually contain hydroxide, carbonate, or bicarbonate ions (Table 4.4). Antiulcer drugs, such as Tagamet® and Zantac®, are acid inhibitors. They act on acid-producing cells in the lining of the stomach. Formulations that control acid in this way are now available as over-the-counter drugs.

**Related Exercise: 4.95**

▲ **Figure 4.10 Antacids.** These products all serve as acid-neutralizing agents in the stomach.

**TABLE 4.4 Some Common Antacids**

| Commercial Name  | Acid-Neutralizing Agents                              |
|------------------|---|
| Alka-Seltzer®    | $\text{NaHCO}_3$                                      |
| Amphojel®        | $\text{Al}(\text{OH})_3$                              |
| Di-Gel®          | $\text{Mg}(\text{OH})_2$ and $\text{CaCO}_3$          |

| Rolaid®          | $\text{Mg}(\text{OH})_2$ and $\text{CaCO}_3$          |
| Tums®            | $\text{CaCO}_3$                                       |

## 4.4 | Oxidation-Reduction Reactions

In precipitation reactions, cations and anions come together to form an insoluble ionic compound. In neutralization reactions, protons are transferred from one reactant to another. Now let's consider a third kind of reaction, one in which electrons are transferred from one reactant to another. Such reactions are called either **oxidation-reduction reactions** or **redox reactions**. In this chapter we concentrate on redox reactions where one of the reactants is a metal in its elemental form. Redox reactions are critical in understanding many biological and geological processes in the world around us; they also form the basis for energy-related technologies such as batteries and fuel cells (Chapter 20).

### Oxidation and Reduction

One of the most familiar redox reactions is *corrosion* of a metal (Figure 4.11). In some instances, corrosion is limited to the surface of the metal, as is the case with the green coating that forms on copper roofs and statues. In other instances, the corrosion goes deeper, eventually compromising the structural integrity of the metal, as happens with the rusting of iron.

Corrosion is the conversion of a metal into a metal compound, by a reaction between the metal and some substance in its environment. When a metal corrodes, each metal atom loses one or more electrons to form a cation, which can combine with an anion to form an ionic compound. The green coating on the Statue of Liberty contains  $\text{Cu}^{2+}$  combined with carbonate and hydroxide anions; rust contains  $\text{Fe}^{3+}$  combined with oxide and hydroxide anions; and silver tarnish contains  $\text{Ag}^+$  combined with sulfide anions.

When an atom, ion, or molecule becomes more positively charged (that is, when it loses electrons), we say that it has been *oxidized*. Loss of electrons by a substance is

(a)

(b)

(c)

▲ **Figure 4.11 Familiar corrosion products.** (a) A green coating forms when copper is oxidized. (b) Rust forms when iron corrodes. (c) A black tarnish forms as silver corrodes.

called **oxidation**. The term *oxidation* is used because the first reactions of this sort to be studied were reactions with oxygen. Many metals react directly with  $O_2$  in air to form metal oxides. In these reactions, the metal loses electrons to oxygen, forming an ionic compound of the metal ion and oxide ion. The familiar example of rusting involves the reaction between iron metal and oxygen in the presence of water. In this process, Fe is *oxidized* (loses electrons) to form  $Fe^{3+}$ .

The reaction between iron and oxygen tends to be relatively slow, but other metals, such as the alkali and alkaline earth metals, react quickly upon exposure to air. **Figure 4.12** shows how the bright metallic surface of calcium tarnishes as  $CaO$  forms in the reaction

In this reaction, Ca is oxidized to  $Ca^{2+}$  and neutral  $O_2$  is transformed to  $O^{2-}$  ions. In Equation 4.22, the oxidation involves transfer of electrons from the calcium metal to the  $O_2$ , leading to formation of  $CaO$ . When an atom, ion, or molecule becomes more negatively charged (gains electrons), we say that it is *reduced*. The gain of electrons by a substance is called **reduction**. When one reactant loses electrons (that is, when it is oxidized), another reactant must gain them. In other words, oxidation of one substance must be accompanied by reduction of some other substance. In Equation 4.22, then, molecular oxygen is reduced to oxide ( $O^{2-}$ ) ions.

▲ **Figure 4.12** Oxidation of calcium metal by molecular oxygen.

## Oxidation Numbers

Before we can identify an oxidation-reduction reaction, we must have a bookkeeping system—a way of keeping track of electrons gained by the substance being reduced and electrons lost by the substance being oxidized. The concept of oxidation numbers (also called *oxidation states*) was devised as a way of doing this. Each atom in a neutral substance or ion is assigned an **oxidation number** (also known as an **oxidation state**). For monatomic ions, the oxidation number is the same as the charge. For neutral molecules and polyatomic ions, the oxidation number of a given atom is a hypothetical charge. This charge is assigned by artificially dividing up the electrons among the atoms in the molecule or ion. We use the following rules for assigning oxidation numbers:

1. For an atom in its **elemental form**, the oxidation number is always zero. Thus, each H atom in the  $H_2$  molecule has an oxidation number of 0, and each P atom in the  $P_4$  molecule has an oxidation number of 0.
2. For any **monatomic ion**, the oxidation number equals the ionic charge. Thus,  $K^+$  has an oxidation number of +1,  $S^{2-}$  has an oxidation number of -2, and so forth.

In ionic compounds the alkali metal ions (group 1A) always have a 1+ charge and therefore an oxidation number of +1. The alkaline earth metals (group 2A) are always +2, and aluminum (group 3A) is always +3 in ionic compounds. (In writing oxidation numbers, we will write the sign before the number to distinguish them from the actual electronic charges, which we write with the number first.)

**3. Nonmetals** usually have negative oxidation numbers, although they can sometimes be positive:

- (a) The oxidation number of **oxygen** is usually  $-2$  in both ionic and molecular compounds. The major exception is in compounds called peroxides, which contain the  $\text{O}_2^{2-}$  ion, giving each oxygen an oxidation number of  $-1$ .
- (b) The oxidation number of **hydrogen** is usually  $+1$  when bonded to nonmetals and  $-1$  when bonded to metals (for example, metal hydrides such as sodium hydride,  $\text{NaH}$ ).
- (c) The oxidation number of **fluorine** is  $-1$  in all compounds. The other **halogens** have an oxidation number of  $-1$  in most binary compounds. When combined with oxygen, as in oxyanions, however, they have positive oxidation states.

**4. The sum of the oxidation numbers** of all atoms in a neutral compound is zero. The sum of the oxidation numbers in a polyatomic ion equals the charge of the ion. For example, in the hydronium ion  $\text{H}_3\text{O}^+$ , which is a more accurate description of  $\text{H}^+(\text{aq})$ , the oxidation number of each hydrogen is  $+1$  and that of oxygen is  $-2$ . Thus, the sum of the oxidation numbers is  $3(+1) + (-2) = +1$ , which equals the net charge of the ion. This rule is useful in obtaining the oxidation number of one atom in a compound or ion if you know the oxidation numbers of the other atoms, as illustrated in Sample Exercise 4.8.

### Give It Some Thought

What is the oxidation number of nitrogen (a) in aluminum nitride,  $\text{AlN}$ , and (b) in nitric acid,  $\text{HNO}_3$ ?

### Sample Exercise 4.8

#### Determining Oxidation Numbers

Determine the oxidation number of sulfur in (a)  $\text{H}_2\text{S}$ , (b)  $\text{S}_8$ , (c)  $\text{SCl}_2$ , (d)  $\text{Na}_2\text{SO}_3$ , (e)  $\text{SO}_4^{2-}$ .

#### SOLUTION

**Analyze** We are asked to determine the oxidation number of sulfur in two molecular species, in the elemental form, and in two substances containing ions.

**Plan** In each species, the sum of oxidation numbers of all the atoms must equal the charge on the species. We will use the rules outlined previously to assign oxidation numbers.

#### Solve

- (a) When bonded to a nonmetal, hydrogen has an oxidation number of  $+1$ . Because the  $\text{H}_2\text{S}$  molecule is neutral, the sum of the oxidation numbers must equal zero. Letting  $x$  equal the oxidation number of S, we have  $2(+1) + x = 0$ . Thus, S has an oxidation number of  $-2$ .
- (b) Because  $\text{S}_8$  is an elemental form of sulfur, the oxidation number of S is 0.
- (c) Because  $\text{SCl}_2$  is a binary compound, we expect chlorine to have an oxidation number of  $-1$ . The sum of the oxidation numbers must equal zero. Letting  $x$  equal the oxidation number of S, we have  $x + 2(-1) = 0$ . Consequently, the oxidation number of S must be  $+2$ .
- (d) Sodium, an alkali metal, always has an oxidation number of  $+1$  in its compounds. Oxygen commonly has an oxidation

state of  $-2$ . Letting  $x$  equal the oxidation number of S, we have  $2(+1) + x + 3(-2) = 0$ . Therefore, the oxidation number of S in this compound ( $\text{Na}_2\text{SO}_3$ ) is  $+4$ .

- (e) The oxidation state of O is  $-2$ . The sum of the oxidation numbers equals  $-2$ , the net charge of the  $\text{SO}_4^{2-}$  ion. Thus, we have  $x + 4(-2) = -2$ . From this relation we conclude that the oxidation number of S in this ion is  $+6$ .

**Comment** These examples illustrate that the oxidation number of a given element depends on the compound in which it occurs. The oxidation numbers of sulfur, as seen in these examples, range from  $-2$  to  $+6$ .

#### Practice Exercise 1

In which compound is the oxidation state of oxygen  $-1$ ?  
(a)  $\text{O}_2$  (b)  $\text{H}_2\text{O}$  (c)  $\text{H}_2\text{SO}_4$  (d)  $\text{H}_2\text{O}_2$  (e)  $\text{KCH}_3\text{COO}$

#### Practice Exercise 2

What is the oxidation state of the boldfaced element in  
(a)  $\text{P}_2\text{O}_5$ , (b)  $\text{NaH}$ , (c)  $\text{Cr}_2\text{O}_7^{2-}$ , (d)  $\text{SnBr}_4$ , (e)  $\text{BaO}_2$ ?

## Oxidation of Metals by Acids and Salts

The reaction between a metal and either an acid or a metal salt conforms to the general pattern

Examples:

These reactions are called **displacement reactions** because the ion in solution is *displaced* (replaced) through oxidation of an element.

Many metals undergo displacement reactions with acids, producing salts and hydrogen gas. For example, magnesium metal reacts with hydrochloric acid to form magnesium chloride and hydrogen gas (Figure 4.13):

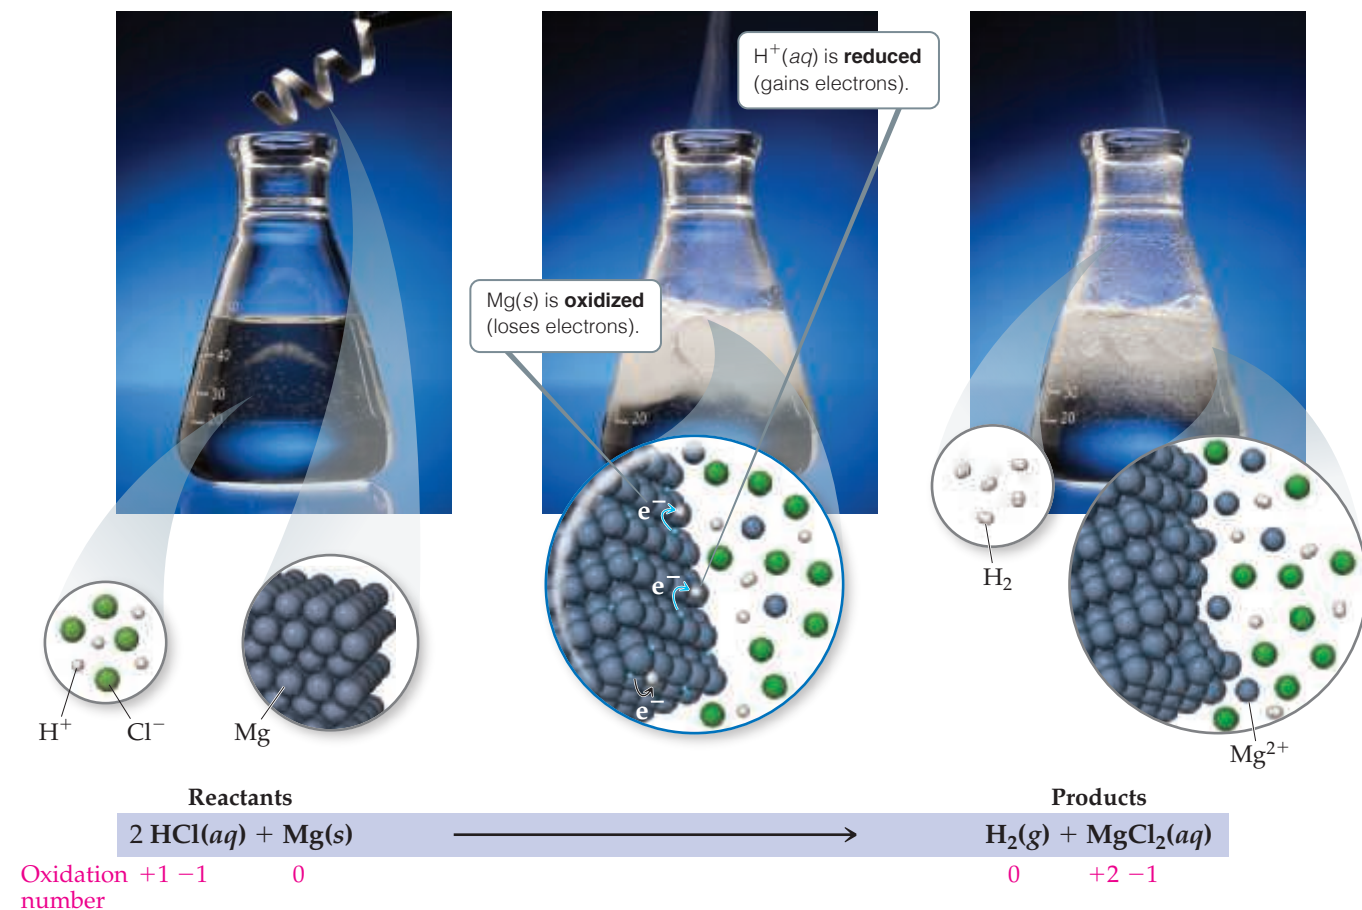

The oxidation number of Mg changes from 0 to +2, an increase that indicates the atom has lost electrons and has therefore been oxidized. The oxidation number of  $\text{H}^+$  in the acid decreases from +1 to 0, indicating that this ion has gained electrons and has therefore

### Go Figure

How many moles of hydrogen gas would be produced for every mole of magnesium added into the HCl solution?

▲ **Figure 4.13** Reaction of magnesium metal with hydrochloric acid. The metal is readily oxidized by the acid, producing hydrogen gas,  $\text{H}_2(g)$ , and  $\text{MgCl}_2(aq)$ .

been reduced. Chlorine has an oxidation number of  $-1$  both before and after the reaction, indicating that it is neither oxidized nor reduced. In fact, the  $\text{Cl}^-$  ions are spectator ions, dropping out of the net ionic equation:

Metals can also be oxidized by aqueous solutions of various salts. Iron metal, for example, is oxidized to  $\text{Fe}^{2+}$  by aqueous solutions of  $\text{Ni}^{2+}$  such as  $\text{Ni}(\text{NO}_3)_2(aq)$ :

The oxidation of  $\text{Fe}$  to  $\text{Fe}^{2+}$  in this reaction is accompanied by the reduction of  $\text{Ni}^{2+}$  to  $\text{Ni}$ . Remember: *Whenever one substance is oxidized, another substance must be reduced.*

## Sample Exercise 4.9

### Writing Equations for Oxidation-Reduction Reactions

Write the balanced molecular and net ionic equations for the reaction of aluminum with hydrobromic acid.

#### SOLUTION

**Analyze** We must write two equations—molecular and net ionic—for the redox reaction between a metal and an acid.

**Plan** Metals react with acids to form salts and  $\text{H}_2$  gas. To write the balanced equations, we must write the chemical formulas for the two reactants and then determine the formula of the salt, which is composed of the cation formed by the metal and the anion of the acid.

**Solve** The reactants are  $\text{Al}$  and  $\text{HBr}$ . The cation formed by  $\text{Al}$  is  $\text{Al}^{3+}$ , and the anion from hydrobromic acid is  $\text{Br}^-$ . Thus, the salt formed in the reaction is  $\text{AlBr}_3$ . Writing the reactants and products and then balancing the equation gives the molecular equation:

Both  $\text{HBr}$  and  $\text{AlBr}_3$  are soluble strong electrolytes. Thus, the complete ionic equation is

Because  $\text{Br}^-$  is a spectator ion, the net ionic equation is

**Comment** The substance oxidized is the aluminum metal because its oxidation state changes from 0 in the metal to  $+3$  in the cation, thereby increasing in oxidation number. The  $\text{H}^+$  is reduced because its oxidation state changes from  $+1$  in the acid to 0 in  $\text{H}_2$ .

#### Practice Exercise 1

Which of the following statements is true about the reaction between zinc and copper sulfate? **(a)** Zinc is oxidized, and copper ion is reduced. **(b)** Zinc is reduced, and copper ion is oxidized. **(c)** All reactants and products are soluble strong electrolytes. **(d)** The oxidation state of copper in copper sulfate is 0. **(e)** More than one of the previous choices are true.

#### Practice Exercise 2

**(a)** Write the balanced molecular and net ionic equations for the reaction between magnesium and cobalt(II) sulfate. **(b)** What is oxidized, and what is reduced in the reaction?

## The Activity Series

Can we predict whether a certain metal will be oxidized either by an acid or by a particular salt? This question is of practical importance as well as chemical interest. According to Equation 4.26, for example, it would be unwise to store a solution of nickel nitrate in an iron container because the solution would dissolve the container. When a metal is oxidized, it forms various compounds. Extensive oxidation can lead to the failure of metal machinery parts or the deterioration of metal structures.

Different metals vary in the ease with which they are oxidized.  $\text{Zn}$  is oxidized by aqueous solutions of  $\text{Cu}^{2+}$ , for example, but  $\text{Ag}$  is not.  $\text{Zn}$ , therefore, loses electrons more readily than  $\text{Ag}$ ; that is,  $\text{Zn}$  is easier to oxidize than  $\text{Ag}$ .

A list of metals arranged in order of decreasing ease of oxidation, such as in Table 4.5, is called an **activity series**. The metals at the top of the table, such as the alkali metals and the alkaline earth metals, are most easily oxidized; that is, they react most readily to form compounds. They are called the *active metals*. The metals at the bottom of the activity series, such as the transition elements from groups 8B and 1B, are very stable and form compounds less readily. These metals, which are used to make coins and jewelry, are called *noble metals* because of their low reactivity.

The activity series can be used to predict the outcome of reactions between metals and either metal salts or acids. *Any metal on the list can be oxidized by the ions of elements below it.*

**TABLE 4.5 Activity Series of Metals in Aqueous Solution**

| Metal     | Oxidation Reaction                                       |
|-----------|--|
| Lithium   | $\text{Li}(s) \longrightarrow \text{Li}^+(aq) + e^-$     |
| Potassium | $\text{K}(s) \longrightarrow \text{K}^+(aq) + e^-$       |
| Barium    | $\text{Ba}(s) \longrightarrow \text{Ba}^{2+}(aq) + 2e^-$ |
| Calcium   | $\text{Ca}(s) \longrightarrow \text{Ca}^{2+}(aq) + 2e^-$ |
| Sodium    | $\text{Na}(s) \longrightarrow \text{Na}^+(aq) + e^-$     |
| Magnesium | $\text{Mg}(s) \longrightarrow \text{Mg}^{2+}(aq) + 2e^-$ |
| Aluminum  | $\text{Al}(s) \longrightarrow \text{Al}^{3+}(aq) + 3e^-$ |
| Manganese | $\text{Mn}(s) \longrightarrow \text{Mn}^{2+}(aq) + 2e^-$ |
| Zinc      | $\text{Zn}(s) \longrightarrow \text{Zn}^{2+}(aq) + 2e^-$ |
| Chromium  | $\text{Cr}(s) \longrightarrow \text{Cr}^{3+}(aq) + 3e^-$ |
| Iron      | $\text{Fe}(s) \longrightarrow \text{Fe}^{2+}(aq) + 2e^-$ |
| Cobalt    | $\text{Co}(s) \longrightarrow \text{Co}^{2+}(aq) + 2e^-$ |
| Nickel    | $\text{Ni}(s) \longrightarrow \text{Ni}^{2+}(aq) + 2e^-$ |
| Tin       | $\text{Sn}(s) \longrightarrow \text{Sn}^{2+}(aq) + 2e^-$ |
| Lead      | $\text{Pb}(s) \longrightarrow \text{Pb}^{2+}(aq) + 2e^-$ |
| Hydrogen  | $\text{H}_2(g) \longrightarrow 2\text{H}^+(aq) + 2e^-$   |
| Copper    | $\text{Cu}(s) \longrightarrow \text{Cu}^{2+}(aq) + 2e^-$ |
| Silver    | $\text{Ag}(s) \longrightarrow \text{Ag}^+(aq) + e^-$     |
| Mercury   | $\text{Hg}(l) \longrightarrow \text{Hg}^{2+}(aq) + 2e^-$ |
| Platinum  | $\text{Pt}(s) \longrightarrow \text{Pt}^{2+}(aq) + 2e^-$ |
| Gold      | $\text{Au}(s) \longrightarrow \text{Au}^{3+}(aq) + 3e^-$ |

For example, copper is above silver in the series. Thus, copper metal is oxidized by silver ions:

The oxidation of copper to copper ions is accompanied by the reduction of silver ions to silver metal. The silver metal is evident on the surface of the copper wire in [Figure 4.14](#). The copper(II) nitrate produces a blue color in the solution, as can be seen most clearly in the photograph on the right of [Figure 4.14](#).

### Give It Some Thought

Does a reaction occur **(a)** when an aqueous solution of  $\text{NiCl}_2(aq)$  is added to a test tube containing strips of metallic zinc, and **(b)** when  $\text{NiCl}_2(aq)$  is added to a test tube containing  $\text{Zn}(\text{NO}_3)_2(aq)$ ?

Only metals above hydrogen in the activity series are able to react with acids to form  $\text{H}_2$ . For example, Ni reacts with  $\text{HCl}(aq)$  to form  $\text{H}_2$ :

Because elements below hydrogen in the activity series are not oxidized by  $\text{H}^+$ , Cu does not react with  $\text{HCl}(aq)$ . Interestingly, copper does react with nitric acid, as shown in [Figure 1.11](#), but the reaction is not oxidation of Cu by  $\text{H}^+$  ions. Instead, the metal is oxidized to  $\text{Cu}^{2+}$  by the nitrate ion, accompanied by the formation of brown nitrogen dioxide,  $\text{NO}_2(g)$ :

As the copper is oxidized in this reaction,  $\text{NO}_3^-$ , where the oxidation number of nitrogen is +5, is reduced to  $\text{NO}_2$ , where the oxidation number of nitrogen is +4. We will examine reactions of this type in Chapter 20.

## Go Figure

Why does this solution turn blue?

**Figure 4.14** Reaction of copper metal with silver ion. When copper metal is placed in a solution of silver nitrate, a redox reaction forms silver metal and a blue solution of copper(II) nitrate.

## Sample Exercise 4.10

## Determining If an Oxidation-Reduction Reaction Will Occur

Will an aqueous solution of iron(II) chloride oxidize magnesium metal? If so, write the balanced molecular and net ionic equations for the reaction.

## SOLUTION

**Analyze** We are given two substances—an aqueous salt,  $\text{FeCl}_2$ , and a metal,  $\text{Mg}$ —and asked if they react with each other.

**Plan** A reaction occurs if the reactant that is a metal in its elemental form ( $\text{Mg}$ ) is located above the reactant that is a metal in its oxidized form ( $\text{Fe}^{2+}$ ) in Table 4.5. If the reaction occurs, the  $\text{Fe}^{2+}$  ion in  $\text{FeCl}_2$  is reduced to  $\text{Fe}$ , and the  $\text{Mg}$  is oxidized to  $\text{Mg}^{2+}$ .

**Solve** Because  $\text{Mg}$  is above  $\text{Fe}$  in the table, the reaction occurs. To write the formula for the salt produced in the reaction, we must remember the charges on common ions. Magnesium is always present in compounds as  $\text{Mg}^{2+}$ ; the chloride ion is  $\text{Cl}^-$ . The magnesium salt formed in the reaction is  $\text{MgCl}_2$ , meaning the balanced molecular equation is

Both  $\text{FeCl}_2$  and  $\text{MgCl}_2$  are soluble strong electrolytes and can be written in ionic form, which shows us that  $\text{Cl}^-$  is a spectator ion in the reaction. The net ionic equation is

The net ionic equation shows that  $\text{Mg}$  is oxidized and  $\text{Fe}^{2+}$  is reduced in this reaction.

**Check** Note that the net ionic equation is balanced with respect to both charge and mass.

## Practice Exercise 1

Which of these metals is the easiest to oxidize?  
(a) gold (b) lithium (c) iron (d) sodium (e) aluminum

## Practice Exercise 2

Which of the following metals will be oxidized by  $\text{Pb}(\text{NO}_3)_2$ :  $\text{Zn}$ ,  $\text{Cu}$ ,  $\text{Fe}$ ?

## STRATEGIES FOR SUCCESS Analyzing Chemical Reactions

In this chapter, you have been introduced to a great number of chemical reactions. It's not easy to get a "feel" for what happens when chemicals react. One goal of this textbook is to help you become more adept at predicting the outcomes of reactions. The key to gaining this "chemical intuition" is to learn how to categorize reactions.

Attempting to memorize individual reactions would be a futile task. It is far more fruitful to recognize patterns to determine the general category of a reaction, such as metathesis or oxidation-reduction. When faced with the challenge of predicting the outcome of a chemical reaction, ask yourself the following questions:

- What are the reactants?
- Are they electrolytes or nonelectrolytes?
- Are they acids or bases?
- If the reactants are electrolytes, will metathesis produce a precipitate? Water? A gas?

- If metathesis cannot occur, can the reactants engage in an oxidation-reduction reaction? This requires that there be both a reactant that can be oxidized and a reactant that can be reduced.

Being able to predict what happens during a reaction follows from asking basic questions like the ones above. Each question narrows the set of possible outcomes, steering you ever closer to a likely outcome. Your prediction might not always be entirely correct, but if you keep your wits about you, you will not be far off. As you gain experience, you will begin to look for reactants that might not be immediately obvious, such as water from the solution or oxygen from the atmosphere. Because proton transfer (acid-base) and electron transfer (oxidation-reduction) are involved in a huge number of chemical reactions, knowing the hallmarks of such reactions will mean you are well on your way to becoming an excellent chemist!

## 4.5 | Concentrations of Solutions

Scientists use the term **concentration** to designate the amount of solute dissolved in a given quantity of solvent or quantity of solution. The greater the amount of solute dissolved in a certain amount of solvent, the more concentrated the resulting solution. In chemistry we often need to express the concentrations of solutions quantitatively.

### Molarity

**Molarity** (symbol  $M$ ) expresses the concentration of a solution as the number of moles of solute in a liter of solution (soln):

$$\text{Molarity} = \frac{\text{moles solute}}{\text{volume of solution in liters}} \quad [4.31]$$

A 1.00 molar solution (written 1.00  $M$ ) contains 1.00 mol of solute in every liter of solution. **Figure 4.15** shows the preparation of 0.250 L of a 1.00  $M$  solution of  $\text{CuSO}_4$ . The molarity of the solution is  $(0.250 \text{ mol CuSO}_4) / (0.250 \text{ L soln}) = 1.00 M$ . Note that we use the abbreviation "soln" for "solution."

▲ **Figure 4.15** Preparing 0.250 L of a 1.00  $M$  solution of  $\text{CuSO}_4$ .

### Sample Exercise 4.11

#### Calculating Molarity

Calculate the molarity of a solution made by dissolving 23.4 g of sodium sulfate ( $\text{Na}_2\text{SO}_4$ ) in enough water to form 125 mL of solution.

#### SOLUTION

**Analyze** We are given the number of grams of solute (23.4 g), its chemical formula ( $\text{Na}_2\text{SO}_4$ ), and the volume of the solution (125 mL) and asked to calculate the molarity of the solution.

**Plan** We can calculate molarity using Equation 4.31. To do so, we must convert the number of grams of solute to moles and the volume of the solution from milliliters to liters.

#### Solve

The number of moles of  $\text{Na}_2\text{SO}_4$  is obtained by using its molar mass:

$$\text{Moles Na}_2\text{SO}_4 = (23.4 \text{ g Na}_2\text{SO}_4) \left( \frac{1 \text{ mol Na}_2\text{SO}_4}{142.1 \text{ g Na}_2\text{SO}_4} \right) = 0.165 \text{ mol Na}_2\text{SO}_4$$

$$\text{Converting the volume of the solution to liters: } \text{Liters soln} = (125 \text{ mL}) \left( \frac{1 \text{ L}}{1000 \text{ mL}} \right) = 0.125 \text{ L}$$

$$\text{Thus, the molarity is: } \text{Molarity} = \frac{0.165 \text{ mol Na}_2\text{SO}_4}{0.125 \text{ L soln}} = 1.32 \frac{\text{mol Na}_2\text{SO}_4}{\text{L soln}} = 1.32 \text{ M}$$

**Check** Because the numerator is only slightly larger than the denominator, it is reasonable for the answer to be a little over 1 M. The units (mol/L) are appropriate for molarity, and three significant figures are appropriate for the answer because each of the initial pieces of data had three significant figures.

#### Practice Exercise 1

What is the molarity of a solution that is made by dissolving 3.68 g of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) in sufficient water to form

275.0 mL of solution? (a) 13.4 M (b)  $7.43 \times 10^{-2} \text{ M}$  (c)  $3.91 \times 10^{-2} \text{ M}$  (d)  $7.43 \times 10^{-5} \text{ M}$  (e)  $3.91 \times 10^{-5} \text{ M}$

#### Practice Exercise 2

Calculate the molarity of a solution made by dissolving 5.00 g of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in sufficient water to form exactly 100 mL of solution.

## Expressing the Concentration of an Electrolyte

In biology, the total concentration of ions in solution is very important in metabolic and cellular processes. When an ionic compound dissolves, the relative concentrations of the ions in the solution depend on the chemical formula of the compound. For example, a 1.0 M solution of NaCl is 1.0 M in  $\text{Na}^+$  ions and 1.0 M in  $\text{Cl}^-$  ions, and a 1.0 M solution of  $\text{Na}_2\text{SO}_4$  is 2.0 M in  $\text{Na}^+$  ions and 1.0 M in  $\text{SO}_4^{2-}$  ions. Thus, the concentration of an electrolyte solution can be specified either in terms of the compound used to make the solution (1.0 M  $\text{Na}_2\text{SO}_4$ ) or in terms of the ions in the solution (2.0 M  $\text{Na}^+$  and 1.0 M  $\text{SO}_4^{2-}$ ).

### Sample Exercise 4.12

#### Calculating Molar Concentrations of Ions

What is the molar concentration of each ion present in a 0.025 M aqueous solution of calcium nitrate?

#### SOLUTION

**Analyze** We are given the concentration of the ionic compound used to make the solution and asked to determine the concentrations of the ions in the solution.

**Plan** We can use the subscripts in the chemical formula of the compound to determine the relative ion concentrations.

**Solve** Calcium nitrate is composed of calcium ions ( $\text{Ca}^{2+}$ ) and nitrate ions ( $\text{NO}_3^-$ ), so its chemical formula is  $\text{Ca}(\text{NO}_3)_2$ . Because there are two  $\text{NO}_3^-$  ions for each  $\text{Ca}^{2+}$  ion, each mole of  $\text{Ca}(\text{NO}_3)_2$  that dissolves dissociates into 1 mol of  $\text{Ca}^{2+}$  and 2 mol of  $\text{NO}_3^-$ . Thus, a solution that is 0.025 M in  $\text{Ca}(\text{NO}_3)_2$  is 0.025 M in  $\text{Ca}^{2+}$  and  $2 \times 0.025 \text{ M} = 0.050 \text{ M}$  in  $\text{NO}_3^-$ :

$$\begin{aligned} \frac{\text{mol NO}_3^-}{\text{L}} &= \left( \frac{0.025 \text{ mol Ca}(\text{NO}_3)_2}{\text{L}} \right) \left( \frac{2 \text{ mol NO}_3^-}{1 \text{ mol Ca}(\text{NO}_3)_2} \right) \\ &= 0.050 \text{ M} \end{aligned}$$

**Check** The concentration of  $\text{NO}_3^-$  ions is twice that of  $\text{Ca}^{2+}$  ions, as the subscript 2 after the  $\text{NO}_3^-$  in the chemical formula  $\text{Ca}(\text{NO}_3)_2$  suggests.

#### Practice Exercise 1

What is the ratio of the concentration of potassium ions to the concentration of carbonate ions in a 0.015 M solution of potassium carbonate? (a) 1:0.015 (b) 0.015:1 (c) 1:1 (d) 1:2 (e) 2:1

#### Practice Exercise 2

What is the molar concentration of  $\text{K}^+$  ions in a 0.015 M solution of potassium carbonate?

## Interconverting Molarity, Moles, and Volume

If we know any two of the three quantities in the definition of molarity (Equation 4.31), we can calculate the third. For example, if we know the molarity of an  $\text{HNO}_3$  solution to be  $0.200\text{ M}$ , which means  $0.200\text{ mol}$  of  $\text{HNO}_3$  per liter of solution, we can calculate the number of moles of solute in a given volume, say  $2.0\text{ L}$ . Molarity therefore is a conversion factor between volume of solution and moles of solute:

$$\text{Moles HNO}_3 = (2.0\text{ L soln})\left(\frac{0.200\text{ mol HNO}_3}{1\text{ L soln}}\right) = 0.40\text{ mol HNO}_3$$

To illustrate the conversion of moles to volume, let's calculate the volume of  $0.30\text{ M HNO}_3$  solution required to supply  $2.0\text{ mol}$  of  $\text{HNO}_3$ :

$$\text{Liters soln} = (2.0\text{ mol HNO}_3)\left(\frac{1\text{ L soln}}{0.30\text{ mol HNO}_3}\right) = 6.7\text{ L soln}$$

Note that in this case we used the reciprocal of molarity in the conversion:

$$\text{Liters} = \text{mol} \times 1/\text{M} = \text{mol} \times \text{liters/mol}$$

If one of the solutes is a liquid, we can use its density to convert its mass to volume and vice versa. For example, a typical American beer contains  $5.0\%$  ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) by volume in water (along with other components). The density of ethanol is  $0.789\text{ g/mL}$ . Therefore, if we wanted to calculate the molarity of ethanol (usually just called “alcohol” in everyday language) in beer, we would first consider  $1.00\text{ L}$  of beer.

This  $1.00\text{ L}$  of beer contains  $0.950\text{ L}$  of water and  $0.050\text{ L}$  of ethanol:

$$5\% = 5/100 = 0.050$$

Then we can calculate the moles of ethanol by proper cancellation of units, taking into account the density of ethanol and its molar mass ( $46.0\text{ g/mol}$ ):

$$\text{Moles ethanol} = (0.050\text{ L})\left(\frac{1000\text{ mL}}{\text{L}}\right)\left(\frac{0.789\text{ g}}{\text{mL}}\right)\left(\frac{1\text{ mol}}{46.0\text{ g}}\right) = 0.858\text{ mol}$$

Because there are  $0.858\text{ moles}$  of ethanol in  $1.00\text{ L}$  of beer, the concentration of ethanol in beer is  $0.86\text{ M}$  (taking into account significant figures).

### Sample Exercise 4.13

#### Using Molarity to Calculate Grams of Solute

How many grams of  $\text{Na}_2\text{SO}_4$  are required to make  $0.350\text{ L}$  of  $0.500\text{ M Na}_2\text{SO}_4$ ?

#### SOLUTION

**Analyze** We are given the volume of the solution ( $0.350\text{ L}$ ), its concentration ( $0.500\text{ M}$ ), and the identity of the solute  $\text{Na}_2\text{SO}_4$  and asked to calculate the number of grams of the solute in the solution.

**Plan** We can use the definition of molarity (Equation 4.31) to determine the number of moles of solute, and then convert moles to grams using the molar mass of the solute.

$$M_{\text{Na}_2\text{SO}_4} = \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}}$$

**Solve** Calculating the moles of  $\text{Na}_2\text{SO}_4$  using the molarity and volume of solution gives

$$\begin{aligned} M_{\text{Na}_2\text{SO}_4} &= \frac{\text{moles Na}_2\text{SO}_4}{\text{liters soln}} \\ \text{Moles Na}_2\text{SO}_4 &= \text{liters soln} \times M_{\text{Na}_2\text{SO}_4} \\ &= (0.350\text{ L soln})\left(\frac{0.500\text{ mol Na}_2\text{SO}_4}{1\text{ L soln}}\right) \\ &= 0.175\text{ mol Na}_2\text{SO}_4 \end{aligned}$$

Because each mole of  $\text{Na}_2\text{SO}_4$  has a mass of  $142.1\text{ g}$ , the required number of grams of  $\text{Na}_2\text{SO}_4$  is

$$\begin{aligned} \text{Grams Na}_2\text{SO}_4 &= (0.175\text{ mol Na}_2\text{SO}_4)\left(\frac{142.1\text{ g Na}_2\text{SO}_4}{1\text{ mol Na}_2\text{SO}_4}\right) \\ &= 24.9\text{ g Na}_2\text{SO}_4 \end{aligned}$$

**Check** The magnitude of the answer, the units, and the number of significant figures are all appropriate.

#### Practice Exercise 1

What is the concentration of ammonia in a solution made by dissolving  $3.75\text{ g}$  of ammonia in  $120.0\text{ L}$  of water?

(a)  $1.84 \times 10^{-3}\text{ M}$  (b)  $3.78 \times 10^{-2}\text{ M}$  (c)  $0.0313\text{ M}$  (d)  $1.84\text{ M}$  (e)  $7.05\text{ M}$

#### Practice Exercise 2

(a) How many grams of  $\text{Na}_2\text{SO}_4$  are there in  $15\text{ mL}$  of  $0.50\text{ M Na}_2\text{SO}_4$ ? (b) How many milliliters of  $0.50\text{ M Na}_2\text{SO}_4$  solution are needed to provide  $0.038\text{ mol}$  of this salt?

## Dilution

Solutions used routinely in the laboratory are often purchased or prepared in concentrated form (called *stock solutions*). Aqueous solutions of lower concentrations can then be obtained by adding water, a process called **dilution**.\*

Let's see how we can prepare a dilute solution from a concentrated one. Suppose we want to prepare 250.0 mL (that is, 0.2500 L) of 0.100 M  $\text{CuSO}_4$  solution by diluting a 1.00 M  $\text{CuSO}_4$  stock solution. The main point to remember is that when solvent is added to a solution, the number of moles of solute remains unchanged:

$$\text{Moles solute before dilution} = \text{moles solute after dilution} \quad [4.32]$$

Because we know both the volume (250.0 mL) and the concentration (0.100 mol/L) of the dilute solution, we can calculate the number of moles of  $\text{CuSO}_4$  it contains:

$$\begin{aligned} \text{Moles CuSO}_4 \text{ in dilute soln} &= (0.2500 \text{ L soln}) \left( \frac{0.100 \text{ mol CuSO}_4}{\text{L soln}} \right) \\ &= 0.0250 \text{ mol CuSO}_4 \end{aligned}$$

The volume of stock solution needed to provide 0.0250 mol  $\text{CuSO}_4$  is therefore:

$$\text{Liters of conc soln} = (0.0250 \text{ mol CuSO}_4) \left( \frac{1 \text{ L soln}}{1.00 \text{ mol CuSO}_4} \right) = 0.0250 \text{ L}$$

**Figure 4.16** shows the dilution carried out in the laboratory. Notice that the diluted solution is less intensely colored than the concentrated one.

### Give It Some Thought

How is the molarity of a 0.50 M KBr solution changed when water is added to double its volume?

▲ **Figure 4.16** Preparing 250.0 mL of 0.100 M  $\text{CuSO}_4$  by dilution of 1.00 M  $\text{CuSO}_4$ .

\*In diluting a concentrated acid or base, the acid or base should be added to water and then further diluted by adding more water. Adding water directly to concentrated acid or base can cause spattering because of the intense heat generated.

In laboratory situations, calculations of this sort are often made with an equation derived by remembering that the number of moles of solute is the same in both the concentrated and dilute solutions and that  $\text{moles} = \text{molarity} \times \text{liters}$ :

$$\text{Moles solute in conc soln} = \text{moles solute in dilute soln}$$

$$M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}} \quad [4.33]$$

Although we derived Equation 4.33 in terms of liters, any volume unit can be used as long as it is used on both sides of the equation. For example, in the calculation we did for the  $\text{CuSO}_4$  solution, we have

$$(1.00 \text{ M})(V_{\text{conc}}) = (0.100 \text{ M})(250.0 \text{ mL})$$

Solving for  $V_{\text{conc}}$  gives  $V_{\text{conc}} = 25.0 \text{ mL}$  as before.

### Sample Exercise 4.14

#### Preparing a Solution by Dilution

How many milliliters of  $3.0 \text{ M H}_2\text{SO}_4$  are needed to make  $450 \text{ mL}$  of  $0.10 \text{ M H}_2\text{SO}_4$ ?

#### SOLUTION

**Analyze** We need to dilute a concentrated solution. We are given the molarity of a more concentrated solution ( $3.0 \text{ M}$ ) and the volume and molarity of a more dilute one containing the same solute ( $450 \text{ mL}$  of  $0.10 \text{ M}$  solution). We must calculate the volume of the concentrated solution needed to prepare the dilute solution.

**Plan** We can calculate the number of moles of solute,  $\text{H}_2\text{SO}_4$ , in the dilute solution and then calculate the volume of the concentrated solution needed to supply this amount of solute. Alternatively, we can directly apply Equation 4.33. Let's compare the two methods.

#### Solve

Calculate the moles of  $\text{H}_2\text{SO}_4$  in the dilute solution:

$$\begin{aligned} \text{Moles H}_2\text{SO}_4 \text{ in dilute solution} &= (0.450 \text{ L soln}) \left( \frac{0.10 \text{ mol H}_2\text{SO}_4}{1 \text{ L soln}} \right) \\ &= 0.045 \text{ mol H}_2\text{SO}_4 \end{aligned}$$

Calculate the volume of the concentrated solution that contains  $0.045 \text{ mol H}_2\text{SO}_4$ :  
Converting liters to milliliters gives  $15 \text{ mL}$ .

$$\text{Liters conc soln} = (0.045 \text{ mol H}_2\text{SO}_4) \left( \frac{1 \text{ L soln}}{3.0 \text{ mol H}_2\text{SO}_4} \right) = 0.015 \text{ L soln}$$

If we apply Equation 4.33, we get the same result:

$$\begin{aligned} (3.0 \text{ M})(V_{\text{conc}}) &= (0.10 \text{ M})(450 \text{ mL}) \\ (V_{\text{conc}}) &= \frac{(0.10 \text{ M})(450 \text{ mL})}{3.0 \text{ M}} = 15 \text{ mL} \end{aligned}$$

Either way, we see that if we start with  $15 \text{ mL}$  of  $3.0 \text{ M H}_2\text{SO}_4$  and dilute it to a total volume of  $450 \text{ mL}$ , the desired  $0.10 \text{ M}$  solution will be obtained.

**Check** The calculated volume seems reasonable because a small volume of concentrated solution is used to prepare a large volume of dilute solution.

**Comment** The first approach can also be used to find the final concentration when two solutions of different concentrations are mixed, whereas the second approach, using Equation 4.33, can be used only for diluting a concentrated solution with pure solvent.

#### Practice Exercise 1

What volume of a  $1.00 \text{ M}$  stock solution of glucose must be used to make  $500.0 \text{ mL}$  of a  $1.75 \times 10^{-2} \text{ M}$  glucose solution in water?

(a)  $1.75 \text{ mL}$  (b)  $8.75 \text{ mL}$  (c)  $48.6 \text{ mL}$  (d)  $57.1 \text{ mL}$  (e)  $28,570 \text{ mL}$

#### Practice Exercise 2

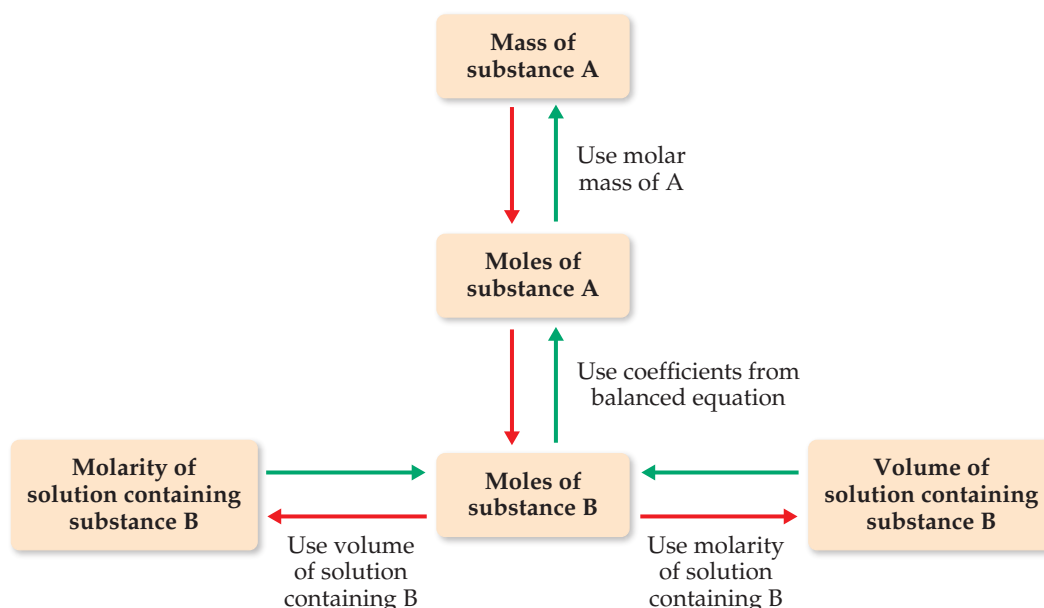

(a) What volume of  $2.50 \text{ M}$  lead(II) nitrate solution contains  $0.0500 \text{ mol}$  of  $\text{Pb}^{2+}$ ? (b) How many milliliters of  $5.0 \text{ M K}_2\text{Cr}_2\text{O}_7$  solution must be diluted to prepare  $250 \text{ mL}$  of  $0.10 \text{ M}$  solution? (c) If  $10.0 \text{ mL}$  of a  $10.0 \text{ M}$  stock solution of  $\text{NaOH}$  is diluted to  $250 \text{ mL}$ , what is the concentration of the resulting stock solution?

## 4.6 | Solution Stoichiometry and Chemical Analysis

In Chapter 3 we learned that given the chemical equation for a reaction and the amount of one reactant consumed in the reaction, you can calculate the quantities of other reactants and products. In this section we extend this concept to reactions involving solutions.

Recall that the coefficients in a balanced equation give the relative number of moles of reactants and products. (Section 3.6) To use this information, we must convert the

▲ **Figure 4.17** Procedure for solving stoichiometry problems involving reactions between a pure substance A and a solution containing a known concentration of substance B. Starting from a known mass of substance A, we follow the red arrows to determine either the volume of the solution containing B (if the molarity of B is known) or the molarity of the solution containing B (if the volume of B is known). Starting from either a known volume or a known molarity of the solution containing B, we follow the green arrows to determine the mass of substance A.

masses of substances involved in a reaction into moles. When dealing with pure substances, as we did in Chapter 3, we use molar mass to convert between grams and moles of the substances. This conversion is not valid when working with a solution because both solute and solvent contribute to its mass. However, if we know the solute concentration, we can use molarity and volume to determine the number of moles (moles solute =  $M \times V$ ). **Figure 4.17** summarizes this approach to using stoichiometry for the reaction between a pure substance and a solution.

### Sample Exercise 4.15

#### Using Mass Relations in a Neutralization Reaction

How many grams of  $\text{Ca}(\text{OH})_2$  are needed to neutralize 25.0 mL of 0.100 M  $\text{HNO}_3$ ?

#### SOLUTION

**Analyze** The reactants are an acid,  $\text{HNO}_3$ , and a base,  $\text{Ca}(\text{OH})_2$ . The volume and molarity of  $\text{HNO}_3$  are given, and we are asked how many grams of  $\text{Ca}(\text{OH})_2$  are needed to neutralize this quantity of  $\text{HNO}_3$ .

**Plan** Following the steps outlined by the green arrows in Figure 4.17, we use the molarity and volume of the  $\text{HNO}_3$  solution (substance B in Figure 4.17) to calculate the number of moles of  $\text{HNO}_3$ . We then use the balanced equation to relate moles of  $\text{HNO}_3$  to moles of  $\text{Ca}(\text{OH})_2$  (substance A). Finally, we use the molar mass to convert moles to grams of  $\text{Ca}(\text{OH})_2$ :

#### Solve

The product of the molar concentration of a solution and its volume in liters gives the number of moles of solute:

$$\begin{aligned} \text{Moles HNO}_3 &= V_{\text{HNO}_3} \times M_{\text{HNO}_3} = (0.0250 \text{ L}) \left( \frac{0.100 \text{ mol HNO}_3}{\text{L}} \right) \\ &= 2.50 \times 10^{-3} \text{ mol HNO}_3 \end{aligned}$$

Because this is a neutralization reaction,  $\text{HNO}_3$  and  $\text{Ca}(\text{OH})_2$  react to form  $\text{H}_2\text{O}$  and the salt containing  $\text{Ca}^{2+}$  and  $\text{NO}_3^-$ :

Continued

Thus,  $2 \text{ mol HNO}_3 \approx 1 \text{ mol Ca(OH)}_2$ . Therefore,  $\text{Grams Ca(OH)}_2 = (2.50 \times 10^{-3} \text{ mol HNO}_3) \times \left( \frac{1 \text{ mol Ca(OH)}_2}{2 \text{ mol HNO}_3} \right) \left( \frac{74.1 \text{ g Ca(OH)}_2}{1 \text{ mol Ca(OH)}_2} \right)$   
 $= 0.0926 \text{ g Ca(OH)}_2$

**Check** The answer is reasonable because a small volume of dilute acid requires only a small amount of base to neutralize it.

### Practice Exercise 1

How many milligrams of sodium sulfide are needed to completely react with 25.00 mL of a 0.0100 M aqueous solution of

cadmium nitrate, to form a precipitate of  $\text{CdS(s)}$ ?

(a) 13.8 mg (b) 19.5 mg (c) 23.5 mg (d) 32.1 mg (e) 39.0 mg

### Practice Exercise 2

(a) How many grams of NaOH are needed to neutralize 20.0 mL of 0.150 M  $\text{H}_2\text{SO}_4$  solution? (b) How many liters of 0.500 M  $\text{HCl(aq)}$  are needed to react completely with 0.100 mol of  $\text{Pb(NO}_3)_2\text{(aq)}$ , forming a precipitate of  $\text{PbCl}_2\text{(s)}$ ?

## Titration

To determine the concentration of a particular solute in a solution, chemists often carry out a **titration**, which involves combining a solution where the solute concentration is not known with a reagent solution of known concentration, called a **standard solution**. Just enough standard solution is added to completely react with the solute in the solution of unknown concentration. The point at which stoichiometrically equivalent quantities are brought together is known as the **equivalence point**.

Titration can be conducted using neutralization, precipitation, or oxidation-reduction reactions. Figure 4.18 illustrates a typical neutralization titration, one between an HCl solution of unknown concentration and a standard NaOH solution. To determine the HCl concentration, we first add a specific volume of the HCl solution, 20.0 mL in this example, to a flask. Next we add a few drops of an acid-base **indicator**. The acid-base indicator is a dye that changes color on passing the equivalence point.\* For example, the dye phenolphthalein is colorless in acidic solution but pink in basic solution. The standard solution is

\*More precisely, the color change of an indicator signals the end point of the titration, which if the proper indicator is chosen lies very near the equivalence point. Acid-base titrations are discussed in more detail in Section 17.3.

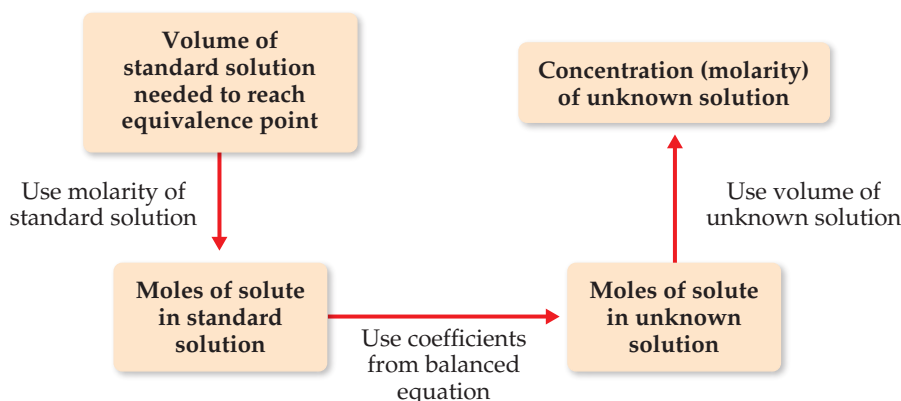

### Go Figure

How would the volume of standard solution added change if that solution were  $\text{Ba(OH)}_2\text{(aq)}$  instead of  $\text{NaOH(aq)}$ ?

**Figure 4.18** Procedure for titrating an acid against a standard solution of NaOH. The acid-base indicator, phenolphthalein, is colorless in acidic solution but takes on a pink color in basic solution.

◀ **Figure 4.19** Procedure for determining the concentration of a solution from titration with a standard solution.

then slowly added until the solution turns pink, telling us that the neutralization reaction between HCl and NaOH is complete. The standard solution is added from a *burette* so that we can accurately determine the added volume of NaOH solution. Knowing the volumes of both solutions and the concentration of the standard solution, we can calculate the concentration of the unknown solution as diagrammed in [Figure 4.19](#).

## Sample Exercise 4.16

### Determining Solution Concentration by an Acid–Base Titration

One commercial method used to peel potatoes is to soak them in a NaOH solution for a short time and then remove the potatoes and spray off the peel. The NaOH concentration is normally 3 to 6 *M*, and the solution must be analyzed periodically. In one such analysis, 45.7 mL of 0.500 *M* H<sub>2</sub>SO<sub>4</sub> is required to neutralize 20.0 mL of NaOH solution. What is the concentration of the NaOH solution?

### SOLUTION

**Analyze** We are given the volume (45.7 mL) and molarity (0.500 *M*) of an H<sub>2</sub>SO<sub>4</sub> solution (the standard solution) that reacts completely with 20.0 mL of NaOH solution. We are asked to calculate the molarity of the NaOH solution.

**Plan** Following the steps given in Figure 4.19, we use the H<sub>2</sub>SO<sub>4</sub> volume and molarity to calculate the number of moles of H<sub>2</sub>SO<sub>4</sub>. Then we can use this quantity and the balanced equation for the reaction to calculate moles of NaOH. Finally, we can use moles of NaOH and the NaOH volume to calculate NaOH molarity.

### Solve

The number of moles of H<sub>2</sub>SO<sub>4</sub> is the product of the volume and molarity of this solution:

$$\begin{aligned}\text{Moles H}_2\text{SO}_4 &= (45.7 \text{ mL soln}) \left( \frac{1 \text{ L soln}}{1000 \text{ mL soln}} \right) \left( \frac{0.500 \text{ mol H}_2\text{SO}_4}{1 \text{ L soln}} \right) \\ &= 2.28 \times 10^{-2} \text{ mol H}_2\text{SO}_4\end{aligned}$$

Acids react with metal hydroxides to form water and a salt. Thus, the balanced equation for the neutralization reaction is:

According to the balanced equation, 1 mol H<sub>2</sub>SO<sub>4</sub>  $\approx$  2 mol NaOH. Therefore,

$$\begin{aligned}\text{Moles NaOH} &= (2.28 \times 10^{-2} \text{ mol H}_2\text{SO}_4) \left( \frac{2 \text{ mol NaOH}}{1 \text{ mol H}_2\text{SO}_4} \right) \\ &= 4.56 \times 10^{-2} \text{ mol NaOH}\end{aligned}$$

Knowing the number of moles of NaOH in 20.0 mL of solution allows us to calculate the molarity of this solution:

$$\begin{aligned}\text{Molarity NaOH} &= \frac{\text{mol NaOH}}{\text{L soln}} \\ &= \left( \frac{4.56 \times 10^{-2} \text{ mol NaOH}}{20.0 \text{ mL soln}} \right) \left( \frac{1000 \text{ mL soln}}{1 \text{ L soln}} \right) \\ &= 2.28 \frac{\text{mol NaOH}}{\text{L soln}} = 2.28 \text{ M}\end{aligned}$$

### Practice Exercise 1

What is the molarity of an HCl solution if 27.3 mL of it neutralizes 134.5 mL of 0.0165 *M* Ba(OH)<sub>2</sub>?  
(a) 0.0444 *M* (b) 0.0813 *M* (c) 0.163 *M* (d) 0.325 *M* (e) 3.35 *M*

### Practice Exercise 2

What is the molarity of a NaOH solution if 48.0 mL neutralizes 35.0 mL of 0.144 *M* H<sub>2</sub>SO<sub>4</sub>?

## Sample Exercise 4.17

## Determining the Quantity of Solute by Titration

The quantity of  $\text{Cl}^-$  in a municipal water supply is determined by titrating the sample with  $\text{Ag}^+$ . The precipitation reaction taking place during the titration is

(a) How many grams of chloride ion are in a sample of the water if 20.2 mL of 0.100 M  $\text{Ag}^+$  is needed to react with all the chloride in the sample? (b) If the sample has a mass of 10.0 g, what percentage of  $\text{Cl}^-$  does it contain?

## SOLUTION

**Analyze** We are given the volume (20.2 mL) and molarity (0.100 M) of a solution of  $\text{Ag}^+$  and the chemical equation for reaction of this ion with  $\text{Cl}^-$ . We are asked to calculate the number of grams of  $\text{Cl}^-$  in the sample and the mass percentage of  $\text{Cl}^-$  in the sample.

**Plan** (a) We can use the procedure outlined by the green arrows in Figure 4.17. We begin by using the volume and molarity of  $\text{Ag}^+$  to calculate the number of moles of  $\text{Ag}^+$  used in the titration. We then use the balanced equation to determine the moles of  $\text{Cl}^-$  in the sample and from that the grams of  $\text{Cl}^-$ . (b) To calculate the percentage of  $\text{Cl}^-$  in the sample, we compare the number of grams of  $\text{Cl}^-$  in the sample with the original mass of the sample, 10.0 g.

## Solve

(a) Calculate the number of moles of  $\text{Ag}^+$  used in the titration.

$$\begin{aligned}\text{Moles Ag}^+ &= (20.2 \text{ mL soln}) \left( \frac{1 \text{ L soln}}{1000 \text{ mL soln}} \right) \left( \frac{0.100 \text{ mol Ag}^+}{\text{L soln}} \right) \\ &= 2.02 \times 10^{-3} \text{ mol Ag}^+\end{aligned}$$

From the balanced equation we see that  
1 mol  $\text{Ag}^+ \approx 1 \text{ mol Cl}^-$ . Using this information and the molar mass of  $\text{Cl}$ , we have:

$$\begin{aligned}\text{Grams Cl}^- &= (2.02 \times 10^{-3} \text{ mol Ag}^+) \left( \frac{1 \text{ mol Cl}^-}{1 \text{ mol Ag}^+} \right) \left( \frac{35.5 \text{ g Cl}^-}{\text{mol Cl}^-} \right) \\ &= 7.17 \times 10^{-2} \text{ g Cl}^-\end{aligned}$$

(b) Calculate the percentage of  $\text{Cl}^-$  used in the sample.

$$\text{Percent Cl}^- = \frac{7.17 \times 10^{-2} \text{ g}}{10.0 \text{ g}} \times 100\% = 0.717\% \text{ Cl}^-$$

## Practice Exercise 1

A mysterious white powder is found at a crime scene. A simple chemical analysis concludes that the powder is a mixture of sugar and morphine ( $\text{C}_{17}\text{H}_{19}\text{NO}_3$ ), a weak base similar to ammonia. The crime lab takes 10.00 mg of the mysterious white powder, dissolves it in 100.00 mL water, and titrates it to the equivalence point with 2.84 mL of a standard 0.0100 M HCl solution. What is the percentage of morphine in the white powder?

- (a) 8.10%
- (b) 17.3%
- (c) 32.6%
- (d) 49.7%
- (e) 81.0%

## Practice Exercise 2

A sample of an iron ore is dissolved in acid, and the iron is converted to  $\text{Fe}^{2+}$ . The sample is then titrated with 47.20 mL of 0.02240 M  $\text{MnO}_4^-$  solution. The oxidation-reduction reaction that occurs during titration is

- (a) How many moles of  $\text{MnO}_4^-$  were added to the solution?
- (b) How many moles of  $\text{Fe}^{2+}$  were in the sample? (c) How many grams of iron were in the sample? (d) If the sample had a mass of 0.8890 g, what is the percentage of iron in the sample?

## Sample Integrative Exercise

## Putting Concepts Together

**Note:** Integrative exercises require skills from earlier chapters as well as ones from the present chapter.

A sample of 70.5 mg of potassium phosphate is added to 15.0 mL of 0.050 M silver nitrate, resulting in the formation of a precipitate. (a) Write the molecular equation for the reaction. (b) What is the limiting reactant in the reaction? (c) Calculate the theoretical yield, in grams, of the precipitate that forms.

## SOLUTION

(a) Potassium phosphate and silver nitrate are both ionic compounds. Potassium phosphate contains  $\text{K}^+$  and  $\text{PO}_4^{3-}$  ions, so its chemical formula is  $\text{K}_3\text{PO}_4$ . Silver nitrate contains  $\text{Ag}^+$  and  $\text{NO}_3^-$  ions, so its chemical formula is

$\text{AgNO}_3$ . Because both reactants are strong electrolytes, the solution contains  $\text{K}^+$ ,  $\text{PO}_4^{3-}$ ,  $\text{Ag}^+$ , and  $\text{NO}_3^-$  ions before the reaction occurs. According to the solubility guidelines in Table 4.1,  $\text{Ag}^+$  and  $\text{PO}_4^{3-}$  form an insoluble compound, so

$\text{Ag}_3\text{PO}_4$  will precipitate from the solution. In contrast,  $\text{K}^+$  and  $\text{NO}_3^-$  will remain in solution because  $\text{KNO}_3$  is water soluble. Thus, the balanced molecular equation for the reaction is:

- (b) To determine the limiting reactant, we must examine the number of moles of each reactant.  $\infty$  (Section 3.7) The number of moles of  $\text{K}_3\text{PO}_4$  is calculated from the mass of the sample using the molar mass as a conversion factor.  $\infty$  (Section 3.4) The molar mass of  $\text{K}_3\text{PO}_4$  is  $3(39.1) + 31.0 + 4(16.0) = 212.3 \text{ g/mol}$ . Converting milligrams to grams and then to moles, we have:

$$\begin{aligned} (70.5 \text{ mg K}_3\text{PO}_4) & \left( \frac{10^{-3} \text{ g K}_3\text{PO}_4}{1 \text{ mg K}_3\text{PO}_4} \right) \left( \frac{1 \text{ mol K}_3\text{PO}_4}{212.3 \text{ g K}_3\text{PO}_4} \right) \\ & = 3.32 \times 10^{-4} \text{ mol K}_3\text{PO}_4 \end{aligned}$$

We determine the number of moles of  $\text{AgNO}_3$  from the volume and molarity of the solution. (Section 4.5) Converting milliliters to liters and then to moles, we have:

$$\begin{aligned} (15.0 \text{ mL}) & \left( \frac{10^{-3} \text{ L}}{1 \text{ mL}} \right) \left( \frac{0.050 \text{ mol AgNO}_3}{\text{L}} \right) \\ & = 7.5 \times 10^{-4} \text{ mol AgNO}_3 \end{aligned}$$

Comparing the amounts of the two reactants, we find that there are  $(7.5 \times 10^{-4}) / (3.32 \times 10^{-4}) = 2.3$  times as many moles of  $\text{AgNO}_3$  as there are moles of  $\text{K}_3\text{PO}_4$ . According to the balanced equation, however, 1 mol  $\text{K}_3\text{PO}_4$  requires 3 mol  $\text{AgNO}_3$ . Thus, there is insufficient  $\text{AgNO}_3$  to consume the  $\text{K}_3\text{PO}_4$ , and  $\text{AgNO}_3$  is the limiting reactant.

- (c) The precipitate is  $\text{Ag}_3\text{PO}_4$ , whose molar mass is  $3(107.9) + 31.0 + 4(16.0) = 418.7 \text{ g/mol}$ . To calculate the number of grams of  $\text{Ag}_3\text{PO}_4$  that could be produced in this reaction (the theoretical yield), we use the number of moles of the limiting reactant, converting  $\text{mol AgNO}_3 \Rightarrow \text{mol Ag}_3\text{PO}_4 \Rightarrow \text{g Ag}_3\text{PO}_4$ . We use the coefficients in the balanced equation to convert moles of  $\text{AgNO}_3$  to moles  $\text{Ag}_3\text{PO}_4$ , and we use the molar mass of  $\text{Ag}_3\text{PO}_4$  to convert the number of moles of this substance to grams.

The answer has only two significant figures because the quantity of  $\text{AgNO}_3$  is given to only two significant figures.

$$\begin{aligned} (7.5 \times 10^{-4} \text{ mol AgNO}_3) & \left( \frac{1 \text{ mol Ag}_3\text{PO}_4}{3 \text{ mol AgNO}_3} \right) \left( \frac{418.7 \text{ g Ag}_3\text{PO}_4}{1 \text{ mol Ag}_3\text{PO}_4} \right) \\ & = 0.10 \text{ g Ag}_3\text{PO}_4 \end{aligned}$$

## Chapter Summary and Key Terms

**GENERAL PROPERTIES OF AQUEOUS SOLUTIONS (INTRODUCTION AND SECTION 4.1)** Solutions in which water is the dissolving medium are called **aqueous solutions**. The component of the solution that is present in the greatest quantity is the **solvent**. The other components are **solutes**.

Any substance whose aqueous solution contains ions is called an **electrolyte**. Any substance that forms a solution containing no ions is a **nonelectrolyte**. Electrolytes that are present in solution entirely as ions are **strong electrolytes**, whereas those that are present partly as ions and partly as molecules are **weak electrolytes**. Ionic compounds dissociate into ions when they dissolve, and they are strong electrolytes. The solubility of ionic substances is made possible by **solvation**, the interaction of ions with polar solvent molecules. Most molecular compounds are nonelectrolytes, although some are weak electrolytes and a few are strong electrolytes. When representing the ionization of a weak electrolyte in solution, half-arrows in both directions are used, indicating that the forward and reverse reactions can achieve a chemical balance called a **chemical equilibrium**.

**PRECIPITATION REACTIONS (SECTION 4.2)** Precipitation reactions are those in which an insoluble product, called a **precipitate**, forms. Solubility guidelines help determine whether an ionic compound will be soluble in water. (The **solubility** of a substance is the amount that dissolves in a given quantity of solvent.) Reactions such as precipitation reactions, in which cations and anions appear to exchange partners, are called **exchange reactions**, or **metathesis reactions**.

Chemical equations can be written to show whether dissolved substances are present in solution predominantly as ions or molecules. When the complete chemical formulas of all reactants and products are used, the equation is called a **molecular equation**. A **complete ionic equation** shows all dissolved strong electrolytes as their component ions. In a **net ionic equation**, those ions that go through the reaction unchanged (**spectator ions**) are omitted.

### ACIDS, BASES, AND NEUTRALIZATION REACTIONS (SECTION 4.3)

Acids and bases are important electrolytes. **Acids** are proton donors; they increase the concentration of  $\text{H}^+(aq)$  in aqueous solutions to which they are added. **Bases** are proton acceptors; they increase the concentration of  $\text{OH}^-(aq)$  in aqueous solutions. Those acids and bases that are strong electrolytes are called **strong acids** and **strong bases**, respectively. Those that are weak electrolytes are **weak acids** and **weak bases**. When solutions of acids and bases are mixed, a neutralization reaction occurs. The **neutralization reaction** between an acid and a metal hydroxide produces water and a **salt**. Gases can also be formed as a result of neutralization reactions. The reaction of a sulfide with an acid forms  $\text{H}_2\text{S}(g)$ ; the reaction between a carbonate and an acid forms  $\text{CO}_2(g)$ .

**OXIDATION-REDUCTION REACTIONS (SECTION 4.4)** Oxidation is the loss of electrons by a substance, whereas **reduction** is the gain of electrons by a substance. **Oxidation numbers** keep track of electrons during chemical reactions and are assigned to atoms using specific

rules. The oxidation of an element results in an increase in its oxidation number, whereas reduction is accompanied by a decrease in oxidation number. Oxidation is always accompanied by reduction, giving **oxidation-reduction**, or **redox**, reactions.

Many metals are oxidized by  $O_2$ , acids, and salts. The redox reactions between metals and acids as well as those between metals and salts are called **displacement reactions**. The products of these displacement reactions are always an element ( $H_2$  or a metal) and a salt. Comparing such reactions allows us to rank metals according to their ease of oxidation. A list of metals arranged in order of decreasing ease of oxidation is called an **activity series**. Any metal on the list can be oxidized by ions of metals (or  $H^+$ ) below it in the series.

**CONCENTRATIONS OF SOLUTIONS (SECTION 4.5)** The **concentration** of a solution expresses the amount of a solute dissolved in the solution. One of the common ways to express the concentration of a solute is in terms of molarity. The **molarity** of a solution is the number of moles of solute per liter of solution. Molarity makes it possible to

interconvert solution volume and number of moles of solute. If the solute is a liquid, its density can be used in molarity calculations to convert between mass, volume, and moles. Solutions of known molarity can be formed either by weighing out the solute and diluting it to a known volume or by the **dilution** of a more concentrated solution of known concentration (a stock solution). Adding solvent to the solution (the process of dilution) decreases the concentration of the solute without changing the number of moles of solute in the solution ( $M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}}$ ).

**SOLUTION STOICHIOMETRY AND CHEMICAL ANALYSIS (SECTION 4.6)** In the process called **titration**, we combine a solution of known concentration (a **standard solution**) with a solution of unknown concentration to determine the unknown concentration or the quantity of solute in the unknown. The point in the titration at which stoichiometrically equivalent quantities of reactants are brought together is called the **equivalence point**. An indicator can be used to show the end point of the titration, which coincides closely with the equivalence point.

## Learning Outcomes After studying this chapter, you should be able to:

- Identify compounds as acids or bases, and as strong, weak, or nonelectrolytes. (Sections 4.1 and 4.3) *Related Exercises: 4.31–4.38*
- Recognize reactions by type and be able to predict the products of simple acid-base, precipitation, and redox reactions. (Sections 4.2–4.4) *Related Exercises: 4.39–4.44, 4.53–4.58*
- Calculate molarity and use it to convert between moles of a substance in solution and volume of the solution. (Section 4.5) *Related Exercises: 4.61–4.72*
- Describe how to carry out a dilution to achieve a desired solution concentration. (Section 4.5) *Related Exercises: 4.73–4.78*
- Describe how to perform and interpret the results of a titration. (Section 4.6) *Related Exercises: 4.83–4.90*

## Key Equations

$$\text{Molarity} = \frac{\text{moles solute}}{\text{volume of solution in liters}} \quad [4.31]$$

Molarity is the most commonly used unit of concentration in chemistry.

$$M_{\text{conc}} \times V_{\text{conc}} = M_{\text{dil}} \times V_{\text{dil}} \quad [4.33]$$

When adding solvent to a concentrated solution to make a dilute solution, molarities and volumes of both concentrated and dilute solutions can be calculated if three of the quantities are known.

## Exercises

### Visualizing Concepts

- 4.1** Which of the following schematic drawings best describes a solution of  $Li_2SO_4$  in water (water molecules not shown for simplicity)? [Section 4.1]

- 4.2** Aqueous solutions of three different substances, AX, AY, and AZ, are represented by the three accompanying diagrams. Identify each substance as a strong electrolyte, a weak electrolyte, or a nonelectrolyte. [Section 4.1]

- 4.3** Use the molecular representations shown here to classify each compound as a nonelectrolyte, a weak electrolyte, or a strong electrolyte (see Figure 4.6 for the element color scheme). [Sections 4.1 and 4.3]

- 4.4** The concept of chemical equilibrium is very important. Which one of the following statements is the most correct way to think about equilibrium?

- (a) If a system is at equilibrium, nothing is happening.
- (b) If a system is at equilibrium, the rate of the forward reaction is equal to the rate of the back reaction.
- (c) If a system is at equilibrium, the product concentration is changing over time. [Section 4.1]

- 4.5** You are presented with a white solid and told that due to careless labeling it is not clear if the substance is barium chloride, lead chloride, or zinc chloride. When you transfer the solid to a beaker and add water, the solid dissolves to give a clear solution. Next a  $\text{Na}_2\text{SO}_4(aq)$  solution is added and a white precipitate forms. What is the identity of the unknown white solid? [Section 4.2]

- 4.6** Which of the following ions will *always* be a spectator ion in a precipitation reaction? (a)  $\text{Cl}^-$ , (b)  $\text{NO}_3^-$ , (c)  $\text{NH}_4^+$ , (d)  $\text{S}^{2-}$ , (e)  $\text{SO}_4^{2-}$ . [Section 4.2]
- 4.7** The labels have fallen off three bottles containing powdered samples of metals; one contains zinc, one lead, and the other platinum. You have three solutions at your disposal: 1 M sodium nitrate, 1 M nitric acid, and 1 M nickel nitrate. How could you use these solutions to determine the identities of each metal powder? [Section 4.4]
- 4.8** Explain how a redox reaction involves electrons in the same way that a neutralization reaction involves protons. [Sections 4.3 and 4.4]
- 4.9** What kind of reaction is the “water-splitting” reaction?  
 $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2(g) + \frac{1}{2} \text{O}_2(g)$   
 (a) an acid-base reaction  
 (b) a metathesis reaction  
 (c) a redox reaction  
 (d) a precipitation reaction [Section 4.4]
- 4.10** An aqueous solution contains 1.2 mM of total ions. (a) If the solution is  $\text{NaCl}(aq)$ , what is the concentration of chloride ion? (b) If the solution is  $\text{FeCl}_3(aq)$ , what is the concentration of chloride ion? [Section 4.5]
- 4.11** Which data set, of the two graphed here, would you expect to observe from a titration like that shown in Figure 4.18? [Section 4.6]

- 4.12** You are titrating an acidic solution with a basic one, and just realized you forgot to add the indicator that tells you when the equivalence point is reached. In this titration, the indicator turns blue at the equivalence point from an initially colorless solution. You quickly grab a bottle of indicator and add some to your titration beaker, and the whole solution turns dark blue. What do you do now? [Section 4.6]

### General Properties of Aqueous Solutions (Section 4.1)

- 4.13** State whether each of the following statements is true or false. Justify your answer in each case.
- (a) Electrolyte solutions conduct electricity because electrons are moving through the solution.
  - (b) If you add a nonelectrolyte to an aqueous solution that already contains an electrolyte, the electrical conductivity will not change.
- 4.14** State whether each of the following statements is true or false. Justify your answer in each case.
- (a) When methanol,  $\text{CH}_3\text{OH}$ , is dissolved in water, a conducting solution results.
  - (b) When acetic acid,  $\text{CH}_3\text{COOH}$ , dissolves in water, the solution is weakly conducting and acidic in nature.
- 4.15** We have learned in this chapter that many ionic solids dissolve in water as strong electrolytes; that is, as separated ions in solution. Which statement is most correct about this process? (a) Water is a strong acid and therefore is good at dissolving ionic solids. (b) Water is good at solvating ions because the hydrogen and oxygen atoms in water molecules bear partial charges. (c) The hydrogen and oxygen bonds of water are easily broken by ionic solids.
- 4.16** Would you expect that an anion would be physically closer to the oxygen or to the hydrogens of water molecules that surround it in solution?
- 4.17** Specify what ions are present in solution upon dissolving each of the following substances in water: (a)  $\text{FeCl}_2$ , (b)  $\text{HNO}_3$ , (c)  $(\text{NH}_4)_2\text{SO}_4$ , (d)  $\text{Ca}(\text{OH})_2$ .
- 4.18** Specify what ions are present upon dissolving each of the following substances in water: (a)  $\text{MgI}_2$ , (b)  $\text{K}_2\text{CO}_3$ , (c)  $\text{HClO}_4$ , (d)  $\text{NaCH}_3\text{COO}$ .

- 4.19** Formic acid,  $\text{HCOOH}$ , is a weak electrolyte. What solutes are present in an aqueous solution of this compound? Write the chemical equation for the ionization of  $\text{HCOOH}$ .
- 4.20** Acetone,  $\text{CH}_3\text{COCH}_3$ , is a nonelectrolyte; hypochlorous acid,  $\text{HClO}$ , is a weak electrolyte; and ammonium chloride,  $\text{NH}_4\text{Cl}$ , is a strong electrolyte. (a) What are the solutes present in aqueous solutions of each compound? (b) If 0.1 mol of each compound is dissolved in solution, which one contains 0.2 mol of solute particles, which contains 0.1 mol of solute particles, and which contains somewhere between 0.1 and 0.2 mol of solute particles?

### Precipitation Reactions (Section 4.2)

- 4.21** Using solubility guidelines, predict whether each of the following compounds is soluble or insoluble in water: (a)  $\text{MgBr}_2$ , (b)  $\text{PbI}_2$ , (c)  $(\text{NH}_4)_2\text{CO}_3$ , (d)  $\text{Sr}(\text{OH})_2$ , (e)  $\text{ZnSO}_4$ .
- 4.22** Predict whether each of the following compounds is soluble in water: (a)  $\text{AgI}$ , (b)  $\text{Na}_2\text{CO}_3$ , (c)  $\text{BaCl}_2$ , (d)  $\text{Al}(\text{OH})_3$ , (e)  $\text{Zn}(\text{CH}_3\text{COO})_2$ .
- 4.23** Will precipitation occur when the following solutions are mixed? If so, write a balanced chemical equation for the reaction. (a)  $\text{Na}_2\text{CO}_3$  and  $\text{AgNO}_3$ , (b)  $\text{NaNO}_3$  and  $\text{NiSO}_4$ , (c)  $\text{FeSO}_4$  and  $\text{Pb}(\text{NO}_3)_2$ .
- 4.24** Identify the precipitate (if any) that forms when the following solutions are mixed, and write a balanced equation for each reaction. (a)  $\text{NaCH}_3\text{COO}$  and  $\text{HCl}$ , (b)  $\text{KOH}$  and  $\text{Cu}(\text{NO}_3)_2$ , (c)  $\text{Na}_2\text{S}$  and  $\text{CdSO}_4$ .
- 4.25** Which ions remain in solution, unreacted, after each of the following pairs of solutions is mixed?
- potassium carbonate and magnesium sulfate
  - lead nitrate and lithium sulfide
  - ammonium phosphate and calcium chloride
- 4.26** Write balanced net ionic equations for the reactions that occur in each of the following cases. Identify the spectator ion or ions in each reaction.
- $\text{Cr}_2(\text{SO}_4)_3(aq) + (\text{NH}_4)_2\text{CO}_3(aq) \longrightarrow$
  - $\text{Ba}(\text{NO}_3)_2(aq) + \text{K}_2\text{SO}_4(aq) \longrightarrow$
  - $\text{Fe}(\text{NO}_3)_2(aq) + \text{KOH}(aq) \longrightarrow$
- 4.27** Separate samples of a solution of an unknown salt are treated with dilute solutions of  $\text{HBr}$ ,  $\text{H}_2\text{SO}_4$ , and  $\text{NaOH}$ . A precipitate forms in all three cases. Which of the following cations could be present in the unknown salt solution:  $\text{K}^+$ ,  $\text{Pb}^{2+}$ ,  $\text{Ba}^{2+}$ ?
- 4.28** Separate samples of a solution of an unknown ionic compound are treated with dilute  $\text{AgNO}_3$ ,  $\text{Pb}(\text{NO}_3)_2$ , and  $\text{BaCl}_2$ . Precipitates form in all three cases. Which of the following could be the anion of the unknown salt:  $\text{Br}^-$ ,  $\text{CO}_3^{2-}$ ,  $\text{NO}_3^-$ ?
- 4.29** You know that an unlabeled bottle contains an aqueous solution of one of the following:  $\text{AgNO}_3$ ,  $\text{CaCl}_2$ , or  $\text{Al}_2(\text{SO}_4)_3$ . A friend suggests that you test a portion of the solution with  $\text{Ba}(\text{NO}_3)_2$  and then with  $\text{NaCl}$  solutions. According to your friend's logic, which of these chemical reactions could occur, thus helping you identify the solution in the bottle? (a) Barium sulfate could precipitate. (b) Silver chloride could precipitate. (c) Silver sulfate could precipitate. (d) More than one, but not all, of the reactions described in answers a–c could occur. (e) All three reactions described in answers a–c could occur.
- 4.30** Three solutions are mixed together to form a single solution; in the final solution, there are 0.2 mol  $\text{Pb}(\text{CH}_3\text{COO})_2$ , 0.1 mol  $\text{Na}_2\text{S}$ , and 0.1 mol  $\text{CaCl}_2$  present. What solid(s) will precipitate?

### Acids, Bases, and Neutralization Reactions (Section 4.3)

- 4.31** Which of the following solutions is the most acidic? (a) 0.2 M  $\text{LiOH}$ , (b) 0.2 M  $\text{HI}$ , (c) 1.0 M methanol ( $\text{CH}_3\text{OH}$ ).
- 4.32** Which of the following solutions is the most basic? (a) 0.6 M  $\text{NH}_3$ , (b) 0.150 M  $\text{KOH}$ , (c) 0.100 M  $\text{Ba}(\text{OH})_2$ .
- 4.33** State whether each of the following statements is true or false. Justify your answer in each case.
- Sulfuric acid is a monoprotic acid.
  - $\text{HCl}$  is a weak acid.
  - Methanol is a base.
- 4.34** State whether each of the following statements is true or false. Justify your answer in each case.
- $\text{NH}_3$  contains no  $\text{OH}^-$  ions, and yet its aqueous solutions are basic.
  - $\text{HF}$  is a strong acid.
  - Although sulfuric acid is a strong electrolyte, an aqueous solution of  $\text{H}_2\text{SO}_4$  contains more  $\text{HSO}_4^-$  ions than  $\text{SO}_4^{2-}$  ions.
- 4.35** Label each of the following substances as an acid, base, salt, or none of the above. Indicate whether the substance exists in aqueous solution entirely in molecular form, entirely as ions, or as a mixture of molecules and ions. (a)  $\text{HF}$ , (b) acetonitrile,  $\text{CH}_3\text{CN}$ , (c)  $\text{NaClO}_4$ , (d)  $\text{Ba}(\text{OH})_2$ .
- 4.36** An aqueous solution of an unknown solute is tested with litmus paper and found to be acidic. The solution is weakly conducting compared with a solution of  $\text{NaCl}$  of the same concentration. Which of the following substances could the unknown be:  $\text{KOH}$ ,  $\text{NH}_3$ ,  $\text{HNO}_3$ ,  $\text{KClO}_2$ ,  $\text{H}_3\text{PO}_3$ ,  $\text{CH}_3\text{COCH}_3$  (acetone)?
- 4.37** Classify each of the following substances as a nonelectrolyte, weak electrolyte, or strong electrolyte in water: (a)  $\text{H}_2\text{SO}_3$ , (b)  $\text{CH}_3\text{CH}_2\text{OH}$  (ethanol), (c)  $\text{NH}_3$ , (d)  $\text{KClO}_3$ , (e)  $\text{Cu}(\text{NO}_3)_2$ .
- 4.38** Classify each of the following aqueous solutions as a nonelectrolyte, weak electrolyte, or strong electrolyte: (a)  $\text{LiClO}_4$ , (b)  $\text{HClO}$ , (c)  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  (propanol), (d)  $\text{HClO}_3$ , (e)  $\text{CuSO}_4$ , (f)  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  (sucrose).
- 4.39** Complete and balance the following molecular equations, and then write the net ionic equation for each:
- $\text{HBr}(aq) + \text{Ca}(\text{OH})_2(aq) \longrightarrow$
  - $\text{Cu}(\text{OH})_2(s) + \text{HClO}_4(aq) \longrightarrow$
  - $\text{Al}(\text{OH})_3(s) + \text{HNO}_3(aq) \longrightarrow$
- 4.40** Write the balanced molecular and net ionic equations for each of the following neutralization reactions:
- Aqueous acetic acid is neutralized by aqueous barium hydroxide.
  - Solid chromium(III) hydroxide reacts with nitrous acid.
  - Aqueous nitric acid and aqueous ammonia react.
- 4.41** Write balanced molecular and net ionic equations for the following reactions, and identify the gas formed in each: (a) solid cadmium sulfide reacts with an aqueous solution of sulfuric acid; (b) solid magnesium carbonate reacts with an aqueous solution of perchloric acid.
- 4.42** Because the oxide ion is basic, metal oxides react readily with acids. (a) Write the net ionic equation for the following reaction:
- $$\text{FeO}(s) + 2\text{HClO}_4(aq) \longrightarrow \text{Fe}(\text{ClO}_4)_2(aq) + \text{H}_2\text{O}(l)$$
- (b) Based on the equation in part (a), write the net ionic equation for the reaction that occurs between  $\text{NiO}(s)$  and an aqueous solution of nitric acid.

**4.43** Magnesium carbonate, magnesium oxide, and magnesium hydroxide are all white solids that react with acidic solutions. (a) Write a balanced molecular equation and a net ionic equation for the reaction that occurs when each substance reacts with a hydrochloric acid solution. (b) By observing the reactions in part (a), how could you distinguish any of the three magnesium substances from the other two?

**4.44** As  $K_2O$  dissolves in water, the oxide ion reacts with water molecules to form hydroxide ions. (a) Write the molecular and net ionic equations for this reaction. (b) Based on the definitions of acid and base, what ion is the base in this reaction? (c) What is the acid in the reaction? (d) What is the spectator ion in the reaction?

## Oxidation-Reduction Reactions (Section 4.4)

**4.45** True or false:

- (a) If a substance is oxidized, it is gaining electrons.
- (b) If an ion is oxidized, its oxidation number increases.

**4.46** True or false:

- (a) Oxidation can occur without oxygen.
- (b) Oxidation can occur without reduction.

**4.47** (a) Which region of the periodic table shown here contains elements that are easiest to oxidize? (b) Which region contains the least readily oxidized elements?

**4.48** Determine the oxidation number of sulfur in each of the following substances: (a) barium sulfate,  $BaSO_4$ , (b) sulfurous acid,  $H_2SO_3$ , (c) strontium sulfide,  $SrS$ , (d) hydrogen sulfide,  $H_2S$ . (e) Locate sulfur in the periodic table in Exercise 4.47; what region is it in? (f) Which region(s) of the periodic table contains elements that can adopt both positive and negative oxidation numbers?

**4.49** Determine the oxidation number for the indicated element in each of the following substances: (a) S in  $SO_2$ , (b) C in  $COCl_2$ , (c) Mn in  $KMnO_4$ , (d) Br in  $HBrO_4$ , (e) P in  $PF_3$ , (f) O in  $K_2O_2$ .

**4.50** Determine the oxidation number for the indicated element in each of the following compounds: (a) Co in  $LiCoO_2$ , (b) Al in  $NaAlH_4$ , (c) C in  $CH_3OH$  (methanol), (d) N in  $GaN$ , (e) Cl in  $HClO_2$ , (f) Cr in  $BaCrO_4$ .

**4.51** Which element is oxidized, and which is reduced in the following reactions?

**4.52** Which of the following are redox reactions? For those that are, indicate which element is oxidized and which is reduced. For those that are not, indicate whether they are precipitation or neutralization reactions.

**4.53** Write balanced molecular and net ionic equations for the reactions of (a) manganese with dilute sulfuric acid, (b) chromium with hydrobromic acid, (c) tin with hydrochloric acid, (d) aluminum with formic acid,  $HCOOH$ .

**4.54** Write balanced molecular and net ionic equations for the reactions of (a) hydrochloric acid with nickel, (b) dilute sulfuric acid with iron, (c) hydrobromic acid with magnesium, (d) acetic acid,  $CH_3COOH$ , with zinc.

**4.55** Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, write NR. (a) Iron metal is added to a solution of copper(II) nitrate, (b) zinc metal is added to a solution of magnesium sulfate, (c) hydrobromic acid is added to tin metal, (d) hydrogen gas is bubbled through an aqueous solution of nickel(II) chloride, (e) aluminum metal is added to a solution of cobalt(II) sulfate.

**4.56** Using the activity series (Table 4.5), write balanced chemical equations for the following reactions. If no reaction occurs, write NR. (a) Nickel metal is added to a solution of copper(II) nitrate, (b) a solution of zinc nitrate is added to a solution of magnesium sulfate, (c) hydrochloric acid is added to gold metal, (d) chromium metal is immersed in an aqueous solution of cobalt(II) chloride, (e) hydrogen gas is bubbled through a solution of silver nitrate.

**4.57** The metal cadmium tends to form  $Cd^{2+}$  ions. The following observations are made: (i) When a strip of zinc metal is placed in  $CdCl_2(aq)$ , cadmium metal is deposited on the strip. (ii) When a strip of cadmium metal is placed in  $Ni(NO_3)_2(aq)$ , nickel metal is deposited on the strip. (a) Write net ionic equations to explain each of the preceding observations. (b) Which elements more closely define the position of cadmium in the activity series? (c) What experiments would you need to perform to locate more precisely the position of cadmium in the activity series?

**4.58** The following reactions (note that the arrows are pointing only one direction) can be used to prepare an activity series for the halogens:

(a) Which elemental halogen would you predict is the most stable, upon mixing with other halides? (b) Predict whether a reaction will occur when elemental chlorine and potassium iodide are mixed. (c) Predict whether a reaction will occur when elemental bromine and lithium chloride are mixed.

## Concentrations of Solutions (Section 4.5)

**4.59** (a) Is the concentration of a solution an intensive or an extensive property? (b) What is the difference between 0.50 mol HCl and 0.50 M HCl?

**4.60** You make 1.000 L of an aqueous solution that contains 35.0 g of sucrose ( $C_{12}H_{22}O_{11}$ ). (a) What is the molarity of sucrose in this solution? (b) How many liters of water would you have to add to this solution to reduce the molarity you calculated in part (a) by a factor of two?

**4.61** (a) Calculate the molarity of a solution that contains 0.175 mol  $ZnCl_2$  in exactly 150 mL of solution. (b) How many moles of protons are present in 35.0 mL of a 4.50 M solution of nitric acid? (c) How many milliliters of a 6.00 M NaOH solution are needed to provide 0.350 mol of NaOH?

- 4.62** (a) Calculate the molarity of a solution made by dissolving 12.5 grams of  $\text{Na}_2\text{CrO}_4$  in enough water to form exactly 750 mL of solution. (b) How many moles of KBr are present in 150 mL of a 0.112 M solution? (c) How many milliliters of 6.1 M HCl solution are needed to obtain 0.150 mol of HCl?
- 4.63** The average adult human male has a total blood volume of 5.0 L. If the concentration of sodium ion in this average individual is 0.135 M, what is the mass of sodium ion circulating in the blood?
- 4.64** A person suffering from hyponatremia has a sodium ion concentration in the blood of 0.118 M and a total blood volume of 4.6 L. What mass of sodium chloride would need to be added to the blood to bring the sodium ion concentration up to 0.138 M, assuming no change in blood volume?
- 4.65** The concentration of alcohol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) in blood, called the “blood alcohol concentration” or BAC, is given in units of grams of alcohol per 100 mL of blood. The legal definition of intoxication, in many states of the United States, is that the BAC is 0.08 or higher. What is the concentration of alcohol, in terms of molarity, in blood if the BAC is 0.08?
- 4.66** The average adult male has a total blood volume of 5.0 L. After drinking a few beers, he has a BAC of 0.10 (see Exercise 4.65). What mass of alcohol is circulating in his blood?
- 4.67** (a) How many grams of ethanol,  $\text{CH}_3\text{CH}_2\text{OH}$ , should you dissolve in water to make 1.00 L of vodka (which is an aqueous solution that is 6.86 M ethanol)? (b) Using the density of ethanol (0.789 g/mL), calculate the volume of ethanol you need to make 1.00 L of vodka.
- 4.68** One cup of fresh orange juice contains 124 mg of ascorbic acid (vitamin C,  $\text{C}_6\text{H}_8\text{O}_6$ ). Given that one cup = 236.6 mL, calculate the molarity of vitamin C in orange juice.
- 4.69** (a) Which will have the highest concentration of potassium ion: 0.20 M KCl, 0.15 M  $\text{K}_2\text{CrO}_4$ , or 0.080 M  $\text{K}_3\text{PO}_4$ ? (b) Which will contain the greater number of moles of potassium ion: 30.0 mL of 0.15 M  $\text{K}_2\text{CrO}_4$  or 25.0 mL of 0.080 M  $\text{K}_3\text{PO}_4$ ?
- 4.70** In each of the following pairs, indicate which has the higher concentration of  $\text{I}^-$  ion: (a) 0.10 M  $\text{BaI}_2$  or 0.25 M KI solution, (b) 100 mL of 0.10 M KI solution or 200 mL of 0.040 M  $\text{ZnI}_2$  solution, (c) 3.2 M HI solution or a solution made by dissolving 145 g of NaI in water to make 150 mL of solution.
- 4.71** Indicate the concentration of each ion or molecule present in the following solutions: (a) 0.25 M  $\text{NaNO}_3$ , (b)  $1.3 \times 10^{-2}$  M  $\text{MgSO}_4$ , (c) 0.0150 M  $\text{C}_6\text{H}_{12}\text{O}_6$ , (d) a mixture of 45.0 mL of 0.272 M NaCl and 65.0 mL of 0.0247 M  $(\text{NH}_4)_2\text{CO}_3$ . Assume that the volumes are additive.
- 4.72** Indicate the concentration of each ion present in the solution formed by mixing (a) 42.0 mL of 0.170 M NaOH with 37.6 mL of 0.400 M NaOH, (b) 44.0 mL of 0.100 M  $\text{Na}_2\text{SO}_4$  with 25.0 mL of 0.150 M KCl, (c) 3.60 g KCl in 75.0 mL of 0.250 M  $\text{CaCl}_2$  solution. Assume that the volumes are additive.
- 4.73** (a) You have a stock solution of 14.8 M  $\text{NH}_3$ . How many milliliters of this solution should you dilute to make 1000.0 mL of 0.250 M  $\text{NH}_3$ ? (b) If you take a 10.0-mL portion of the stock solution and dilute it to a total volume of 0.500 L, what will be the concentration of the final solution?
- 4.74** (a) How many milliliters of a stock solution of 6.0 M  $\text{HNO}_3$  would you have to use to prepare 110 mL of 0.500 M  $\text{HNO}_3$ ? (b) If you dilute 10.0 mL of the stock solution to a final volume of 0.250 L, what will be the concentration of the diluted solution?
- 4.75** A medical lab is testing a new anticancer drug on cancer cells. The drug stock solution concentration is  $1.5 \times 10^{-9}$  M, and 1.00 mL of this solution will be delivered to a dish containing  $2.0 \times 10^5$  cancer cells in 5.00 mL of aqueous fluid. What is the ratio of drug molecules to the number of cancer cells in the dish?

**4.76** Calicheamicin gamma-1,  $\text{C}_{55}\text{H}_{74}\text{IN}_3\text{O}_{21}\text{S}_4$ , is one of the most potent antibiotics known: one molecule kills one bacterial cell. Describe how you would (carefully!) prepare 25.00 mL of an aqueous calicheamicin gamma-1 solution that could kill  $1.0 \times 10^8$  bacteria, starting from a  $5.00 \times 10^{-9}$  M stock solution of the antibiotic.

**4.77** Pure acetic acid, known as glacial acetic acid, is a liquid with a density of 1.049 g/mL at 25 °C. Calculate the molarity of a solution of acetic acid made by dissolving 20.00 mL of glacial acetic acid at 25 °C in enough water to make 250.0 mL of solution.

**4.78** Glycerol,  $\text{C}_3\text{H}_8\text{O}_3$ , is a substance used extensively in the manufacture of cosmetics, foodstuffs, antifreeze, and plastics. Glycerol is a water-soluble liquid with a density of 1.2656 g/mL at 15 °C. Calculate the molarity of a solution of glycerol made by dissolving 50.000 mL glycerol at 15 °C in enough water to make 250.00 mL of solution.

## Solution Stoichiometry and Chemical Analysis (Section 4.6)

**4.79** You want to analyze a silver nitrate solution. (a) You could add  $\text{HCl}(aq)$  to the solution to precipitate out  $\text{AgCl}(s)$ . What volume of a 0.150 M  $\text{HCl}(aq)$  solution is needed to precipitate the silver ions from 15.0 mL of a 0.200 M  $\text{AgNO}_3$  solution? (b) You could add solid KCl to the solution to precipitate out  $\text{AgCl}(s)$ . What mass of KCl is needed to precipitate the silver ions from 15.0 mL of 0.200 M  $\text{AgNO}_3$  solution? (c) Given that a 0.150 M  $\text{HCl}(aq)$  solution costs \$39.95 for 500 mL and that KCl costs \$10/ton, which analysis procedure is more cost-effective?

**4.80** You want to analyze a cadmium nitrate solution. What mass of NaOH is needed to precipitate the  $\text{Cd}^{2+}$  ions from 35.0 mL of 0.500 M  $\text{Cd}(\text{NO}_3)_2$  solution?

**4.81** (a) What volume of 0.115 M  $\text{HClO}_4$  solution is needed to neutralize 50.00 mL of 0.0875 M NaOH? (b) What volume of 0.128 M HCl is needed to neutralize 2.87 g of  $\text{Mg}(\text{OH})_2$ ? (c) If 25.8 mL of an  $\text{AgNO}_3$  solution is needed to precipitate all the  $\text{Cl}^-$  ions in a 785-mg sample of KCl (forming  $\text{AgCl}$ ), what is the molarity of the  $\text{AgNO}_3$  solution? (d) If 45.3 mL of a 0.108 M HCl solution is needed to neutralize a solution of KOH, how many grams of KOH must be present in the solution?

**4.82** (a) How many milliliters of 0.120 M HCl are needed to completely neutralize 50.0 mL of 0.101 M  $\text{Ba}(\text{OH})_2$  solution? (b) How many milliliters of 0.125 M  $\text{H}_2\text{SO}_4$  are needed to neutralize 0.200 g of NaOH? (c) If 55.8 mL of a  $\text{BaCl}_2$  solution is needed to precipitate all the sulfate ion in a 752-mg sample of  $\text{Na}_2\text{SO}_4$ , what is the molarity of the  $\text{BaCl}_2$  solution? (d) If 42.7 mL of 0.208 M HCl solution is needed to neutralize a solution of  $\text{Ca}(\text{OH})_2$ , how many grams of  $\text{Ca}(\text{OH})_2$  must be in the solution?

**4.83** Some sulfuric acid is spilled on a lab bench. You can neutralize the acid by sprinkling sodium bicarbonate on it and then mopping up the resulting solution. The sodium bicarbonate reacts with sulfuric acid according to:

Sodium bicarbonate is added until the fizzing due to the formation of  $\text{CO}_2(g)$  stops. If 27 mL of 6.0 M  $\text{H}_2\text{SO}_4$  was spilled, what is the minimum mass of  $\text{NaHCO}_3$  that must be added to the spill to neutralize the acid?

**4.84** The distinctive odor of vinegar is due to acetic acid,  $\text{CH}_3\text{COOH}$ , which reacts with sodium hydroxide according to:

If 3.45 mL of vinegar needs 42.5 mL of 0.115 M NaOH to reach the equivalence point in a titration, how many grams of acetic acid are in a 1.00-qt sample of this vinegar?

- 4.85** A 4.36-g sample of an unknown alkali metal hydroxide is dissolved in 100.0 mL of water. An acid–base indicator is added, and the resulting solution is titrated with 2.50 M HCl(aq) solution. The indicator changes color, signaling that the equivalence point has been reached, after 17.0 mL of the hydrochloric acid solution has been added. **(a)** What is the molar mass of the metal hydroxide? **(b)** What is the identity of the alkali metal cation:  $\text{Li}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Rb}^+$ , or  $\text{Cs}^+$ ?
- 4.86** An 8.65-g sample of an unknown group 2A metal hydroxide is dissolved in 85.0 mL of water. An acid–base indicator is added and the resulting solution is titrated with 2.50 M HCl(aq) solution. The indicator changes color, signaling that the equivalence point has been reached, after 56.9 mL of the hydrochloric acid solution has been added. **(a)** What is the molar mass of the metal hydroxide? **(b)** What is the identity of the metal cation:  $\text{Ca}^{2+}$ ,  $\text{Sr}^{2+}$ , or  $\text{Ba}^{2+}$ ?
- 4.87** A solution of 100.0 mL of 0.200 M KOH is mixed with a solution of 200.0 mL of 0.150 M  $\text{NiSO}_4$ . **(a)** Write the balanced

chemical equation for the reaction that occurs. **(b)** What precipitate forms? **(c)** What is the limiting reactant? **(d)** How many grams of this precipitate form? **(e)** What is the concentration of each ion that remains in solution?

- 4.88** A solution is made by mixing 15.0 g of  $\text{Sr}(\text{OH})_2$  and 55.0 mL of 0.200 M  $\text{HNO}_3$ . **(a)** Write a balanced equation for the reaction that occurs between the solutes. **(b)** Calculate the concentration of each ion remaining in solution. **(c)** Is the resulting solution acidic or basic?
- 4.89** A 0.5895-g sample of impure magnesium hydroxide is dissolved in 100.0 mL of 0.2050 M HCl solution. The excess acid then needs 19.85 mL of 0.1020 M NaOH for neutralization. Calculate the percentage by mass of magnesium hydroxide in the sample, assuming that it is the only substance reacting with the HCl solution.
- 4.90** A 1.248-g sample of limestone rock is pulverized and then treated with 30.00 mL of 1.035 M HCl solution. The excess acid then requires 11.56 mL of 1.010 M NaOH for neutralization. Calculate the percentage by mass of calcium carbonate in the rock, assuming that it is the only substance reacting with the HCl solution.

## Additional Exercises

- 4.91** Uranium hexafluoride,  $\text{UF}_6$ , is processed to produce fuel for nuclear reactors and nuclear weapons.  $\text{UF}_6$  is made from the reaction of elemental uranium with  $\text{ClF}_3$ , which also produces  $\text{Cl}_2$  as a by-product.
- (a)** Write the balanced molecular equation for the conversion of U and  $\text{ClF}_3$  into  $\text{UF}_6$  and  $\text{Cl}_2$ .
- (b)** Is this a metathesis reaction?
- (c)** Is this a redox reaction?
- 4.92** The accompanying photo shows the reaction between a solution of  $\text{Cd}(\text{NO}_3)_2$  and one of  $\text{Na}_2\text{S}$ . **(a)** What is the identity of the precipitate? **(b)** What ions remain in solution? **(c)** Write the net ionic equation for the reaction. **(d)** Is this a redox reaction?

- 4.93** Suppose you have a solution that might contain any or all of the following cations:  $\text{Ni}^{2+}$ ,  $\text{Ag}^+$ ,  $\text{Sr}^{2+}$ , and  $\text{Mn}^{2+}$ . Addition of HCl solution causes a precipitate to form. After filtering off the precipitate,  $\text{H}_2\text{SO}_4$  solution is added to the resulting solution and another precipitate forms. This is filtered off, and a solution of NaOH is added to the resulting solution. No precipitate is observed. Which ions are present in each of the precipitates? Which of the four ions listed above must be absent from the original solution?

- 4.94** You choose to investigate some of the solubility guidelines for two ions not listed in Table 4.1, the chromate ion ( $\text{CrO}_4^{2-}$ ) and the oxalate ion ( $\text{C}_2\text{O}_4^{2-}$ ). You are given 0.01 M solutions (A, B, C, D) of four water-soluble salts:

| Solution | Solute                                | Color of Solution |
|----------|---------------------------------------|-------------------|
| A        | $\text{Na}_2\text{CrO}_4$             | Yellow            |
| B        | $(\text{NH}_4)_2\text{C}_2\text{O}_4$ | Colorless         |
| C        | $\text{AgNO}_3$                       | Colorless         |
| D        | $\text{CaCl}_2$                       | Colorless         |

When these solutions are mixed, the following observations are made:

| Experiment Number | Solutions Mixed | Result                          |
|-------------------|-----------------|---------------------------------|
| 1                 | A + B           | No precipitate, yellow solution |
| 2                 | A + C           | Red precipitate forms           |
| 3                 | A + D           | Yellow precipitate forms        |
| 4                 | B + C           | White precipitate forms         |
| 5                 | B + D           | White precipitate forms         |
| 6                 | C + D           | White precipitate forms         |

**(a)** Write a net ionic equation for the reaction that occurs in each of the experiments. **(b)** Identify the precipitate formed, if any, in each of the experiments.

- 4.95** Antacids are often used to relieve pain and promote healing in the treatment of mild ulcers. Write balanced net ionic equations for the reactions between the aqueous HCl in the stomach and each of the following substances used in various antacids: **(a)**  $\text{Al}(\text{OH})_3(\text{s})$ , **(b)**  $\text{Mg}(\text{OH})_2(\text{s})$ , **(c)**  $\text{MgCO}_3(\text{s})$ , **(d)**  $\text{NaAl}(\text{CO}_3)(\text{OH})_2(\text{s})$ , **(e)**  $\text{CaCO}_3(\text{s})$ .
- 4.96** The commercial production of nitric acid involves the following chemical reactions:

(a) Which of these reactions are redox reactions? (b) In each redox reaction identify the element undergoing oxidation and the element undergoing reduction. (c) How many grams of ammonia must you start with to make 1000.0 L of a 0.150 M aqueous solution of nitric acid? Assume all the reactions give 100% yield.

- 4.97** Consider the following reagents: zinc, copper, mercury (density 13.6 g/mL), silver nitrate solution, nitric acid solution. (a) Given a 500-mL Erlenmeyer flask and a balloon, can you combine two or more of the foregoing reagents to initiate a chemical reaction that will inflate the balloon? Write a balanced chemical equation to represent this process. What is the identity of the substance that inflates the balloon? (b) What is the theoretical yield of the substance that fills the balloon? (c) Can you combine two or more of the foregoing reagents to initiate a chemical reaction that will produce metallic silver? Write a balanced chemical equation to represent this process. What ions are left behind in solution? (d) What is the theoretical yield of silver?

- 4.98** Bronze is a *solid solution* of Cu(s) and Sn(s); solutions of metals like this that are solids are called *alloys*. There is a range of compositions over which the solution is considered a bronze. Bronzes are stronger and harder than either copper or tin alone. (a) A 100.0-g sample of a certain bronze is 90.0% copper by mass and 10.0% tin. Which metal can be called the solvent, and which the solute? (b) Based on part (a), calculate the concentration of the solute metal in the alloy in units of molarity, assuming a density of 7.9 g/cm<sup>3</sup>. (c) Suggest a reaction that you could do to remove all the tin from this bronze to leave a pure copper sample. Justify your reasoning.
- 4.99** A 35.0-mL sample of 1.00 M KBr and a 60.0-mL sample of 0.600 M KBr are mixed. The solution is then heated to evaporate water until the total volume is 50.0 mL. How many grams of silver nitrate are required to precipitate out silver bromide in the final solution?
- 4.100** Neurotransmitters are molecules that are released by nerve cells to other cells in our bodies, and are needed for muscle motion, thinking, feeling, and memory. Dopamine is a common neurotransmitter in the human brain.

(a) Predict what kind of reaction dopamine is most likely to undergo in water: redox, acid-base, precipitation, or metathesis? Explain your reasoning. (b) Patients with Parkinson's disease suffer from a shortage of dopamine and may need to take it to reduce symptoms. An IV (intravenous fluid) bag is filled with a solution that contains 400.0 mg dopamine per 250.0 mL of solution. What is the concentration of dopamine in the IV bag in units of molarity? (c) Experiments with rats show that if rats are dosed with 3.0 mg/kg of cocaine (that is, 3.0 mg cocaine per kg of animal mass), the concentration of dopamine in their brains increases by 0.75  $\mu\text{M}$  after 60 seconds. Calculate how many molecules of dopamine would be produced in a rat (average brain volume 5.00 mm<sup>3</sup>) after 60 seconds of a 3.0 mg/kg dose of cocaine.

- 4.101** Hard water contains  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ , and  $\text{Fe}^{2+}$ , which interfere with the action of soap and leave an insoluble coating on the insides of containers and pipes when heated. Water softeners replace these ions with  $\text{Na}^+$ . Keep in mind that charge balance must be maintained. (a) If 1500 L of hard water contains 0.020 M  $\text{Ca}^{2+}$  and 0.0040 M  $\text{Mg}^{2+}$ , how many moles of  $\text{Na}^+$  are needed to replace these ions? (b) If the sodium is added to the water softener in the form of NaCl, how many grams of sodium chloride are needed?
- 4.102** Tartaric acid,  $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ , has two acidic hydrogens. The acid is often present in wines and a salt derived from the acid precipitates from solution as the wine ages. A solution containing an unknown concentration of the acid is titrated with NaOH. It requires 24.65 mL of 0.2500 M NaOH solution to titrate both acidic protons in 50.00 mL of the tartaric acid solution. Write a balanced net ionic equation for the neutralization reaction, and calculate the molarity of the tartaric acid solution.
- 4.103** (a) A strontium hydroxide solution is prepared by dissolving 12.50 g of  $\text{Sr}(\text{OH})_2$  in water to make 50.00 mL of solution. What is the molarity of this solution? (b) Next the strontium hydroxide solution prepared in part (a) is used to titrate a nitric acid solution of unknown concentration. Write a balanced chemical equation to represent the reaction between strontium hydroxide and nitric acid solutions. (c) If 23.9 mL of the strontium hydroxide solution was needed to neutralize a 37.5 mL aliquot of the nitric acid solution, what is the concentration (molarity) of the acid?
- 4.104** A solid sample of  $\text{Zn}(\text{OH})_2$  is added to 0.350 L of 0.500 M aqueous HBr. The solution that remains is still acidic. It is then titrated with 0.500 M NaOH solution, and it takes 88.5 mL of the NaOH solution to reach the equivalence point. What mass of  $\text{Zn}(\text{OH})_2$  was added to the HBr solution?

## Integrative Exercises

- 4.105** Suppose you have 5.00 g of powdered magnesium metal, 1.00 L of 2.00 M potassium nitrate solution, and 1.00 L of 2.00 M silver nitrate solution. (a) Which one of the solutions will react with the magnesium powder? (b) What is the net

ionic equation that describes this reaction? (c) What volume of solution is needed to completely react with the magnesium? (d) What is the molarity of the  $\text{Mg}^{2+}$  ions in the resulting solution?

- 4.106** (a) By titration, 15.0 mL of 0.1008 M sodium hydroxide is needed to neutralize a 0.2053-g sample of a weak acid. What is the molar mass of the acid if it is monoprotic? (b) An elemental analysis of the acid indicates that it is composed of 5.89% H, 70.6% C, and 23.5% O by mass. What is its molecular formula?
- 4.107** Gold is isolated from rocks by reaction with aqueous cyanide,  $\text{CN}^-$ :  $4 \text{Au(s)} + 8 \text{NaCN(aq)} + \text{O}_2\text{(g)} + \text{H}_2\text{O(l)} \longrightarrow 4 \text{Na[Au(CN)}_2\text{](aq)} + 4 \text{NaOH(aq)}$ . (a) Which atoms from which compounds are being oxidized, and which atoms from which compounds are being reduced? (b) The  $[\text{Au(CN)}_2]^-$  ion can be converted back to Au(0) by reaction with Zn(s) powder. Write a balanced chemical equation for this reaction. (c) How many liters of a 0.200 M sodium cyanide solution would be needed to react with 40.0 kg of rocks that contain 2.00% by mass of gold?
- 4.108** A fertilizer railroad car carrying 34,300 gallons of commercial aqueous ammonia (30% ammonia by mass) tips over and spills. The density of the aqueous ammonia solution is 0.88 g/cm<sup>3</sup>. What mass of citric acid,  $\text{C(OH)(COOH)(CH}_2\text{COOH)}_2$ , (which contains three acidic protons) is required to neutralize the spill? 1 gallon = 3.785 L.
- 4.109** A sample of 7.75 g of  $\text{Mg(OH)}_2$  is added to 25.0 mL of 0.200 M  $\text{HNO}_3$ . (a) Write the chemical equation for the reaction that occurs. (b) Which is the limiting reactant in the reaction? (c) How many moles of  $\text{Mg(OH)}_2$ ,  $\text{HNO}_3$ , and  $\text{Mg(NO}_3)_2$  are present after the reaction is complete?
- 4.110** In 2014, a major chemical leak at a facility in West Virginia released 7500 gallons of MCHM (4-methylcyclohexylmethanol,  $\text{C}_8\text{H}_{16}\text{O}$ ) into the Elk River. The density of MCHM is 0.9074 g/mL. (a) Calculate the initial molarity of MCHM in the river, assuming that the first part of the river is 7.00 feet deep, 100.0 yards wide, and 100.0 yards long. 1 gallon = 3.785 L. (b) How much farther down the river would the spill have to spread in order to achieve a “safe” MCHM concentration of  $1.00 \times 10^{-4} \text{ M}$ ? Assume the depth and width of the river are constant and the concentration of MCHM is uniform along the length of the spill.
- 4.111** Ritalin is the trade name of a drug, methylphenidate, used to treat attention-deficit/hyperactivity disorder in young adults. The chemical structure of methylphenidate is

(a) Is Ritalin an acid or a base? An electrolyte or a non-electrolyte? (b) A tablet contains a 10.0-mg dose of Ritalin. Assuming all the drug ends up in the bloodstream, and the average man has a total blood volume of 5.0 L, calculate the initial molarity of Ritalin in a man's bloodstream. (c) Ritalin has a half-life of 3 hours in the blood, which means that after 3 hours the concentration in the blood has decreased by half of its initial value. For the man in part (b), what is the concentration of Ritalin in his blood after 6 hours?

- 4.112** The mass percentage of chloride ion in a 25.00-mL sample of seawater was determined by titrating the sample with silver nitrate, precipitating silver chloride. It took 42.58 mL of 0.2997 M silver nitrate solution to reach the equivalence point in the titration. What is the mass percentage of chloride ion in seawater if its density is 1.025 g/mL?
- 4.113** The arsenic in a 1.22-g sample of a pesticide was converted to  $\text{AsO}_4^{3-}$  by suitable chemical treatment. It was then titrated using  $\text{Ag}^+$  to form  $\text{Ag}_3\text{AsO}_4$  as a precipitate. (a) What is the oxidation state of As in  $\text{AsO}_4^{3-}$ ? (b) Name  $\text{Ag}_3\text{AsO}_4$  by analogy to the corresponding compound containing phosphorus in place of arsenic. (c) If it took 25.0 mL of 0.102 M  $\text{Ag}^+$  to reach the equivalence point in this titration, what is the mass percentage of arsenic in the pesticide?
- 4.114** The U.S. standard for arsenate in drinking water requires that public water supplies must contain no greater than 10 parts per billion (ppb) arsenic. If this arsenic is present as arsenate,  $\text{AsO}_4^{3-}$ , what mass of sodium arsenate would be present in a 1.00-L sample of drinking water that just meets the standard? Parts per billion is defined on a mass basis as

$$\text{ppb} = \frac{\text{g solute}}{\text{g solution}} \times 10^9$$

- 4.115** Federal regulations set an upper limit of 50 parts per million (ppm) of  $\text{NH}_3$  in the air in a work environment [that is, 50 molecules of  $\text{NH}_3\text{(g)}$  for every million molecules in the air]. Air from a manufacturing operation was drawn through a solution containing  $1.00 \times 10^2 \text{ mL}$  of 0.0105 M  $\text{HCl}$ . The  $\text{NH}_3$  reacts with  $\text{HCl}$  according to:

After drawing air through the acid solution for 10.0 min at a rate of 10.0 L/min, the acid was titrated. The remaining acid needed 13.1 mL of 0.0588 M  $\text{NaOH}$  to reach the equivalence point. (a) How many grams of  $\text{NH}_3$  were drawn into the acid solution? (b) How many ppm of  $\text{NH}_3$  were in the air? (Air has a density of 1.20 g/L and an average molar mass of 29.0 g/mol under the conditions of the experiment.) (c) Is this manufacturer in compliance with regulations?

## Design an Experiment

You are cleaning out a chemistry lab and find three unlabeled bottles, each containing white powder. Near these bottles are three loose labels: “Sodium sulfide,” “Sodium bicarbonate,” and “Sodium chloride.” Let's design an experiment to figure out which label goes with which bottle.

(a) You could try to use the physical properties of the three solids to distinguish among them. Using an Internet resource or the *CRC Handbook of Chemistry and Physics*, look up the melting points, aqueous solubilities, or other properties of these salts. Are the differences

among these properties for each salt large enough to distinguish among them? If so, design a set of experiments to distinguish each salt and therefore figure out which label goes on which bottle.

(b) You could use the chemical reactivity of each salt to distinguish it from the others. Which of these salts, if any, will act as an acid? A base? A strong electrolyte? Can any of these salts be easily oxidized or reduced? Can any of these salts react to produce a gas? Based on your answers to these questions, design a set of experiments to distinguish each salt and thus determine which label goes on which bottle.

# THERMOCHEMISTRY

Everything we do is connected in one way or another with energy. Without energy modern society could not function and life itself would not exist. The issues surrounding energy—its sources, production, distribution, consumption, and environmental impact—pervade conversations in science, politics, economics, and public policy.

With the exception of the energy from the Sun, most of the energy used in our daily lives comes from chemical reactions. The combustion of gasoline, the production of electricity from coal, the heating of homes by natural gas, and the use of batteries to power electronic devices are all examples of how chemical reactions are used to produce energy. But that's only the beginning. Chemical reactions provide the energy that sustains living systems. Plants use solar energy to carry out photosynthesis, allowing them to grow. In the process, they store a portion of the Sun's energy in the chemical bonds of the molecules that are produced during photosynthesis. When animals eat and digest plants, they derive the energy needed to move, maintain body temperature, and carry out all other bodily functions from that same chemical energy.

In this chapter we begin to explore energy and its changes. We are motivated not only by the impact of energy on so many aspects of our daily lives but also because if we are to properly understand chemistry, we must understand the energy changes that accompany chemical reactions.

◀ **THERMITE REACTION.** The reaction between aluminum metal and iron oxide produces aluminum oxide and iron metal. It also generates enough heat to melt the iron metal formed in the reaction. The thermite reaction is a dramatic illustration of how potential energy stored in chemical bonds can be converted to heat.

## WHAT'S AHEAD

- 5.1 ▶ The Nature of Chemical Energy** Learn that chemical energy is a form of potential energy that arises largely from the electrostatic interactions of charged particles at the atomic level. Describe energy changes associated with chemical reactions by defining the reactants and products as the *system* and everything else in the universe as the *surroundings*.
- 5.2 ▶ The First Law of Thermodynamics** Explore the *first law of thermodynamics*, which states that energy cannot be created or destroyed but can be transformed from one form to another or transferred between systems and surroundings. The energy possessed by a system is called its *internal energy*. Internal energy is a *state function*, a quantity whose value depends only on the current state of a system, not on how the system came to be in that state.
- 5.3 ▶ Enthalpy** Define a state function called *enthalpy* that is useful because the change in enthalpy measures the quantity of heat energy gained or lost by a system in a process occurring under constant pressure.
- 5.4 ▶ Enthalpies of Reaction** Discover that the enthalpy change associated with a given chemical reaction is equal to the enthalpies of the products minus the enthalpies of the reactants. This quantity is directly proportional to the amount of reactant consumed in the reaction.
- 5.5 ▶ Calorimetry** Examine *calorimetry*, an experimental technique used to measure heat changes in chemical processes.
- 5.6 ▶ Hess's Law** Learn that the enthalpy change for a given reaction can be calculated using appropriate enthalpy changes for related reactions. To do so, we apply *Hess's law*.
- 5.7 ▶ Enthalpies of Formation** Establish standard values for enthalpy changes in chemical reactions and use them to calculate enthalpy changes for reactions.
- 5.8 ▶ Bond Enthalpies** Use average bond enthalpies to estimate gas-phase reaction enthalpies.
- 5.9 ▶ Foods and Fuels** Examine foods and fuels as sources of energy and discuss some related health and social issues.

The study of energy and its transformations is known as **thermodynamics** (Greek: *thérme*-, “heat”; *dy’namis*, “power”). This area of study began during the Industrial Revolution in order to develop the relationships among heat, work, and fuels in steam engines. Here we will examine the relationships between chemical reactions and energy changes that involve heat. This portion of thermodynamics is called **thermochemistry**. We will discuss additional aspects of thermodynamics in Chapter 19.

## 5.1 | The Nature of Chemical Energy

As we learned in Chapter 1 (Section 1.4), energy is defined as the capacity to do work or transfer heat. Anyone who has sat by a fire or used a propane grill has witnessed chemical reactions that release heat [Figure 5.1(a)]. Some chemical reactions also absorb heat, such as those that occur when you cook. Chemical reactions can also do work in various ways. Recall the definition of work from Chapter 1:

$$w = F \times d \quad [5.1]$$

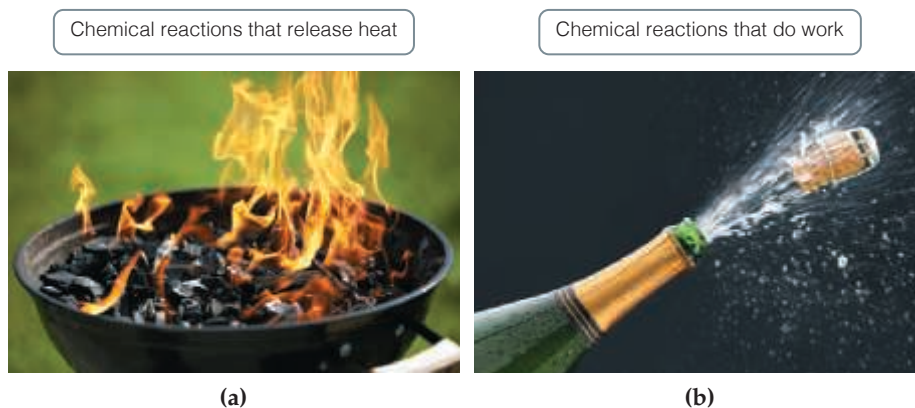

For example, the combustion reaction between gasoline and oxygen produces gases that expand and in the process do work that can be used to power an automobile. Champagne is made when yeasts use chemical reactions to ferment sugars into ethanol and carbon dioxide. By carrying out the last stages of fermentation in a corked bottle, pressure from the generated  $\text{CO}_2$  builds up and can be used to do work when the cork is popped [Figure 5.1(b)]. Yet another example is a battery, where redox reactions produce electrical energy that can be used to do work.

All forms of energy can be classified as either kinetic or potential energy  $\infty$  (Section 1.4). The energy that originates from chemical reactions is associated mainly with changes in potential energy. This energy results from electrostatic interactions at the atomic level. Thus, if we are to understand the energy associated with chemical reactions, we must first understand electrostatic potential energy, which arises from the interactions between charged particles.

The electrostatic potential energy,  $E_{\text{el}}$ , associated with two charged particles is proportional to their electrical charges,  $Q_1$  and  $Q_2$ , and is inversely proportional to the distance,  $d$ , separating them:

$$E_{\text{el}} = \frac{\kappa Q_1 Q_2}{d} \quad [5.2]$$

where  $\kappa$  is a proportionality constant whose value is  $8.99 \times 10^9 \text{ J}\cdot\text{m}/\text{C}^2$ .<sup>\*</sup> Recall from Chapter 1 that the units used to measure energy are joules, where  $1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2$ . At the

▲ **Figure 5.1** Chemical reactions and energy. Energy changes in chemical reactions can be used to transfer heat or do work.

<sup>\*</sup>We read the combined units  $\text{J}\cdot\text{m}/\text{C}^2$  as joule-meters per coulomb squared. You may see combinations of units such as  $\text{J}\cdot\text{m}/\text{C}^2$  expressed with dots separating units instead of short dashes,  $\text{J}\cdot\text{m}/\text{C}^2$ , or with dashes and dots totally absent,  $\text{J m}/\text{C}^2$ .

## Go Figure

A positively charged particle and a negatively charged particle are initially far apart. What happens to their electrostatic potential energy as they are brought closer together?

**Figure 5.2 Electrostatic potential energy.** At finite separation distances the electrostatic potential energy,  $E_{el}$ , is positive for objects with like charges, and negative for objects that are oppositely charged. As the particles move farther apart, their electrostatic potential energy approaches zero.

atomic level, the charges  $Q_1$  and  $Q_2$  are typically on the order of magnitude of the charge of an electron ( $1.60 \times 10^{-19}$  C), while distances range from tenths to tens of nanometers ( $1 \text{ nm} = 1 \times 10^{-9} \text{ m}$ ).

Inspection of Equation 5.2 shows that electrostatic potential energy goes to zero as  $d$  becomes infinite. Thus, zero electrostatic potential energy is defined as infinite separation of the charged particles. **Figure 5.2** illustrates how  $E_{el}$  behaves as the distance between two charges is varied. When  $Q_1$  and  $Q_2$  have the same sign (for example, both are positive), the two charged particles repel each other, and a repulsive force pushes them apart. In order to bring two positively charged objects close together, one would have to do work to overcome the repulsive force that exists between the two. Upon releasing them, they would move away from each other as potential energy is converted to kinetic energy. In this case,  $E_{el}$  is positive, and the potential energy decreases as the distance between particles increases. When  $Q_1$  and  $Q_2$  have opposite signs, the particles attract each other, and an attractive force pulls them toward each other. In this case  $E_{el}$  is negative, and the potential energy increases (becomes less negative) as the particles move apart.

To understand the relationship between electrostatic potential energy and the energy stored in chemical bonds, it is instructive to consider an ionic compound like NaCl. The  $\text{Na}^+$  cations and  $\text{Cl}^-$  anions are held together by the electrostatic attraction between the oppositely charged ions. In chemistry we refer to this force as ionic bonding. We'll go into the details of ionic bonding in Chapter 8, but for now it is sufficient to understand that the ionic bonds that hold sodium and chloride ions together are based on the electrostatic attraction between cations and anions. To separate the ions, we must overcome, or break, the ionic bonds between  $\text{Na}^+$  and  $\text{Cl}^-$ , increasing the potential energy, as illustrated in **Figure 5.3**. The energy to do this must come from some other source. The reverse process where ions separated by a large distance are allowed to come together to

**Go Figure**

If the ions in the figure on the right were released and allowed to move, would they move closer together or farther apart?

**Figure 5.3 Electrostatic potential energy and ionic bonding.** As the separation between ions increases, the electrostatic potential energy increases (becomes less negative). As the distance separating the ions goes toward infinity, the electrostatic potential energy goes to zero. In real compounds, repulsions between core electrons place a lower limit on how closely the ions can approach each other.

form ionic bonds lowers the potential energy and therefore releases energy. This illustrates a fundamental principle of thermochemistry:

*Energy is released when chemical bonds are formed;  
energy is consumed when chemical bonds are broken.*

You may be wondering how these same principles apply to molecular substances such as water,  $\text{H}_2\text{O}$ , and methane,  $\text{CH}_4$ , that do not contain cations and anions. As we will learn in Chapters 8 and 9, the atoms in a molecule are held together by covalent bonds. While the link to electrostatic potential energy is less obvious, the forces that underlie covalent bonds are also electrostatic in nature. Just like ionic bonds, energy must be provided to break covalent bonds and is released when they form.

## 5.2 | The First Law of Thermodynamics

Energy comes in many different forms, including kinetic energy, which we encountered in Chapter 1, and various types of potential energy. You don't have to look far to find processes that involve conversions from one form of energy to another. Dropping a stone down a deep well converts gravitational potential energy into kinetic energy. Heating your house by reacting natural gas with oxygen converts chemical energy into heat. In both cases—and every other one you can imagine—*energy can be converted from one form to another, but it is neither created nor destroyed*. This observation, one of the most important in all of science, is known as the **first law of thermodynamics**. To apply this law quantitatively we need to divide the universe into a finite system of interest to us, and define the energy of that system more precisely. We explore these concepts next.

### System and Surroundings

When analyzing energy changes, we need to focus on a limited and well-defined part of the universe to keep track of the energy changes that occur. The portion we single out for study is called the **system**; everything else is called the **surroundings**. When we study the energy

change that accompanies a chemical reaction in a laboratory, the reactants and products constitute the system. The container and everything beyond it are considered the surroundings.

Systems may be open, closed, or isolated. An *open* system is one in which matter and energy can be exchanged with the surroundings. An uncovered pot of boiling water on a stove is an open system: Heat comes into the system from the stove, and water is released to the surroundings as steam.

The systems we can most readily study in thermochemistry are called *closed systems*—systems that can exchange energy but not matter with their surroundings. For example, consider a mixture of hydrogen gas,  $\text{H}_2$ , and oxygen gas,  $\text{O}_2$ , in a cylinder fitted with a piston (Figure 5.4). The system is just the hydrogen and oxygen; the cylinder, piston, and everything beyond them (including us) are the surroundings. If the gases react to form water, energy is liberated:

Although the chemical form of the hydrogen and oxygen atoms in the system is changed by this reaction, the system has not lost or gained mass, which means it has not exchanged any matter with its surroundings. However, it can exchange energy with its surroundings in the form of *work* and *heat*.

An *isolated* system is one in which neither energy nor matter can be exchanged with the surroundings. An insulated thermos containing hot coffee approximates an isolated system. We know, however, that the coffee eventually cools, so it is not perfectly isolated.

### Give It Some Thought

Is a human being an isolated, closed, or open system?

## Internal Energy

The **internal energy**,  $E$ , of a system is the sum of *all* the kinetic and potential energies of the components of the system. For the system in Figure 5.4, for example, the internal energy includes not only the motions and interactions of the  $\text{H}_2$  and  $\text{O}_2$  molecules but also the motions and interactions of their component nuclei and electrons. We generally do not know the numerical value of a system's internal energy. In thermodynamics, we are mainly concerned with the *change* in  $E$  (and, as we shall see, changes in other quantities as well) that accompanies a change in the system.

Imagine that we start with a system with an initial internal energy  $E_{\text{initial}}$ . The system then undergoes a change, which might involve work being done or heat being transferred. After the change, the final internal energy of the system is  $E_{\text{final}}$ . We define the *change* in internal energy, denoted  $\Delta E$  (read “delta E”),\* as the difference between  $E_{\text{final}}$  and  $E_{\text{initial}}$ :

$$\Delta E = E_{\text{final}} - E_{\text{initial}} \quad [5.3]$$

We generally cannot determine the actual values of  $E_{\text{final}}$  and  $E_{\text{initial}}$  for any system of practical interest. Nevertheless, we can determine the value of  $\Delta E$  experimentally by applying the first law of thermodynamics.

Thermodynamic quantities such as  $\Delta E$  have three parts:

1. a number
2. a unit
3. a sign

(1) and (2) together give the magnitude of the change, while (3) gives the direction. A *positive* value of  $\Delta E$  results when  $E_{\text{final}} > E_{\text{initial}}$ , indicating that the system has gained energy from its surroundings. A *negative* value of  $\Delta E$  results when  $E_{\text{final}} < E_{\text{initial}}$ , indicating that the system has lost energy to its surroundings. Notice that we are taking the point of view of the system rather than that of the surroundings in discussing the energy

### Go Figure

If the  $\text{H}_2$  and  $\text{O}_2$  molecules in the cylinder react to form  $\text{H}_2\text{O}$ , will the number of molecules in the cylinder change? Will the mass in the cylinder change?

Energy can enter or leave system as heat or as work done on piston.

▲ Figure 5.4 A closed system.

\*The symbol  $\Delta$  is commonly used to denote *change*. For example, a change in height,  $h$ , can be represented by  $\Delta h$ .

## Go Figure

What is the value of  $\Delta E$  if  $E_{\text{final}}$  equals  $E_{\text{initial}}$ ?

▲ Figure 5.5 Changes in internal energy.

## Go Figure

Sketch the energy diagram representing the reaction  $\text{MgCl}_2(\text{s}) \longrightarrow \text{Mg}(\text{s}) + \text{Cl}_2(\text{g})$  knowing that the internal energy for a mixture of  $\text{Mg}(\text{s})$  and  $\text{Cl}_2(\text{g})$  is larger than that of  $\text{MgCl}_2(\text{s})$ .

▲ Figure 5.6 Energy diagram for the reaction  $2 \text{H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{H}_2\text{O}(\text{l})$ .

changes. We need to remember, however, that any increase in the energy of the system is accompanied by a decrease in the energy of the surroundings, and vice versa. These features of energy changes are summarized in Figure 5.5.

In a chemical reaction, the initial state of the system refers to the reactants and the final state refers to the products. In the reaction

for instance, the initial state is  $2 \text{H}_2(\text{g}) + \text{O}_2(\text{g})$  and the final state is  $2 \text{H}_2\text{O}(\text{l})$ . When hydrogen and oxygen form water at a given temperature, the system loses energy to the surroundings. Because energy is lost from the system, the internal energy of the products (final state) is less than that of the reactants (initial state), and  $\Delta E$  for the process is negative. Thus, the energy diagram in Figure 5.6 shows that the internal energy of the mixture of  $\text{H}_2$  and  $\text{O}_2$  is greater than that of the  $\text{H}_2\text{O}$  produced in the reaction.

Relating  $\Delta E$  to Heat and Work

As we noted in Section 5.1, a system may exchange energy with its surroundings in two general ways: as heat or as work. The internal energy of a system changes in magnitude as heat is added to or removed from the system or as work is done on or by the system. If we think of internal energy as the system's bank account of energy, we see that deposits or withdrawals can be made in the form of either heat or work. Deposits increase the energy of the system (positive  $\Delta E$ ), whereas withdrawals decrease the energy of the system (negative  $\Delta E$ ).

We can use these ideas to write a useful algebraic expression of the first law of thermodynamics. When a system undergoes any chemical or physical change, the accompanying change in internal energy,  $\Delta E$ , is the sum of the heat added to or liberated from the system,  $q$ , and the work done on or by the system,  $w$ :

$$\Delta E = q + w \quad [5.4]$$

When heat is added to a system or work is done on a system, its internal energy increases. Therefore, when heat is transferred to the system from the surroundings,  $q$  has a positive value. Adding heat to the system is like making a deposit to the energy account—the energy of the system increases (Figure 5.7). Likewise, when work is done on the system by the surroundings,  $w$  has a positive value. Conversely, both the heat lost by the system to the surroundings and the work done by the system on the surroundings have negative values; that is, they lower the internal energy of the system. They are energy withdrawals and lower the amount of energy in the system's account.

## Go Figure

Suppose a system receives a “deposit” of 50 J of work from the surroundings and loses a “withdrawal” of 85 J of heat to the surroundings. What is the magnitude and the sign of  $\Delta E$  for this process?

▲ **Figure 5.7** Sign conventions for heat and work. Heat,  $q$ , transferred into a system and work,  $w$ , done on a system are both positive quantities, corresponding to “deposits” of internal energy into the system. Conversely, heat transferred out of a system to the surroundings and work done by the system on the surroundings are both “withdrawals” of internal energy from the system.

The sign conventions for  $q$ ,  $w$ , and  $\Delta E$  are summarized in **Table 5.1**. Notice that any energy entering the system as either heat or work carries a positive sign.

**TABLE 5.1** Sign Conventions for  $q$ ,  $w$ , and  $\Delta E$

|                |   |   |
|----------------|---|---|
| For $q$        | + means system <i>gains</i> heat            | – means system <i>loses</i> heat            |
| For $w$        | + means work done <i>on</i> system          | – means work done <i>by</i> system          |
| For $\Delta E$ | + means <i>net gain</i> of energy by system | – means <i>net loss</i> of energy by system |

## Sample Exercise 5.1

## Relating Heat and Work to Changes of Internal Energy

Gases  $A(g)$  and  $B(g)$  are confined in a cylinder-and-piston arrangement like that in Figure 5.4 and react to form a solid product  $C(s)$ :  $A(g) + B(g) \longrightarrow C(s)$ . As the reaction occurs, the system loses 1150 J of heat to the surroundings. The piston moves downward as the gases react to form a solid. As the volume of the gas decreases under the constant pressure of the atmosphere, the surroundings do 480 J of work on the system. What is the change in the internal energy of the system?

**SOLUTION**

**Analyze** The question asks us to determine  $\Delta E$ , given information about  $q$  and  $w$ .

**Plan** We first determine the signs of  $q$  and  $w$  (Table 5.1) and then use Equation 5.4,  $\Delta E = q + w$ , to calculate  $\Delta E$ .

*Continued*

**Solve** Heat is transferred from the system to the surroundings, and work is done on the system by the surroundings, so  $q$  is negative and  $w$  is positive:  $q = -1150\text{ J}$  and  $w = 480\text{ J}$ . Thus,

$$\Delta E = q + w = (-1150\text{ J}) + (480\text{ J}) = -670\text{ J}$$

The negative value of  $\Delta E$  tells us that a net quantity of 670 J of energy has been transferred from the system to the surroundings.

**Comment** You can think of this change as a decrease of 670 J in the net value of the system's energy bank account (hence, the negative sign); 1150 J is withdrawn in the form of heat, while 480 J is deposited in the form of work. Notice that as the volume of the gases decreases, work is being done *on* the system *by* the surroundings, resulting in a deposit of energy.

### ► Practice Exercise 1

A mixture of gases  $A_2$  and  $B_2$  are introduced to a slender metal cylinder that has one end closed and the other fitted with a

piston that makes a gas-tight seal so that the gases are a closed system. The cylinder is submerged in a large beaker of water whose temperature is  $25^\circ\text{C}$ , and a spark is used to trigger a reaction in the cylinder. At the completion of the reaction, the piston has moved downward, and the temperature of the water bath has increased to  $28^\circ\text{C}$ . If we define the system as the gases inside the cylinder, which of the following best describes the signs of  $q$ ,  $w$ , and  $\Delta E$  for this reaction?

- (a)  $q < 0$ ,  $w < 0$ ,  $\Delta E < 0$
- (b)  $q < 0$ ,  $w > 0$ ,  $\Delta E < 0$
- (c)  $q < 0$ ,  $w > 0$ , the sign of  $\Delta E$  cannot be determined from the information given
- (d)  $q > 0$ ,  $w > 0$ ,  $\Delta E > 0$
- (e)  $q > 0$ ,  $w < 0$ , the sign of  $\Delta E$  cannot be determined from the information given

### ► Practice Exercise 2

Calculate the change in the internal energy for a process in which a system absorbs 140 J of heat from the surroundings and does 85 J of work on the surroundings.

## Endothermic and Exothermic Processes

Because transfer of heat to and from the system is central to our discussion in this chapter, we have some special terminology to indicate the direction of transfer. When a process occurs in which the system absorbs heat, the process is called **endothermic** (*endo-* means “into”). During an endothermic process, such as the melting of ice, heat flows *into* the system from its surroundings [Figure 5.8(a)]. If we, as part of the surroundings, touch a container in which ice is melting, the container feels cold to us because heat has passed from our hand to the container.

A process in which the system loses heat is called **exothermic** (*exo-* means “out of”). During an exothermic process, such as the combustion of gasoline, heat *exits* or flows *out* of the system into the surroundings [Figure 5.8(b)].

### Give It Some Thought

When  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$  react to form  $\text{H}_2\text{O}(\text{l})$ , heat is released to the surroundings. Consider the reverse reaction, namely, the formation of  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$  from  $\text{H}_2\text{O}(\text{l})$ :  $2\text{H}_2\text{O}(\text{l}) \rightarrow 2\text{H}_2(\text{g}) + \text{O}_2(\text{g})$ . Is this reaction exothermic or endothermic? (*Hint:* Refer to Figure 5.6.)

## State Functions

Although we usually have no way of knowing the precise value of the internal energy of a system,  $E$ , it does have a fixed value for a given set of conditions. The conditions that influence internal energy include the temperature and pressure. Furthermore, the internal energy of a system is proportional to the total quantity of matter in the system because energy is an extensive property.  $\infty$ (Section 1.3)

Suppose we define our system as 50 g of water at  $25^\circ\text{C}$  (Figure 5.9). The system could have reached this state by cooling 50 g of water from  $100$  to  $25^\circ\text{C}$  or by melting 50 g of ice and subsequently warming the water to  $25^\circ\text{C}$ . The internal energy of the water at  $25^\circ\text{C}$  is the same in either case. Internal energy is an example of a **state function**, a property of a system that is determined by specifying the system's condition, or state (in terms of temperature, pressure, and so forth). *The value of a state function depends only on the present state of the system, not on the path the system took to reach that state.* Because  $E$  is a state function,  $\Delta E$  depends only on the initial and final states of the system, not on how the change occurs.

System =  $\text{NH}_4\text{SCN} + \text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Heat flows from surroundings into system, temperature of beaker and surrounding air drops.

System =  $\text{K} + \text{H}_2\text{O}$

Heat flows (violently) from system into surroundings, temperature of the water and surrounding air increases.

◀ **Figure 5.8** Endothermic and exothermic reactions. In both instances, the system is defined as the reactants and products, while surroundings are the containers and everything else in the universe.

▲ **Figure 5.9** Internal energy,  $E$ , a state function. Any state function depends only on the present state of the system and not on the path by which the system arrived at that state.

### Go Figure

If the battery is defined as the system, what is the sign on  $w$  in part (b)?

▲ **Figure 5.10** Internal energy is a state function, but heat and work are not. (a) A battery shorted out by a wire loses energy to the surroundings only as heat; no work is performed. (b) A battery discharged through a motor loses energy as work (to make the fan turn) and also loses some energy as heat. The value of  $\Delta E$  is the same for both processes even though the values of  $q$  and  $w$  in (a) are different from those in (b).

An analogy may help you understand the difference between quantities that are state functions and those that are not. Suppose you drive from Chicago, which is 596 ft above sea level, to Denver, which is 5280 ft above sea level. No matter which route you take, the altitude change is 4684 ft. The distance you travel, however, depends on your route. Altitude is analogous to a state function because the change in altitude is independent of the path taken. Distance traveled is not a state function.

Some thermodynamic quantities, such as  $E$ , are state functions. Other quantities, such as  $q$  and  $w$ , are not. This means that, although  $\Delta E = q + w$  does not depend on how the change occurs, the specific amounts of heat and work depend on the way in which the change occurs. Thus, if changing the path by which a system goes from an initial state to a final state increases the value of  $q$ , that path change will also decrease the value of  $w$  by exactly the same amount. The result is that  $\Delta E$  is the same for the two paths.

We can illustrate this principle using a flashlight battery as our system. As the battery is discharged, its internal energy decreases as the energy stored in the battery is released to the surroundings. In Figure 5.10, we consider two possible ways of discharging the battery at constant temperature. In Figure 5.10(a), a wire shorts out the battery and no work is accomplished because nothing is moved against a force. All the energy lost from the battery is in the form of heat. (The wire gets warmer and releases heat to the surroundings.) In Figure 5.10(b), the battery is used to make a motor turn and the discharge produces work. Some heat is released, but not as much as when the battery is shorted out. We see that the magnitudes of  $q$  and  $w$  must be different for these two cases. If the initial and final states of the battery are identical in the two cases, however, then  $\Delta E = q + w$  must be the same in both cases because  $E$  is a state function. *Remember:  $\Delta E$  depends only on the initial and final states of the system, not on the specific path taken from the initial to the final state.*

### Give It Some Thought

You lose 5 pounds over a 30-day period. Which of the following quantities act like a state function: the amount of calories you consume, your weight, or the number of calories burned through exercise?

## 5.3 | Enthalpy

The chemical and physical changes that occur around us, such as photosynthesis in the leaves of a plant, evaporation of water from a lake, or a reaction in an open beaker in a laboratory, occur under the essentially constant pressure of Earth's atmosphere.\* These changes can result in the release or absorption of heat and can be accompanied by work done by or on the system. In exploring these changes, it is useful to have a thermodynamic function that is a state function and relates mainly to heat flow. Under conditions of constant pressure, a thermodynamic quantity called *enthalpy* (from the Greek *enthalpein*, "to warm") provides such a function.

**Enthalpy**, which we denote by the symbol  $H$ , is defined as the internal energy plus the product of the *pressure*,  $P$ , and *volume*,  $V$ , of the system:

$$H = E + PV \quad [5.5]$$

Like internal energy  $E$ , both  $P$  and  $V$  are state functions—they depend only on the current state of the system and not on the path taken to that state. Because energy, pressure, and volume are all state functions, enthalpy is also a state function.

### Pressure–Volume Work

To better understand the significance of enthalpy, recall from Equation 5.4 that  $\Delta E$  involves not only the heat  $q$  added to or removed from the system but also the work  $w$  done

\*You are probably familiar with the notion of atmospheric pressure from a previous course in chemistry. We will discuss it in detail in Chapter 10. Here we need realize only that the atmosphere exerts a pressure on the surface of Earth that is nearly constant.

## Go Figure

If we define the system as the reactants and products, what is the sign of work in this process, positive or negative?

▲ **Figure 5.11** A system that does work on its surroundings.

by or on the system. Most commonly, the only kind of work produced by chemical or physical changes open to the atmosphere is the mechanical work associated with a change in volume. For example, when the reaction of zinc metal with hydrochloric acid solution

is run at constant pressure in the apparatus illustrated in **Figure 5.11**, the piston moves up or down to maintain a constant pressure in the vessel. If we assume for simplicity that the piston has no mass, the pressure in the apparatus is the same as atmospheric pressure. As the reaction proceeds,  $\text{H}_2$  gas forms, and the piston rises. The gas within the flask is thus doing work on the surroundings by lifting the piston against the force of atmospheric pressure.

The work involved in the expansion or compression of gases is called **pressure-volume work** ( $P$ - $V$  work). When pressure is constant in a process, as in our preceding example, the sign and magnitude of the pressure-volume work are given by

$$w = -P \Delta V \quad [5.7]$$

where  $P$  is pressure and  $\Delta V = V_{\text{final}} - V_{\text{initial}}$  is the change in volume of the system. The pressure  $P$  is always either a positive number or zero. If the volume of the system expands, then  $\Delta V$  is positive as well. The negative sign in Equation 5.7 is necessary to conform to the sign convention for  $w$  (Table 5.1). When a gas expands, the system does work on the surroundings, as indicated by a negative value of  $w$ . (The negative sign  $\times$  positive  $P \times$  positive  $\Delta V$  results in a negative number for  $w$ .) On the other hand, if the gas is compressed,  $\Delta V$  is negative (the volume decreases), and Equation 5.7 indicates that  $w$  is therefore positive, meaning work is done on the system by the surroundings. The box “A Closer Look: Energy, Enthalpy, and  $P$ - $V$  Work” discusses pressure-volume work in detail, but all you need to keep in mind for now is Equation 5.7, which applies to processes occurring at constant pressure.

The units of work obtained by using Equation 5.7 will be those of pressure (usually atm) multiplied by those of volume (usually L). To express the work in the more familiar unit of joules, we use the conversion factor  $1 \text{ L}\cdot\text{atm} = 101.3 \text{ J}$ .

## Give It Some Thought

If a system does not change its volume during the course of a process, does it do pressure-volume work?

## Sample Exercise 5.2

## Calculating Pressure-Volume Work

A fuel is burned in a cylinder equipped with a piston. The initial volume of the cylinder is 0.250 L, and the final volume is 0.980 L. If the piston expands against a constant pressure of 1.35 atm, how much work (in J) is done? (1 L·atm = 101.3 J)

## SOLUTION

**Analyze** We are given an initial volume and a final volume from which we can calculate  $\Delta V$ . We are also given the pressure,  $P$ . We are asked to calculate work,  $w$ .

**Plan** The equation  $w = -P\Delta V$  allows us to calculate the work done by the system from the given information.

**Solve** The volume change is

$$\Delta V = V_{\text{final}} - V_{\text{initial}} = 0.980 \text{ L} - 0.250 \text{ L} = 0.730 \text{ L}$$

Thus, the quantity of work is

$$w = -P\Delta V = -(1.35 \text{ atm})(0.730 \text{ L}) = -0.9855 \text{ L}\cdot\text{atm}$$

Converting L·atm to J, we have

$$-(0.9855 \text{ L}\cdot\text{atm})\left(\frac{101.3 \text{ J}}{1 \text{ L}\cdot\text{atm}}\right) = -99.8 \text{ J}$$

**Check** The significant figures are correct (3), and the units are the requested ones for energy (J). The negative sign is consistent with an expanding gas doing work on its surroundings.

## Practice Exercise 1

If a balloon is expanded from 0.055 to 1.403 L against an external pressure of 1.02 atm, how many L·atm of work is done?

- (a)  $-0.056 \text{ L}\cdot\text{atm}$  (b)  $-1.37 \text{ L}\cdot\text{atm}$  (c)  $1.43 \text{ L}\cdot\text{atm}$  (d)  $1.49 \text{ L}\cdot\text{atm}$  (e)  $139 \text{ L}\cdot\text{atm}$

## Practice Exercise 2

Calculate the work, in J, if the volume of a system contracts from 1.55 to 0.85 L at a constant pressure of 0.985 atm.

Constant pressure  
maintained in system

(a) An endothermic reaction

(b) An exothermic reaction

$\Delta H$  is amount of heat that  
flows into or out of system  
under constant pressure.

**Figure 5.12** Endothermic and exothermic processes. (a) An endothermic process ( $\Delta H > 0$ ) deposits heat into the system. (b) An exothermic process ( $\Delta H < 0$ ) withdraws heat from the system.

## Enthalpy Change

Let's now return to our discussion of enthalpy. When a change occurs at constant pressure, the change in enthalpy,  $\Delta H$ , is given by the relationship

$$\begin{aligned}\Delta H &= \Delta(E + PV) \\ &= \Delta E + P\Delta V \quad (\text{constant pressure})\end{aligned}\quad [5.8]$$

That is, the change in enthalpy equals the change in internal energy plus the product of the constant pressure and the change in volume.

Recall that  $\Delta E = q + w$  (Equation 5.4) and that the work involved in the expansion or compression of a gas is  $w = -P\Delta V$  (at constant pressure). Substituting  $-w$  for  $P\Delta V$  and  $q + w$  for  $\Delta E$  into Equation 5.8, we have

$$\Delta H = \Delta E + P\Delta V = (q_p + w) - w = q_p \quad [5.9]$$

The subscript  $P$  on  $q$  indicates that the process occurs at constant pressure. Thus, the equations show:

*The change in enthalpy equals the heat  $q_p$  gained or lost at constant pressure.*

Because  $q_p$  is something we can either measure or calculate and because so many physical and chemical changes of interest to us occur at constant pressure, enthalpy is a more useful function for most reactions than is internal energy. In addition, for most reactions the difference in  $\Delta H$  and  $\Delta E$  is small because  $P\Delta V$  is small.

When  $\Delta H$  is positive (that is, when  $q_p$  is positive), the system has gained heat from the surroundings (Table 5.1), which means the process is endothermic. When  $\Delta H$  is negative, the system has released heat to the surroundings, which means the process is exothermic. To continue the bank analogy of Figure 5.7, under constant pressure, an endothermic process deposits energy in the system in the form of heat and an exothermic process withdraws energy in the form of heat (Figure 5.12).

## Give It Some Thought

When a reaction occurs in a flask, you notice that the flask gets colder. What is the sign of  $\Delta H$ ?

Because  $H$  is a state function,  $\Delta H$  (which equals  $q_p$ ) depends only on the initial and final states of the system, not on how the change occurs. At first glance this statement

might seem to contradict our discussion in Section 5.2, in which we said that  $q$  is *not* a state function. There is no contradiction, however, because the relationship between  $\Delta H$  and  $q_p$  has special limitations that only  $P$ - $V$  work is involved and that the pressure is constant.

### Sample Exercise 5.3

#### Determining the Sign of $\Delta H$

Indicate the sign of the enthalpy change,  $\Delta H$ , in the following processes carried out under atmospheric pressure and indicate whether each process is endothermic or exothermic: **(a)** An ice cube melts; **(b)** 1 g of butane ( $\text{C}_4\text{H}_{10}$ ) is combusted in sufficient oxygen to give complete combustion to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

#### SOLUTION

**Analyze** Our goal is to determine whether  $\Delta H$  is positive or negative for each process. Because each process occurs at constant pressure, the enthalpy change equals the quantity of heat absorbed or released,  $\Delta H = q_p$ .

**Plan** We must predict whether heat is absorbed or released by the system in each process. Processes in which heat is absorbed are endothermic and have a positive sign for  $\Delta H$ ; those in which heat is released are exothermic and have a negative sign for  $\Delta H$ .

**Solve** In (a) the water that makes up the ice cube is the system. The ice cube absorbs heat from the surroundings as it melts, so  $\Delta H$  is positive and the process is endothermic. In (b) the system is the 1 g of butane and the oxygen required to combust it. The

combustion of butane in oxygen gives off heat, so  $\Delta H$  is negative and the process is exothermic.

#### Practice Exercise 1

A chemical reaction that gives off heat to its surroundings is said to be \_\_\_\_\_ and has a \_\_\_\_\_ value of  $\Delta H$ .

- (a) endothermic, positive    (b) endothermic, negative  
(c) exothermic, positive    (d) exothermic, negative

#### Practice Exercise 2

Molten gold poured into a mold solidifies at atmospheric pressure. With the gold defined as the system, is the solidification an exothermic or endothermic process?

## A CLOSER LOOK Energy, Enthalpy, and $P$ - $V$ Work

In chemistry we are interested mainly in two types of work: electrical work and mechanical work done by expanding gases. We focus here on the latter, called pressure-volume, or  $P$ - $V$ , work. Expanding gases in the cylinder of an automobile engine do  $P$ - $V$  work on the piston; this work eventually turns the wheels. Expanding gases from an open reaction vessel do  $P$ - $V$  work on the atmosphere. This work accomplishes nothing in a practical sense, but we must keep track of all work, useful or not, when monitoring energy changes in a system.

Let's consider a gas confined to a cylinder with a movable piston of cross-sectional area  $A$  (Figure 5.13). A downward force  $F$  acts on the piston. The pressure,  $P$ , on the gas is the force per area:  $P = F/A$ .

We assume that the piston is massless and that the only pressure acting on it is the *atmospheric pressure* that is due to Earth's atmosphere, which we assume to be constant.

Suppose the gas expands and the piston moves a distance  $\Delta h$ . From Equation 5.1, the magnitude of the work done by the system is

$$\text{Magnitude of work} = \text{force} \times \text{distance} = F \times \Delta h \quad [5.10]$$

We can rearrange the definition of pressure,  $P = F/A$ , to  $F = P \times A$ . The volume change,  $\Delta V$ , resulting from the movement of the piston is the product of the cross-sectional area of the piston and the distance it moves:  $\Delta V = A \times \Delta h$ . Substituting into Equation 5.10 gives

$$\begin{aligned} \text{Magnitude of work} &= F \times \Delta h = P \times A \times \Delta h \\ &= P \times \Delta V \end{aligned}$$

Because the system (the confined gas) does work on the surroundings, the work is a negative quantity:

$$w = -P\Delta V \quad [5.11]$$

Now, if  $P$ - $V$  work is the only work that can be done, we can substitute Equation 5.11 into Equation 5.4 to give

$$\Delta E = q + w = q - P\Delta V \quad [5.12]$$

When a reaction is carried out in a constant-volume container ( $\Delta V = 0$ ), the heat transferred equals the change in internal energy:

$$\Delta E = q - P\Delta V = q - P(0) = q_V \quad (\text{constant volume}) \quad [5.13]$$

The subscript  $V$  indicates that the volume is constant.

Most reactions are run under constant pressure, so that Equation 5.12 becomes

$$\begin{aligned} \Delta E &= q_p - P\Delta V \\ q_p &= \Delta E + P\Delta V \quad (\text{constant pressure}) \quad [5.14] \end{aligned}$$

We see from Equation 5.8 that the right side of Equation 5.14 is the enthalpy change under constant-pressure conditions. Thus,  $\Delta H = q_p$ , as we saw in Equation 5.9.

▲ **Figure 5.13** Pressure-volume work. The amount of work done by the system on the surroundings is  $w = -P\Delta V$ .

*Continued*

In summary, the change in internal energy is equal to the heat gained or lost at constant volume, and the change in enthalpy is equal to the heat gained or lost at constant pressure. The difference between  $\Delta E$  and  $\Delta H$  is the amount of  $P$ - $V$  work done by the system when the process occurs at constant pressure,  $-P\Delta V$ . The vol-

ume change accompanying many reactions is close to zero, which makes  $P\Delta V$  and, therefore, the difference between  $\Delta E$  and  $\Delta H$  small. Under most circumstances, it is generally satisfactory to use  $\Delta H$  as the measure of energy changes during most chemical processes.

**Related Exercises:** 5.35–5.38

## 5.4 | Enthalpies of Reaction

Because  $\Delta H = H_{\text{final}} - H_{\text{initial}}$ , the enthalpy change for a chemical reaction is given by

$$\Delta H = H_{\text{products}} - H_{\text{reactants}} \quad [5.15]$$

The enthalpy change that accompanies a reaction is called either the **enthalpy of reaction** or the *heat of reaction* and is sometimes written  $\Delta H_{\text{rxn}}$ , where “rxn” is a commonly used abbreviation for “reaction.”

When we give a numerical value for  $\Delta H_{\text{rxn}}$ , we must specify the reaction involved. For example, when 2 mol  $\text{H}_2(\text{g})$  burn to form 2 mol  $\text{H}_2\text{O}(\text{g})$  at a constant pressure, the system releases 483.6 kJ of heat. We can summarize this information as

The negative sign for  $\Delta H$  tells us that this reaction is exothermic. Notice that  $\Delta H$  is reported at the end of the balanced equation, without explicitly specifying the amounts of chemicals involved. In such cases the coefficients in the balanced equation represent the number of moles of reactants and products producing the associated enthalpy change. Balanced chemical equations that show the associated enthalpy change in this way are called *thermochemical equations*.

The exothermic nature of this reaction is also shown in the *enthalpy diagram* in Figure 5.14. Notice that the enthalpy of the reactants is greater (more positive) than the enthalpy of the products. Thus,  $\Delta H = H_{\text{products}} - H_{\text{reactants}}$  is negative.

### Give It Some Thought

If the reaction to form water were written  $\text{H}_2(\text{g}) + \frac{1}{2}\text{O}_2(\text{g}) \longrightarrow \text{H}_2\text{O}(\text{g})$ , would you expect the same value of  $\Delta H$  as in Equation 5.16? Why or why not?

► **Figure 5.14** Exothermic reaction of hydrogen with oxygen. When a mixture of  $\text{H}_2(\text{g})$  and  $\text{O}_2(\text{g})$  is ignited to form  $\text{H}_2\text{O}(\text{g})$ , the resultant explosion produces a ball of flame. Because the system releases heat to the surroundings, the reaction is exothermic as indicated in the enthalpy diagram.

The following guidelines are helpful when using thermochemical equations and enthalpy diagrams:

- 1. Enthalpy is an extensive property.** The magnitude of  $\Delta H$  is proportional to the amount of reactant consumed in the process. For example, 890 kJ of heat is produced when 1 mol of  $\text{CH}_4$  is burned in a constant-pressure system:

Because the combustion of 1 mol of  $\text{CH}_4$  with 2 mol of  $\text{O}_2$  releases 890 kJ of heat, the combustion of 2 mol of  $\text{CH}_4$  with 4 mol of  $\text{O}_2$  releases twice as much heat, 1780 kJ. Although chemical equations are usually written with whole-number coefficients, thermochemical equations sometimes utilize fractions, as in the preceding Give It Some Thought question.

- 2. The enthalpy change for a reaction is equal in magnitude, but opposite in sign, to  $\Delta H$  for the reverse reaction.** For example,  $\Delta H$  for the reverse of Equation 5.17 is +890 kJ:

When we reverse a reaction, we reverse the roles of the products and the reactants. From Equation 5.15, we see that reversing the products and reactants leads to the same magnitude of  $\Delta H$ , but a change in sign (Figure 5.15).

- 3. The enthalpy change for a reaction depends on the states of the reactants and products.** If the product in Equation 5.17 were  $\text{H}_2\text{O}(\text{g})$  instead of  $\text{H}_2\text{O}(\text{l})$ ,  $\Delta H_{\text{rxn}}$  would be -802 kJ instead of -890 kJ. Less heat would be available for transfer to the surroundings because the enthalpy of  $\text{H}_2\text{O}(\text{g})$  is greater than that of  $\text{H}_2\text{O}(\text{l})$ . One way to see this is to imagine that the product is initially liquid water. The liquid water must be converted to water vapor, and the conversion of 2 mol  $\text{H}_2\text{O}(\text{l})$  to 2 mol  $\text{H}_2\text{O}(\text{g})$  is an endothermic process that absorbs 88 kJ:

Thus, it is important to specify the states of the reactants and products in thermochemical equations. In addition, we will generally assume that the reactants and products are both at the same temperature, 25 °C, unless otherwise indicated.

▲ **Figure 5.15**  $\Delta H$  for a reverse reaction. Reversing a reaction changes the sign but not the magnitude of the enthalpy change:  $\Delta H_2 = -\Delta H_1$ .

## Sample Exercise 5.4

### Relating $\Delta H$ to Quantities of Reactants and Products

How much heat is released when 4.50 g of methane gas is burned in a constant-pressure system? (Use the information given in Equation 5.17.)

### SOLUTION

**Analyze** Our goal is to use a thermochemical equation to calculate the heat produced when a specific amount of methane gas is combusted. According to Equation 5.17, 890 kJ is released by the system when 1 mol  $\text{CH}_4$  is burned at constant pressure.

**Plan** Equation 5.17 provides us with a stoichiometric conversion factor: (1 mol  $\text{CH}_4 \approx -890 \text{ kJ}$ ). Thus, we can convert moles of  $\text{CH}_4$  to kJ of energy. First, however, we must convert grams of  $\text{CH}_4$  to moles of  $\text{CH}_4$ .

### Solve

The conversion sequence is:

By adding the atomic weights of C and 4 H, we have 1 mol  $\text{CH}_4 = 16.0 \text{ g CH}_4$ . We can use the appropriate conversion factors to convert grams of  $\text{CH}_4$  to moles of  $\text{CH}_4$  to kilojoules:

$$\text{Heat} = (4.50 \text{ g CH}_4) \left( \frac{1 \text{ mol CH}_4}{16.0 \text{ g CH}_4} \right) \left( \frac{-890 \text{ kJ}}{1 \text{ mol CH}_4} \right) = -250 \text{ kJ}$$

The negative sign indicates that the system released 250 kJ into the surroundings.

*Continued*

## ► Practice Exercise 1

The complete combustion of ethanol,  $\text{C}_2\text{H}_5\text{OH}$  (molar mass = 46.0 g/mol), proceeds as follows:

What is the enthalpy change for combustion of 15.0 g of ethanol?

(a)  $-12.1 \text{ kJ}$  (b)  $-181 \text{ kJ}$  (c)  $-422 \text{ kJ}$  (d)  $-555 \text{ kJ}$  (e)  $-1700 \text{ kJ}$

## ► Practice Exercise 2

Hydrogen peroxide can decompose to water and oxygen by the reaction

Calculate the quantity of heat released when 5.00 g of  $\text{H}_2\text{O}_2(l)$  decomposes at constant pressure.

## A CLOSER LOOK Using Enthalpy as a Guide

If you hold a brick in the air and let it go, you know what happens: It falls as the force of gravity pulls it toward Earth. A process that is thermodynamically favored to happen, such as a brick falling to the ground, is called a *spontaneous* process. A spontaneous process can be either fast or slow; the rate at which processes occur is not governed by thermodynamics.

Chemical processes can be thermodynamically favored, or spontaneous, too. By spontaneous, however, we do not mean that the reaction will form products without any intervention. That can be the case, but often some energy must be imparted to get the process started. Just as it is spontaneous for a rock to roll down the side of a hill once started, so too can it be spontaneous for chemical reactions to proceed once enough energy is imparted to initiate the reaction (Figure 5.16). The enthalpy change in a reaction gives one indication as to whether the reaction is likely to be spontaneous. The combustion of  $\text{H}_2(g)$  and  $\text{O}_2(g)$ , for example, is highly exothermic:

Hydrogen gas and oxygen gas can exist together in a volume indefinitely without noticeable reaction occurring. Once the reaction is initiated, however, energy is rapidly transferred from the system (the reactants) to the surroundings as heat. The system thus loses enthalpy by transferring the heat to the surroundings. (Recall that the first law of thermodynamics tells us that the total energy of the system plus the surroundings does not change; energy is conserved.)

Enthalpy change is not the only consideration in the spontaneity of reactions, nor is it a foolproof guide. For example, even though ice melting is an endothermic process,

this process is spontaneous at temperatures above the freezing point of water ( $0^\circ\text{C}$ ). The reverse process, water freezing, is spontaneous at

▲ **Figure 5.16 Exothermic reactions and spontaneity.** Chemical reactions that are highly exothermic ( $\Delta H$  much less than 0) usually occur spontaneously. Such reactions often need some input of energy to get started, just like it can take a push to get a boulder rolling down a hill to a spot of lower potential energy. However, once they get started, such reactions spontaneously proceed to form the products, which have lower potential energy.

temperatures below  $0^\circ\text{C}$ . Thus, we know that ice at room temperature melts and water put into a freezer at  $-20^\circ\text{C}$  turns into ice. Both processes are spontaneous under different conditions even though they are the reverse of one another. In Chapter 19, we will address the spontaneity of processes more fully. We will see why a process can be spontaneous at one temperature but not at another, as is the case for the conversion of water to ice.

Despite these complicating factors, you should pay attention to the enthalpy changes in reactions. As a general observation, when the enthalpy change is large, it is the dominant factor in determining spontaneity. Thus, reactions for which  $\Delta H$  is *large* (about 100 kJ or more) and *negative* tend to be spontaneous. Reactions for which  $\Delta H$  is *large* and *positive* tend to be spontaneous only in the reverse direction.

**Related Exercises:** 5.47, 5.48

In many situations, we will find it valuable to know the sign and magnitude of the enthalpy change associated with a given chemical process. As we see in the following sections,  $\Delta H$  can be either determined directly by experiment or calculated from known enthalpy changes of other reactions.

## 5.5 | Calorimetry

The value of  $\Delta H$  can be determined experimentally by measuring the heat flow accompanying a reaction at constant pressure. Typically, we can determine the magnitude of the heat flow by measuring the magnitude of the temperature change the heat flow produces. The measurement of heat flow is **calorimetry**; a device used to measure heat flow is a **calorimeter**.

## Heat Capacity and Specific Heat

The more heat an object gains, the hotter it gets. All substances change temperature when they are heated, but the magnitude of the temperature change produced by a given quantity of heat varies from substance to substance. The temperature change experienced by an object when it absorbs a certain amount of heat is determined by its **heat capacity**, denoted  $C$ . The heat capacity of an object is the amount of heat required to raise its temperature by 1 K (or 1 °C). The greater the heat capacity, the greater the heat required to produce a given increase in temperature.

For pure substances the heat capacity is usually given for a specified amount of the substance. The heat capacity of one mole of a substance is called its **molar heat capacity**,  $C_m$ . The heat capacity of one gram of a substance is called its *specific heat capacity*, or merely its **specific heat**,  $C_s$ . The specific heat,  $C_s$ , of a substance can be determined experimentally by measuring the temperature change,  $\Delta T$ , that a known mass  $m$  of the substance undergoes when it gains or loses a specific quantity of heat  $q$ :

$$\text{Specific heat} = \frac{(\text{quantity of heat transferred})}{(\text{grams of substance}) \times (\text{temperature change})}$$

$$C_s = \frac{q}{m \times \Delta T} \quad [5.20]$$

For example, 209 J is required to increase the temperature of 50.0 g of water by 1.00 K. Thus, the specific heat of water is

$$C_s = \frac{209 \text{ J}}{(50.0 \text{ g})(1.00 \text{ K})} = 4.18 \text{ J/g}\cdot\text{K}$$

Notice how the units combine in the calculation. A temperature change in kelvins is equal in magnitude to the temperature change in degrees Celsius:  $\Delta T$  in K =  $\Delta T$  in °C. (Section 1.5) Therefore, this specific heat for water can also be reported as 4.18 J/g·°C, where the unit is pronounced “Joules per gram-degree Celsius.”

Because the specific heat values for a given substance can vary slightly with temperature, the temperature is often precisely specified. The 4.18 J/g·K value we use here for water, for instance, is for water initially at 14.5 °C (Figure 5.17). Water’s specific heat at this temperature is used to define the calorie at the value given in Section 5.1: 1 cal = 4.184 J exactly.

When a sample absorbs heat (positive  $q$ ), its temperature increases (positive  $\Delta T$ ). Rearranging Equation 5.20, we get

$$q = C_s \times m \times \Delta T \quad [5.21]$$

Thus, we can calculate the quantity of heat a substance gains or loses by using its specific heat together with its measured mass and temperature change.

Table 5.2 lists the specific heats of several substances. Notice that the specific heat of liquid water is higher than those of the other substances listed. The high specific heat of water affects Earth’s climate because it makes the temperatures of the oceans relatively resistant to change.

### Give It Some Thought

Which substance in Table 5.2 undergoes the greatest temperature change when the same mass of each substance absorbs the same quantity of heat?

### Go Figure

Is the process shown in the figure endothermic or exothermic?

▲ Figure 5.17 Specific heat of water.

TABLE 5.2 Specific Heats of Some Substances at 298 K

| Elements           |                       | Compounds             |                       |
|--------------------|-----------------------|-----------------------|-----------------------|
| Substance          | Specific Heat (J/g·K) | Substance             | Specific Heat (J/g·K) |

## Sample Exercise 5.5

## Relating Heat, Temperature Change, and Heat Capacity

(a) How much heat is needed to warm 250 g of water (about 1 cup) from 22 °C (about room temperature) to 98 °C (near its boiling point)? (b) What is the molar heat capacity of water?

## SOLUTION

**Analyze** In part (a) we must find the quantity of heat ( $q$ ) needed to warm the water, given the mass of water ( $m$ ), its temperature change ( $\Delta T$ ), and its specific heat ( $C_s$ ). In part (b) we must calculate the molar heat capacity (heat capacity per mole,  $C_m$ ) of water from its specific heat (heat capacity per gram).

**Plan** (a) Given  $C_s$ ,  $m$ , and  $\Delta T$ , we can calculate the quantity of heat,  $q$ , using Equation 5.21. (b) We can use the molar mass of water and dimensional analysis to convert from heat capacity per gram to heat capacity per mole.

## Solve

(a) The water undergoes a temperature change of:

$$\Delta T = 98^\circ\text{C} - 22^\circ\text{C} = 76^\circ\text{C} = 76\text{ K}$$

Using Equation 5.21, we have:

$$\begin{aligned} q &= C_s \times m \times \Delta T \\ &= (4.18\text{ J/g}\cdot\text{K})(250\text{ g})(76\text{ K}) = 7.9 \times 10^4\text{ J} \end{aligned}$$

(b) The molar heat capacity is the heat capacity of one mole of substance. Using the atomic weights of hydrogen and oxygen, we have:

$$1\text{ mol H}_2\text{O} = 18.0\text{ g H}_2\text{O}$$

From the specific heat used in part (a), we have:

$$C_m = \left(4.18\frac{\text{J}}{\text{g}\cdot\text{K}}\right)\left(\frac{18.0\text{ g}}{1\text{ mol}}\right) = 75.2\text{ J/mol}\cdot\text{K}$$

## Practice Exercise 1

The coinage metals (Group 1B) copper, silver, and gold have specific heats of 0.385, 0.233, and 0.129 J/g·K, respectively. Among this group, the specific heat capacity \_\_\_\_\_ and the molar heat capacity \_\_\_\_\_ as the atomic weight increases. (a) increases, increases (b) increases, decreases (c) decreases, increases (d) decreases, decreases

## Practice Exercise 2

(a) Large beds of rocks are used in some solar-heated homes to store heat. Assume that the specific heat of the rocks is 0.82 J/g·K. Calculate the quantity of heat absorbed by 50.0 kg of rocks if their temperature increases by 12.0 °C. (b) What temperature change would these rocks undergo if they emitted 450 kJ of heat?

## Go Figure

Why do you think two Styrofoam® cups are often used instead of just one.

▲ **Figure 5.18** Coffee-cup calorimeter. This simple apparatus is used to measure temperature changes of reactions at constant pressure.

## Constant-Pressure Calorimetry

The techniques and equipment employed in calorimetry depend on the nature of the process being studied. For many reactions, such as those occurring in solution, it is easy to control pressure so that  $\Delta H$  is measured directly. Although the calorimeters used for highly accurate work are precision instruments, a simple “coffee-cup” calorimeter (Figure 5.18) is often used in general chemistry laboratories to illustrate the principles of calorimetry. Because the calorimeter is not sealed, the reaction occurs under the essentially constant pressure of the atmosphere.

Imagine adding two aqueous solutions, each containing a reactant, to a coffee-cup calorimeter. Once mixed, a reaction occurs. In this case, there is no physical boundary between the system and the surroundings. The reactants and products of the reaction are the system, and the water in which they are dissolved is part of the surroundings. (The calorimeter apparatus is also part of the surroundings.) If we assume that the calorimeter is perfectly insulated, then any heat released or absorbed by the reaction will raise or lower the temperature of the water in the solution. Thus, we measure the temperature change of the solution and assume that any changes are due to heat transferred from the reaction to the water (for an exothermic process) or transferred from the water to the reaction (endothermic). In other words, by monitoring the temperature of the solution, we are seeing the flow of heat between the system (the reactants and products in the solution) and the surroundings (the water that forms the bulk of the solution).

For an exothermic reaction, heat is “lost” by the reaction and “gained” by the water in the solution, so the temperature of the solution rises. The opposite occurs for an

endothermic reaction: Heat is gained by the reaction and lost by the water in the solution, and the temperature of the solution decreases. The heat gained or lost by the solution,  $q_{\text{soln}}$ , is therefore equal in magnitude but opposite in sign to the heat absorbed or released by the reaction,  $q_{\text{rxn}}$ , in mathematical terms  $q_{\text{soln}} = -q_{\text{rxn}}$ . The value of  $q_{\text{soln}}$  is readily calculated from the mass of the solution, its specific heat, and the temperature change:

$$q_{\text{soln}} = (\text{specific heat of solution}) \times (\text{grams of solution}) \times \Delta T = -q_{\text{rxn}} \quad [5.22]$$

For dilute aqueous solutions we usually assume that the specific heat of the solution is the same as that of water,  $4.18 \text{ J/g}\cdot\text{K}$ .

Equation 5.22 makes it possible to calculate  $q_{\text{rxn}}$  from the temperature change of the solution in which the reaction occurs. A temperature increase ( $\Delta T > 0$ ) means the reaction is exothermic ( $q_{\text{rxn}} < 0$ ).

## Sample Exercise 5.6

### Measuring $\Delta H$ Using a Coffee-Cup Calorimeter

When a student mixes 50 mL of 1.0 M HCl and 50 mL of 1.0 M NaOH in a coffee-cup calorimeter, the temperature of the resultant solution increases from 21.0 to 27.5 °C. Calculate the enthalpy change for the reaction in kJ/mol HCl, assuming that the calorimeter loses only a negligible quantity of heat, that the total volume of the solution is 100 mL, that its density is 1.0 g/mL, and that its specific heat is  $4.18 \text{ J/g}\cdot\text{K}$ .

### SOLUTION

**Analyze** Mixing solutions of HCl and NaOH results in an acid-base reaction:

We need to calculate the heat produced per mole of HCl, given the temperature increase of the solution, the number of moles of HCl and NaOH involved, and the density and specific heat of the solution.

**Plan** The total heat produced can be calculated using Equation 5.22. The number of moles of HCl consumed in the reaction must be calculated from the volume and molarity of this substance, and this amount is then used to determine the heat produced per mol HCl.

### Solve

Because the total volume of the solution is 100 mL, its mass is:  $(100 \text{ mL})(1.0 \text{ g/mL}) = 100 \text{ g}$

The temperature change is:  $\Delta T = 27.5^\circ\text{C} - 21.0^\circ\text{C} = 6.5^\circ\text{C} = 6.5 \text{ K}$

Using Equation 5.22, we have:  $q_{\text{rxn}} = -C_s \times m \times \Delta T$   
 $= -(4.18 \text{ J/g}\cdot\text{K})(100 \text{ g})(6.5 \text{ K}) = -2.7 \times 10^3 \text{ J} = -2.7 \text{ kJ}$

Because the process occurs at constant pressure,  $\Delta H = q_p = -2.7 \text{ kJ}$

To express the enthalpy change on a molar basis, we use the fact that the number of moles of HCl is given by the product of the volume (50 mL = 0.050 L) and concentration ( $1.0 \text{ M} = 1.0 \text{ mol/L}$ ) of the HCl solution:  $(0.050 \text{ L})(1.0 \text{ mol/L}) = 0.050 \text{ mol}$

Thus, the enthalpy change per mole of HCl is:  $\Delta H = -2.7 \text{ kJ}/0.050 \text{ mol} = -54 \text{ kJ/mol}$

**Check**  $\Delta H$  is negative (exothermic), as evidenced by the observed increase in the temperature. The magnitude of the molar enthalpy change seems reasonable.

### Practice Exercise 1

When 0.243 g of Mg metal is combined with enough HCl to make 100 mL of solution in a constant-pressure calorimeter, the following reaction occurs:

If the temperature of the solution increases from 23.0 to 34.1 °C as a result of this reaction, calculate  $\Delta H$  in kJ/mol Mg. Assume that the solution has a specific heat of  $4.18 \text{ J/g}\cdot^\circ\text{C}$  and

a density of 1.00 g/mL. (a)  $-19.1 \text{ kJ/mol}$  (b)  $-111 \text{ kJ/mol}$  (c)  $-191 \text{ kJ/mol}$  (d)  $-464 \text{ kJ/mol}$  (e)  $-961 \text{ kJ/mol}$

### Practice Exercise 2

When 50.0 mL of 0.100 M  $\text{AgNO}_3$  and 50.0 mL of 0.100 M HCl are mixed in a constant-pressure calorimeter, the temperature of the mixture increases from 22.30 to 23.11 °C. The temperature increase is caused by the following reaction:

Calculate  $\Delta H$  for this reaction in kJ/mol  $\text{AgNO}_3$ , assuming that the combined solution has a mass of 100.0 g and a specific heat of  $4.18 \text{ J/g}\cdot^\circ\text{C}$ .

### Go Figure

Is the water surrounding the reaction chamber part of the system or the surroundings?

▲ Figure 5.19 Bomb calorimeter.

## Bomb Calorimetry (Constant-Volume Calorimetry)

An important type of reaction studied using calorimetry is combustion, in which a compound reacts completely with excess oxygen. ∞ (Section 3.2) Combustion reactions are most accurately studied using a **bomb calorimeter** (Figure 5.19). The substance to be studied is placed in a small cup within an insulated sealed vessel called a *bomb*. The bomb, which is designed to withstand high pressures, has an inlet valve for adding oxygen and electrical leads for initiating the reaction. After the sample has been placed in the bomb, the bomb is sealed and pressurized with oxygen. It is then placed in the calorimeter and covered with an accurately measured quantity of water. The combustion reaction is initiated by passing an electrical current through a fine wire in contact with the sample. When the wire becomes sufficiently hot, the sample ignites.

The heat released when combustion occurs is absorbed by the water and the various components of the calorimeter (which all together make up the surroundings), causing the water temperature to rise. The change in water temperature caused by the reaction is measured very precisely.

To calculate the heat of combustion from the measured temperature increase, we must know the total heat capacity of the calorimeter,  $C_{\text{cal}}$ . This quantity is determined by combusting a sample that releases a known quantity of heat and measuring the temperature change. For example, combustion of exactly 1 g of benzoic acid,  $\text{C}_6\text{H}_5\text{COOH}$ , in a bomb calorimeter produces 26.38 kJ of heat. Suppose 1.000 g of benzoic acid is combusted in a calorimeter, leading to a temperature increase of  $4.857^\circ\text{C}$ . The heat capacity of the calorimeter is then  $C_{\text{cal}} = 26.38 \text{ kJ}/4.857^\circ\text{C} = 5.431 \text{ kJ}/^\circ\text{C}$ . Once we know  $C_{\text{cal}}$ , we can measure temperature changes produced by other reactions, and from these we can calculate the heat evolved in the reaction,  $q_{\text{rxn}}$ :

$$q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T \quad [5.23]$$

Because reactions in a bomb calorimeter are carried out at constant volume, the heat transferred corresponds to the change in internal energy,  $\Delta E$ , rather than the change in enthalpy,  $\Delta H$  (Equation 5.13). For most reactions, however, the difference between  $\Delta E$  and  $\Delta H$  is very small. For the reaction discussed in Sample Exercise 5.7, for example, the difference between  $\Delta E$  and  $\Delta H$  is about 1 kJ/mol—a difference of less than 0.1%. It is possible to calculate  $\Delta H$  from  $\Delta E$ , but we need not concern ourselves with how these small corrections are made.

## Sample Exercise 5.7

### Measuring $q_{\text{rxn}}$ Using a Bomb Calorimeter

The combustion of methylhydrazine ( $\text{CH}_6\text{N}_2$ ), a liquid rocket fuel, produces  $\text{N}_2(\text{g})$ ,  $\text{CO}_2(\text{g})$ , and  $\text{H}_2\text{O}(\text{l})$ :

When 4.00 g of methylhydrazine is combusted in a bomb calorimeter, the temperature of the calorimeter increases from  $25.00^\circ\text{C}$  to  $39.50^\circ\text{C}$ . In a separate experiment the heat capacity of the calorimeter is measured to be  $7.794 \text{ kJ}/^\circ\text{C}$ . Calculate the heat of reaction for the combustion of a mole of  $\text{CH}_6\text{N}_2$ .

### SOLUTION

**Analyze** We are given a temperature change and the total heat capacity of the calorimeter. We are also given the amount of reactant combusted. Our goal is to calculate the enthalpy change per mole for combustion of the reactant.

**Plan** We will first calculate the heat evolved for the combustion of the 4.00-g sample. We will then convert this heat to a molar quantity.

### Solve

For combustion of the 4.00-g sample of methylhydrazine, the temperature change of the calorimeter is:

$$\Delta T = (39.50^\circ\text{C} - 25.00^\circ\text{C}) = 14.50^\circ\text{C}$$

We can use  $\Delta T$  and the value for  $C_{\text{cal}}$  to calculate the heat of reaction (Equation 5.23):

$$q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T = -(7.794 \text{ kJ}/^{\circ}\text{C})(14.50^{\circ}\text{C}) = -113.0 \text{ kJ}$$

We can readily convert this value to the heat of reaction for a mole of  $\text{CH}_6\text{N}_2$ :

$$\left( \frac{-113.0 \text{ kJ}}{4.00 \text{ g CH}_6\text{N}_2} \right) \times \left( \frac{46.1 \text{ g CH}_6\text{N}_2}{1 \text{ mol CH}_6\text{N}_2} \right) = -1.30 \times 10^3 \text{ kJ/mol CH}_6\text{N}_2$$

**Check** The units cancel properly, and the sign of the answer is negative as it should be for an exothermic reaction. The magnitude of the answer seems reasonable.

### ► Practice Exercise 1

The combustion of exactly 1.000 g of benzoic acid in a bomb calorimeter releases 26.38 kJ of heat. If the combustion of 0.550 g of benzoic acid causes the temperature of the

calorimeter to increase from 22.01 to 24.27  $^{\circ}\text{C}$ , calculate the heat capacity of the calorimeter.

- (a) 0.660 kJ/ $^{\circ}\text{C}$  (b) 6.42 kJ/ $^{\circ}\text{C}$  (c) 14.5 kJ/ $^{\circ}\text{C}$   
(d) 21.2 kJ/g- $^{\circ}\text{C}$  (e) 32.7 kJ/ $^{\circ}\text{C}$

### ► Practice Exercise 2

A 0.5865-g sample of lactic acid ( $\text{HC}_3\text{H}_5\text{O}_3$ ) reacts with oxygen in a calorimeter whose heat capacity is 4.812 kJ/ $^{\circ}\text{C}$ . The temperature increases from 23.10 to 24.95  $^{\circ}\text{C}$ . Calculate the heat of combustion of lactic acid (a) per gram and (b) per mole.

## CHEMISTRY AND LIFE The Regulation of Body Temperature

For most of us, being asked the question “Are you running a fever?” was one of our first introductions to medical diagnosis. Indeed, a deviation in body temperature of only a few degrees indicates something amiss. Maintaining a near-constant temperature is one of the primary physiological functions of the human body.

To understand how the body's heating and cooling mechanisms operate, we can view the body as a thermodynamic system. The body increases its internal energy content by ingesting foods from the surroundings. The foods, such as glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), are metabolized—a process that is essentially controlled oxidation to  $\text{CO}_2$  and  $\text{H}_2\text{O}$ :

Roughly 40% of the energy produced is ultimately used to do work in the form of muscle contractions and nerve cell activities. The remainder is released as heat, part of which is used to maintain body temperature. When the body produces too much heat, as in times of heavy physical exertion, it dissipates the excess to the surroundings.

Heat is transferred from the body to its surroundings primarily by *radiation*, *convection*, and *evaporation*. Radiation is the direct loss of heat from the body to cooler surroundings, much as a hot stovetop radiates heat to its surroundings. Convection is heat loss by virtue of heating air that is in contact with the body. The heated air rises and is replaced with cooler air, and the process continues. Warm clothing decreases convective heat loss in cold weather. Evaporative cooling occurs when perspiration is generated at the skin surface by the sweat glands (Figure 5.20). Heat is removed from the body as the perspiration evaporates. Perspiration is predominantly water, so the process is the endothermic conversion of liquid water into water vapor:

The speed with which evaporative cooling occurs decreases as the atmospheric humidity increases, which is why we feel more sweaty and uncomfortable on hot, humid days.

When body temperature becomes too high, heat loss increases in two principal ways. First, blood flow near the skin surface increases,

▲ Figure 5.20 Perspiration.

which allows for increased radiational and convective cooling. The red-dish, “flushed” appearance of a hot individual is due to this increased blood flow. Second, we sweat, which increases evaporative cooling. During extreme activity, the amount of perspiration can be as high as 2 to 4 liters per hour. As a result, the body's water supply must be replenished during these periods. If the body loses too much liquid through perspiration, it will no longer be able to cool itself and blood volume decreases, which can lead to either *heat exhaustion* or the more serious *heat stroke*. However, replenishing water without replenishing the electrolytes lost during perspiration can also lead to serious problems. If the normal blood sodium level drops too low, dizziness and confusion set in, and the condition can become critical. Drinking a sport drink that contains some electrolytes helps to prevent this problem.

When body temperature drops too low, blood flow to the skin surface decreases, thereby decreasing heat loss. The lower temperature also triggers small involuntary contractions of the muscles (shivering); the biochemical reactions that generate the energy to do this work also generate heat for the body. If the body is unable to maintain a normal temperature, the very dangerous condition called *hypothermia* can result.

## 5.6 | Hess's Law

It is often possible to calculate the  $\Delta H$  for a reaction from the tabulated  $\Delta H$  values of other reactions. Thus, it is not necessary to make calorimetric measurements for all reactions.

Because enthalpy is a state function, the enthalpy change,  $\Delta H$ , associated with any chemical process depends only on the amount of matter that undergoes change and on the nature of the initial state of the reactants and the final state of the products. This means that whether a particular reaction is carried out in one step or in a series of steps, the sum of the enthalpy changes associated with the individual steps must be the same as the enthalpy change associated with the one-step process. As an example, combustion of methane gas,  $\text{CH}_4(\text{g})$ , to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$  can be thought of as occurring in one step, as represented on the left in Figure 5.21, or in two steps, as represented on the right in Figure 5.21: (1) combustion of  $\text{CH}_4(\text{g})$  to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$  and (2) condensation of  $\text{H}_2\text{O}(\text{g})$  to form  $\text{H}_2\text{O}(\text{l})$ . The enthalpy change for the overall process is the sum of the enthalpy changes for these two steps:

The net equation is

**Hess's law** states that *if a reaction is carried out in a series of steps,  $\Delta H$  for the overall reaction equals the sum of the enthalpy changes for the individual steps*. The overall enthalpy change for the process is independent of the number of steps and independent of the path by which the reaction is carried out. This law is a consequence of the fact that enthalpy is a state function. We can therefore calculate  $\Delta H$  for any process as long as we find a route for which  $\Delta H$  is known for each step. This means that a relatively small number of experimental measurements can be used to calculate  $\Delta H$  for a vast number of reactions.

Hess's law provides a useful means of calculating energy changes that are difficult to measure directly. For instance, it is impossible to measure directly the enthalpy for the combustion of carbon to form carbon monoxide. Combustion of 1 mol of carbon with 0.5 mol of  $\text{O}_2$  produces both  $\text{CO}$  and  $\text{CO}_2$ , leaving some carbon unreacted. However, solid carbon and carbon monoxide can both be completely burned in  $\text{O}_2$  to produce  $\text{CO}_2$ . We can therefore use the enthalpy changes of these reactions to calculate the heat of combustion of carbon as illustrated in Sample Exercise 5.8.

### Go Figure

What process corresponds to the  $-88 \text{ kJ}$  enthalpy change?

▲ **Figure 5.21** Enthalpy diagram for combustion of 1 mol of methane. The enthalpy change of the one-step reaction equals the sum of the enthalpy changes of the reaction run in two steps:  $-890 \text{ kJ} = -802 \text{ kJ} + (-88 \text{ kJ})$ .

### Give It Some Thought

What effect do these changes have on  $\Delta H$  for a reaction:

- Reversing the reaction
- Multiplying the coefficients of the equation for the reaction by 2?

## Sample Exercise 5.8

### Using Hess's Law to Calculate $\Delta H$

The enthalpy of reaction for the combustion of  $\text{C}$  to  $\text{CO}_2$  is  $-393.5 \text{ kJ/mol C}$ , and the enthalpy for the combustion of  $\text{CO}$  to  $\text{CO}_2$  is  $-283.0 \text{ kJ/mol CO}$ :

Using these data, calculate the enthalpy for the combustion of  $\text{C}$  to  $\text{CO}$ :

**SOLUTION**

**Analyze** We are given two thermochemical equations, and our goal is to combine them in such a way as to obtain the third equation and its enthalpy change.

**Plan** We will use Hess's law. In doing so, we first note the number of moles of substances among the reactants and products in the target equation (3). We then manipulate equations (1) and (2) to give the same number of moles of these substances, so that when the resulting equations are added, we obtain the target equation. At the same time, we keep track of the enthalpy changes, which we add.

**Solve** To use equations (1) and (2), we arrange them so that C(s) is on the reactant side and CO(g) is on the product side of the arrow, as in the target reaction, equation (3). Because equation (1) has C(s) as a reactant, we can use that equation just as it is. We need to turn equation (2) around, however, so that CO(g) is a product. Remember that when reactions are turned around, the sign of  $\Delta H$  is reversed. We arrange the two equations so that they can be added to give the desired equation:

When we add the two equations,  $\text{CO}_2\text{(g)}$  appears on both sides of the arrow and therefore cancels out. Likewise,  $\frac{1}{2} \text{O}_2\text{(g)}$  is eliminated from each side.

**Practice Exercise 1**

Calculate  $\Delta H$  for  $2 \text{NO(g)} + \text{O}_2\text{(g)} \longrightarrow \text{N}_2\text{O}_4\text{(g)}$ , using the following information:

(a) 2.7 kJ (b) -55.2 kJ (c) -85.5 kJ (d) -171.0 kJ (e) +55.2 kJ

**Practice Exercise 2**

Carbon occurs in two forms, graphite and diamond. The enthalpy of the combustion of graphite is  $-393.5 \text{ kJ/mol}$ , and that of diamond is  $-395.4 \text{ kJ/mol}$ :

Calculate  $\Delta H$  for the conversion of graphite to diamond:

**Sample Exercise 5.9**

Using Hess's Law with Three Equations to Calculate  $\Delta H$

Calculate  $\Delta H$  for the reaction

given the following chemical equations and their respective enthalpy changes:

**SOLUTION**

**Analyze** We are given a chemical equation and asked to calculate its  $\Delta H$  using three chemical equations and their associated enthalpy changes.

**Plan** We will use Hess's law, summing the three equations or their reverses and multiplying each by an appropriate coefficient so that they add to give the net equation for the reaction of interest. At the same time, we keep track of the  $\Delta H$  values, reversing their signs if the reactions are reversed and multiplying them by whatever coefficient is employed in the equation.

**Solve** Because the target equation has  $\text{C}_2\text{H}_2$  as a product, we turn the first equation around; the sign of  $\Delta H$  is therefore changed. The desired equation has  $2 \text{C(s)}$  as a reactant, so we multiply the second equation and its  $\Delta H$  by 2. Because the target equation has  $\text{H}_2$  as a reactant, we keep the third equation as it is. We then add the three equations and their enthalpy changes in accordance with Hess's law:

When the equations are added, there are  $2 \text{CO}_2$ ,  $\frac{5}{2} \text{O}_2$ , and  $\text{H}_2\text{O}$  on both sides of the arrow. These are canceled in writing the net equation.

**Check** The procedure must be correct because we obtained the correct net equation. In cases like this, you should go back over the numerical manipulations of the  $\Delta H$  values to ensure that you did not make an inadvertent error with signs.

**Practice Exercise 1**

Calculate  $\Delta H$  for the reaction

given the following thermochemical equations:

(a) -1443.1 kJ (b) -918.3 kJ (c) 131.3 kJ (d) 262.6 kJ (e) 656.1 kJ

**Practice Exercise 2**

Calculate  $\Delta H$  for the reaction

given the following information:

### Go Figure

Suppose the overall reaction were modified to produce 2 H<sub>2</sub>O(g) rather than 2 H<sub>2</sub>O(l). Would any of the values of  $\Delta H$  in the diagram stay the same?

▲ **Figure 5.22** Enthalpy diagram illustrating Hess's law. The net reaction is the same as in Figure 5.21, but here we imagine different reactions in our two-step version. As long as we can write a series of equations, each with a known value of  $\Delta H$ , that add up to the equation we need, we can calculate the overall  $\Delta H$ .

The key point of these examples is that  $H$  is a state function.

*Because  $H$  is a state function, for a particular set of reactants and products,  $\Delta H$  is the same whether the reaction takes place in one step or in a series of steps.*

We reinforce this point by giving one more example of an enthalpy diagram and Hess's law. Again we use combustion of methane to form CO<sub>2</sub> and H<sub>2</sub>O, our reaction from Figure 5.21. This time we envision a different two-step path, with the initial formation of CO, which is then combusted to CO<sub>2</sub> (Figure 5.22). Even though the two-step path is different from that in Figure 5.21, the overall reaction again has  $\Delta H_1 = -890$  kJ. Because  $H$  is a state function, both paths *must* produce the same value of  $\Delta H$ . In Figure 5.22, that means  $\Delta H_1 = \Delta H_2 + \Delta H_3$ . We will soon see that breaking up reactions in this way allows us to derive the enthalpy changes for reactions that are hard to carry out in the laboratory.

## 5.7 | Enthalpies of Formation

We can use the methods just discussed to calculate enthalpy changes for a great many reactions from tabulated  $\Delta H$  values. For example, extensive tables exist of *enthalpies of vaporization* ( $\Delta H$  for converting liquids to gases), *enthalpies of fusion* ( $\Delta H$  for melting solids), *enthalpies of combustion* ( $\Delta H$  for combusting a substance in oxygen), and so forth. A particularly important process used for tabulating thermochemical data is the formation of a compound from its constituent elements. The enthalpy change associated with this process is called the **enthalpy of formation** (or *heat of formation*),  $\Delta H_f$ , where the subscript  $f$  indicates that the substance has been *formed* from its constituent elements.

The magnitude of any enthalpy change depends on the temperature, pressure, and state (gas, liquid, or solid crystalline form) of the reactants and products. To compare enthalpies of different reactions, we must define a set of conditions, called a *standard state*, at which most enthalpies are tabulated. The standard state of a substance is its pure form at atmospheric pressure (1 atm) and the temperature of interest, which we usually choose to be 298 K (25 °C).\* The **standard enthalpy change** of a reaction is defined as the enthalpy change when all reactants and products are in their standard states. We denote a standard enthalpy change as  $\Delta H^\circ$ , where the superscript  $^\circ$  indicates standard-state conditions.

The **standard enthalpy of formation** of a compound,  $\Delta H_f^\circ$ , is the change in enthalpy for the reaction that forms one mole of the compound from its elements with all substances in their standard states:

We usually report  $\Delta H_f^\circ$  values at 298 K. If an element exists in more than one form under standard conditions, the most stable form of the element is usually used for the formation reaction. For example, the standard enthalpy of formation for ethanol, C<sub>2</sub>H<sub>5</sub>OH, is the enthalpy change for the reaction

The elemental source of oxygen is O<sub>2</sub>, not O or O<sub>3</sub>, because O<sub>2</sub> is the stable form of oxygen at 298 K and atmospheric pressure. Similarly, the elemental source of carbon is graphite and not diamond because graphite is the more stable (lower-energy) form at 298 K and atmospheric pressure. Likewise, the most stable form of hydrogen under standard conditions is H<sub>2</sub>(g), so this is used as the source of hydrogen in Equation 5.25.

The stoichiometry of formation reactions always indicates that one mole of the desired substance is produced, as in Equation 5.25. As a result, standard enthalpies of formation are reported in kJ/mol of the substance being formed. Some values are given in Table 5.3, and a more extensive table is provided in Appendix C.

\*The definition of the standard state for gases has been changed to 1 bar (1 atm = 1.013 bar), a slightly lower pressure than 1 atm. For most purposes, this change makes very little difference in the standard enthalpy changes.

TABLE 5.3 Standard Enthalpies of Formation,  $\Delta H_f^\circ$ , at 298 K

| Substance         | Formula                                | $\Delta H_f^\circ$ (kJ/mol) | Substance          | Formula                                      | $\Delta H_f^\circ$ (kJ/mol) |
|-------------------|--|-----------------------------|--------------------|--|-----------------------------|
| Acetylene         | $\text{C}_2\text{H}_2(g)$              | 226.7                       | Hydrogen chloride  | $\text{HCl}(g)$                              | -92.30                      |
| Ammonia           | $\text{NH}_3(g)$                       | -46.19                      | Hydrogen fluoride  | $\text{HF}(g)$                               | -268.60                     |
| Benzene           | $\text{C}_6\text{H}_6(l)$              | 49.0                        | Hydrogen iodide    | $\text{HI}(g)$                               | 25.9                        |
| Calcium carbonate | $\text{CaCO}_3(s)$                     | -1207.1                     | Methane            | $\text{CH}_4(g)$                             | -74.80                      |
| Calcium oxide     | $\text{CaO}(s)$                        | -635.5                      | Methanol           | $\text{CH}_3\text{OH}(l)$                    | -238.6                      |
| Carbon dioxide    | $\text{CO}_2(g)$                       | -393.5                      | Propane            | $\text{C}_3\text{H}_8(g)$                    | -103.85                     |
| Carbon monoxide   | $\text{CO}(g)$                         | -110.5                      | Silver chloride    | $\text{AgCl}(s)$                             | -127.0                      |
| Diamond           | $\text{C}(s)$                          | 1.88                        | Sodium bicarbonate | $\text{NaHCO}_3(s)$                          | -947.7                      |
| Ethane            | $\text{C}_2\text{H}_6(g)$              | -84.68                      | Sodium carbonate   | $\text{Na}_2\text{CO}_3(s)$                  | -1130.9                     |
| Ethanol           | $\text{C}_2\text{H}_5\text{OH}(l)$     | -277.7                      | Sodium chloride    | $\text{NaCl}(s)$                             | -410.9                      |
| Ethylene          | $\text{C}_2\text{H}_4(g)$              | 52.30                       | Sucrose            | $\text{C}_{12}\text{H}_{22}\text{O}_{11}(s)$ | -2221                       |
| Glucose           | $\text{C}_6\text{H}_{12}\text{O}_6(s)$ | -1273                       | Water              | $\text{H}_2\text{O}(l)$                      | -285.8                      |
| Hydrogen bromide  | $\text{HBr}(g)$                        | -36.23                      | Water vapor        | $\text{H}_2\text{O}(g)$                      | -241.8                      |

By definition, the standard enthalpy of formation of the most stable form of any element is zero because there is no formation reaction needed when the element is already in its standard state. Thus, the values of  $\Delta H_f^\circ$  for  $\text{C}(\text{graphite})$ ,  $\text{H}_2(g)$ ,  $\text{O}_2(g)$ , and the standard states of other elements are zero by definition.

### Sample Exercise 5.10

#### Equations Associated with Enthalpies of Formation

For which of these reactions at 25 °C does the enthalpy change represent a standard enthalpy of formation? For each that does not, what changes are needed to make it an equation whose  $\Delta H$  is an enthalpy of formation?

- (a)  $2 \text{Na}(s) + \frac{1}{2} \text{O}_2(g) \longrightarrow \text{Na}_2\text{O}(s)$   
 (b)  $2 \text{K}(l) + \text{Cl}_2(g) \longrightarrow 2 \text{KCl}(s)$   
 (c)  $\text{C}_6\text{H}_{12}\text{O}_6(s) \longrightarrow 6 \text{C}(\text{diamond}) + 6 \text{H}_2(g) + 3 \text{O}_2(g)$

#### SOLUTION

**Analyze** The standard enthalpy of formation is represented by a reaction in which each reactant is an element in its standard state and the product is one mole of the compound.

**Plan** We need to examine each equation to determine (1) whether the reaction is one in which one mole of substance is formed from the elements, and (2) whether the reactant elements are in their standard states.

**Solve** In (a) 1 mol  $\text{Na}_2\text{O}$  is formed from the elements sodium and oxygen in their proper states, solid Na and  $\text{O}_2$  gas, respectively. Therefore, the enthalpy change for reaction (a) corresponds to a standard enthalpy of formation.

In (b) potassium is given as a liquid. It must be changed to the solid form, its standard state at room temperature. Furthermore, 2 mol KCl are formed, so the enthalpy change for the reaction as written is twice the standard enthalpy of formation of KCl(s). The equation for the formation reaction of 1 mol of KCl(s) is

Reaction (c) does not form a substance from its elements. Instead, a substance decomposes to its elements, so this reaction must be

reversed. Next, the element carbon is given as diamond, whereas graphite is the standard state of carbon at room temperature and 1 atm pressure. The equation that correctly represents the enthalpy of formation of glucose from its elements is

#### Practice Exercise 1

If the heat of formation of  $\text{H}_2\text{O}(l)$  is -286 kJ/mol, which of the following thermochemical equations is correct?

- (a)  $2 \text{H}(g) + \text{O}(g) \longrightarrow \text{H}_2\text{O}(l)$   $\Delta H = -286 \text{ kJ}$   
 (b)  $2 \text{H}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{H}_2\text{O}(l)$   $\Delta H = -286 \text{ kJ}$   
 (c)  $\text{H}_2(g) + \frac{1}{2} \text{O}_2(g) \longrightarrow \text{H}_2\text{O}(l)$   $\Delta H = -286 \text{ kJ}$   
 (d)  $\text{H}_2(g) + \text{O}(g) \longrightarrow \text{H}_2\text{O}(g)$   $\Delta H = -286 \text{ kJ}$   
 (e)  $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2(g) + \frac{1}{2} \text{O}_2(g)$   $\Delta H = -286 \text{ kJ}$

#### Practice Exercise 2

Write the equation corresponding to the standard enthalpy of formation of liquid carbon tetrachloride ( $\text{CCl}_4$ ) and look up  $\Delta H_f^\circ$  for this compound in Appendix C.

**Give It Some Thought**

Ozone,  $\text{O}_3(\text{g})$ , is a form of elemental oxygen produced during electrical discharge. Is  $\Delta H_f^\circ$  for  $\text{O}_3(\text{g})$  necessarily zero?

## Using Enthalpies of Formation to Calculate Enthalpies of Reaction

We can use Hess's law and tabulations of  $\Delta H_f^\circ$  values, such as those in Table 5.3 and Appendix C, to calculate the standard enthalpy change for any reaction for which we know the  $\Delta H_f^\circ$  values for all reactants and products. For example, consider the combustion of propane under standard conditions:

We can write this equation as the sum of three equations associated with standard enthalpies of formation:

(Note that it is sometimes useful to add subscripts to the enthalpy changes, as we have done here, to keep track of the associations between reactions and their  $\Delta H$  values.)

Notice that we have used Hess's law to write the standard enthalpy change for Equation 5.29 as the sum of the enthalpy changes for Equations 5.26 through 5.28. We can use values from Table 5.3 to calculate  $\Delta H_{\text{rxn}}^\circ$ :

$$\begin{aligned} \Delta H_{\text{rxn}}^\circ &= \Delta H_1 + \Delta H_2 + \Delta H_3 \\ &= -\Delta H_f^\circ[\text{C}_3\text{H}_8(\text{g})] + 3\Delta H_f^\circ[\text{CO}_2(\text{g})] + 4\Delta H_f^\circ[\text{H}_2\text{O}(\text{l})] \\ &= -(-103.85 \text{ kJ}) + 3(-393.5 \text{ kJ}) + 4(-285.8 \text{ kJ}) = -2220 \text{ kJ} \end{aligned} \quad [5.30]$$

The enthalpy diagram in **Figure 5.23** shows the components of this calculation. In Step ❶ the reactants are decomposed into their constituent elements in their standard states. In Steps ❷ and ❸ the products are formed from the elements. Several aspects of how we use enthalpy changes in this process depend on the guidelines we discussed in Section 5.4.

- ❶ **Decomposition.** Equation 5.26 is the reverse of the formation reaction for  $\text{C}_3\text{H}_8(\text{g})$ , so the enthalpy change for this decomposition reaction is the negative of the  $\Delta H_f^\circ$  value for the propane formation reaction:  $-\Delta H_f^\circ[\text{C}_3\text{H}_8(\text{g})]$ .
- ❷ **Formation of  $\text{CO}_2$ .** Equation 5.27 is the formation reaction for 3 mol of  $\text{CO}_2(\text{g})$ . Because enthalpy is an extensive property, the enthalpy change for this step is  $3\Delta H_f^\circ[\text{CO}_2(\text{g})]$ .
- ❸ **Formation of  $\text{H}_2\text{O}$ .** The enthalpy change for Equation 5.28, formation of 4 mol of  $\text{H}_2\text{O}$ , is  $4\Delta H_f^\circ[\text{H}_2\text{O}(\text{l})]$ . The reaction specifies that  $\text{H}_2\text{O}(\text{l})$  is produced, so be careful to use the value of  $\Delta H_f^\circ$  for  $\text{H}_2\text{O}(\text{l})$  and not the value for  $\text{H}_2\text{O}(\text{g})$ .

Note that in this analysis we assume that the stoichiometric coefficients in the balanced equation represent the number of moles of each substance. For Equation 5.29, therefore,  $\Delta H_{\text{rxn}}^\circ = -2220 \text{ kJ}$  represents the enthalpy change for the reaction of 1 mol  $\text{C}_3\text{H}_8$  and 5 mol  $\text{O}_2$  to form 3 mol  $\text{CO}_2$  and 4 mol  $\text{H}_2\text{O}$ .

We can break down any reaction into formation reactions as we have done here. When we do, we obtain the general result that the standard enthalpy change of a

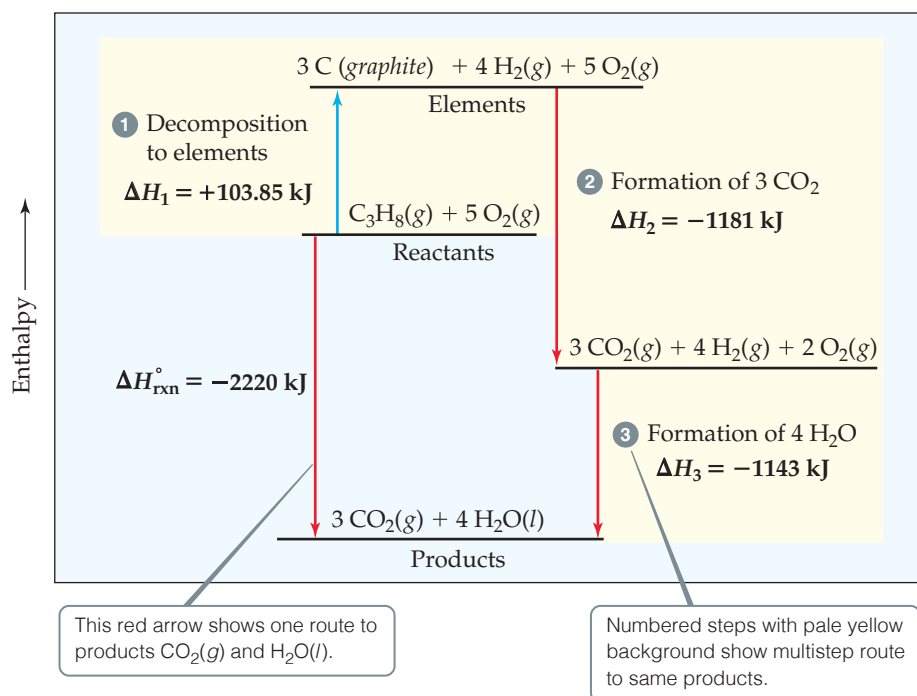

Figure 5.23 Enthalpy diagram for propane combustion.

reaction is the sum of the standard enthalpies of formation of the products minus the standard enthalpies of formation of the reactants:

$$\Delta H_{\text{rxn}}^\circ = \sum n \Delta H_f^\circ(\text{products}) - \sum m \Delta H_f^\circ(\text{reactants}) \quad [5.31]$$

The symbol  $\Sigma$  (sigma) means “the sum of,” and  $n$  and  $m$  are the stoichiometric coefficients of the relevant chemical equation. The first term on the right in Equation 5.31 represents the formation reactions of the products, which are written in the “forward” direction in the chemical equation, that is, elements reacting to form products. This term is analogous to Equations 5.27 and 5.28. The second term on the right in Equation 5.31 represents the reverse of the formation reactions of the reactants, analogous to Equation 5.26, which is why this term is preceded by a minus sign.

### Sample Exercise 5.11

#### Calculating an Enthalpy of Reaction from Enthalpies of Formation

- (a) Calculate the standard enthalpy change for the combustion of 1 mol of benzene,  $\text{C}_6\text{H}_6(\text{l})$ , to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ .  
 (b) Compare the quantity of heat produced by combustion of 1.00 g propane with that produced by 1.00 g benzene.

#### SOLUTION

**Analyze** (a) We are given a reaction [combustion of  $\text{C}_6\text{H}_6(\text{l})$  to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ ] and asked to calculate its standard enthalpy change,  $\Delta H^\circ$ . (b) We then need to compare the quantity of heat produced by combustion of 1.00 g  $\text{C}_6\text{H}_6$  with that produced by 1.00 g  $\text{C}_3\text{H}_8$ , whose combustion was treated previously in the text. (See Equations 5.29 and 5.30.)

**Plan** (a) We first write the balanced equation for the combustion of  $\text{C}_6\text{H}_6$ . We then look up  $\Delta H_f^\circ$  values in Appendix C or in Table 5.3 and apply Equation 5.31 to calculate the enthalpy change for the reaction. (b) We use the molar mass of  $\text{C}_6\text{H}_6$  to change the enthalpy change per mole to that per gram. We similarly use the molar mass of  $\text{C}_3\text{H}_8$  and the enthalpy change per mole calculated in the text previously to calculate the enthalpy change per gram of that substance.

#### Solve

- (a) We know that a combustion reaction involves  $\text{O}_2(\text{g})$  as a reactant. Thus, the balanced equation for the combustion reaction of 1 mol  $\text{C}_6\text{H}_6(\text{l})$  is:

Continued

We can calculate  $\Delta H^\circ$  for this reaction by using Equation 5.31 and data in Table 5.3. Remember to multiply the  $\Delta H_f^\circ$  value for each substance in the reaction by that substance's stoichiometric coefficient. Recall also that  $\Delta H_f^\circ = 0$  for any element in its most stable form under standard conditions, so  $\Delta H_f^\circ[\text{O}_2(\text{g})] = 0$ .

$$\begin{aligned}\Delta H_{\text{rxn}}^\circ &= [6\Delta H_f^\circ(\text{CO}_2) + 3\Delta H_f^\circ(\text{H}_2\text{O})] - [\Delta H_f^\circ(\text{C}_6\text{H}_6) + \tfrac{15}{2}\Delta H_f^\circ(\text{O}_2)] \\ &= [6(-393.5 \text{ kJ}) + 3(-285.8 \text{ kJ})] - [(49.0 \text{ kJ}) + \tfrac{15}{2}(0 \text{ kJ})] \\ &= (-2361 - 857.4 - 49.0) \text{ kJ} \\ &= -3267 \text{ kJ}\end{aligned}$$

- (b) From the example worked in the text,  $\Delta H^\circ = -2220 \text{ kJ}$  for the combustion of 1 mol of propane. In part (a) of this exercise we determined that  $\Delta H^\circ = -3267 \text{ kJ}$  for the combustion of 1 mol benzene. To determine the heat of combustion per gram of each substance, we use the molar masses to convert moles to grams:

$$\text{C}_3\text{H}_8(\text{g}): (-2220 \text{ kJ/mol})(1 \text{ mol}/44.1 \text{ g}) = -50.3 \text{ kJ/g}$$

$$\text{C}_6\text{H}_6(\text{l}): (-3267 \text{ kJ/mol})(1 \text{ mol}/78.1 \text{ g}) = -41.8 \text{ kJ/g}$$

**Comment** Both propane and benzene are hydrocarbons. As a rule, the energy obtained from the combustion of a gram of hydrocarbon is between 40 and 50 kJ.

### ► Practice Exercise 1

Calculate the enthalpy change for the reaction

using enthalpies of formation:

$$\Delta H_f^\circ[\text{H}_2\text{O}_2(\text{l})] = -187.8 \text{ kJ/mol} \quad \Delta H_f^\circ[\text{H}_2\text{O}(\text{l})] = -285.8 \text{ kJ/mol}$$

- (a)  $-88.0 \text{ kJ}$
- (b)  $-196.0 \text{ kJ}$
- (c)  $+88.0 \text{ kJ}$
- (d)  $+196.0 \text{ kJ}$
- (e) more information needed

### ► Practice Exercise 2

Use Table 5.3 to calculate the enthalpy change for the combustion of 1 mol of ethanol:

## Sample Exercise 5.12

### Calculating an Enthalpy of Formation Using an Enthalpy of Reaction

The standard enthalpy change for the reaction  $\text{CaCO}_3[\text{s}] \longrightarrow \text{CaO}[\text{s}] + \text{CO}_2[\text{g}]$  is  $178.1 \text{ kJ}$ . Use Table 5.3 to calculate the standard enthalpy of formation of  $\text{CaCO}_3[\text{s}]$ .

### SOLUTION

**Analyze** Our goal is to obtain  $\Delta H_f^\circ[\text{CaCO}_3]$ .

**Plan** We begin by writing the expression for the standard enthalpy change for the reaction:

$$\Delta H_{\text{rxn}}^\circ = \Delta H_f^\circ[\text{CaO}] + \Delta H_f^\circ[\text{CO}_2] - \Delta H_f^\circ[\text{CaCO}_3]$$

### Solve

Inserting the given  $\Delta H_{\text{rxn}}^\circ$  and the known  $\Delta H_f^\circ$  values from Table 5.3 or Appendix C, we have:

$$178.1 \text{ kJ} = -635.5 \text{ kJ} - 393.5 \text{ kJ} - \Delta H_f^\circ[\text{CaCO}_3]$$

Solving for  $\Delta H_f^\circ[\text{CaCO}_3]$  gives:

$$\Delta H_f^\circ[\text{CaCO}_3] = -1207.1 \text{ kJ/mol}$$

**Check** We expect the enthalpy of formation of a stable solid such as calcium carbonate to be negative, as obtained.

### ► Practice Exercise 1

Given  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{SO}_3(\text{g})$ , which of the following equations is correct?

- (a)  $\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ - \Delta H_f^\circ[\text{SO}_2]$
- (b)  $\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ + \Delta H_f^\circ[\text{SO}_2]$
- (c)  $2\Delta H_f^\circ[\text{SO}_3] = \Delta H_{\text{rxn}}^\circ + 2\Delta H_f^\circ[\text{SO}_2]$

### ► Practice Exercise 2

Given the following standard enthalpy change, use the standard enthalpies of formation in Table 5.3 to calculate the standard enthalpy of formation of  $\text{CuO}(\text{s})$ :

## 5.8 | Bond Enthalpies

The energy changes that accompany chemical reactions are closely related to the changes associated with forming and breaking chemical bonds—breaking bonds requires energy and forming bonds releases energy. It follows that if we measure the enthalpy of a reaction and keep track of the bonds that are broken and formed, we can assign an enthalpy

value to specific bonds. The **bond enthalpy** is the enthalpy change,  $\Delta H$ , for the breaking of a particular bond in one mole of a gaseous substance. It is easiest to determine bond enthalpies from simple reactions where only one bond is broken, such as the dissociation of  $\text{Cl}_2(g)$ . A  $\text{Cl}_2$  molecule is held together by a single covalent bond, which is represented as  $\text{Cl—Cl}$ . The dissociation of  $\text{Cl}_2(g)$  into chlorine atoms results when the  $\text{Cl—Cl}$  bond is broken:

The bond enthalpy for a  $\text{Cl—Cl}$  bond is equal to the enthalpy of this reaction, 242 kJ/mol. The bond enthalpy is a positive number because energy must be supplied from the surroundings to break the  $\text{Cl—Cl}$  bond. We use the letter  $D$  followed by the bond in question to represent bond enthalpies. For example,  $D(\text{Cl—Cl})$  is the bond enthalpy for the  $\text{Cl}_2$  bond, and  $D(\text{H—Br})$  is the bond enthalpy for the  $\text{HBr}$  bond.

### Give It Some Thought

Which is more stable at room temperature, a  $\text{Cl}_2$  molecule or two separate  $\text{Cl}$  atoms? What is the energy difference between the  $\text{Cl}_2$  molecule and the separated atoms?

It is straightforward to assign bond enthalpies for a reaction involving the breaking of a bond in a diatomic molecule: the bond enthalpy is simply equal to the enthalpy of the reaction. However, many important bonds, such as the  $\text{C—H}$  bond, exist only in polyatomic molecules. For these bonds, we usually use average bond enthalpies. For example, the enthalpy change for the following process in which a methane molecule is decomposed into its five constituent atoms can be used to define an average bond enthalpy for the  $\text{C—H}$  bond:

Because there are four equivalent  $\text{C—H}$  bonds in methane, the enthalpy of this reaction is four times the enthalpy needed to break a single  $\text{C—H}$  bond. Therefore, the average  $\text{C—H}$  bond enthalpy in  $\text{CH}_4$  is  $D(\text{C—H}) = (1660/4) \text{ kJ/mol} = 415 \text{ kJ/mol}$ .

The exact bond enthalpy for a given pair of atoms, say  $\text{C—H}$ , depends on the rest of the molecule containing the atom pair. However, the variation from one molecule to another is generally small. If we consider  $\text{C—H}$  bond enthalpies in many different compounds, we find that the average bond enthalpy is 413 kJ/mol, close to the 415 kJ/mol value we just calculated from for the dissociation of  $\text{CH}_4$ .

*The bond enthalpy is always a positive quantity because energy is required to break chemical bonds. Conversely, energy is always released when a bond forms between two gaseous atoms or molecular fragments. The greater the bond enthalpy, the stronger the bond.*

**Table 5.4** lists average bond enthalpies for a number of atom pairs. Further, a molecule with strong chemical bonds is generally less likely to undergo chemical change than

TABLE 5.4 Average Bond Enthalpies (kJ/mol)

|      |     |      |     |      |     |       |     |
|------|-----|------|-----|------|-----|-------|-----|
| C—H  | 413 | N—H  | 391 | O—H  | 463 | F—F   | 155 |
| C—C  | 348 | N—N  | 163 | O—O  | 146 |       |     |
| C=C  | 614 | N—O  | 201 | O=O  | 495 | Cl—F  | 253 |
| C—N  | 293 | N—F  | 272 | O—F  | 190 | Cl—Cl | 242 |
| C—O  | 358 | N—Cl | 200 | O—Cl | 203 |       |     |
| C=O  | 799 | N—Br | 243 | O—I  | 234 | Br—F  | 237 |
| C—F  | 485 |      |     |      |     | Br—Cl | 218 |
| C—Cl | 328 | H—H  | 436 |      |     | Br—Br | 193 |
| C—Br | 276 | H—F  | 567 |      |     |       |     |
| C—I  | 240 | H—Cl | 431 |      |     | I—Cl  | 208 |
|      |     | H—Br | 366 |      |     | I—Br  | 175 |
|      |     | H—I  | 299 |      |     | I—I   | 151 |

one with weak bonds. As we will learn in later chapters, atom pairs are sometimes held together by multiple bonds. For example, the oxygen atoms in an  $O_2$  molecule are held together by a double bond,  $O=O$ , rather than a single bond,  $O—O$ .

Inspection of Table 5.4 shows that  $D(O=O) = 495 \text{ kJ/mol}$ , which is larger but not exactly twice the enthalpy of an oxygen–oxygen single bond,  $D(O—O) = 146 \text{ kJ/mol}$ . We will consider the variations in bond enthalpy for double and triple bonds in more detail in Chapter 8.

## Bond Enthalpies and the Enthalpies of Reactions

Because enthalpy is a state function, we can use average bond enthalpies to estimate the enthalpies of reactions in which bonds are broken and new bonds are formed. This procedure allows us to estimate quickly whether a given reaction will be endothermic ( $\Delta H > 0$ ) or exothermic ( $\Delta H < 0$ ), even if we do not know  $\Delta H_f^\circ$  for all of the species involved.

Our strategy for estimating reaction enthalpies is a straightforward application of Hess's law. We use the fact that breaking bonds is always endothermic and forming bonds is always exothermic. We therefore imagine that the reaction occurs in two steps:

1. We supply enough energy to break those bonds in the reactants that are not present in the products. The enthalpy of the system is increased by the sum of the bond enthalpies of the bonds that are broken.
2. We form the bonds in the products that were not present in the reactants. This step releases energy and therefore lowers the enthalpy of the system by the sum of the bond enthalpies of the bonds that are formed.

The enthalpy of the reaction,  $\Delta H_{\text{rxn}}$ , is estimated as the sum of the bond enthalpies of the bonds broken minus the sum of the bond enthalpies of the bonds formed:

$$\Delta H_{\text{rxn}} = \sum (\text{bond enthalpies of bonds broken}) - \sum (\text{bond enthalpies of bonds formed}) \quad [5.32]$$

If the total enthalpy of the broken bonds is larger, the reaction is endothermic ( $\Delta H_{\text{rxn}} > 0$ ); if the total enthalpy of the newly formed bonds is larger, the reaction is exothermic ( $\Delta H_{\text{rxn}} < 0$ ).

Consider for example, the gas-phase reaction between methane,  $\text{CH}_4$ , and chlorine to produce methyl chloride,  $\text{CH}_3\text{Cl}$ , and hydrogen chloride,  $\text{HCl}$ :

Our two-step procedure is outlined in **Figure 5.24**. We note that the following bonds are broken and formed:

*Bonds broken:* 1 mol C—H, 1 mol Cl—Cl

*Bonds formed:* 1 mole C—Cl, 1 mol H—Cl

We first supply enough energy to break the C—H and Cl—Cl bonds, which raises the enthalpy of the system (indicated as  $\Delta H_1 > 0$  in Figure 5.24). We then form the C—Cl and H—Cl bonds, which release energy and lower the enthalpy of the system ( $\Delta H_2 < 0$  in Figure 5.24). We then use Equation 5.32 to estimate the enthalpy of the reaction:

$$\Delta H_{\text{rxn}} = [D(\text{C}-\text{H}) + D(\text{Cl}-\text{Cl})] - [D(\text{C}-\text{Cl}) + D(\text{H}-\text{Cl})]$$

$$\Delta H_{\text{rxn}} = (413 \text{ kJ} + 242 \text{ kJ}) - (328 \text{ kJ} + 431 \text{ kJ}) = -104 \text{ kJ}$$

The reaction is exothermic because the bonds in the products are stronger than the bond in the reactants.

Typically, bond enthalpies are used to estimate  $\Delta H_{\text{rxn}}$  only if the needed  $\Delta H_f^\circ$  values are not readily available. For the preceding reaction, we cannot calculate  $\Delta H_{\text{rxn}}$  from  $\Delta H_f^\circ$

### Sample Exercise 5.13

#### Estimating Reaction Enthalpies from Bond Enthalpies

Use Table 5.4 to estimate  $\Delta H$  for the following combustion reaction.

#### SOLUTION

**Analyze** We are asked to use average bond enthalpies to estimate the enthalpy change for a chemical reaction.

**Plan** Energy is required to break twelve C—H bonds and two C—C bonds in the two molecules of  $\text{C}_2\text{H}_6$ , and seven O=O bonds in the seven  $\text{O}_2$  molecules. Energy is released by forming eight C=O bonds, two per molecule of  $\text{CO}_2$ , and twelve O—H bonds, two per  $\text{H}_2\text{O}$  molecule.

**Solve** Using Equation 5.32 and data from Table 5.4, we have

$$\begin{aligned}
 \Delta H &= [12D(\text{C}-\text{H}) + 2D(\text{C}-\text{C}) + 7D(\text{O}=\text{O})] \\
 &\quad - [8D(\text{C}=\text{O}) + 12D(\text{O}-\text{H})] \\
 &= [12(413 \text{ kJ}) + 2(348 \text{ kJ}) + 7(495 \text{ kJ})] \\
 &\quad - [8(799 \text{ kJ}) + 12(463 \text{ kJ})] \\
 &= 9117 \text{ kJ} - 11948 \text{ kJ} \\
 &= -2831 \text{ kJ}
 \end{aligned}$$

**Check** This estimate can be compared with the value of  $-2856 \text{ kJ}$  calculated from more accurate thermochemical data; the agreement is good.

#### Practice Exercise 1

Use the average bond enthalpies in Table 5.4 to estimate  $\Delta H$  for the “water splitting reaction”:  $\text{H}_2\text{O}(\text{g}) \longrightarrow \text{H}_2(\text{g}) + \frac{1}{2} \text{O}_2(\text{g})$ .  
(a) 242 kJ (b) 417 kJ (c) 5 kJ (d)  $-5 \text{ kJ}$  (e)  $-468 \text{ kJ}$

#### Practice Exercise 2

Use the average bond enthalpies in Table 5.4 to estimate  $\Delta H$  for the combustion of ethanol.

values and Hess's law because  $\Delta H_f^\circ$  for  $\text{CH}_3\text{Cl}(\text{g})$  is not given in Appendix C. If we obtain the value of  $\Delta H_f^\circ$  for  $\text{CH}_3\text{Cl}(\text{g})$  from another source and use Equation 5.31, we find that  $\Delta H_{\text{rxn}} = -99.8 \text{ kJ}$  for the reaction in Equation 5.33. The two values are slightly different because bond enthalpies are averaged over many compounds, but the use of average bond enthalpies provides a reasonably accurate estimate of the actual reaction enthalpy change.

It is important to remember that bond enthalpies are derived for gaseous molecules. In solids, liquids, and solutions, intermolecular forces between different molecules must also be taken into account. We will examine the strengths of those forces in detail in Chapter 11, but for now it is sufficient to remember that bond enthalpies cannot be used to accurately estimate the enthalpies of reactions containing solids, liquids, or solutions.

## 5.9 | Foods and Fuels

Most chemical reactions used for the production of heat are combustion reactions. The energy released when one gram of any substance is combusted is the **fuel value** of the substance. The fuel value of any food or fuel can be measured by calorimetry.

### Foods

Most of the energy our bodies need comes from carbohydrates and fats. The carbohydrates known as starches are decomposed in the intestines into glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ . Glucose is soluble in blood, and in the human body it is known as blood sugar. It is transported by the blood to cells where it reacts with  $\text{O}_2$  in a series of steps, eventually producing  $\text{CO}_2(\text{g})$ ,  $\text{H}_2\text{O}(\text{l})$ , and energy:

Because carbohydrates break down rapidly, their energy is quickly supplied to the body. However, the body stores only a very small amount of carbohydrates. The average fuel value of carbohydrates is 17 kJ/g (4 kcal/g). Although fuel values represent the heat released in a combustion reaction, by convention fuel values are reported as positive numbers.

### Give It Some Thought

Based on the enthalpy of the above reaction, what is the fuel value of glucose on a per gram basis?

Like carbohydrates, fats produce  $\text{CO}_2$  and  $\text{H}_2\text{O}$  when metabolized. The reaction of tristearin,  $\text{C}_{57}\text{H}_{110}\text{O}_6$ , a typical fat, is

The body uses the chemical energy from foods to maintain body temperature (see the “Chemistry and Life” box in Section 5.5), to contract muscles, and to construct and repair tissues. Any excess energy is stored as fats. Fats are well suited to serve as the body’s energy reserve for at least two reasons: (1) They are insoluble in water, which facilitates storage in the body, and (2) they produce more energy per gram than either proteins or carbohydrates, which makes them efficient energy sources on a mass basis. The average fuel value of fats is 38 kJ/g (9 kcal/g).

The combustion of carbohydrates and fats in a bomb calorimeter gives the same products as when they are metabolized in the body. The metabolism of proteins produces less energy than combustion in a calorimeter because the products are different. Proteins contain nitrogen, which is released in the bomb calorimeter as  $\text{N}_2$ . In the body this nitrogen ends up mainly as urea,  $(\text{NH}_2)_2\text{CO}$ . Proteins are used by the body mainly as building materials for organ walls, skin, hair, muscle, and so forth. On average, the metabolism of proteins produces 17 kJ/g (4 kcal/g), the same as for carbohydrates.

Fuel values for some common foods are shown in Table 5.5. Labels on packaged foods show the amounts of carbohydrate, fat, and protein contained in an average serving, as well as the amount of energy supplied by a serving (Figure 5.25).

The amount of energy our bodies require varies considerably, depending on such factors as weight, age, and muscular activity. About 100 kJ per kilogram of body mass per

**TABLE 5.5 Compositions and Fuel Values of Some Common Foods**

|                   | Approximate Composition (% by Mass) |     |         | Fuel Value |                |
|-------------------|-------------------------------------|-----|---------|------------|----------------|
|                   | Carbohydrate                        | Fat | Protein | kJ/g       | kcal/g (Cal/g) |

day is required to keep the body functioning at a minimal level. An average 70-kg (154-lb) person expends about 800 kJ/h when doing light work, and strenuous activity often requires 2000 kJ/h or more. When the fuel value, or caloric content, of the food we ingest exceeds the energy we expend, our body stores the surplus as fat.

### Give It Some Thought

Which releases the greatest amount of energy per gram when metabolized? Carbohydrates, proteins, or fats.

## Sample Exercise 5.14

### Estimating the Fuel Value of a Food from Its Composition

- (a) A 28-g (1-oz) serving of a popular breakfast cereal served with 120 mL of skim milk provides 8 g protein, 26 g carbohydrates, and 2 g fat. Using the average fuel values of these substances, estimate the fuel value (caloric content) of this serving.  
 (b) A person of average weight uses about 100 Cal/mi when running or jogging. How many servings of this cereal provide the fuel value requirements to run 3 mi?

### SOLUTION

**Analyze** (a) The fuel value of the serving will be the sum of the fuel values of the protein, carbohydrates, and fat. (b) Here we are faced with the reverse problem, calculating the quantity of food that provides a specific fuel value.

**Plan** (a) We are given the masses of the protein, carbohydrates, and fat contained in a serving. We can use the data in Table 5.4 to convert these masses to their fuel values, which we can sum to get the total fuel value. (b) The problem statement provides a conversion factor between Calories and miles. The answer to part (a) provides us with a conversion factor between servings and Calories.

### Solve

$$\begin{aligned} \text{(a)} \quad & (8 \text{ g protein}) \left( \frac{17 \text{ kJ}}{1 \text{ g protein}} \right) + (26 \text{ g carbohydrate}) \left( \frac{17 \text{ kJ}}{1 \text{ g carbohydrate}} \right) \\ & + (2 \text{ g fat}) \left( \frac{38 \text{ kJ}}{1 \text{ g fat}} \right) = 650 \text{ kJ (to two significant figures)} \end{aligned}$$

This corresponds to 160 kcal:

$$(650 \text{ kJ}) \left( \frac{1 \text{ kcal}}{4.18 \text{ kJ}} \right) = 160 \text{ kcal}$$

Recall that the dietary Calorie is equivalent to 1 kcal. Thus, the serving provides 160 Cal.

- (b) We can use these factors in a straightforward dimensional analysis to determine the number of servings needed, rounded to the nearest whole number:

$$\text{Servings} = (3 \text{ mi}) \left( \frac{100 \text{ Cal}}{1 \text{ mi}} \right) \left( \frac{1 \text{ serving}}{160 \text{ Cal}} \right) = 2 \text{ servings}$$

### Practice Exercise 1

A stalk of celery has a caloric content (fuel value) of 9.0 kcal. If 1.0 kcal is provided by fat and there is very little protein, estimate the number of grams of carbohydrate and fat in the celery.  
 (a) 2 g carbohydrate and 0.1 g fat (b) 2 g carbohydrate and 1 g fat (c) 1 g carbohydrate and 2 g fat (d) 32 g carbohydrate and 10 g fat

### Practice Exercise 2

(a) Dry red beans contain 62% carbohydrate, 22% protein, and 1.5% fat. Estimate the fuel value of these beans.  
 (b) During a very light activity, such as reading or watching television, the average adult expends about 7 kJ/min. How many minutes of such activity can be sustained by the energy provided by a serving of chicken noodle soup containing 13 g protein, 15 g carbohydrate, and 5 g fat?

## Fuels

During the complete combustion of fuels, carbon is converted to  $\text{CO}_2$  and hydrogen is converted to  $\text{H}_2\text{O}$ , both of which have large negative enthalpies of formation. Consequently, the greater the percentage of carbon and hydrogen in a fuel, the higher its fuel value. In Table 5.6, for example, compare the compositions and fuel values of bituminous coal and wood. The coal has a higher fuel value because of its greater carbon content.

In 2013 the United States consumed  $1.02 \times 10^{17}$  kJ of energy. This value corresponds to an average daily energy consumption per person of  $9.3 \times 10^5$  kJ, roughly 100 times greater than the per capita food-energy needs. Figure 5.26 illustrates the sources of this energy.

Coal, petroleum, and natural gas, which are the world's major sources of energy, are known as **fossil fuels**. All have formed over millions of years from the decomposition of plants and animals and are being depleted far more rapidly than they are being formed.

**Natural gas** consists of gaseous hydrocarbons, compounds of hydrogen and carbon. It contains primarily methane ( $\text{CH}_4$ ), with small amounts of ethane ( $\text{C}_2\text{H}_6$ ), propane ( $\text{C}_3\text{H}_8$ ), and butane ( $\text{C}_4\text{H}_{10}$ ). We determined the fuel value of propane in Sample Exercise 5.10.

**TABLE 5.6 Fuel Values and Compositions of Some Common Fuels**

|                                | Approximate Elemental Composition (Mass %) |     |    | Fuel Value (kJ/g) |
|--------------------------------|--|-----|----|-------------------|
|                                | C  | H   | O  |                   |
| Wood (pine)                    | 50   | 6   | 44 | 18                |
| Anthracite coal (Pennsylvania) | 82   | 1   | 2  | 31                |
| Bituminous coal (Pennsylvania) | 77   | 5   | 7  | 32                |
| Charcoal                       | 100  | 0   | 0  | 34                |
| Crude oil (Texas)              | 85   | 12  | 0  | 45                |
| Gasoline                       | 85   | 15  | 0  | 48                |
| Natural gas                    | 70   | 23  | 0  | 49                |
| Hydrogen                       | 0  | 100 | 0  | 142               |

Natural gas burns with far fewer by-products and produces less  $\text{CO}_2$  than either petroleum or coal. **Petroleum** is a liquid composed of hundreds of compounds, most of which are hydrocarbons, with the remainder being chiefly organic compounds containing sulfur, nitrogen, or oxygen. **Coal**, which is solid, contains hydrocarbons of high molecular weight as well as compounds containing sulfur, oxygen, or nitrogen. Coal is the most abundant fossil fuel; current reserves are projected to last for well over 100 years at current consumption rates. However, the use of coal presents a number of problems.

Coal is a complex mixture of substances, and it contains components that cause air pollution. When coal is combusted, the sulfur it contains is converted mainly to sulfur dioxide,  $\text{SO}_2$ , a troublesome air pollutant. Because coal is a solid, recovery from its underground deposits is expensive and often dangerous. Furthermore, coal deposits are not always close to locations of high-energy use, so there are often substantial shipping costs.

Fossil fuels release energy in combustion reactions, which ideally produce only  $\text{CO}_2$  and  $\text{H}_2\text{O}$ . The production of  $\text{CO}_2$  has become a major issue that involves science and public policy because of concerns that increasing concentrations of atmospheric  $\text{CO}_2$  are causing global climate changes. We will discuss the environmental aspects of atmospheric  $\text{CO}_2$  in Chapter 18.

## Other Energy Sources

**Nuclear energy** is the energy released in either the fission (splitting) or the fusion (combining) of atomic nuclei. Nuclear power based on nuclear fission is currently used to produce about 19% of the electric power in the United States and makes up about 8.6% of the total U.S. energy production (Figure 5.26). Nuclear energy is, in principle, free of the polluting emissions that are a major problem with fossil fuels. However, nuclear power plants produce radioactive waste products, and their use has therefore been controversial. We will discuss issues related to the production of nuclear energy in Chapter 21.

Fossil fuels and nuclear energy are *nonrenewable* sources of energy—they are limited resources that we are consuming at a much greater rate than they can be regenerated. Eventually these fuels will be expended, although estimates vary greatly as to when this will occur. Because nonrenewable energy sources will eventually be used up, a great deal of research is being conducted on **renewable energy sources**, sources that are essentially inexhaustible. Renewable energy sources include *solar energy* from the Sun, *wind energy* harnessed by windmills, *geothermal energy* from the heat stored inside Earth, *hydroelectric energy* from flowing rivers, and *biomass energy* from crops and biological waste matter. Currently, renewable sources provide about 9.9% of the U.S. annual energy consumption. Electricity is typically generated by using a moving gas or liquid to turn a turbine that is connected to a generator, although there are some exceptions like solar cells. Of the  $4.0 \times 10^{13}$  kJ of electricity consumed in 2015 in the United States approximately

▲ **Figure 5.26** Energy consumption in the United States.\* In 2015 the United States consumed a total of  $1.02 \times 10^{17}$  kJ of energy.

\*Annual Energy Review 2015, U.S. Energy Information Administration, U. S. Department of Energy.

67% came from burning fossil fuels. Other sources of electricity include nuclear energy (20%), hydroelectric (6%), wind (4.7%), biomass (1.6%) and solar (0.6%).

Fulfilling our future energy needs will depend on developing technology to harness solar energy with greater efficiency. Solar energy is the world's largest energy source. On a clear day about 1 kJ of solar energy reaches each square meter of Earth's surface every second. The average solar energy falling on only 0.1% of U.S. land area is equivalent to all the energy this nation currently uses. Harnessing this energy is difficult because it is dilute (that is, distributed over a wide area) and varies with time of day and weather conditions. The effective use of solar energy will depend on the development of some means of storing and distributing it. One practical way to do this is to use the Sun's energy to drive an endothermic chemical process that can be later reversed to release heat. One such reaction is

This reaction proceeds in the forward direction at high temperatures, which can be obtained in a solar furnace. The CO and H<sub>2</sub> formed in the reaction could then be stored and allowed to react later, with the heat released being put to useful work.

## CHEMISTRY PUT TO WORK The Scientific and Political Challenges of Biofuels\*

One of the biggest challenges facing us in the twenty-first century is production of abundant sources of energy, both food and fuels. At the end of 2015, the global population was estimated to be 7.4 billion people, and growing at a rate of about 750 million per decade. A growing world population puts greater demands on the global food supply, especially in Asia and Africa, which together make up more than 75% of the world population.

A growing population also increases demands on the production of fuels for transportation, industry, electricity, heating, and cooling. As populous countries such as China and India have modernized, their per capita consumption of energy has increased significantly. In China, for instance, per capita energy consumption roughly doubled between 1990 and 2010, and in 2010 China passed the United States as the world's largest user of energy (although it is still less than 20% of U.S. per capita energy consumption).

Global fuel energy consumption in 2012 was more than  $5 \times 10^{17}$  kJ, a staggeringly large number. More than 80% of current energy requirements comes from combustion of nonrenewable fossil fuels, especially coal and petroleum. The exploration of new fossil fuel sources often involves environmentally sensitive regions, making the search for new supplies of fossil fuels a major political and economic issue.

The global importance of petroleum is in large part because it provides liquid fuels, such as gasoline, that are critical to supplying transportation needs. One of the most promising—but controversial—alternatives to petroleum-based fuels is *biofuels*, liquid fuels derived from biological matter. The most common approach to producing biofuels is to transform plant sugars and other carbohydrates into combustible liquids.

The most commonly produced biofuel is *bioethanol*, which is ethanol (C<sub>2</sub>H<sub>5</sub>OH) made from fermentation of plant carbohydrates. The fuel value of ethanol is about two-thirds that of gasoline and is therefore comparable to that of coal (Table 5.6). The United States and Brazil dominate bioethanol production, together supplying 85% of the world's total.

In the United States, nearly all the bioethanol currently produced is made from yellow feed corn. Glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) in the corn is converted to ethanol and CO<sub>2</sub>:

Notice that this reaction is *anaerobic*—it does not involve O<sub>2</sub>(g)—and that the enthalpy change is positive and much smaller in magnitude than for most combustion reactions. Other carbohydrates can be converted to ethanol in similar fashion.

Producing bioethanol from corn is controversial for two main reasons. First, growing and transporting corn are both energy-intensive processes, and growing it requires the use of fertilizers. It is estimated that the *energy return* on corn-based bioethanol is only 34%—that is, for each 1.00 J of energy expended to produce the corn, 1.34 J of energy is produced in the form of bioethanol. Second, the use of corn as a starting material for making bioethanol competes with its use as an important component of the food chain (the so-called food versus fuel debate).

Much current research focuses on the formation of bioethanol from *cellulosic* plants, plants that contain the complex carbohydrate cellulose. Cellulose is not readily metabolized and so does not compete with the food supply. However, the chemistry for converting cellulose to ethanol is much more complex than that for converting corn. Cellulosic bioethanol could be produced from very fast-growing nonfood plants, such as prairie grasses and switchgrass, which readily renew themselves without the use of fertilizers.

The Brazilian bioethanol industry uses sugarcane as its feedstock (Figure 5.27). Sugarcane grows much faster than corn and without the

▲ Figure 5.27 Sugarcane can be converted to a sustainable bioethanol product.

\* Data from the Annual Energy Outlook 2012, U.S. Energy Information Administration.

need for fertilizers or tending. Because of these differences, the energy return for sugarcane is much higher than the energy return for corn. It is estimated that for each 1.0 J of energy expended in growing and processing sugarcane, 8.0 J of energy is produced as bioethanol.

Other biofuels that are also becoming a major part of the world economy include *biodiesel*, a substitute for petroleum-derived diesel

fuel. Biodiesel is typically produced from crops that have a high oil content, such as soybeans and canola. It can also be produced from animal fats and waste vegetable oil from the food and restaurant industry.

**Related Exercises:** 5.97, 5.98, 5.117

Plants utilize solar energy in *photosynthesis*, the reaction in which the energy of sunlight is used to convert  $\text{CO}_2$  and  $\text{H}_2\text{O}$  into carbohydrates and  $\text{O}_2$ :

Photosynthesis is an important part of Earth's ecosystem because it replenishes atmospheric  $\text{O}_2$ , produces an energy-rich molecule that can be used as fuel, and consumes some atmospheric  $\text{CO}_2$ .

Perhaps the most direct way to use the Sun's energy is to convert it directly into electricity in photovoltaic devices, or *solar cells*, which we mentioned at the beginning of this chapter. The efficiencies of such devices have increased dramatically during the past few years. Technological advances have led to solar panels that last longer and produce electricity with greater efficiency at steadily decreasing unit cost. Indeed, the future of solar energy is, like the Sun itself, very bright.

## SAMPLE INTEGRATIVE EXERCISE

### Putting Concepts Together

Trinitroglycerin,  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9$  (usually referred to simply as nitroglycerin), has been widely used as an explosive. Alfred Nobel used it to make dynamite in 1866. Rather surprisingly, it also is used as a medication, to relieve angina (chest pains resulting from partially blocked arteries to the heart) by dilating the blood vessels. At 1 atm pressure and  $25^\circ\text{C}$ , the enthalpy of decomposition of trinitroglycerin to form nitrogen gas, carbon dioxide gas, liquid water, and oxygen gas is  $-1541.4 \text{ kJ/mol}$ .

- Write a balanced chemical equation for the decomposition of trinitroglycerin.
- Calculate the standard heat of formation of trinitroglycerin.
- A standard dose of trinitroglycerin for relief of angina is 0.60 mg. If the sample is eventually oxidized in the body (not explosively, though!) to nitrogen gas, carbon dioxide gas, and liquid water, what number of calories is released?
- One common form of trinitroglycerin melts at about  $3^\circ\text{C}$ . From this information and the formula for the substance, would you expect it to be a molecular or ionic compound? Explain.
- Describe the various conversions of forms of energy when trinitroglycerin is used as an explosive to break rockfaces in highway construction.

## SOLUTION

- (a) The general form of the equation we must balance is

We go about balancing in the usual way. To obtain an even number of nitrogen atoms on the left, we multiply the formula for  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9$  by 2, which gives us 3 mol of  $\text{N}_2$ , 6 mol of  $\text{CO}_2$  and 5 mol of  $\text{H}_2\text{O}$ . Everything is then balanced except for oxygen. We have an odd number of oxygen atoms on the right. We can balance the oxygen by using the coefficient  $\frac{1}{2}$  for  $\text{O}_2$  on the right:

We multiply through by 2 to convert all coefficients to whole numbers:

(At the temperature of the explosion, water is a gas rather than a liquid as shown in the equation above. The rapid expansion of the gaseous products creates the force of an explosion.)

- (b) We can obtain the standard enthalpy of formation of nitroglycerin by using the heat of decomposition of trinitroglycerin together with the standard enthalpies of formation of the other substances in the decomposition equation:

The enthalpy change for this decomposition is  $4(-1541.4 \text{ kJ}) = -6165.6 \text{ kJ}$ . [We need to multiply by 4 because there are 4 mol of  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)$  in the balanced equation.]

This enthalpy change equals the sum of the heats of formation of the products minus the heats of formation of the reactants, each multiplied by its coefficient in the balanced equation:

$$-6165.6 \text{ kJ} = 6\Delta H_f^\circ[\text{N}_2(g)] + 12\Delta H_f^\circ[\text{CO}_2(g)] + 10\Delta H_f^\circ[\text{H}_2\text{O}(l)] + \Delta H_f^\circ[\text{O}_2(g)] - 4\Delta H_f^\circ[\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)]$$

The  $\Delta H_f^\circ$  values for  $\text{N}_2(g)$  and  $\text{O}_2(g)$  are zero, by definition. Using the values for  $\text{H}_2\text{O}(l)$  and  $\text{CO}_2(g)$  from Table 5.3 or Appendix C, we have

$$-6165.6 \text{ kJ} = 12(-393.5 \text{ kJ}) + 10(-285.8 \text{ kJ}) - 4\Delta H_f^\circ[\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)]$$

$$\Delta H_f^\circ[\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)] = -353.6 \text{ kJ/mol}$$

- (c) Converting 0.60 mg  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)$  to moles and using the fact that the decomposition of 1 mol of  $\text{C}_3\text{H}_5\text{N}_3\text{O}_9(l)$  yields 1541.4 kJ we have:

$$(0.60 \times 10^{-3} \text{ g C}_3\text{H}_5\text{N}_3\text{O}_9) \left( \frac{1 \text{ mol C}_3\text{H}_5\text{N}_3\text{O}_9}{227 \text{ g C}_3\text{H}_5\text{N}_3\text{O}_9} \right) \left( \frac{1541.4 \text{ kJ}}{1 \text{ mol C}_3\text{H}_5\text{N}_3\text{O}_9} \right) = 4.1 \times 10^{-3} \text{ kJ} = 4.1 \text{ J}$$

Continued

(d) Because trinitroglycerin melts below room temperature, we expect that it is a molecular compound. With few exceptions, ionic substances are generally hard, crystalline materials that melt at high temperatures.  (Sections 2.6 and 2.7) Also, the molecular formula suggests that it is a molecular substance because all of its constituent elements are nonmetals.

(e) The energy stored in trinitroglycerin is chemical potential energy. When the substance reacts explosively, it forms carbon dioxide, water, and nitrogen gas, which are of lower potential energy. In the course of the chemical transformation, energy is

released in the form of heat; the gaseous reaction products are very hot. This high heat energy is transferred to the surroundings. Work is done as the gases expand against the surroundings, moving the solid materials and imparting kinetic energy to them. For example, a chunk of rock might be impelled upward. It has been given kinetic energy by transfer of energy from the hot, expanding gases. As the rock rises, its kinetic energy is transformed into potential energy. Eventually, it again acquires kinetic energy as it falls to Earth. When it strikes Earth, its kinetic energy is converted largely to thermal energy, though some work may be done on the surroundings as well.

## Chapter Summary and Key Terms

**CHEMICAL ENERGY (INTRODUCTION AND SECTION 5.1)** **Thermodynamics** is the study of energy and its transformations. In this chapter we have focused on **thermochemistry**, the transformations of energy—especially heat—during chemical reactions.

An object can possess energy in two forms: (1) **kinetic energy**, which is the energy due to the motion of the object, and (2) **potential energy**, which is the energy that an object possesses by virtue of its position relative to other objects. An electron in motion near a proton has kinetic energy because of its motion and potential energy because of its electrostatic attraction to the proton.

Chemical energy originates largely from electrostatic interactions at the atomic level. Energy must be supplied to break chemical bonds leading to an increase in potential energy. Conversely, energy is released when chemical bonds form as the potential energy decreases.

**THE FIRST LAW OF THERMODYNAMICS (SECTION 5.2)** When we study thermodynamic properties, we define a specific amount of matter as the **system**. Everything outside the system is the **surroundings**. When we study a chemical reaction, the system is generally the reactants and products. A closed system can exchange energy, but not matter, with the surroundings. The **internal energy** of a system is the sum of all the kinetic and potential energies of its component parts. The internal energy of a system can change because of energy transferred between the system and the surroundings.

According to the **first law of thermodynamics**, the change in the internal energy of a system,  $\Delta E$ , is the sum of the heat,  $q$ , transferred into or out of the system and the work,  $w$ , done on or by the system:  $\Delta E = q + w$ . Both  $q$  and  $w$  have a sign that indicates the direction of energy transfer. When heat is transferred from the surroundings to the system,  $q > 0$ . Likewise, when the surroundings do work on the system,  $w > 0$ . In an **endothermic** process the system absorbs heat from the surroundings; in an **exothermic** process the system releases heat to the surroundings.

The internal energy,  $E$ , is a **state function**. The value of any state function depends only on the state or condition of the system and not on the details of how it came to be in that state. Heat,  $q$ , and work,  $w$ , are not state functions; their values depend on the particular way by which a system changes its state.

**ENTHALPY (SECTIONS 5.3 AND 5.4)** When a gas is produced or consumed in a chemical reaction occurring at constant pressure, the system may perform **pressure-volume (P-V) work** against the prevailing pressure of the surroundings. For this reason, we define a new state function called **enthalpy**,  $H$ , which is related to energy:  $H = E + PV$ . In systems where only pressure-volume work is involved, the change in the enthalpy of a system,  $\Delta H$ , equals the heat gained or lost by the system at constant pressure:  $\Delta H = q_p$

(the subscript  $P$  denotes constant pressure). For an endothermic process,  $\Delta H > 0$ ; for an exothermic process,  $\Delta H < 0$ .

In a chemical process, the **enthalpy of reaction** is the enthalpy of the products minus the enthalpy of the reactants:  $\Delta H_{\text{rxn}} = H(\text{products}) - H(\text{reactants})$ . Enthalpies of reaction follow some simple rules: (1) The enthalpy of reaction is proportional to the amount of reactant that reacts. (2) Reversing a reaction changes the sign of  $\Delta H$ . (3) The enthalpy of reaction depends on the physical states of the reactants and products.

**CALORIMETRY (SECTION 5.5)** The amount of heat transferred between the system and the surroundings is measured experimentally by **calorimetry**. A **calorimeter** measures the temperature change accompanying a process. The temperature change of a calorimeter depends on its **heat capacity**, the amount of heat required to raise its temperature by 1 K. The heat capacity for one mole of a pure substance is called its **molar heat capacity**; for one gram of the substance, we use the term **specific heat**. Water has a very high specific heat, 4.18 J/g·K. The amount of heat,  $q$ , absorbed by a substance is the product of its specific heat ( $C_s$ ), its mass, and its temperature change:  $q = C_s \times m \times \Delta T$ .

If a calorimetry experiment is carried out under a constant pressure, the heat transferred provides a direct measure of the enthalpy change of the reaction. Constant-volume calorimetry is carried out in a vessel of fixed volume called a **bomb calorimeter**. The heat transferred under constant-volume conditions is equal to  $\Delta E$ . Corrections can be applied to  $\Delta E$  values to yield  $\Delta H$ .

**HESS'S LAW (SECTION 5.6)** Because enthalpy is a state function,  $\Delta H$  depends only on the initial and final states of the system. Thus, the enthalpy change of a process is the same whether the process is carried out in one step or in a series of steps. **Hess's law** states that if a reaction is carried out in a series of steps,  $\Delta H$  for the reaction will be equal to the sum of the enthalpy changes for the steps. We can therefore calculate  $\Delta H$  for any process, as long as we can write the process as a series of steps for which  $\Delta H$  is known.

**ENTHALPIES OF FORMATION (SECTION 5.7)** The **enthalpy of formation**,  $\Delta H_f^\circ$ , of a substance is the enthalpy change for the reaction in which the substance is formed from its constituent elements. Usually, enthalpies are tabulated for reactions where reactants and products are in their **standard states**. The standard state of a substance is its pure, most stable form at 1 atm and the temperature of interest (usually 298 K). Thus, the **standard enthalpy change** of a reaction,  $\Delta H^\circ$ , is the enthalpy change when all reactants and products are in their standard states. The **standard enthalpy of formation**,  $\Delta H_f^\circ$ , of a substance is the change in enthalpy for the reaction that forms one mole of the substance from its elements in their standard states. For any element in its standard state,  $\Delta H_f^\circ = 0$ .

The standard enthalpy change for any reaction can be readily calculated from the standard enthalpies of formation of the reactants and products in the reaction:

$$\Delta H_{\text{rxn}}^{\circ} = \sum n\Delta H_f^{\circ}(\text{products}) - \sum m\Delta H_f^{\circ}(\text{reactants})$$

**BOND ENTHALPIES (SECTION 5.8)** The strength of a covalent bond is measured by its bond enthalpy, which is the molar enthalpy change required to break a particular bond. Average bond enthalpies can be determined for a wide variety of covalent bonds. We can estimate the enthalpy changes during chemical reactions involving gaseous substances by adding the average bond enthalpies of the bonds that are broken and subtracting the average bond enthalpies of the bonds that are formed. When the energy needed to break bonds is

larger than the energy released by forming bonds the reaction enthalpy is positive; when the opposite situation holds the reaction enthalpy is negative.

**FOODS AND FUELS (SECTION 5.9)** The **fuel value** of a substance is the heat released when one gram of the substance is combusted. Different types of foods have different fuel values and differing abilities to be stored in the body. The most common fuels are hydrocarbons that are found as **fossil fuels**, such as **natural gas**, **petroleum**, and **coal**. **Renewable energy sources** include solar energy, wind energy, biomass, and hydroelectric energy. Nuclear power does not utilize fossil fuels but does create controversial waste-disposal problems.

## Learning Outcomes After studying this chapter, you should be able to:

- Describe the changes in potential energy that accompany the formation and breaking of chemical bonds. (Section 5.1) *Related Exercises: 5.17, 5.18*
- Distinguish between the system and the surroundings in thermodynamics. (Section 5.2) *Related Exercises: 5.21, 5.22*
- Calculate internal energy from heat and work and state the sign conventions of these quantities. (Section 5.2) *Related Exercises: 5.25–5.28*
- Explain the concept of a state function and give examples. (Section 5.2) *Related Exercises: 5.29, 5.30*
- Calculate  $\Delta H$  from  $\Delta E$  and  $P\Delta V$  (Section 5.3) *Related Exercises: 5.36–5.38*
- Relate  $q_p$  to  $\Delta H$  and indicate how the signs of  $q$  and  $\Delta H$  relate to whether a process is exothermic or endothermic. (Sections 5.2 and 5.3) *Related Exercises: 5.43, 5.44*
- Use thermochemical equations to relate the amount of heat energy transferred in reactions at constant pressure ( $\Delta H$ ) to the amount of substance involved in the reaction. (Section 5.4) *Related Exercises: 5.45–5.48*
- Calculate the heat transferred in a process from temperature measurements together with heat capacities or specific heats (calorimetry). (Section 5.5) *Related Exercises: 5.50, 5.52–5.54*
- Use Hess's law to determine enthalpy changes for reactions. (Section 5.6) *Related Exercises: 5.63–5.66*
- Use standard enthalpies of formation to calculate  $\Delta H^{\circ}$  for reactions. (Section 5.7) *Related Exercises: 5.69, 5.71, 5.73, 5.75*
- Use average bond enthalpies to estimate the reaction enthalpies of reactions where all reactants and products are in the gas phase. (Section 5.8) *Related Exercises: 5.81, 5.83, 5.85, 5.87*

## Key Equations

- |  |        |   |
|--|--------|---|
| • $w = F \times d$   | [5.1]  | Relates work to force and distance  |
| • $E_{\text{el}} = \kappa Q_1 Q_2 / d$   | [5.2]  | Electrostatic potential energy.   |
| • $\Delta E = E_{\text{final}} - E_{\text{initial}}$   | [5.3]  | The change in internal energy   |
| • $\Delta E = q + w$   | [5.4]  | Relates the change in internal energy to heat and work (the first law of thermodynamics)                    |
| • $H = E + PV$   | [5.5]  | Defines enthalpy  |
| • $w = -P\Delta V$   | [5.7]  | The work done by an expanding gas at constant pressure  |
| • $\Delta H = \Delta E + P\Delta V = q_p$  | [5.9]  | Enthalpy change at constant pressure  |
| • $q = C_s \times m \times \Delta T$   | [5.21] | Heat gained or lost based on specific heat, mass, and temperature change                                    |
| • $q_{\text{rxn}} = -C_{\text{cal}} \times \Delta T$   | [5.23] | Heat exchanged between a reaction and calorimeter   |

## Exercises

### Visualizing Concepts

- 5.1** Two positively charged spheres, each with a charge of  $2.0 \times 10^{-5}$  C, a mass of 1.0 kg, and separated by a distance of 1.0 cm, are held in place on a frictionless track. **(a)** What is the electrostatic potential energy of this system? **(b)** If the spheres are released, will they move toward or away from each other? **(c)** What speed will each sphere attain as the distance between the spheres approaches infinity? [Section 5.1]
- 5.2** The accompanying photo shows a pipevine swallowtail caterpillar climbing up a twig. **(a)** As the caterpillar climbs, its potential energy is increasing. What source of energy has been used to effect this change in potential energy? **(b)** If the caterpillar is the system, can you predict the sign of  $q$  as the caterpillar climbs? **(c)** Does the caterpillar do work in climbing the twig? Explain. **(d)** Does the amount of work done in climbing a 12-inch section of the twig depend on the speed of the caterpillar's climb? **(e)** Does the change in potential energy depend on the caterpillar's speed of climb? [Section 5.1]

- 5.3** Consider the accompanying energy diagram. **(a)** Does this diagram represent an increase or decrease in the internal energy of the system? **(b)** What sign is given to  $\Delta E$  for this process? **(c)** If there is no work associated with the process, is it exothermic or endothermic? [Section 5.2]

- 5.4** The contents of the closed box in each of the following illustrations represent a system, and the arrows show the changes to the system during some process. The lengths of the arrows represent the relative magnitudes of  $q$  and  $w$ . **(a)** Which of these processes is endothermic? **(b)** For which of these processes, if any, is  $\Delta E < 0$ ? **(c)** For which process, if any, does the system experience a net gain in internal energy? [Section 5.2]

- 5.5** Imagine that you are climbing a mountain. **(a)** Is the distance you travel to the top a state function? **(b)** Is the change in elevation between your base camp and the peak a state function? [Section 5.2]
- 5.6** The diagram shows four states of a system, each with different internal energy,  $E$ . **(a)** Which of the states of the system has the greatest internal energy? **(b)** In terms of the  $\Delta E$  values, write two expressions for the difference in internal energy between State A and State B. **(c)** Write an expression for the difference in energy between State C and State D. **(d)** Suppose there is another state of the system, State E, and its energy relative to State A is  $\Delta E = \Delta E_1 + \Delta E_4$ . Where would State E be on the diagram? [Section 5.2]

- 5.7** You may have noticed that when you compress the air in a bicycle pump, the body of the pump gets warmer. **(a)** Assuming the pump and the air in it comprise the system, what is the sign of  $w$  when you compress the air? **(b)** What is the sign of  $q$  for this process? **(c)** Based on your answers to parts (a) and (b), can you determine the sign of  $\Delta E$  for compressing the air in the pump? If not, what would you expect for the sign of  $\Delta E$ ? What is your reasoning? [Section 5.2]
- 5.8** Imagine a container placed in a tub of water, as depicted in the accompanying diagram. **(a)** If the contents of the container are the system and heat is able to flow through the container walls, what qualitative changes will occur in the temperatures of the system and in its surroundings? From the system's perspective, is the process exothermic or endothermic? **(b)** If neither the volume nor the pressure of the system changes during the process, how is the change in internal energy related to the change in enthalpy? [Sections 5.2 and 5.3]

- 5.9** In the accompanying cylinder diagram, a chemical process occurs at constant temperature and pressure. **(a)** Is the sign of  $w$  indicated by this change positive or negative? **(b)** If the process is endothermic, does the internal energy of the system within the cylinder increase or decrease during the change and is  $\Delta E$  positive or negative? [Sections 5.2 and 5.3]

- 5.10** The gas-phase reaction shown, between  $N_2$  and  $O_2$ , was run in an apparatus designed to maintain a constant pressure. **(a)** Write a balanced chemical equation for the reaction depicted and predict whether  $w$  is positive, negative, or zero. **(b)** Using data from Appendix C, determine  $\Delta H$  for the formation of one mole of the product. [Sections 5.3 and 5.7]

- 5.11** Consider the two diagrams that follow. **(a)** Based on (i), write an equation showing how  $\Delta H_A$  is related to  $\Delta H_B$  and  $\Delta H_C$ . **(b)** Based on (ii), write an equation relating  $\Delta H_Z$  to the other enthalpy changes in the diagram. **(c)** The equations you obtained in parts (a) and (b) are based on what law? **(d)** Would similar relationships hold for the work involved in each process? [Section 5.6]

- 5.12** Consider the conversion of compound A into compound B:  $A \rightarrow B$ . For both compounds A and B,  $\Delta H_f^\circ > 0$ . **(a)** Sketch an enthalpy diagram for the reaction that is analogous to Figure 5.23. **(b)** Suppose the overall reaction is exothermic. What can you conclude? [Section 5.7]

### The Nature of Chemical Energy (Section 5.1)

- 5.13** **(a)** What is the electrostatic potential energy (in joules) between an electron and a proton that are separated by 53 pm? **(b)** What is the change in potential energy if the distance separating the electron and proton is increased to 1.0 nm? **(c)** Does the potential energy of the two particles increase or decrease when the distance is increased to 1.0 nm?
- 5.14** **(a)** What is the electrostatic potential energy (in joules) between two protons that are separated by 62 pm? **(b)** What is the change in potential energy if the distance separating the two is increased to 1.0 nm? **(c)** Does the potential energy of the two particles increase or decrease when the distance is increased to 1.0 nm?
- 5.15** **(a)** The electrostatic force (not energy) of attraction between two oppositely charged objects is given by the equation  $F = \kappa(Q_1Q_2/d^2)$  where  $\kappa = 8.99 \times 10^9 \text{ N}\cdot\text{m}^2/\text{C}^2$ ,  $Q_1$  and  $Q_2$  are the charges of the two objects in Coulombs, and  $d$  is the distance separating the two objects in meters. What is the electrostatic force of attraction (in Newtons) between an electron and a proton that are separated by  $1.00 \times 10^2$  pm? **(b)** The force of gravity acting between two objects is given by the equation  $F = G(m_1m_2/d^2)$ , where  $G$  is the gravitational constant,  $G = 6.674 \times 10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2$ ,  $m_1$  and  $m_2$  are the masses of the two objects, and  $d$  is the distance separating them. What is the gravitational force of attraction (in Newtons) between the electron and proton? **(c)** How many times larger is the electrostatic force of attraction?
- 5.16** Use the equations given in Problem 5.15 to calculate: **(a)** The electrostatic force of repulsion for two protons separated by 75 pm. **(b)** The gravitational force of attraction for two protons separated by 75 pm. **(c)** If allowed to move, will the protons be repelled or attracted to one another?
- 5.17** A sodium ion,  $\text{Na}^+$ , with a charge of  $1.6 \times 10^{-19} \text{ C}$  and a chloride ion,  $\text{Cl}^-$ , with charge of  $-1.6 \times 10^{-19} \text{ C}$ , are separated by a distance of 0.50 nm. How much work would be required to increase the separation of the two ions to an infinite distance?
- 5.18** A magnesium ion,  $\text{Mg}^{2+}$ , with a charge of  $3.2 \times 10^{-19} \text{ C}$  and an oxide ion,  $\text{O}^{2-}$ , with a charge of  $-3.2 \times 10^{-19} \text{ C}$ , are separated by a distance of 0.35 nm. How much work would be required to increase the separation of the two ions to an infinite distance?
- 5.19** Identify the force present and explain whether work is being performed in the following cases: **(a)** You lift a pencil off the top of a desk. **(b)** A spring is compressed to half its normal length.
- 5.20** Identify the force present and explain whether work is done when **(a)** a positively charged particle moves in a circle at a fixed distance from a negatively charged particle, **(b)** an iron nail is pulled off a magnet.

## The First Law of Thermodynamics (Section 5.2)

- 5.21** (a) Which of the following cannot leave or enter a closed system: heat, work, or matter? (b) Which cannot leave or enter an isolated system? (c) What do we call the part of the universe that is not part of the system?
- 5.22** In a thermodynamic study, a scientist focuses on the properties of a solution in an apparatus as illustrated. A solution is continuously flowing into the apparatus at the top and out at the bottom, such that the amount of solution in the apparatus is constant with time. (a) Is the solution in the apparatus a closed system, open system, or isolated system? (b) If the inlet and outlet were closed, what type of system would it be?

- 5.23** (a) According to the first law of thermodynamics, what quantity is conserved? (b) What is meant by the *internal energy* of a system? (c) By what means can the internal energy of a closed system increase?
- 5.24** (a) Write an equation that expresses the first law of thermodynamics in terms of heat and work. (b) Under what conditions will the quantities  $q$  and  $w$  be negative numbers?
- 5.25** Calculate  $\Delta E$  and determine whether the process is endothermic or exothermic for the following cases: (a)  $q = 0.763$  kJ and  $w = -840$  J. (b) A system releases 66.1 kJ of heat to its surroundings while the surroundings do 44.0 kJ of work on the system.
- 5.26** For the following processes, calculate the change in internal energy of the system and determine whether the process is endothermic or exothermic: (a) A balloon is cooled by removing 0.655 kJ of heat. It shrinks on cooling, and the atmosphere does 382 J of work on the balloon. (b) A 100.0-g bar of gold is heated from 25 °C to 50 °C during which it absorbs 322 J of heat. Assume the volume of the gold bar remains constant.
- 5.27** A gas is confined to a cylinder fitted with a piston and an electrical heater, as shown here:

Suppose that current is supplied to the heater so that 100 J of energy is added. Consider two different situations. In case (1) the piston is allowed to move as the energy is added. In case

(2) the piston is fixed so that it cannot move. (a) In which case does the gas have the higher temperature after addition of the electrical energy? (b) Identify the sign (positive, negative, or zero) of  $q$  and  $w$  in each case? (c) In which case is  $\Delta E$  for the system (the gas in the cylinder) larger?

- 5.28** Consider a system consisting of two oppositely charged spheres hanging by strings and separated by a distance  $r_1$ , as shown in the accompanying illustration. Suppose they are separated to a larger distance  $r_2$ , by moving them apart. (a) What change, if any, has occurred in the potential energy of the system? (b) What effect, if any, does this process have on the value of  $\Delta E$ ? (c) What can you say about  $q$  and  $w$  for this process?

- 5.29** (a) What is meant by the term *state function*? (b) Give an example of a quantity that is a state function and one that is not. (c) Is the volume of a system a state function? Why or why not?
- 5.30** Indicate which of the following is independent of the path by which a change occurs: (a) the change in potential energy when a book is transferred from table to shelf, (b) the heat evolved when a cube of sugar is oxidized to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ , (c) the work accomplished in burning a gallon of gasoline.

## Enthalpy (Section 5.3 and 5.4)

- 5.31** During a normal breath, our lungs expand about 0.50 L against an external pressure of 1.0 atm. How much work is involved in this process (in J)?
- 5.32** How much work (in J) is involved in a chemical reaction if the volume decreases from 5.00 to 1.26 L against a constant pressure of 0.857 atm?
- 5.33** (a) Why is the change in enthalpy usually easier to measure than the change in internal energy? (b)  $H$  is a state function, but  $q$  is not a state function. Explain. (c) For a given process at constant pressure,  $\Delta H$  is positive. Is the process endothermic or exothermic?
- 5.34** (a) Under what condition will the enthalpy change of a process equal the amount of heat transferred into or out of the system? (b) During a constant-pressure process, the system releases heat to the surroundings. Does the enthalpy of the system increase or decrease during the process? (c) In a constant-pressure process,  $\Delta H = 0$ . What can you conclude about  $\Delta E$ ,  $q$ , and  $w$ ?

- 5.35** Assume that the following reaction occurs at constant pressure:

- (a) If you are given  $\Delta H$  for the reaction, what additional information do you need to determine  $\Delta E$  for the process? (b) Which quantity is larger for this reaction? (c) Explain your answer to part (b).

**5.36** Suppose that the gas-phase reaction  $2\text{NO}(g) + \text{O}_2(g) \longrightarrow 2\text{NO}_2(g)$  were carried out in a constant-volume container at constant temperature. **(a)** Would the measured heat change represent  $\Delta H$  or  $\Delta E$ ? **(b)** If there is a difference, which quantity is larger for this reaction? **(c)** Explain your answer to part (b).

**5.37** A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.4. When the gas undergoes a particular chemical reaction, it absorbs 824 J of heat from its surroundings and has 0.65 kJ of  $P$ - $V$  work done on it by its surroundings. What are the values of  $\Delta H$  and  $\Delta E$  for this process?

**5.38** A gas is confined to a cylinder under constant atmospheric pressure, as illustrated in Figure 5.4. When 0.49 kJ of heat is added to the gas, it expands and does 214 J of work on the surroundings. What are the values of  $\Delta H$  and  $\Delta E$  for this process?

**5.39** The complete combustion of ethanol,  $\text{C}_2\text{H}_5\text{OH}(l)$ , to form  $\text{H}_2\text{O}(g)$  and  $\text{CO}_2(g)$  at constant pressure releases 1235 kJ of heat per mole of  $\text{C}_2\text{H}_5\text{OH}$ . **(a)** Write a balanced thermochemical equation for this reaction. **(b)** Draw an enthalpy diagram for the reaction.

**5.40** The decomposition of  $\text{Ca}(\text{OH})_2(s)$  into  $\text{CaO}(s)$  and  $\text{H}_2\text{O}(g)$  at constant pressure requires the addition of 109 kJ of heat per mole of  $\text{Ca}(\text{OH})_2$ . **(a)** Write a balanced thermochemical equation for the reaction. **(b)** Draw an enthalpy diagram for the reaction.

**5.41** Ozone,  $\text{O}_3(g)$ , is a form of elemental oxygen that plays an important role in the absorption of ultraviolet radiation in the stratosphere. It decomposes to  $\text{O}_2(g)$  at room temperature and pressure according to the following reaction:

**(a)** What is the enthalpy change for this reaction per mole of  $\text{O}_3(g)$ ?

**(b)** Which has the higher enthalpy under these conditions,  $2\text{O}_3(g)$  or  $3\text{O}_2(g)$ ?

**5.42** Without referring to tables, predict which of the following has the higher enthalpy in each case: **(a)** 1 mol  $\text{CO}_2(s)$  or 1 mol  $\text{CO}_2(g)$  at the same temperature, **(b)** 2 mol of hydrogen atoms or 1 mol of  $\text{H}_2$ , **(c)** 1 mol  $\text{H}_2(g)$  and 0.5 mol  $\text{O}_2(g)$  at  $25^\circ\text{C}$  or 1 mol  $\text{H}_2\text{O}(g)$  at  $25^\circ\text{C}$ , **(d)** 1 mol  $\text{N}_2(g)$  at  $100^\circ\text{C}$  or 1 mol  $\text{N}_2(g)$  at  $300^\circ\text{C}$ .

**5.43** Consider the following reaction:

**(a)** Is this reaction exothermic or endothermic?

**(b)** Calculate the amount of heat transferred when 3.55 g of  $\text{Mg}(s)$  reacts at constant pressure.

**(c)** How many grams of  $\text{MgO}$  are produced during an enthalpy change of  $-234 \text{ kJ}$ ?

**(d)** How many kilojoules of heat are absorbed when 40.3 g of  $\text{MgO}(s)$  is decomposed into  $\text{Mg}(s)$  and  $\text{O}_2(g)$  at constant pressure?

**5.44** Consider the following reaction:

**(a)** Is this reaction exothermic or endothermic? **(b)** Calculate the amount of heat transferred when 24.0 g of  $\text{CH}_3\text{OH}(g)$  is decomposed by this reaction at constant pressure. **(c)** For a given sample of  $\text{CH}_3\text{OH}$ , the enthalpy change during the reaction is 82.1 kJ. How many grams of methane gas are produced? **(d)** How many kilojoules of heat are released when 38.5 g of  $\text{CH}_4(g)$  reacts completely with  $\text{O}_2(g)$  to form  $\text{CH}_3\text{OH}(g)$  at constant pressure?

**5.45** When solutions containing silver ions and chloride ions are mixed, silver chloride precipitates

**(a)** Calculate  $\Delta H$  for the production of 0.450 mol of  $\text{AgCl}$  by this reaction. **(b)** Calculate  $\Delta H$  for the production of 9.00 g of  $\text{AgCl}$ . **(c)** Calculate  $\Delta H$  when  $9.25 \times 10^{-4}$  mol of  $\text{AgCl}$  dissolves in water.

**5.46** At one time, a common means of forming small quantities of oxygen gas in the laboratory was to heat  $\text{KClO}_3$ :

For this reaction, calculate  $\Delta H$  for the formation of **(a)** 1.36 mol of  $\text{O}_2$  and **(b)** 10.4 g of  $\text{KCl}$ . **(c)** The decomposition of  $\text{KClO}_3$  proceeds spontaneously when it is heated. Do you think that the reverse reaction, the formation of  $\text{KClO}_3$  from  $\text{KCl}$  and  $\text{O}_2$ , is likely to be feasible under ordinary conditions? Explain your answer.

**5.47** Consider the combustion of liquid methanol,  $\text{CH}_3\text{OH}(l)$ :

$$\Delta H = -726.5 \text{ kJ}$$

**(a)** What is the enthalpy change for the reverse reaction? **(b)** Balance the forward reaction with whole-number coefficients. What is  $\Delta H$  for the reaction represented by this equation? **(c)** Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction? **(d)** If the reaction were written to produce  $\text{H}_2\text{O}(g)$  instead of  $\text{H}_2\text{O}(l)$ , would you expect the magnitude of  $\Delta H$  to increase, decrease, or stay the same? Explain.

**5.48** Consider the decomposition of liquid benzene,  $\text{C}_6\text{H}_6(l)$ , to gaseous acetylene,  $\text{C}_2\text{H}_2(g)$ :

**(a)** What is the enthalpy change for the reverse reaction?

**(b)** What is  $\Delta H$  for the formation of 1 mol of acetylene?

**(c)** Which is more likely to be thermodynamically favored, the forward reaction or the reverse reaction?

**(d)** If  $\text{C}_6\text{H}_6(g)$  were consumed instead of  $\text{C}_6\text{H}_6(l)$ , would you expect the magnitude of  $\Delta H$  to increase, decrease, or stay the same? Explain.

## Calorimetry (Section 5.5)

**5.49** **(a)** What are the units of molar heat capacity? **(b)** What are the units of specific heat? **(c)** If you know the specific heat of copper, what additional information do you need to calculate the heat capacity of a particular piece of copper pipe?

**5.50** Two solid objects, A and B, are placed in boiling water and allowed to come to the temperature of the water. Each is then lifted out and placed in separate beakers containing 1000 g water at  $10.0^\circ\text{C}$ . Object A increases the water temperature by  $3.50^\circ\text{C}$ ; B increases the water temperature by  $2.60^\circ\text{C}$ . **(a)** Which object has the larger heat capacity? **(b)** What can you say about the specific heats of A and B?

**5.51** **(a)** What is the specific heat of liquid water? **(b)** What is the molar heat capacity of liquid water? **(c)** What is the heat capacity of 185 g of liquid water? **(d)** How many kJ of heat are needed to raise the temperature of 10.00 kg of liquid water from  $24.6$  to  $46.2^\circ\text{C}$ ?

**5.52** **(a)** Which substance in Table 5.2 requires the smallest amount of energy to increase the temperature of 50.0 g of that substance by  $10 \text{ K}$ ? **(b)** Calculate the energy needed for this temperature change.

**5.53** The specific heat of octane,  $C_8H_{18}(l)$ , is  $2.22\text{ J/g}\cdot\text{K}$ . (a) How many J of heat are needed to raise the temperature of  $80.0\text{ g}$  of octane from  $10.0$  to  $25.0^\circ\text{C}$ ? (b) Which will require more heat, increasing the temperature of  $1\text{ mol}$  of  $C_8H_{18}(l)$  by a certain amount or increasing the temperature of  $1\text{ mol}$  of  $H_2O(l)$  by the same amount?

**5.54** Consider the data about gold metal in Exercise 5.26(b). (a) Based on the data, calculate the specific heat of  $Au(s)$ . (b) Suppose that the same amount of heat is added to two  $10.0\text{-g}$  blocks of metal, both initially at the same temperature. One block is gold metal, and one is iron metal. Which block will have the greater rise in temperature after the addition of the heat? (c) What is the molar heat capacity of  $Au(s)$ ?

**5.55** When a  $6.50\text{-g}$  sample of solid sodium hydroxide dissolves in  $100.0\text{ g}$  of water in a coffee-cup calorimeter (Figure 5.18), the temperature rises from  $21.6$  to  $37.8^\circ\text{C}$ . (a) Calculate the quantity of heat (in kJ) released in the reaction. (b) Using your result from part (a), calculate  $\Delta H$  (in kJ/mol  $NaOH$ ) for the solution process. Assume that the specific heat of the solution is the same as that of pure water.

**5.56** (a) When a  $4.25\text{-g}$  sample of solid ammonium nitrate dissolves in  $60.0\text{ g}$  of water in a coffee-cup calorimeter (Figure 5.18), the temperature drops from  $22.0$  to  $16.9^\circ\text{C}$ . Calculate  $\Delta H$  (in kJ/mol  $NH_4NO_3$ ) for the solution process:

Assume that the specific heat of the solution is the same as that of pure water. (b) Is this process endothermic or exothermic?

**5.57** A  $2.200\text{-g}$  sample of quinone ( $C_6H_4O_2$ ) is burned in a bomb calorimeter whose total heat capacity is  $7.854\text{ kJ}/^\circ\text{C}$ . The temperature of the calorimeter increases from  $23.44$  to  $30.57^\circ\text{C}$ . What is the heat of combustion per gram of quinone? Per mole of quinone?

**5.58** A  $1.800\text{-g}$  sample of phenol ( $C_6H_5OH$ ) was burned in a bomb calorimeter whose total heat capacity is  $11.66\text{ kJ}/^\circ\text{C}$ . The temperature of the calorimeter plus contents increased from  $21.36$  to  $26.37^\circ\text{C}$ . (a) Write a balanced chemical equation for the bomb calorimeter reaction. (b) What is the heat of combustion per gram of phenol? Per mole of phenol?

**5.59** Under constant-volume conditions, the heat of combustion of glucose ( $C_6H_{12}O_6$ ) is  $15.57\text{ kJ/g}$ . A  $3.500\text{-g}$  sample of glucose is burned in a bomb calorimeter. The temperature of the calorimeter increases from  $20.94$  to  $24.72^\circ\text{C}$ . (a) What is the total heat capacity of the calorimeter? (b) If the size of the glucose sample had been exactly twice as large, what would the temperature change of the calorimeter have been?

**5.60** Under constant-volume conditions, the heat of combustion of benzoic acid ( $C_6H_5COOH$ ) is  $26.38\text{ kJ/g}$ . A  $2.760\text{-g}$  sample of benzoic acid is burned in a bomb calorimeter. The temperature of the calorimeter increases from  $21.60$  to  $29.93^\circ\text{C}$ . (a) What is the total heat capacity of the calorimeter? (b) A  $1.440\text{-g}$  sample of a new organic substance is combusted in the same calorimeter. The temperature of the calorimeter increases from  $22.14$  to  $27.09^\circ\text{C}$ . What is the heat of combustion per gram of the new substance? (c) Suppose that in changing samples, a portion of the water in the calorimeter were lost. In what way, if any, would this change the heat capacity of the calorimeter?

**5.62** Consider the following hypothetical reactions:

(a) Use Hess's law to calculate the enthalpy change for the reaction  $A \longrightarrow C$ .

(b) Construct an enthalpy diagram for substances A, B, and C, and show how Hess's law applies.

**5.63** Calculate the enthalpy change for the reaction

given the following enthalpies of reaction:

**5.64** From the enthalpies of reaction

calculate  $\Delta H$  for the reaction

**5.65** From the enthalpies of reaction

calculate  $\Delta H$  for the reaction of ethylene with  $F_2$ :

**5.66** Given the data

use Hess's law to calculate  $\Delta H$  for the reaction

## Enthalpies of Formation (Section 5.7)

**5.67** (a) What is meant by the term *standard conditions* with reference to enthalpy changes? (b) What is meant by the term *enthalpy of formation*? (c) What is meant by the term *standard enthalpy of formation*?

**5.68** (a) What is the value of the standard enthalpy of formation of an element in its most stable form? (b) Write the chemical equation for the reaction whose enthalpy change is the standard enthalpy of formation of sucrose (table sugar),  $C_{12}H_{22}O_{11}(s)$ ,  $\Delta H_f^\circ[C_{12}H_{22}O_{11}(s)]$ .

**5.69** For each of the following compounds, write a balanced thermochemical equation depicting the formation of one mole of the compound from its elements in their standard states and then look up  $\Delta H_f^\circ$  for each substance in Appendix C. (a)  $NO_2(g)$ , (b)  $SO_3(g)$ , (c)  $NaBr(s)$ , (d)  $Pb(NO_3)_2(s)$ .

**5.70** Write balanced equations that describe the formation of the following compounds from elements in their standard states, and then look up the standard enthalpy of formation for each substance in Appendix C: (a)  $H_2O_2(g)$ , (b)  $CaCO_3(s)$ , (c)  $POCl_3(l)$ , (d)  $C_2H_5OH(l)$ .

**5.71** The following is known as the thermite reaction:

This highly exothermic reaction is used for welding massive units, such as propellers for large ships. Using standard enthalpies of formation in Appendix C, calculate  $\Delta H^\circ$  for this reaction.

## Hess's Law (Section 5.6)

**5.61** Can you use an approach similar to Hess's law to calculate the change in internal energy,  $\Delta E$ , for an overall reaction by summing the  $\Delta E$  values of individual reactions that add up to give the desired overall reaction?

**5.72** Many portable gas heaters and grills use propane,  $\text{C}_3\text{H}_8(\text{g})$ , as a fuel. Using standard enthalpies of formation, calculate the quantity of heat produced when 10.0 g of propane is completely combusted in air under standard conditions.

**5.73** Using values from Appendix C, calculate the standard enthalpy change for each of the following reactions:

**5.74** Using values from Appendix C, calculate the value of  $\Delta H^\circ$  for each of the following reactions:

**5.75** Complete combustion of 1 mol of acetone ( $\text{C}_3\text{H}_6\text{O}$ ) liberates 1790 kJ:

Using this information together with the standard enthalpies of formation of  $\text{O}_2(\text{g})$ ,  $\text{CO}_2(\text{g})$ , and  $\text{H}_2\text{O}(\text{l})$  from Appendix C, calculate the standard enthalpy of formation of acetone.

**5.76** Calcium carbide ( $\text{CaC}_2$ ) reacts with water to form acetylene ( $\text{C}_2\text{H}_2$ ) and  $\text{Ca}(\text{OH})_2$ . From the following enthalpy of reaction data and data in Appendix C, calculate  $\Delta H_f^\circ$  for  $\text{CaC}_2(\text{s})$ :

**5.77** Gasoline is composed primarily of hydrocarbons, including many with eight carbon atoms, called *octanes*. One of the cleanest-burning octanes is a compound called 2,3,4-trimethylpentane, which has the following structural formula:

The complete combustion of one mole of this compound to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$  leads to  $\Delta H^\circ = -5064.9 \text{ kJ}$ . (a) Write a balanced equation for the combustion of 1 mol of  $\text{C}_8\text{H}_{18}(\text{l})$ . (b) By using the information in this problem and data in Table 5.3, calculate  $\Delta H_f^\circ$  for 2,3,4-trimethylpentane.

**5.78** Diethyl ether,  $\text{C}_4\text{H}_{10}\text{O}(\text{l})$ , a flammable compound that was once used as a surgical anesthetic, has the structure

The complete combustion of 1 mol of  $\text{C}_4\text{H}_{10}\text{O}(\text{l})$  to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$  yields  $\Delta H^\circ = -2723.7 \text{ kJ}$ . (a) Write a balanced equation for the combustion of 1 mol of  $\text{C}_4\text{H}_{10}\text{O}(\text{l})$ . (b) By using the information in this problem and data in Table 5.3, calculate  $\Delta H_f^\circ$  for diethyl ether.

**5.79** Ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) is blended with gasoline as an automobile fuel. (a) Write a balanced equation for the combustion of liquid ethanol in air. (b) Calculate the standard enthalpy change for the reaction, assuming  $\text{H}_2\text{O}(\text{g})$  as a product. (c) Calculate the heat produced per liter of ethanol by combustion of ethanol under constant pressure. Ethanol has a density of 0.789 g/mL. (d) Calculate the mass of  $\text{CO}_2$  produced per kJ of heat emitted.

**5.80** Methanol ( $\text{CH}_3\text{OH}$ ) is used as a fuel in race cars. (a) Write a balanced equation for the combustion of liquid methanol in air. (b) Calculate the standard enthalpy change for the reaction, assuming  $\text{H}_2\text{O}(\text{g})$  as a product. (c) Calculate the heat produced by combustion per liter of methanol. Methanol has a density of 0.791 g/mL. (d) Calculate the mass of  $\text{CO}_2$  produced per kJ of heat emitted.

## Bond Enthalpies (Section 5.8)

**5.81** Without doing any calculations, predict the sign of  $\Delta H$  for each of the following reactions:

**5.82** Without doing any calculations, predict the sign of  $\Delta H$  for each of the following reactions:

**5.83** Use bond enthalpies in Table 5.4 to estimate  $\Delta H$  for each of the following reactions:

(b)

**5.84** Use bond enthalpies in Table 5.4 to estimate  $\Delta H$  for each of the following reactions:

(a)

(b)

**5.85** (a) Use enthalpies of formation given in Appendix C to calculate  $\Delta H$  for the reaction  $\text{Br}_2(\text{g}) \longrightarrow 2\text{Br}(\text{g})$ , and use this value to estimate the bond enthalpy  $D(\text{Br}-\text{Br})$ . (b) How large is the difference between the value calculated in part (a) and the value given in Table 5.4?

**5.86** (a) The nitrogen atoms in an  $\text{N}_2$  molecule are held together by a triple bond; use enthalpies of formation in Appendix C to estimate the enthalpy of this bond,  $D(\text{N}\equiv\text{N})$ . (b) Consider the reaction between hydrazine and hydrogen to produce ammonia,  $\text{N}_2\text{H}_4(\text{g}) + \text{H}_2(\text{g}) \longrightarrow 2\text{NH}_3(\text{g})$ . Use enthalpies of formation and bond enthalpies to estimate the enthalpy of the nitrogen–nitrogen bond in  $\text{N}_2\text{H}_4$ . (c) Based on your answers to parts (a) and (b), would you predict that the nitrogen–nitrogen bond in hydrazine is weaker than, similar to, or stronger than the bond in  $\text{N}_2$ ?

- 5.87** Consider the reaction  $2\text{H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2\text{H}_2\text{O}(\text{l})$ . (a) Use the bond enthalpies in Table 5.4 to estimate  $\Delta H$  for this reaction, ignoring the fact that water is in the liquid state. (b) Without doing a calculation, predict whether your estimate in part (a) is more negative or less negative than the true reaction enthalpy. (c) Use the enthalpies of formation in Appendix C to determine the true reaction enthalpy.
- 5.88** Consider the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{s}) \longrightarrow 2\text{HI}(\text{g})$ . (a) Use the bond enthalpies in Table 5.4 to estimate  $\Delta H$  for this reaction, ignoring the fact that iodine is in the solid state. (b) Without doing a calculation, predict whether your estimate in part (a) is more negative or less negative than the true reaction enthalpy. (c) Use the enthalpies of formation in Appendix C to determine the true reaction enthalpy.

### Foods and Fuels (Section 5.9)

- 5.89** (a) What is meant by the term *fuel value*? (b) Which is a greater source of energy as food, 5 g of fat or 9 g of carbohydrate? (c) The metabolism of glucose produces  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ . How does the human body expel these reaction products?
- 5.90** (a) Which releases the most energy when metabolized, 1 g of carbohydrates or 1 g of fat? (b) A particular chip snack food is composed of 12% protein, 14% fat, and the rest carbohydrate. What percentage of the calorie content of this food is fat? (c) How many grams of protein provide the same fuel value as 25 g of fat?
- 5.91** (a) A serving of a particular ready-to-serve chicken noodle soup contains 2.5 g fat, 14 g carbohydrate, and 7 g protein. Estimate the number of Calories in a serving. (b) According to its nutrition label, the same soup also contains 690 mg of sodium. Do you think the sodium contributes to the caloric content of the soup?
- 5.92** A pound of plain M&M<sup>®</sup> candies contains 96 g fat, 320 g carbohydrate, and 21 g protein. What is the fuel value in kJ in a 42-g (about 1.5 oz) serving? How many Calories does it provide?
- 5.93** The heat of combustion of fructose,  $\text{C}_6\text{H}_{12}\text{O}_6$ , is  $-2812\text{ kJ/mol}$ . If a fresh golden delicious apple weighing 4.23 oz (120 g) contains 16.0 g of fructose, what caloric content does the fructose contribute to the apple?
- 5.94** The heat of combustion of ethanol,  $\text{C}_2\text{H}_5\text{OH}(\text{l})$ , is  $-1367\text{ kJ/mol}$ . A batch of Sauvignon Blanc wine contains 10.6% ethanol by mass. Assuming the density of the wine to be 1.0 g/mL, what is the caloric content due to the alcohol (ethanol) in a 6-oz glass of wine (177 mL)?
- 5.95** The standard enthalpies of formation of gaseous propyne ( $\text{C}_3\text{H}_4$ ), propylene ( $\text{C}_3\text{H}_6$ ), and propane ( $\text{C}_3\text{H}_8$ ) are  $+185.4$ ,  $+20.4$ , and  $-103.8\text{ kJ/mol}$ , respectively. (a) Calculate the heat evolved per mole on combustion of each substance to yield  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ . (b) Calculate the heat evolved on combustion of 1 kg of each substance. (c) Which is the most efficient fuel in terms of heat evolved per unit mass?
- 5.96** It is interesting to compare the “fuel value” of a hydrocarbon in a hypothetical world where oxygen is not the combustion agent. The enthalpy of formation of  $\text{CF}_4(\text{g})$  is  $-679.9\text{ kJ/mol}$ . Which of the following two reactions is the more exothermic?
- $$\text{CH}_4(\text{g}) + 2\text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + 2\text{H}_2\text{O}(\text{g})$$
- $$\text{CH}_4(\text{g}) + 4\text{F}_2(\text{g}) \longrightarrow \text{CF}_4(\text{g}) + 4\text{HF}(\text{g})$$
- 5.97** At the end of 2012, global population was about 7.0 billion people. What mass of glucose in kg would be needed to provide 1500 Cal/person/day of nourishment to the global population for one year? Assume that glucose is metabolized entirely to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$  according to the following thermochemical equation:
- $$\text{C}_6\text{H}_{12}\text{O}_6(\text{s}) + 6\text{O}_2(\text{g}) \longrightarrow 6\text{CO}_2(\text{g}) + 6\text{H}_2\text{O}(\text{l})$$
- $$\Delta H^\circ = -2803\text{ kJ}$$
- 5.98** The automobile fuel called E85 consists of 85% ethanol and 15% gasoline. E85 can be used in the so-called flex-fuel vehicles (FFVs), which can use gasoline, ethanol, or a mix as fuels. Assume that gasoline consists of a mixture of octanes (different isomers of  $\text{C}_8\text{H}_{18}$ ), that the average heat of combustion of  $\text{C}_8\text{H}_{18}(\text{l})$  is  $5400\text{ kJ/mol}$ , and that gasoline has an average density of  $0.70\text{ g/mL}$ . The density of ethanol is  $0.79\text{ g/mL}$ . (a) By using the information given as well as data in Appendix C, compare the energy produced by combustion of 1.0 L of gasoline and of 1.0 L of ethanol. (b) Assume that the density and heat of combustion of E85 can be obtained by using 85% of the values for ethanol and 15% of the values for gasoline. How much energy could be released by the combustion of 1.0 L of E85? (c) How many gallons of E85 would be needed to provide the same energy as 10 gal of gasoline? (d) If gasoline costs \$3.88 per gallon in the United States, what is the break-even price per gallon of E85 if the same amount of energy is to be delivered?

## Additional Exercises

- 5.99** The air bags that provide protection in automobiles in the event of an accident expand because of a rapid chemical reaction. From the viewpoint of the chemical reactants as the system, what do you expect for the signs of  $q$  and  $w$  in this process?
- 5.100** An aluminum can of a soft drink is placed in a freezer. Later, you find that the can is split open and its contents have frozen. Work was done on the can in splitting it open. Where did the energy for this work come from?
- 5.101** Consider a system consisting of the following apparatus, in which gas is confined in one flask and there is a vacuum in the other flask. The flasks are separated by a valve. Assume that the flasks are perfectly insulated and will not allow the flow of heat into or out of the flasks to the surroundings. When the valve is opened, gas flows from the filled flask to the evacuated one. (a) Is work performed during the expansion of the gas? (b) Why or why not? (c) Can you determine the value of  $\Delta E$  for the process?

- 5.102** A sample of gas is contained in a cylinder-and-piston arrangement. It undergoes the change in state shown in the drawing. (a) Assume first that the cylinder and piston are perfect thermal insulators that do not allow heat to be transferred. What is the value of  $q$  for the state change? What is the sign of  $w$  for the state change? What can be said about  $\Delta E$  for the state change? (b) Now assume that the cylinder and piston are made up of a thermal conductor such as a metal. During the state change, the cylinder gets warmer to the touch. What is the sign of  $q$  for the state change in this case?

Describe the difference in the state of the system at the end of the process in the two cases. What can you say about the relative values of  $\Delta E$ ?

- 5.103** Limestone stalactites and stalagmites are formed in caves by the following reaction:

If 1 mol of  $\text{CaCO}_3$  forms at 298 K under 1 atm pressure, the reaction performs 2.47 kJ of  $P$ - $V$  work, pushing back the atmosphere as the gaseous  $\text{CO}_2$  forms. At the same time, 38.95 kJ of heat is absorbed from the environment. What are the values of  $\Delta H$  and of  $\Delta E$  for this reaction?

- 5.104** Consider the systems shown in Figure 5.10. In one case the battery becomes completely discharged by running the current through a heater, and in the other case by running a fan. Both processes occur at constant pressure. In both cases the change in state of the system is the same: The battery goes from being fully charged to being fully discharged. Yet in one case the heat evolved is large, and in the other it is small. Is the enthalpy change the same in the two cases? If not, how can enthalpy be considered a state function? If it is, what can you say about the relationship between enthalpy change and  $q$  in this case, as compared with others that we have considered?
- 5.105** A house is designed to have passive solar energy features. Brickwork incorporated into the interior of the house acts as a heat absorber. Each brick weighs approximately 1.8 kg. The specific heat of the brick is 0.85 J/g·K. How many bricks must be incorporated into the interior of the house to provide the same total heat capacity as  $1.7 \times 10^3$  gal of water?
- 5.106** A coffee-cup calorimeter of the type shown in Figure 5.18 contains 150.0 g of water at 25.1 °C. A 121.0-g block of copper metal is heated to 100.4 °C by putting it in a beaker of boiling water. The specific heat of Cu(s) is 0.385 J/g·K. The Cu is added to the calorimeter, and after a time the contents of the cup reach a constant temperature of 30.1 °C. (a) Determine the amount of heat, in J, lost by the copper block. (b) Determine the amount of heat gained by the water. The specific heat of water is 4.18 J/g·K. (c) The difference between your answers for (a) and (b) is due to heat loss through the Styrofoam® cups and the heat necessary to raise the temperature of the inner wall of the apparatus. The heat capacity of the calorimeter is the amount of heat necessary to raise the temperature of the apparatus (the cups and the stopper) by 1 K. Calculate the heat capacity of the calorimeter in J/K. (d) What would be the final temperature of the system if all the heat lost by the copper block were absorbed by the water in the calorimeter?
- 5.107** (a) When a 0.235-g sample of benzoic acid is combusted in a bomb calorimeter (Figure 5.19), the temperature rises 1.642 °C. When a 0.265-g sample of caffeine,  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ ,

is burned, the temperature rises 1.525 °C. Using the value 26.38 kJ/g for the heat of combustion of benzoic acid, calculate the heat of combustion per mole of caffeine at constant volume. (b) Assuming that there is an uncertainty of 0.002 °C in each temperature reading and that the masses of samples are measured to 0.001 g, what is the estimated uncertainty in the value calculated for the heat of combustion per mole of caffeine?

- 5.108** Meals-ready-to-eat (MREs) are military meals that can be heated on a flameless heater. The heat is produced by the following reaction:

- (a) Calculate the standard enthalpy change for this reaction. (b) Calculate the number of grams of Mg needed for this reaction to release enough energy to increase the temperature of 75 mL of water from 21 to 79 °C.
- 5.109** Burning methane in oxygen can produce three different carbon-containing products: soot (very fine particles of graphite),  $\text{CO}(g)$ , and  $\text{CO}_2(g)$ . (a) Write three balanced equations for the reaction of methane gas with oxygen to produce these three products. In each case assume that  $\text{H}_2\text{O}(l)$  is the only other product. (b) Determine the standard enthalpies for the reactions in part (a). (c) Why, when the oxygen supply is adequate, is  $\text{CO}_2(g)$  the predominant carbon-containing product of the combustion of methane?
- 5.110** We can use Hess's law to calculate enthalpy changes that cannot be measured. One such reaction is the conversion of methane to ethylene:

Calculate the  $\Delta H^\circ$  for this reaction using the following thermochemical data:

- 5.111** From the following data for three prospective fuels, calculate which could provide the most energy per unit volume:

| Fuel  | Density at 20 °C (g/cm <sup>3</sup> ) | Molar Enthalpy of Combustion (kJ/mol) |
|---|---------------------------------------|---------------------------------------|
| Nitroethane, $\text{C}_2\text{H}_5\text{NO}_2(l)$ | 1.052                                 | −1368                                 |
| Ethanol, $\text{C}_2\text{H}_5\text{OH}(l)$       | 0.789                                 | −1367                                 |
| Methylhydrazine, $\text{CH}_6\text{N}_2(l)$       | 0.874                                 | −1307                                 |

- 5.112** The hydrocarbons acetylene ( $\text{C}_2\text{H}_2$ ) and benzene ( $\text{C}_6\text{H}_6$ ) have the same empirical formula. Benzene is an “aromatic” hydrocarbon, one that is unusually stable because of its structure. (a) By using data in Appendix C, determine the standard enthalpy change for the reaction  $3\text{C}_2\text{H}_2(g) \longrightarrow \text{C}_6\text{H}_6(l)$ . (b) Which has greater enthalpy, 3 mol of acetylene gas or 1 mol of liquid benzene? (c) Determine the fuel value, in kJ/g, for acetylene and benzene.
- 5.113** Ammonia ( $\text{NH}_3$ ) boils at −33 °C; at this temperature it has a density of 0.81 g/cm<sup>3</sup>. The enthalpy of formation of  $\text{NH}_3(g)$  is −46.2 kJ/mol, and the enthalpy of vaporization of  $\text{NH}_3(l)$  is 23.2 kJ/mol. Calculate the enthalpy change when 1 L of liquid  $\text{NH}_3$  is burned in air to give  $\text{N}_2(g)$  and  $\text{H}_2\text{O}(g)$ . How does this compare with  $\Delta H$  for the complete combustion of 1 L of liquid methanol,  $\text{CH}_3\text{OH}(l)$ ? For  $\text{CH}_3\text{OH}(l)$ , the density at 25 °C is 0.792 g/cm<sup>3</sup>, and  $\Delta H_f^\circ = -239$  kJ/mol.

- 5.114** Three common hydrocarbons that contain four carbons are listed here, along with their standard enthalpies of formation:

| Hydrocarbon      | Formula        | $\Delta H_f^\circ$ (kJ/mol) |
|------------------|----------------|-----------------------------|
| 1,3-Butadiene    | $C_4H_6(g)$    | 111.9                       |
| 1-Butene         | $C_4H_8(g)$    | 1.2                         |
| <i>n</i> -Butane | $C_4H_{10}(g)$ | -124.7                      |

- (a) For each of these substances, calculate the molar enthalpy of combustion to  $CO_2(g)$  and  $H_2O(l)$ . (b) Calculate the fuel value, in kJ/g, for each of these compounds. (c) For each hydrocarbon, determine the percentage of hydrogen by mass. (d) By comparing your answers for parts (b) and (c), propose a relationship between hydrogen content and fuel value in hydrocarbons.
- 5.115** A 201-lb man decides to add to his exercise routine by walking up three flights of stairs (45 ft) 20 times per day. He figures that the work required to increase his potential energy in this way will permit him to eat an extra order of French

fries, at 245 Cal, without adding to his weight. Is he correct in this assumption?

- 5.116** The Sun supplies about 1.0 kilowatt of energy for each square meter of surface area ( $1.0 \text{ kW/m}^2$ , where a watt =  $1 \text{ J/s}$ ). Plants produce the equivalent of about 0.20 g of sucrose ( $C_{12}H_{22}O_{11}$ ) per hour per square meter. Assuming that the sucrose is produced as follows, calculate the percentage of sunlight used to produce sucrose.

$$\Delta H = 5645 \text{ kJ}$$

- 5.117** It is estimated that the net amount of carbon dioxide fixed by photosynthesis on the landmass of Earth is  $5.5 \times 10^{16} \text{ g/yr}$  of  $CO_2$ . Assume that all this carbon is converted into glucose. (a) Calculate the energy stored by photosynthesis on land per year, in kJ. (b) Calculate the average rate of conversion of solar energy into plant energy in megawatts, MW ( $1 \text{ W} = 1 \text{ J/s}$ ). A large nuclear power plant produces about  $10^3 \text{ MW}$ . The energy of how many such nuclear power plants is equivalent to the solar energy conversion?

## Integrative Exercises

- 5.118** At  $20^\circ\text{C}$  (approximately room temperature) the average velocity of  $N_2$  molecules in air is 1050 mph. (a) What is the average speed in m/s? (b) What is the kinetic energy (in J) of an  $N_2$  molecule moving at this speed? (c) What is the total kinetic energy of 1 mol of  $N_2$  molecules moving at this speed?
- 5.119** Suppose an Olympic diver who weighs 52.0 kg executes a straight dive from a 10-m platform. At the apex of the dive, the diver is 10.8 m above the surface of the water. (a) What is the potential energy of the diver at the apex of the dive, relative to the surface of the water? (b) Assuming that all the potential energy of the diver is converted into kinetic energy at the surface of the water, at what speed, in m/s, will the diver enter the water? (c) Does the diver do work on entering the water? Explain.
- 5.120** Consider the combustion of a single molecule of  $CH_4(g)$ , forming  $H_2O(l)$  as a product. (a) How much energy, in J, is produced during this reaction? (b) A typical X-ray light source has an energy of 8 keV (see inside back cover for conversion between eV and J). Is the energy released by the combustion of a  $CH_4$  molecule larger or smaller than the energy of an X-ray from this source?
- 5.121** Consider the following unbalanced oxidation-reduction reactions in aqueous solution:

- (a) Balance each of the reactions. (b) By using data in Appendix C, calculate  $\Delta H^\circ$  for each of the reactions. (c) Based on the values you obtain for  $\Delta H^\circ$ , which of the reactions would you expect to be thermodynamically favored? (d) Use the activity series to predict which of these reactions should occur.  (Section 4.4) Are these results in accord with your conclusion in part (c) of this problem?
- 5.122** Consider the following acid-neutralization reactions involving the strong base  $NaOH(aq)$ :

(a) By using data in Appendix C, calculate  $\Delta H^\circ$  for each of the reactions. (b) As we saw in Section 4.3, nitric acid and hydrochloric acid are strong acids. Write net ionic equations for the neutralization of these acids. (c) Compare the values of  $\Delta H^\circ$  for the first two reactions. What can you conclude? (d) In the third equation  $NH_4^+(aq)$  is acting as an acid. Based on the value of  $\Delta H^\circ$  for this reaction, do you think it is a strong or a weak acid? Explain.

- 5.123** Consider two solutions, the first being 50.0 mL of 1.00 M  $CuSO_4$  and the second 50.0 mL of 2.00 M  $KOH$ . When the two solutions are mixed in a constant-pressure calorimeter, a precipitate forms and the temperature of the mixture rises from  $21.5^\circ\text{C}$  to  $27.7^\circ\text{C}$ . (a) Before mixing, how many grams of Cu are present in the solution of  $CuSO_4$ ? (b) Predict the identity of the precipitate in the reaction. (c) Write complete and net ionic equations for the reaction that occurs when the two solutions are mixed. (d) From the calorimetric data, calculate  $\Delta H$  for the reaction that occurs on mixing. Assume that the calorimeter absorbs only a negligible quantity of heat, that the total volume of the solution is 100.0 mL, and that the specific heat and density of the solution after mixing are the same as those of pure water.

- 5.124** The precipitation reaction between  $AgNO_3(aq)$  and  $NaCl(aq)$  proceeds as follows:

(a) By using data in Appendix C, calculate  $\Delta H^\circ$  for the net ionic equation of this reaction. (b) What would you expect for the value of  $\Delta H^\circ$  of the overall molecular equation compared to that for the net ionic equation? Explain. (c) Use the results from (a) and (b) along with data in Appendix C to determine the value of  $\Delta H_f^\circ$  for  $AgNO_3(aq)$ .

- 5.125** A sample of a hydrocarbon is combusted completely in  $O_2(g)$  to produce 21.83 g  $CO_2(g)$ , 4.47 g  $H_2O(g)$ , and 311 kJ of heat. (a) What is the mass of the hydrocarbon sample that was combusted? (b) What is the empirical formula of the hydrocarbon? (c) Calculate the value of  $\Delta H_f^\circ$  per empirical-formula unit of the hydrocarbon. (d) Do you think that the hydrocarbon is one of those listed in Appendix C? Explain your answer.
- 5.126** The methane molecule,  $CH_4$ , has the geometry shown in Figure 2.17. Imagine a hypothetical process in which the

methane molecule is “expanded,” by simultaneously extending all four C—H bonds to infinity. We then have the process

(a) Compare this process with the reverse of the reaction that represents the standard enthalpy of formation of  $\text{CH}_4(g)$ . (b) Calculate the enthalpy change in each case. Which is the more endothermic process? What accounts for the difference in  $\Delta H^\circ$  values? (c) Suppose that 3.45 g  $\text{CH}_4(g)$  reacts with 1.22 g  $\text{F}_2(g)$ , forming  $\text{CF}_4(g)$  and  $\text{HF}(g)$  as sole products. What is the limiting reagent in this reaction? If the reaction occurs at constant pressure, what amount of heat is evolved?

**5.127** One of the best-selling light, or low-calorie, beers is 4.2% alcohol by volume and a 12-oz serving contains 110 Calories; remember: 1 Calorie = 1000 cal = 1 kcal. To estimate the percentage of Calories that comes from the alcohol, consider the following questions. (a) Write a balanced chemical equation for the reaction of ethanol,  $\text{C}_2\text{H}_5\text{OH}$ , with oxygen to make carbon dioxide and water. (b) Use enthalpies of formation in Appendix C to determine  $\Delta H$  for this reaction. (c) If 4.2% of the total volume is ethanol and the density of ethanol is 0.789 g/mL, what mass of ethanol does a 12-oz serving of light beer contain? (d) How many Calories are released by the metabolism of ethanol, the reaction from part (a)? (e) What percentage of the 110 Calories comes from the ethanol?

## Design an Experiment

One of the important ideas of thermodynamics is that energy can be transferred in the form of heat or work. Imagine that you lived 180 years ago when the relationships between heat and work were not well understood. You have formulated a hypothesis that work can be converted to heat with the same amount of work always generating the same amount of heat. To test this idea, you have designed an experiment using a device in which a falling weight is connected through pulleys to a shaft with an attached paddle wheel that is immersed in water. This is actually a classic experiment performed by James Joule in the 1840s. You can see various images of Joule’s apparatus by searching the internet for “Joule experiment images.”

(a) Using this device, what measurements would you need to make to test your hypothesis? (b) What equations would you use in analyzing your experiment? (c) Do you think you could obtain a reasonable result from a single experiment? Why or why not? (d) In what way could the precision of your instruments affect the conclusions that you make? (e) List ways that you could modify the equipment to improve the data you obtain if you were performing this experiment today instead of 180 years ago. (f) Give an example of how you could demonstrate the relationship between heat and a form of energy other than mechanical work.

# ELECTRONIC STRUCTURE OF ATOMS

The beginning of the twentieth century was truly one of the most revolutionary periods of scientific discovery. Two theoretical developments caused dramatic changes in our view of the universe. The first, Einstein's theory of relativity, forever changed our views of the relationships between space and time. The second—which will be the focus of this chapter—is *quantum theory*, which explains much of the behavior of electrons in atoms.

Quantum theory led to the explosion in technological developments in the twentieth century, including remarkable new light sources, such as light-emitting diodes (LEDs) that are now being used as high-quality, low-energy-consumption light sources in many applications, and lasers, which have revolutionized so many aspects of our lives. Quantum theory also led to the development of the solid-state electronics that are at the heart of computers, cellular telephones, and countless other electronic devices.

In this chapter, we explore quantum theory and its importance in chemistry. We begin by looking at the nature of light and how our description of light was changed by quantum theory. We will explore some of the tools used in *quantum mechanics*, the “new” physics that had to be developed to describe atoms correctly. We will then use quantum theory to describe the arrangements of electrons in atoms—what we call the **electronic structure** of atoms. The electronic structure of an atom refers to the number of electrons in the atom as well as their distribution around the nucleus and their energies. We will see that the quantum description of the electronic structure of atoms helps us to understand the arrangement of the elements in the periodic table—why, for example, helium and neon are both unreactive gases, whereas sodium and potassium are both soft, reactive metals.

◀ **THE AURORA BOREALIS OR NORTHERN LIGHTS** offer a brilliant display of color in the night sky. They result when ionized particles in the solar wind, mostly electrons and protons, excite atoms and molecules in the atmosphere. Light is produced when electrons in these excited atoms lose energy and fall back to their ground state orbitals.

## WHAT'S AHEAD

- 6.1 ▶ The Wave Nature of Light** Learn that light (radiant energy, or *electromagnetic radiation*) has wave-like properties and is characterized by *wavelength*, *frequency*, and *speed*.
- 6.2 ▶ Quantized Energy and Photons** Recognize that electromagnetic radiation also has particle-like properties and can be described as “particles” of light called *photons*.
- 6.3 ▶ Line Spectra and the Bohr Model** Examine the light emitted by electrically excited atoms (*line spectra*) and infer from those spectra that only certain energy levels are allowed for electrons in atoms. These observations lead to the Bohr model of the atom, which pictures the electrons moving around the nucleus only in certain allowed orbits.
- 6.4 ▶ The Wave Behavior of Matter** Recognize that matter also has wave-like properties. As a result, it is impossible to determine simultaneously the exact position and the exact momentum of an electron in an atom (*Heisenberg's uncertainty principle*).
- 6.5 ▶ Quantum Mechanics and Atomic Orbitals** Describe how the electron exists in the hydrogen atom by treating it as if it were a wave. The *wave functions* that mathematically describe the electron's position and energy in an atom are called *atomic orbitals*. Each orbital is characterized by a set of *quantum numbers*.
- 6.6 ▶ Representations of Orbitals** Consider the three-dimensional shapes of orbitals and how they can be represented by graphs of electron density.
- 6.7 ▶ Many-Electron Atoms** Learn that the energy levels of an atom having more than one electron are different from those of the hydrogen atom, and that each electron has an additional quantum-mechanical property called *spin*. The *Pauli exclusion principle* states that no two electrons in an atom can have the same four quantum numbers. Therefore, each orbital can hold a maximum of two electrons.
- 6.8 ▶ Electron Configurations** Learn how the orbitals of the hydrogen atom can be used to describe the arrangements of electrons in many-electron atoms. Using patterns in orbital energies as well as some fundamental characteristics of electrons described by *Hund's rule*, we determine how electrons are distributed among the orbitals (*electron configurations*).
- 6.9 ▶ Electron Configurations and the Periodic Table** Recognize that the electron configuration of an atom is related to the location of the element in the periodic table.

▲ **Figure 6.1 Water waves.** The movement of a boat through the water forms waves. The regular variation of peaks and troughs enables us to sense the motion of the waves away from the boat.

▲ **Figure 6.2 Water waves.** The *wavelength* is the distance between two adjacent peaks or two adjacent troughs.

### Go Figure

If wave (a) has a wavelength of 2.0 m and a frequency of  $1.5 \times 10^8$  cycles/s, what are the wavelength and frequency of wave (b)?

▲ **Figure 6.3 Electromagnetic waves.** Like water waves, electromagnetic radiation can be characterized by a wavelength. Notice that the shorter the wavelength,  $\lambda$ , the greater the frequency,  $\nu$ . The wavelength in (b) is half as long as that in (a), and the frequency of the wave in (b) is therefore twice as great as that in (a).

## 6.1 | The Wave Nature of Light

Much of our present understanding of the electronic structure of atoms has come from analysis of the light either emitted or absorbed by substances. To understand electronic structure, therefore, we must first learn more about light. The light we see with our eyes, *visible light*, is one type of **electromagnetic radiation**. Because electromagnetic radiation carries energy through space, it is also known as *radiant energy*.

There are many types of electromagnetic radiation in addition to visible light. These different types—radio waves, infrared radiation (heat), X rays—may seem very different from one another, but they all share certain fundamental characteristics.

All types of electromagnetic radiation move through a vacuum at  $2.998 \times 10^8$  m/s, the *speed of light*. All have wave-like characteristics similar to those of waves that move through water. Water waves are the result of energy imparted to the water, perhaps by a dropped stone or the movement of a boat across the water's surface (Figure 6.1). This energy is expressed as the up-and-down movements of the water.

A cross section of a water wave (Figure 6.2) shows that it is *periodic*, which means that the pattern of peaks and troughs repeats itself at regular intervals. The distance between two adjacent peaks (or between two adjacent troughs) is called the **wavelength**. The number of complete wavelengths, or *cycles*, that pass a given point each second is the **frequency** of the wave.

Just as with water waves, we can assign a frequency and wavelength to electromagnetic waves, as illustrated in Figure 6.3. These and all other wave characteristics of electromagnetic radiation are due to the periodic oscillations in the intensities of the electric and magnetic fields associated with the radiation.

The speed of water waves can vary depending on how they are created—for example, the waves produced by a speed boat travel faster than those produced by a rowboat. In contrast, *all electromagnetic radiation moves at the same speed, namely, the speed of light*. As a result, the wavelength and frequency of electromagnetic radiation are always related in a straightforward way. If the wavelength is long, fewer cycles of the wave pass a given point per second, and so the frequency is low. Conversely, for a wave to have a high frequency, it must have a short wavelength. This inverse relationship between the frequency and wavelength of electromagnetic radiation is expressed by the equation

$$\lambda\nu = c \quad [6.1]$$

where  $\lambda$  (lambda) is wavelength,  $\nu$  (nu) is frequency, and  $c$  is the speed of light.

Why do different types of electromagnetic radiation have different properties? Their differences are due to their different wavelengths. Figure 6.4 shows the various types of electromagnetic radiation arranged in order of increasing wavelength, a display called the *electromagnetic spectrum*. Notice that the wavelengths span an enormous range. The wavelengths of gamma rays are comparable to the diameters of atomic nuclei, whereas the wavelengths of radio waves can be longer than a football field. Notice also that visible light, which corresponds to wavelengths of about 400 to 750 nm ( $4 \times 10^{-7}$  to  $7 \times 10^{-7}$  m), is an extremely small portion of the electromagnetic spectrum. The unit of length chosen to express wavelength depends on the type of radiation, as shown in Table 6.1.

Frequency is expressed in cycles per second, a unit also called a *hertz* (Hz). Because it is understood that cycles are involved, the units of frequency are normally given simply as “per second,” which is denoted by  $s^{-1}$  or /s. For example, a frequency of 698 megahertz (MHz), a typical frequency for a cellular telephone, could be written as 698 MHz, 698,000,000 Hz,  $698,000,000 s^{-1}$ , or 698,000,000/s.

### Give It Some Thought

Our bodies are penetrated by X rays but not by visible light. Is this because X rays travel faster than visible light?

## Go Figure

Is the wavelength of a microwave longer or shorter than the wavelength of visible light? By how many orders of magnitude do the two waves differ in wavelength?

▲ **Figure 6.4** The electromagnetic spectrum.\* Wavelengths in the spectrum range from very short gamma rays to very long radio waves.

**TABLE 6.1 Common Wavelength Units for Electromagnetic Radiation**

| Unit       | Symbol        | Length (m) | Type of Radiation    |
|------------|---------------|------------|----------------------|
| Angstrom   | $\text{\AA}$  | $10^{-10}$ | X ray                |
| Nanometer  | nm            | $10^{-9}$  | Ultraviolet, visible |
| Micrometer | $\mu\text{m}$ | $10^{-6}$  | Infrared             |
| Millimeter | mm            | $10^{-3}$  | Microwave            |
| Centimeter | cm            | $10^{-2}$  | Microwave            |
| Meter      | m             | 1          | Television, radio    |
| Kilometer  | km            | 1000       | Radio                |

## Sample Exercise 6.1

## Concepts of Wavelength and Frequency

Two electromagnetic waves are represented in the margin. (a) Which wave has the higher frequency? (b) If one wave represents visible light and the other represents infrared radiation, which wave is which?

## SOLUTION

- (a) Wave 1 has a longer wavelength (greater distance between peaks). The longer the wavelength, the lower the frequency ( $\nu = c/\lambda$ ). Thus, Wave 1 has the lower frequency, and Wave 2 has the higher frequency.
- (b) The electromagnetic spectrum (Figure 6.4) indicates that infrared radiation has a longer wavelength than visible light. Thus, Wave 1 is infrared radiation.

## Practice Exercise 1

A source of electromagnetic radiation produces infrared light. Which of the following could be the wavelength of the light?

- (a) 3.0 nm (b) 4.7 cm (c) 66.8 m (d) 34.5  $\mu\text{m}$  (e) 16.5  $\text{\AA}$

## Practice Exercise 2

Which type of visible light has a longer wavelength, red or blue light?

\* Based on B. A. Averill and P. Eldredge, *Chemistry: Principles, Patterns, and Applications* 1e, © 2007 Pearson Education, Inc.

## Sample Exercise 6.2

## Calculating Frequency from Wavelength

The yellow light given off by a sodium vapor lamp used for public lighting has a wavelength of 589 nm. What is the frequency of this radiation?

## SOLUTION

**Analyze** We are given the wavelength,  $\lambda$ , of the radiation and asked to calculate its frequency,  $\nu$ .

**Plan** The relationship between the wavelength and the frequency is given by Equation 6.1. We can solve for  $\nu$  and use the values of  $\lambda$  and  $c$  to obtain a numerical answer. (The speed of light,  $c$ , is  $3.00 \times 10^8$  m/s to three significant figures.)

**Solve** Solving Equation 6.1 for frequency gives  $\nu = c/\lambda$ . When we insert the values for  $c$  and  $\lambda$ , we note that the units of length in these two quantities are different. We use a conversion factor to convert the wavelength from nanometers to meters, so the units cancel:

$$\begin{aligned}\nu &= \frac{c}{\lambda} = \left( \frac{3.00 \times 10^8 \text{ m/s}}{589 \text{ nm}} \right) \left( \frac{1 \text{ nm}}{10^{-9} \text{ m}} \right) \\ &= 5.09 \times 10^{14} \text{ s}^{-1}\end{aligned}$$

**Check** The high frequency is reasonable because of the short wavelength. The units are proper because frequency has units of “per second,” or  $\text{s}^{-1}$ .

## Practice Exercise 1

Consider the following three statements: (i) For any electromagnetic radiation, the product of the wavelength and the frequency is a constant. (ii) If a source of light has a wavelength of  $3.0 \text{ \AA}$ , its frequency is  $1.0 \times 10^{18} \text{ Hz}$ . (iii) The speed of ultraviolet light is greater than the speed of microwave radiation. Which of these three statements is or are true?

(a) Only one statement is true. (b) Statements (i) and (ii) are true. (c) Statements (i) and (iii) are true. (d) Statements (ii) and (iii) are true. (e) All three statements are true.

## Practice Exercise 2

(a) A laser used in orthopedic spine surgery produces radiation with a wavelength of  $2.10 \text{ }\mu\text{m}$ . Calculate the frequency of this radiation. (b) An FM radio station broadcasts electromagnetic radiation at a frequency of  $103.4 \text{ MHz}$  (megahertz;  $1 \text{ MHz} = 10^6 \text{ s}^{-1}$ ). Calculate the wavelength of this radiation. The speed of light is  $2.998 \times 10^8 \text{ m/s}$  to four significant figures.

## 6.2 | Quantized Energy and Photons

Although the wave model of light explains many aspects of the behavior of light, several observations cannot be resolved by this model. Three of these are particularly pertinent to our understanding of how electromagnetic radiation and atoms interact: (1) the emission of light from hot objects (referred to as *blackbody radiation* because the objects studied appear black before heating), (2) the emission of electrons from metal surfaces on which light shines (the *photoelectric effect*), and (3) the emission of light from electronically excited gas atoms (*emission spectra*). We examine the first two phenomena here and the third in Section 6.3.

## Hot Objects and the Quantization of Energy

When solids are heated, they emit radiation, as seen in the red glow of an electric stove burner or the bright white light of a tungsten light bulb. The wavelength distribution of the radiation depends on temperature; a red-hot object, for instance, is cooler than a yellowish or white-hot one (Figure 6.5). During the late 1800s, a number of physicists studied this phenomenon, trying to understand the relationship between the temperature and the intensity and wavelength of the emitted radiation. The prevailing laws of physics could not account for the observations.

In 1900, a German physicist named Max Planck (1858–1947) solved the problem by making a daring assumption: He proposed that energy can be either released or absorbed by atoms only in discrete “chunks” of some minimum size. Planck gave the name **quantum** (meaning “fixed amount”) to the smallest quantity of energy that can be emitted or absorbed as electromagnetic radiation. He proposed that the energy,  $E$ , of a single quantum equals a constant times the frequency of the radiation:

$$E = h\nu \quad [6.2]$$

The constant  $h$  is called the **Planck constant** and has a value of  $6.626 \times 10^{-34} \text{ joule-second (J}\cdot\text{s)}$ .

## Go Figure

Which is at a higher temperature: the part of the nail glowing yellow or the part glowing red?

▲ **Figure 6.5** Color and temperature. The color and intensity of the light emitted by a hot object, such as this nail, depend on the temperature of the object.

According to Planck's theory, matter can emit and absorb energy only in whole number multiples of  $h\nu$ , such as  $h\nu$ ,  $2h\nu$ ,  $3h\nu$ , and so forth. If the quantity of energy emitted by an atom is  $3h\nu$ , for example, we say that three quanta of energy have been emitted (*quanta* being the plural of *quantum*). Because the energy can be released only in specific amounts, we say that the allowed energies are *quantized*—their values are restricted to certain quantities. Planck's revolutionary proposal that energy is quantized was proved correct, and he was awarded the 1918 Nobel Prize in Physics for his work on quantum theory.

If the notion of quantized energies seems strange, it might be helpful to draw an analogy by comparing a ramp and a staircase (Figure 6.6). As you walk up a ramp, your potential energy increases in a uniform, continuous manner. When you climb a staircase, you can step only *on* individual stairs, not *between* them, so that your potential energy is restricted to certain values and is therefore quantized.

If Planck's quantum theory is correct, why are its effects not obvious in our daily lives? Why do energy changes seem continuous rather than quantized, or “jagged”? Notice that the Planck constant is an extremely small number. Thus, a quantum of energy,  $h\nu$ , is an extremely small amount. Planck's rules regarding the gain or loss of energy are always the same, whether we are concerned with objects on the scale of our ordinary experience or with microscopic objects. With everyday objects, however, the gain or loss of a single quantum of energy is so small that it goes completely unnoticed. In contrast, when dealing with matter at the atomic level, the impact of quantized energies is far more significant.

### Give It Some Thought

Consider the notes that can be played on a piano. In what way is a piano an example of a quantized system? In this analogy, would a violin be continuous or quantized?

## The Photoelectric Effect and Photons

A few years after Planck presented his quantum theory, scientists began to see its applicability to many experimental observations. In 1905, Albert Einstein (1879–1955) used Planck's theory to explain the **photoelectric effect** (Figure 6.7). Light shining on a clean metal surface causes electrons to be emitted from the surface. A minimum frequency of light, different for different metals, is required for the emission of electrons. For example, light with a frequency of  $4.60 \times 10^{14} \text{ s}^{-1}$  or greater causes cesium metal to emit electrons, but if the light has frequency less than that, no electrons are emitted.

To explain the photoelectric effect, Einstein assumed that the radiant energy striking the metal surface behaves like a stream of tiny energy packets. Each packet, which is like a “particle” of energy, is called a **photon**. Extending Planck's quantum theory, Einstein deduced that each photon must have an energy equal to the Planck constant times the frequency of the light:

$$\text{Energy of photon} = E = h\nu \quad [6.3]$$

Thus, radiant energy itself is quantized.

Under the right conditions, photons striking a metal surface can transfer their energy to electrons in the metal. A certain amount of energy—called the *work function*—is required for the electrons to overcome the attractive forces holding them in the metal. If the photons striking the metal have less energy than the work function, the electrons do not acquire sufficient energy to escape from the metal. Increasing the intensity of the light source doesn't lead to emission of electrons from the metal; only changing the frequency of the incoming light has that effect. The intensity (brightness) of the light is related to the number of photons striking the surface per unit time but not to the energy of each photon. When the frequency is such that photons have energy greater than the work function of the particular metal, electrons are emitted; any excess energy of the photon is converted into kinetic energy of the emitted electron. Einstein won the Nobel Prize in Physics in 1921 primarily for his explanation of the photoelectric effect.

Potential energy of person walking up ramp increases in uniform, continuous manner

Potential energy of person walking up steps increases in stepwise, quantized manner

▲ Figure 6.6 Quantized versus continuous change in energy.

### Go Figure

If the frequency of the incoming light is increased, will the energy of the ejected electrons increase, decrease, or stay the same?

▲ Figure 6.7 The photoelectric effect.

## Give It Some Thought

If electrons are ejected from a given metal when irradiated with a 10-W red laser pointer, what will happen when the same metal is irradiated with a 5-W green laser pointer? (a) Electrons will be ejected, (b) electrons will not be ejected, (c) more information is needed to answer this question.

To better understand what a photon is, imagine you have a light source that produces radiation of a single wavelength. Further suppose that you could switch the light on and off faster and faster to provide ever-smaller bursts of energy. Einstein's photon theory tells us that you would eventually come to the smallest energy burst, given by  $E = h\nu$ . This smallest burst consists of a single photon of light.

## Sample Exercise 6.3

## Energy of a Photon

Calculate the energy of one photon of yellow light that has a wavelength of 589 nm.

## SOLUTION

**Analyze** Our task is to calculate the energy,  $E$ , of a photon, given its wavelength,  $\lambda = 589 \text{ nm}$ .

**Plan** We can use Equation 6.1 to convert the wavelength to frequency:  $\nu = c/\lambda$ . We can then use Equation 6.3 to calculate energy:  $E = h\nu$

**Solve** The frequency,  $\nu$ , is calculated from the given wavelength, as shown in Sample Exercise 6.2:

$$\nu = (3.00 \times 10^8 \text{ m/s}) / (589 \times 10^{-9} \text{ m}) = 5.09 \times 10^{14} \text{ s}^{-1}$$

The value of the Planck constant,  $h$ , is given both in the text and in the table of physical constants on the inside back cover of the text; thus we can easily calculate  $E$ :

$$E = (6.626 \times 10^{-34} \text{ J}\cdot\text{s})(5.09 \times 10^{14} \text{ s}^{-1}) = 3.37 \times 10^{-19} \text{ J}$$

**Comment** If one photon of radiant energy supplies  $3.37 \times 10^{-19} \text{ J}$ , we calculate that one mole of these photons will supply:

$$(6.02 \times 10^{23} \text{ photons/mol})(3.37 \times 10^{-19} \text{ J/photon}) = 2.03 \times 10^5 \text{ J/mol}$$

## Practice Exercise 1

Which of the following expressions correctly gives the energy of a mole of photons with wavelength  $\lambda$ ?

(a)  $E = \frac{h}{\lambda}$  (b)  $E = N_A \frac{\lambda}{h}$  (c)  $E = \frac{hc}{\lambda}$  (d)  $E = N_A \frac{h}{\lambda}$  (e)  $E = N_A \frac{hc}{\lambda}$

## Practice Exercise 2

(a) A laser emits light that has a frequency of  $4.69 \times 10^{14} \text{ s}^{-1}$ . What is the energy of one photon of this radiation? (b) If the laser emits a pulse containing  $5.0 \times 10^{17}$  photons of this radiation, what is the total energy of that pulse? (c) If the laser emits  $1.3 \times 10^{-2} \text{ J}$  of energy during a pulse, how many photons are emitted?

The idea that the energy of light depends on its frequency helps us understand the diverse effects that different kinds of electromagnetic radiation have on matter. For example, because of the high frequency (short wavelength) of X rays (Figure 6.4), X-ray photons cause tissue damage, which is why warning signs are posted around X-ray equipment.

Although Einstein's theory of light as a stream of photons rather than a wave explains the photoelectric effect and a great many other observations, it also poses a dilemma. Is light a wave, or does it consist of particles? The only way to resolve this dilemma is to adopt what might seem to be a bizarre position: We must consider that light possesses both wave-like and particle-like characteristics and, depending on the situation, will behave more like waves or more like particles. We will soon see that this dual wave-particle nature is also a characteristic trait of matter.

## Give It Some Thought

Do you think that the formation of a rainbow is more a demonstration of the wave-like or particle-like behavior of light?

## 6.3 | Line Spectra and the Bohr Model

The work of Planck and Einstein paved the way for understanding how electrons are arranged in atoms. In 1913, the Danish physicist Niels Bohr (Figure 6.8) offered a theoretical explanation of *line spectra*, another phenomenon that had puzzled scientists during the nineteenth century. We will see that Bohr used the ideas of Planck and Einstein to explain the line spectrum of hydrogen.

### Line Spectra

A particular source of radiant energy may emit a single wavelength, as in the light from a laser. Radiation composed of a single wavelength is *monochromatic*. However, most common radiation sources, including incandescent light bulbs and stars, produce radiation containing many different wavelengths, *polychromatic* radiation. A **spectrum** is produced when radiation from a polychromatic source is separated into its component wavelengths, as shown in Figure 6.9. The resulting spectrum consists of a continuous range of colors—violet merges into indigo, indigo into blue, and so forth, with no (or very few) blank spots. This rainbow of colors, containing light of all wavelengths, is called a **continuous spectrum**. The most familiar example of a continuous spectrum is the rainbow produced when raindrops or mist acts as a prism for sunlight.

Not all radiation sources produce a continuous spectrum. When a high voltage is applied to tubes that contain different gases under reduced pressure, the gases emit different colors of light (Figure 6.10). The light emitted by neon gas is the familiar red-orange glow of many “neon” lights, whereas sodium vapor emits the yellow light characteristic

▲ **Figure 6.8** Niels Bohr (1885–1962). This 1960s-era Danish postage stamp commemorates Bohr's atomic model.

◀ **Figure 6.9** Creating a spectrum. A continuous visible spectrum is produced when a narrow beam of white light is passed through a prism. The white light could be sunlight or light from an incandescent lamp.

Neon (Ne)

Hydrogen (H)

◀ **Figure 6.10** Atomic emission of hydrogen and neon. Different gases emit light of different characteristic colors when an electric current is passed through them.

► **Figure 6.11** Line spectra of hydrogen and neon. The colored lines occur at wavelengths present in the emission. The black regions are wavelengths for which no light is produced in the emission.

of some modern streetlights. When light coming from such tubes is passed through a prism, only a few wavelengths are present in the resultant spectra (Figure 6.11). Each colored line in such spectra represents light of one wavelength. A spectrum containing radiation of only specific wavelengths is called a **line spectrum**.

When scientists first detected the line spectrum of hydrogen in the mid-1800s, they were fascinated by its simplicity. At that time, only four lines at wavelengths of 410 nm (violet), 434 nm (blue), 486 nm (blue-green), and 656 nm (red) were observed (Figure 6.11). In 1885, a Swiss schoolteacher named Johann Balmer showed that the wavelengths of these four lines fit an intriguingly simple formula that relates the wavelengths to integers. Later, additional lines were found in the ultraviolet and infrared regions of hydrogen's line spectrum. Soon Balmer's equation was extended to a more general one, called the *Rydberg equation*, which allows us to calculate the wavelengths of all the spectral lines of hydrogen:

$$\frac{1}{\lambda} = (R_H) \left( \frac{1}{n_1^2} - \frac{1}{n_2^2} \right) \quad [6.4]$$

In this formula,  $\lambda$  is the wavelength of a spectral line,  $R_H$  is the *Rydberg constant* ( $1.096776 \times 10^7 \text{ m}^{-1}$ ), and  $n_1$  and  $n_2$  are positive integers, with  $n_2$  being larger than  $n_1$ . How could the remarkable simplicity of this equation be explained? It took nearly 30 more years to answer this question.

## Bohr's Model

Rutherford's discovery of the nuclear atom (Section 2.2) suggested that an atom might be thought of as a "microscopic solar system" in which the electrons orbit the nucleus. To explain the line spectrum of hydrogen, Bohr assumed that electrons in hydrogen atoms move in circular orbits around the nucleus, but this assumption posed a problem. According to classical physics, a charged particle (such as an electron) moving in a circular path should continuously lose energy. As an electron loses energy, therefore, it should spiral into the positively charged nucleus. This behavior, however, does not happen—hydrogen atoms are stable. So how can we explain this apparent violation of the laws of physics? Bohr approached this problem in much the same way that Planck had approached the problem of the nature of the radiation emitted by hot objects: He assumed that the prevailing laws of physics were inadequate to describe all aspects of atoms. Furthermore, he adopted Planck's idea that energies are quantized.

Bohr based his model on three postulates:

1. Only orbits of certain radii, corresponding to certain specific energies, are permitted for the electron in a hydrogen atom.
2. An electron in a permitted orbit is in an "allowed" energy state. An electron in an allowed energy state does not radiate energy and, therefore, does not spiral into the nucleus.
3. Energy is emitted or absorbed by the electron only as the electron changes from one allowed energy state to another. This energy is emitted or absorbed as a photon that has energy  $E = h\nu$ .

### Give It Some Thought

With reference to Figure 6.6, are the allowed energy states in the Bohr model for the H atom more like steps or more like a ramp?

## The Energy States of the Hydrogen Atom

Starting with his three postulates and using classical equations for motion and for interacting electrical charges, Bohr calculated the energies corresponding to the allowed orbits for the electron in the hydrogen atom. Ultimately, the calculated energies fit the formula

$$E = (-hcR_H)\left(\frac{1}{n^2}\right) = (-2.18 \times 10^{-18} \text{ J})\left(\frac{1}{n^2}\right) \quad [6.5]$$

where  $h$ ,  $c$ , and  $R_H$  are the Planck constant, the speed of light, and the Rydberg constant, respectively. The integer  $n$ , which can have whole-number values of 1, 2, 3, ...  $\infty$ , is called the **principal quantum number**.

Each allowed orbit corresponds to a different value of  $n$ . The radius of the orbit gets larger as  $n$  increases. Thus, the first allowed orbit (the one closest to the nucleus) has  $n = 1$ , the next allowed orbit (the one second closest to the nucleus) has  $n = 2$ , and so forth. The electron in the hydrogen atom can be in any allowed orbit, and Equation 6.5 tells us the energy the electron has in each allowed orbit.

Note that the energies of the electron given by Equation 6.5 are negative for all values of  $n$ . The lower (more negative) the energy is, the more stable the atom is. The energy is lowest (most negative) for  $n = 1$ . As  $n$  gets larger, the energy becomes less negative and therefore increases. We can liken the situation to a ladder in which the rungs are numbered from the bottom. The higher one climbs (the greater the value of  $n$ ), the higher the energy. The lowest-energy state ( $n = 1$ , analogous to the bottom rung) is called the **ground state** of the atom. When the electron is in a higher-energy state ( $n = 2$  or higher), the atom is said to be in an **excited state**. Figure 6.12 shows the allowed energy levels for the hydrogen atom for several values of  $n$ .

### Give It Some Thought

As the energy level of an orbit becomes more negative, does the electron experience a stronger or weaker attraction to the nucleus? Does the radius of the orbit increase or decrease?

What happens as  $n$  becomes infinitely large? The radius increases and the energy of attraction between the electron and the nucleus approaches zero, so when  $n = \infty$  the electron is completely separated from the nucleus and the energy of the electron is zero:

$$E = (-2.18 \times 10^{-18} \text{ J})\left(\frac{1}{\infty^2}\right) = 0$$

The state in which the electron is completely separated from the nucleus is called the *reference*, or zero-energy, state of the hydrogen atom.

In his third postulate, Bohr assumed that the electron can “jump” from one allowed orbit to another by either absorbing or emitting photons whose radiant energy corresponds exactly to the energy difference between the two orbits. The electron must absorb energy in order to move to a higher-energy state (higher value of  $n$ ). Conversely, radiant energy is emitted when the electron jumps to a lower-energy state (lower value of  $n$ ).

Let's consider a case in which the electron jumps from an initial state with principal quantum number  $n_i$  and energy  $E_i$  to a final state with principal quantum number  $n_f$  and energy  $E_f$ . Using Equation 6.5, we see that the change in energy for this transition is

$$\Delta E = E_f - E_i = (-2.18 \times 10^{-18} \text{ J})\left(\frac{1}{n_f^2} - \frac{1}{n_i^2}\right) \quad [6.6]$$

### Go Figure

If the transition of an electron from the  $n = 3$  state to the  $n = 2$  state results in emission of visible light, is the transition from the  $n = 2$  state to the  $n = 1$  state more likely to result in the emission of infrared or ultraviolet radiation?

▲ **Figure 6.12** Energy levels in the hydrogen atom from the Bohr model. The arrows refer to the transitions of the electron from one allowed energy state to another. The states shown are those for which  $n = 1$  through  $n = 6$  and the state for  $n = \infty$  for which the energy,  $E$ , equals zero.

## Go Figure

Which transition will lead to the emission of light with longer wavelength,  $n = 3$  to  $n = 2$ , or  $n = 4$  to  $n = 3$ ?

▲ **Figure 6.13** Change in energy states for absorption and emission of a photon in a hydrogen atom.

What is the significance of the *sign* of  $\Delta E$ ? Notice that  $\Delta E$  is positive when  $n_f$  is greater than  $n_i$ . That makes sense to us because that means the electron is jumping to a higher-energy orbit. Conversely,  $\Delta E$  is negative when  $n_f$  is less than  $n_i$ ; the electron is falling in energy to a lower-energy orbit.

As noted above, transitions from one allowed state to another will involve a photon. *The energy of the photon ( $E_{\text{photon}}$ ) must equal the difference in energy between the two states ( $\Delta E$ ).* When  $\Delta E$  is positive, a photon must be *absorbed* as the electron jumps to a higher energy. When  $\Delta E$  is negative, a photon is *emitted* as the electron falls to a lower-energy level. In both cases, the energy of the photon must match the energy difference between the states. Because the frequency  $\nu$  is always a positive number, the energy of the photon ( $h\nu$ ) must always be positive. Thus, the sign of  $\Delta E$  tells us whether the photon is absorbed or emitted:

$$\Delta E > 0 (n_f > n_i): \text{Photon absorbed with } E_{\text{photon}} = h\nu = \Delta E$$

$$\Delta E < 0 (n_f < n_i): \text{Photon emitted with } E_{\text{photon}} = h\nu = -\Delta E \quad [6.7]$$

These two situations are summarized in **Figure 6.13**. We see that Bohr's model of the hydrogen atom leads to the conclusion that only the specific frequencies of light that satisfy Equation 6.7 can be absorbed or emitted by the atom.

Let's see how to apply these concepts by considering a transition in which the electron moves from  $n_i = 3$  to  $n_f = 1$ . From Equation 6.6 we have

$$\Delta E = (-2.18 \times 10^{-18} \text{ J}) \left( \frac{1}{1^2} - \frac{1}{3^2} \right) = (-2.18 \times 10^{-18} \text{ J}) \left( \frac{8}{9} \right) = -1.94 \times 10^{-18} \text{ J}$$

The value of  $\Delta E$  is negative—that makes sense because the electron is falling from a higher-energy orbit ( $n = 3$ ) to a lower-energy orbit ( $n = 1$ ). A photon is *emitted* during this transition, and the energy of the photon is equal to  $E_{\text{photon}} = h\nu = -\Delta E = +1.94 \times 10^{-18} \text{ J}$ .

## Give It Some Thought

What is the significance of the minus sign in front of  $\Delta E$  in the above equation?

Knowing the energy of the emitted photon, we can calculate either its frequency or its wavelength. For the wavelength, we combine Equations 6.1 ( $\lambda = c/\nu$ ) and 6.3 ( $E_{\text{photon}} = h\nu$ ) to obtain

$$\lambda = \frac{c}{\nu} = \frac{hc}{E_{\text{photon}}} = \frac{hc}{-\Delta E} = \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})(2.998 \times 10^8 \text{ m/s})}{+1.94 \times 10^{-18} \text{ J}} = 1.02 \times 10^{-7} \text{ m}$$

Thus, a photon of wavelength  $1.02 \times 10^{-7} \text{ m}$  (102 nm) is *emitted*.

We are now in a position to understand the remarkable simplicity of the line spectra of hydrogen, first discovered by Balmer. We recognize that the line spectra are the result of emission, so  $E_{\text{photon}} = h\nu = hc/\lambda = -\Delta E$  for these transitions. Combining Equations 6.5 and 6.6, we see that

$$E_{\text{photon}} = \frac{hc}{\lambda} = -\Delta E = hcR_H \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right) \text{ (for emission)}$$

which gives us

$$\frac{1}{\lambda} = \frac{hcR_H}{hc} \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right) = R_H \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right), \text{ where } n_f < n_i$$

Thus, the existence of discrete spectral lines can be attributed to the quantized jumps of electrons between energy levels.

## Give It Some Thought

True or False: There is an upper limit on the energy of a photon that can be emitted from a hydrogen atom.

## Sample Exercise 6.4

## Electronic Transitions in the Hydrogen Atom

In the Bohr model of the hydrogen atom, electrons are confined to orbits with fixed radii, and those radii can be calculated. The radii of the first four orbits are 0.53, 2.12, 4.76, and 8.46 Å, respectively, as depicted below.

- (a) If an electron makes a transition from the  $n_i = 4$  level to a lower-energy level,  $n_f = 3, 2$ , or 1, which transition would produce a photon with the shortest wavelength?
- (b) What are the energy and wavelength of such a photon, and in which region of the electromagnetic spectrum does it lie?
- (c) The image on the right shows the output of a detector that measures the intensity of light emitted from a sample of hydrogen atoms that have been excited so that each atom begins with an electron in the  $n = 4$  state. What is the final state,  $n_f$ , of the transition being detected?

## SOLUTION

**Analyze** We are asked to determine the energy and wavelength associated with various transitions involving an electron relaxing from the  $n = 4$  state of the hydrogen atom to one of three lower-energy states.

**Plan** Given the integers representing the initial and final states of the electron, we can use Equation 6.6 to calculate the energy of the photon emitted and then use the relationships  $E = h\nu$  and  $c = \nu\lambda$  to convert energy to wavelength. The photon with the highest energy will have the shortest wavelength because photon energy is inversely proportional to wavelength.

## Solve

- (a) The wavelength of a photon is related to its energy through the relationship  $E = h\nu = hc/\lambda$ . Hence, the photon with the smallest wavelength will have the largest energy. The energy levels of the electron orbits decrease as  $n$  decreases.

The electron loses the most energy on transitioning from the  $n_i = 4$  state to the  $n_f = 1$  state, and the photon emitted in that transition has the highest energy and the smallest wavelength.

- (b) We first calculate the energy of the photon using Equation 6.6 with  $n_i = 4$  and  $n_f = 1$ :

$$\Delta E = -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{1^2} - \frac{1}{4^2} \right) = -2.04 \times 10^{-18} \text{ J}$$

$$E_{\text{photon}} = -\Delta E = 2.04 \times 10^{-18} \text{ J}$$

Next we rearrange Planck's relationship to calculate the frequency of the emitted photon.

$$\nu = E/h = (2.04 \times 10^{-18} \text{ J}) / (6.626 \times 10^{-34} \text{ J}\cdot\text{s}) = 3.02 \times 10^{15} \text{ s}^{-1}$$

Finally, we use the frequency to determine the wavelength.

$$\lambda = c/\nu = (2.998 \times 10^8 \text{ m/s}) / (3.02 \times 10^{15} \text{ s}^{-1})$$

Light with this wavelength falls in the ultraviolet region of the electromagnetic spectrum.

$$= 9.72 \times 10^{-8} \text{ m} = 97.2 \text{ nm}$$

*Continued*

- (c) From the graph, we estimate the wavelength of the photon to be approximately 480 nm. Starting from the wavelength, it is easiest to estimate  $n_i$  using Equation 6.4:

$$\frac{1}{\lambda} = R_H \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right)$$

Rearranging:

So  $n_f = 2$ , and the photons seen by the detector are those emitted when an electron transitions from the  $n_i = 4$  to the  $n_f = 2$  state.

$$\frac{1}{n_f^2} = \frac{1}{n_i^2} + \frac{1}{R_H \lambda} = \frac{1}{4^2} + \frac{1}{(1.097 \times 10^7 \text{ m}^{-1})(480 \times 10^{-9} \text{ m})}$$

$$\frac{1}{n_f^2} = 0.25$$

**Check** Referring back to Figure 6.12, we confirm that the  $n = 4$  to  $n = 1$  transition should have the largest energy of the three possible transitions.

### ► Practice Exercise 1

In the top part of Figure 6.11, the four lines in the H atom spectrum are due to transitions from a level for which  $n_i > 2$

to the  $n_f = 2$  level. What is the value of  $n_i$  for the red line in the spectrum? (a) 3 (b) 4 (c) 5 (d) 6 (e) 7

### ► Practice Exercise 2

For each of the following transitions, give the sign of  $\Delta E$  and indicate whether a photon is emitted or absorbed. (a)  $n = 3$  to  $n = 1$  (b)  $n = 2$  to  $n = 4$

## Limitations of the Bohr Model

Although the Bohr model explains the line spectrum of the hydrogen atom, it can not explain the spectra of other atoms, except in a crude way. Bohr also avoided the problem of why the negatively charged electron would not just fall into the positively charged nucleus, by simply assuming it would not happen. Furthermore, we will see that Bohr's model of an electron orbiting the nucleus at a fixed distance is not a realistic picture. As we will see in Section 6.4, the electron exhibits wave-like properties, a fact that any acceptable model of electronic structure must accommodate.

As it turns out, the Bohr model was only an important step along the way toward the development of a more comprehensive model. What is most significant about Bohr's model is that it introduces two important ideas that are also incorporated into our current model:

1. *Electrons exist only in certain discrete energy levels, which are described by quantum numbers.*
2. *Energy is involved in the transition of an electron from one level to another.*

We will now start to develop the successor to the Bohr model, which requires that we take a closer look at the behavior of matter.

## 6.4 | The Wave Behavior of Matter

In the years following the development of Bohr's model for the hydrogen atom, the dual nature of radiant energy became a familiar concept. Depending on the experimental circumstances, radiation appears to have either a wave-like or a particle-like (photon) character. Louis de Broglie (1892–1987), who was working on his Ph.D. thesis in physics at the Sorbonne in Paris, boldly extended this idea: If radiant energy could, under appropriate conditions, behave as though it were a stream of particles (photons), could matter, under appropriate conditions, possibly show the properties of a wave?

De Broglie suggested that an electron moving about the nucleus of an atom behaves like a wave and therefore has a wavelength. He proposed that the wavelength of the electron, or of any other particle, depends on its mass,  $m$ , and on its velocity,  $v$ :

$$\lambda = \frac{h}{mv} \quad [6.8]$$

where  $h$  is the Planck constant. The quantity  $mv$  for any object is called its **momentum**. De Broglie used the term **matter waves** to describe the wave characteristics of material particles.

## Sample Exercise 6.5

### Matter Waves

What is the wavelength of an electron moving with a speed of  $5.97 \times 10^6$  m/s? The mass of the electron is  $9.11 \times 10^{-31}$  kg.

### SOLUTION

**Analyze** We are given the mass,  $m$ , and velocity,  $v$ , of the electron, and we must calculate its de Broglie wavelength,  $\lambda$ .

**Plan** The wavelength of a moving particle is given by Equation 6.8, so  $\lambda$  is calculated by inserting the known quantities  $h$ ,  $m$ , and  $v$ . In doing so, however, we must pay attention to units.

### Solve

Using the value of the Planck constant:

$$h = 6.626 \times 10^{-34} \text{ J}\cdot\text{s}$$

we have the following:

$$\begin{aligned}\lambda &= \frac{h}{mv} \\ &= \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s})}{(9.11 \times 10^{-31} \text{ kg})(5.97 \times 10^6 \text{ m/s})} \left( \frac{1 \text{ kg}\cdot\text{m}^2/\text{s}^2}{1 \text{ J}} \right) \\ &= 1.22 \times 10^{-10} \text{ m} = 0.122 \text{ nm} = 1.22 \text{ \AA}\end{aligned}$$

**Comment** By comparing this value with the wavelengths of electromagnetic radiation shown in Figure 6.4, we see that the wavelength of this electron is about the same as that of X rays.

### Practice Exercise 1

Consider the following three moving objects: (i) a golf ball with a mass of 45.9 g moving at a speed of 50.0 m/s, (ii) An electron moving at a speed of  $3.50 \times 10^5$  m/s, (iii) A neutron

moving at a speed of  $2.3 \times 10^2$  m/s. List the three objects in order from shortest to longest de Broglie wavelength.

(a) i < iii < ii (b) ii < iii < i (c) iii < ii < i (d) i < ii < iii (e) iii < i < ii

### Practice Exercise 2

Calculate the velocity of a neutron whose de Broglie wavelength is 505 pm. The mass of a neutron is given in the table inside the back cover of the text.

Because de Broglie's hypothesis is applicable to all matter, any object of mass  $m$  and velocity  $v$  would give rise to a characteristic matter wave. However, Equation 6.8 indicates that the wavelength associated with an object of ordinary size, such as a golf ball, is so tiny as to be completely unobservable. This is not so for an electron because its mass is so small, as we see in Sample Exercise 6.5.

A few years after de Broglie published his theory, the wave properties of the electron were demonstrated experimentally. When X rays pass through a crystal, an interference pattern results that is characteristic of the wave-like properties of electromagnetic radiation, a phenomenon called *X-ray diffraction*. As electrons pass through a crystal, they are similarly diffracted. Thus, a stream of moving electrons exhibits the same kinds of wave behavior as X rays and all other types of electromagnetic radiation.

The technique of electron diffraction has been highly developed. In the electron microscope, for instance, the wave characteristics of electrons are used to obtain images at the atomic scale. This microscope is an important tool for studying surface phenomena at very high magnifications (Figure 6.14). Electron microscopes can magnify objects by 3,000,000 times, far more than can be done with visible light (1000 $\times$ ), because the wavelength of the electrons is so much smaller than the wavelength of visible light.

### Give It Some Thought

A baseball pitcher throws a fastball that moves at 95 miles per hour. Does that moving baseball generate matter waves? If so, can we observe them?

**▲ Figure 6.14** Electrons as waves. Transmission electron micrograph of *graphene*, which has a hexagonal honeycomb arrangement of carbon atoms. Each of the bright yellow "mountains" indicates a carbon atom.

▲ **Figure 6.15** Werner Heisenberg (1901–1976). During his postdoctoral assistantship with Niels Bohr, Heisenberg formulated his famous uncertainty principle. At 32 he was one of the youngest scientists to receive a Nobel Prize.

## The Uncertainty Principle

The discovery of the wave properties of matter raised some new and interesting questions. Consider, for example, a ball rolling down a ramp. Using the equations of classical physics, we can calculate, with great accuracy, the ball's position, direction of motion, and speed at any instant. Can we do the same for an electron, which exhibits wave properties? A wave extends in space, and its location is not precisely defined. We might therefore anticipate that it is impossible to determine exactly where an electron is located at a specific instant.

The German physicist Werner Heisenberg (Figure 6.15) proposed that the dual nature of matter places a fundamental limitation on how precisely we can know both the location and the momentum of an object at a given instant. The limitation becomes important only when we deal with matter at the subatomic level (that is, with masses as small as that of an electron). Heisenberg's principle is called the **uncertainty principle**. When applied to the electrons in an atom, this principle states that it is impossible for us to know simultaneously both the exact momentum of an electron and its exact location in space.

Heisenberg mathematically related the uncertainty in position,  $\Delta x$ , and the uncertainty in momentum,  $\Delta(mv)$ , to a quantity involving the Planck constant:

$$\Delta x \cdot \Delta(mv) \geq \frac{h}{4\pi} \quad [6.9]$$

A brief calculation illustrates the dramatic implications of the uncertainty principle. The electron has a mass of  $9.11 \times 10^{-31}$  kg and moves at an average speed of about  $5 \times 10^6$  m/s in a hydrogen atom. Let's assume that we know the speed to an uncertainty of 1% [that is, an uncertainty of  $(0.01)(5 \times 10^6 \text{ m/s}) = 5 \times 10^4$  m/s] and that this is the only important source of uncertainty in the momentum, so that  $\Delta(mv) = m \Delta v$ . We can use Equation 6.9 to calculate the uncertainty in the position of the electron:

$$\Delta x \geq \frac{h}{4\pi m \Delta v} = \left( \frac{6.626 \times 10^{-34} \text{ J}\cdot\text{s}}{4\pi(9.11 \times 10^{-31} \text{ kg})(5 \times 10^4 \text{ m/s})} \right) = 1 \times 10^{-9} \text{ m}$$

Because the diameter of a hydrogen atom is about  $1 \times 10^{-10}$  m, the uncertainty in the position of the electron in the atom is an order of magnitude greater than the size of the atom. Thus, we have essentially no idea where the electron is located in the atom. On the other hand, if we were to repeat the calculation with an object of ordinary mass, such as a tennis ball, the uncertainty would be so small that it would be inconsequential. In that case,  $m$  is large and  $\Delta x$  is out of the realm of measurement and therefore of no practical consequence.

De Broglie's hypothesis and Heisenberg's uncertainty principle set the stage for a new and more broadly applicable theory of atomic structure. In this approach, any attempt to define precisely the instantaneous location and momentum of the electron is abandoned. The wave nature of the electron is recognized, and its behavior is described in terms appropriate to waves. The result is a model that precisely describes the energy of the electron while describing its location not precisely but rather in terms of probabilities.

## A CLOSER LOOK Measurement and the Uncertainty Principle

Whenever any measurement is made, some uncertainty exists. Our experience with objects of ordinary dimensions, such as balls or trains or laboratory equipment, indicates that using more precise instruments can decrease the uncertainty of a measurement. In fact, we might expect that the uncertainty in a measurement can be made infinitesimally small. However, the uncertainty principle states that there is an actual limit to the accuracy of measurements. This limit is not a restriction on how well instruments can be made; rather, it is inherent in nature. This limit has no practical consequences when dealing with ordinary-sized objects,

but its implications are enormous when dealing with subatomic particles, such as electrons.

To measure an object, we must disturb it, at least a little, with our measuring device. Imagine using a flashlight to locate a large rubber ball in a dark room. You see the ball when the light from the flashlight bounces off the ball and strikes your eyes. When a beam of photons strikes an object of this size, it does not alter its position or momentum to any practical extent. Imagine, however, that you wish to locate an electron by similarly bouncing light off it into some detector. Objects can be located to an accuracy

no greater than the wavelength of the radiation used. Thus, if we want an accurate position measurement for an electron, we must use a short wavelength. This means that photons of high energy must be employed. The more energy the photons have, the more momentum they impart to the electron when they strike it, which changes the electron's motion in an unpredictable way. The attempt to measure accurately the electron's position introduces considerable uncertainty in its momentum; the act of measuring the electron's position at one moment makes our knowledge of its future position inaccurate.

Suppose, then, that we use photons of longer wavelength. Because these photons have lower energy, the momentum of the electron is not so appreciably changed during measurement,

but at the same time the longer wavelength limits the accuracy with which the electron's position can be determined. This is the essence of the uncertainty principle: *There is an uncertainty in simultaneously knowing both the position and the momentum of the electron that cannot be reduced beyond a certain minimum level.* The more accurately one is known, the less accurately the other is known.

Although we can never know the exact position and momentum of the electron, we can talk about the probability of its being at certain locations in space. In Section 6.5, we introduce a model of the atom that provides the probability of finding electrons of specific energies at certain positions in atoms.

**Related Exercises:** 6.51, 6.52, 6.96, 6.97

### Give It Some Thought

Do the implications of the uncertainty principle become more or less important as the mass of an object increases?

## 6.5 | Quantum Mechanics and Atomic Orbitals

In 1926, the Austrian physicist Erwin Schrödinger (1887–1961) proposed an equation, now known as *Schrödinger's wave equation*, that incorporates both the wave-like and particle-like behaviors of the electron. His work opened a new approach to dealing with subatomic particles, an approach known as *quantum mechanics* or *wave mechanics*. The application of Schrödinger's equation requires advanced calculus, and so we will not be concerned with its details. We will, however, qualitatively consider the results Schrödinger obtained because they give us a powerful new way to view electronic structure. Let's begin by examining the electronic structure of the simplest atom, hydrogen.

Schrödinger treated the electron in a hydrogen atom like the wave on a plucked guitar string (Figure 6.16). Because such waves do not travel in space, they are called *standing waves*. Just as the plucked guitar string produces a standing wave that has a fundamental frequency and higher overtones (harmonics), the electron exhibits a lowest-energy

◀ **Figure 6.16** Standing waves in a vibrating string.

standing wave and higher-energy ones. Furthermore, just as the overtones of the guitar string have *nodes*, points where the magnitude of the wave is zero, so do the waves characteristic of the electron.

Solving Schrödinger's equation for the hydrogen atom leads to a series of mathematical functions called **wave functions** that describe the electron in the atom. These wave functions are usually represented by the symbol  $\psi$  (lowercase Greek letter *psi*). Although the wave function has no direct physical meaning, the square of the wave function,  $\psi^2$ , provides information about the electron's location when it is in an allowed energy state.

For the hydrogen atom, the allowed energies are the same as those predicted by the Bohr model. However, the Bohr model assumes that the electron is in a circular orbit of some particular radius about the nucleus. In the quantum-mechanical model, the electron's location cannot be described so simply.

According to the uncertainty principle, if we know the momentum of the electron with high accuracy, our simultaneous knowledge of its location is very uncertain. Thus, we cannot hope to specify the exact location of an individual electron around the nucleus. Rather, we must be content with a kind of statistical knowledge. We therefore speak of the *probability* that the electron will be in a certain region of space at a given instant. As it turns out, the square of the wave function,  $\psi^2$ , at a given point in space represents the probability that the electron will be found at that location. For this reason,  $\psi^2$  is called either the **probability density** or the **electron density**.

### Give It Some Thought

What is the difference between stating “The electron is located at a particular point in space” and “There is a high probability that the electron is located at a particular point in space”?

### Go Figure

Where in the figure is the region of highest electron density?

▲ **Figure 6.17** Electron-density distribution. This rendering represents the probability,  $\psi^2$ , of finding the electron in a hydrogen atom in its ground state. The origin of the coordinate system is at the nucleus.

One way of representing the probability of finding the electron in various regions of an atom is shown in **Figure 6.17**, where the density of the dots represents the probability of finding the electron. The regions with a high density of dots correspond to relatively large values for  $\psi^2$  and are therefore regions where there is a high probability of finding the electron. Based on this representation, we often describe atoms as consisting of a nucleus surrounded by an electron cloud.

## Orbitals and Quantum Numbers

The solution to Schrödinger's equation for the hydrogen atom yields a set of wave functions called **orbitals**. Each orbital has a characteristic shape and energy. For example, the lowest-energy orbital in the hydrogen atom has the spherical shape illustrated in Figure 6.17 and an energy of  $-2.18 \times 10^{-18}$  J. Note that an *orbital* (quantum-mechanical model, which describes electrons in terms of probabilities, visualized as “electron clouds”) is not the same as an *orbit* (the Bohr model, which visualizes the electron moving in a physical orbit, like a planet around a star). The quantum-mechanical model does not refer to orbits because the motion of the electron in an atom cannot be precisely determined (Heisenberg's uncertainty principle).

The Bohr model introduced a single quantum number,  $n$ , to describe an orbit. The quantum-mechanical model uses three quantum numbers,  $n$ ,  $l$ , and  $m_l$ , which result naturally from the mathematics used to describe an orbital.

1. The principal quantum number,  $n$ , can have positive integral values 1, 2, 3, . . . . As  $n$  increases, the orbital becomes larger, and the electron spends more time farther from the nucleus. An increase in  $n$  also means that the electron has a higher energy and is therefore less tightly bound to the nucleus. For the hydrogen atom,  $E_n = -(2.18 \times 10^{-18} \text{ J})(1/n^2)$ , as in the Bohr model.

## A CLOSER LOOK Thought Experiments and Schrödinger's Cat

The revolutions in scientific thinking caused by the theory of relativity and quantum theory not only changed science; it also caused deep changes in how we understand the world around us. Before relativity and quantum theory, the prevailing physical theories were inherently *deterministic*: Once the specific conditions of an object were given (position, velocity, forces acting on the object), we could determine exactly the position and motion of the object at any time in the future. These theories, from Newton's laws to Maxwell's theory of electromagnetism, successfully described physical phenomena such as motion of the planets, the trajectories of projectiles, and the diffraction of light.

Relativity and quantum theory both challenged the deterministic view of the universe, and did so in a way that caused a great deal of uneasiness among even the scientists who were developing the theories. One of the common methods scientists used to test these new theories was through so-called thought experiments. Thought experiments are hypothetical scenarios that can lead to paradoxes within a given theory. Let's briefly discuss one of these thought experiments that was used to test ideas within quantum theory.

Quantum theory caused a great deal of discussion with respect to its nondeterministic description of matter. We have touched on two such areas in this chapter. First, we have seen that the descriptions of light and matter have become less distinct—light has particle-like properties and matter has wave-like properties. The description of matter that results—in which we can talk only about the probability of an electron being at a certain place as opposed to knowing exactly where it is—was very bothersome to many. Einstein, for example, famously said that “God doesn't play dice with the world”<sup>\*</sup> about this probabilistic description. Heisenberg's uncertainty principle, which

assures that we can't know the position and momentum of a particle exactly, also raised many philosophical questions—so many, in fact, that Heisenberg wrote a book entitled *Physics and Philosophy* in 1958.

One of the most famous thought experiments put forward in the early days of the quantum theory was formulated by Schrödinger and is now known as “Schrödinger's cat.” This experiment called into question whether a system could have multiple acceptable wave functions prior to observation of the system. In other words, if we don't actually observe a system, can we know anything about the state it is in? In this paradox, a hypothetical cat is placed in a sealed box with an apparatus that will randomly trigger a lethal dose of poison to the cat (as morbid as that sounds). According to some interpretations of quantum theory, until the box is opened and the cat is observed, the cat must be considered simultaneously alive and dead.

Schrödinger posed this paradox to point out weaknesses in some interpretations of quantum results, but the paradox has led instead to a continuing and lively debate about the fate and meaning of Schrödinger's cat. In 2012, the Nobel Prize in Physics was awarded to Serge Haroche of France and David Wineland of the United States for their ingenious methods for observing the quantum states of photons or particles without having the act of observation destroy the states. In so doing, they observed what is generally called the “cat state” of the systems, in which the photon or particle exists simultaneously in two different quantum states. A puzzling paradox, indeed, but one that might ultimately lead to new ways to harness the simultaneous states to create so-called quantum computers and more accurate clocks.

**Related Exercise: 6.97**

2. The second quantum number—the **angular momentum quantum number,  $l$** —can have integral values from 0 to  $(n - 1)$  for each value of  $n$ . This quantum number defines the shape of the orbital. The value of  $l$  for a particular orbital is generally designated by the letters  $s$ ,  $p$ ,  $d$ , and  $f$ ,\*\* corresponding to  $l$  values of 0, 1, 2, and 3:

|              |     |     |     |     |
|--------------|-----|-----|-----|-----|
| Value of $l$ | 0   | 1   | 2   | 3   |
| Letter used  | $s$ | $p$ | $d$ | $f$ |

3. The **magnetic quantum number,  $m_l$** , can have integral values between  $-l$  and  $l$ , including zero. This quantum number describes the orientation of the orbital in space, as we discuss in Section 6.6.

Notice that because the value of  $n$  can be any positive integer, there is an infinite number of orbitals for the hydrogen atom. At any given instant, however, the electron in a hydrogen atom is described by only one of these orbitals—we say that the electron *occupies* a certain orbital. The remaining orbitals are *unoccupied* for that particular state of the hydrogen atom. We will focus mainly on orbitals that have small values of  $n$ .

### Give It Some Thought

Is the distance between the electron and the nucleus fixed for an electron in a specific *orbit* in the Bohr model of the atom? Is this distance fixed for an electron in a specific *orbital*?

<sup>\*</sup>Hermanns, William, *Einstein and the Poet: In Search of the Cosmic Man*, 1st edition, Branden Books, 1983.

<sup>\*\*</sup>The letters come from the words *sharp*, *principal*, *diffuse*, and *fundamental*, which were used to describe certain features of spectra before quantum mechanics was developed.

TABLE 6.2 Relationship among Values of  $n$ ,  $l$ , and  $m_l$  through  $n = 4$ 

| $n$ | Possible Values of $l$ | Subshell Designation | Possible Values of $m_l$ | Number of Orbitals in Subshell | Total Number of Orbitals in Shell |
|-----|------------------------|----------------------|--------------------------|--------------------------------|-----------------------------------|
| 1   | 0                      | 1s                   | 0                        | 1                              | 1                                 |
| 2   | 0                      | 2s                   | 0                        | 1                              | 4                                 |
|     | 1                      | 2p                   | 1, 0, -1                 | 3                              |                                   |
| 3   | 0                      | 3s                   | 0                        | 1                              | 9                                 |
|     | 1                      | 3p                   | 1, 0, -1                 | 3                              |                                   |
|     | 2                      | 3d                   | 2, 1, 0, -1, -2          | 5                              |                                   |
| 4   | 0                      | 4s                   | 0                        | 1                              | 16                                |
|     | 1                      | 4p                   | 1, 0, -1                 | 3                              |                                   |
|     | 2                      | 4d                   | 2, 1, 0, -1, -2          | 5                              |                                   |
|     | 3                      | 4f                   | 3, 2, 1, 0, -1, -2, -3   | 7                              |                                   |

The collection of orbitals with the same value of  $n$  is called an **electron shell**. All the orbitals that have  $n = 3$ , for example, are said to be in the third shell. The set of orbitals that have the same  $n$  and  $l$  values is called a **subshell**. Each subshell is designated by a number (the value of  $n$ ) and a letter ( $s$ ,  $p$ ,  $d$ , or  $f$ , corresponding to the value of  $l$ ). For example, the orbitals that have  $n = 3$  and  $l = 2$  are called  $3d$  orbitals and are in the  $3d$  subshell.

### Go Figure

Are the energies of the  $n = 1, 2$ , and 3 shells shown here the same as or different from those of the Bohr model of the atom shown in Figure 6.12?

$n = 1$  shell has **one** orbital

$n = 2$  shell has **two** subshells composed of four orbitals

$n = 3$  shell has **three** subshells composed of nine orbitals

▲ Figure 6.18 Energy levels in the hydrogen atom.

Table 6.2 summarizes the possible values of  $l$  and  $m_l$  for values of  $n$  through  $n = 4$ . The restrictions on possible values give rise to the following very important observations:

1. The shell with principal quantum number  $n$  consists of exactly  $n$  subshells. Each subshell corresponds to a different allowed value of  $l$  from 0 to  $(n - 1)$ . Thus, the first shell ( $n = 1$ ) consists of only one subshell, the  $1s$  ( $l = 0$ ); the second shell ( $n = 2$ ) consists of two subshells, the  $2s$  ( $l = 0$ ) and  $2p$  ( $l = 1$ ); the third shell consists of three subshells,  $3s$ ,  $3p$ , and  $3d$ , and so forth.
2. Each subshell consists of a specific number of orbitals. Each orbital corresponds to a different allowed value of  $m_l$ . For a given value of  $l$ , there are  $(2l + 1)$  allowed values of  $m_l$ , ranging from  $-l$  to  $+l$ . Thus, each  $s$  ( $l = 0$ ) subshell consists of one orbital; each  $p$  ( $l = 1$ ) subshell consists of three orbitals; each  $d$  ( $l = 2$ ) subshell consists of five orbitals, and so forth.
3. The total number of orbitals in a shell is  $n^2$ , where  $n$  is the principal quantum number of the shell. The resulting number of orbitals for the shells—1, 4, 9, 16—is related to a pattern seen in the periodic table: We see that the number of elements in the rows of the periodic table—2, 8, 18, and 32—equals twice these numbers. We will discuss this relationship further in Section 6.9.

Figure 6.18 shows the relative energies of the hydrogen atom orbitals through  $n = 3$ . Each box represents an orbital, and orbitals of the same subshell, such as the three  $2p$  orbitals, are grouped together. When the electron occupies the lowest-energy orbital ( $1s$ ), the hydrogen atom is said to be in its **ground state**. When the electron occupies any other orbital, the atom is in an **excited state**. (The electron can be excited to a higher-energy orbital by absorption of a photon of appropriate energy.) At ordinary temperatures, essentially all hydrogen atoms are in the ground state.

## Sample Exercise 6.6

### Subshells of the Hydrogen Atom

(a) Without referring to Table 6.2, predict the number of subshells in the fourth shell, that is, for  $n = 4$ . (b) Give the label for each of these subshells. (c) How many orbitals are in each of these subshells?

#### SOLUTION

**Analyze and Plan** We are given the value of the principal quantum number,  $n$ . We need to determine the allowed values of  $l$  and  $m_l$  for this given value of  $n$  and then count the number of orbitals in each subshell.

**Solve** There are four subshells in the fourth shell, corresponding to the four possible values of  $l$  (0, 1, 2, and 3).

These subshells are labeled  $4s$ ,  $4p$ ,  $4d$ , and  $4f$ . The number given in the designation of a subshell is the principal quantum number,  $n$ ; the letter designates the value of the angular momentum quantum number,  $l$ : for  $l = 0$ ,  $s$ ; for  $l = 1$ ,  $p$ ; for  $l = 2$ ,  $d$ ; for  $l = 3$ ,  $f$ .

There is one  $4s$  orbital (when  $l = 0$ , there is only one possible value of  $m_l$ : 0). There are three  $4p$  orbitals (when  $l = 1$ , there are

three possible values of  $m_l$ : 1, 0,  $-1$ ). There are five  $4d$  orbitals (when  $l = 2$ , there are five allowed values of  $m_l$ : 2, 1, 0,  $-1$ ,  $-2$ ). There are seven  $4f$  orbitals (when  $l = 3$ , there are seven permitted values of  $m_l$ : 3, 2, 1, 0,  $-1$ ,  $-2$ ,  $-3$ ).

#### Practice Exercise 1

An orbital has  $n = 4$  and  $m_l = -1$ . What are the possible values of  $l$  for this orbital? (a) 0, 1, 2, 3 (b)  $-3$ ,  $-2$ ,  $-1$ , 0, 1, 2, 3 (c) 1, 2, 3 (d)  $-3$ ,  $-2$  (e) 1, 2, 3, 4

#### Practice Exercise 2

(a) What is the designation for the subshell with  $n = 5$  and  $l = 1$ ? (b) How many orbitals are in this subshell? (c) Indicate the values of  $m_l$  for each of these orbitals.

## 6.6 | Representations of Orbitals

So far we have emphasized orbital energies, but the wave function also provides information about an electron's probable location in space. Let's examine the ways in which we can picture orbitals, because their shapes help us visualize how the electron density is distributed around the nucleus.

### The $s$ Orbitals

We have already seen one representation of the lowest-energy orbital of the hydrogen atom, the  $1s$  (Figure 6.17). The first thing we notice about the electron density for the  $1s$  orbital is that it is *spherically symmetric*—in other words, the electron density at a given distance from the nucleus is the same regardless of the direction in which we proceed from the nucleus. All of the other  $s$  orbitals ( $2s$ ,  $3s$ ,  $4s$ , and so forth) are also spherically symmetric and centered on the nucleus.

Recall that the  $l$  quantum number for the  $s$  orbitals is 0; therefore, the  $m_l$  quantum number must be 0. Thus, for each value of  $n$ , there is only one  $s$  orbital. So how do  $s$  orbitals differ as the value of  $n$  changes? For example, how does the electron-density distribution of the hydrogen atom change when the electron is excited from the  $1s$  orbital to the  $2s$  orbital? To address this question, we will look at the *radial probability density*, which is the probability that the electron is at a specific distance from the nucleus.

Figure 6.19 shows the radial probability densities for the  $1s$ ,  $2s$ , and  $3s$  orbitals of hydrogen as a function of  $r$ , the distance from the nucleus—each resulting curve is the **radial probability function** for the orbital. Three features of these plots are noteworthy: the number of peaks, the number of points at which the probability function goes to zero (called **nodes**), and how spread out the distribution is, which gives a sense of the size of the orbital.

For the  $1s$  orbital, we see that the probability rises rapidly as we move away from the nucleus, maximizing at about  $0.5 \text{ \AA}$ . Thus, when the electron occupies the  $1s$  orbital, it is *most likely* to be found this distance from the nucleus\*—we still use the probabilistic description, consistent with the uncertainty principle. Notice also that in the  $1s$  orbital the probability of finding the electron at a distance greater than about  $3 \text{ \AA}$  from the nucleus is essentially zero.

\*In the quantum-mechanical model, the most probable distance at which to find the electron in the  $1s$  orbital is actually  $0.529 \text{ \AA}$ , the same as the radius of the orbit predicted by Bohr for  $n = 1$ . The distance  $0.529 \text{ \AA}$  is often called the Bohr radius.

## Go Figure

How many maxima would you expect to find in the radial probability function for the 4s orbital of the hydrogen atom? How many nodes would you expect in this function?

▲ **Figure 6.19** Radial probability functions for the 1s, 2s, and 3s orbitals of hydrogen. These plots show the probability of finding the electron as a function of distance from the nucleus. As  $n$  increases, the most likely distance at which to find the electron (the highest peak) moves farther from the nucleus.

Comparing the radial probability distributions for the 1s, 2s, and 3s orbitals reveals three trends:

1. For an  $ns$  orbital, the number of peaks is equal to  $n$ , with the outermost peak being larger than inner ones.
2. For an  $ns$  orbital, the number of nodes is equal to  $n - 1$ .
3. As  $n$  increases, the electron density becomes more spread out; that is, there is a greater probability of finding the electron further from the nucleus.

One widely used method of representing orbital *shape* is to draw a boundary surface that encloses some substantial portion, say 90%, of the electron density for the orbital. This type of drawing is called a *contour representation*, and the contour representations for the  $s$  orbitals are spheres (**Figure 6.20**). All the orbitals have the same shape, but they differ in size, becoming larger as  $n$  increases, reflecting the fact that the electron density becomes more spread out as  $n$  increases. Although the details of how electron density varies within a given contour representation are lost in these representations, this is not a serious disadvantage. For qualitative discussions, the most important features of orbitals are shape and relative size, which are adequately displayed by contour representations.

► **Figure 6.20** Comparison of the 1s, 2s, and 3s orbitals. (a) Electron-density distribution of a 1s orbital. (b) Contour representations of the 1s, 2s, and 3s orbitals. Each sphere is centered on the atom's nucleus and encloses the volume in which there is a 90% probability of finding the electron.

(a) An electron density model

(b) Contour models

## A CLOSER LOOK Probability Density and Radial Probability Functions

According to quantum mechanics, we must describe the position of the electron in the hydrogen atom in terms of probabilities rather than exact locations. The information about the probability is contained in the wave functions,  $\psi$ , obtained from Schrödinger's equation. The square of the wave function,  $\psi^2$ , called either the probability density or the electron density, as noted earlier, gives the probability that the electron is at any *point* in space. Because *s* orbitals are spherically symmetric, the value of  $\psi$  for an *s* electron depends only on its distance from the nucleus,  $r$ . Thus, the probability density can be written as  $[\psi(r)]^2$ , where  $\psi(r)$  is the value of  $\psi$  at  $r$ . This function  $[\psi(r)]^2$  gives the probability density for any point located a distance  $r$  from the nucleus.

The radial probability function, which we used in Figure 6.19, differs from the probability density. The radial probability function equals the *total* probability of finding the electron at all the points at any distance  $r$  from the nucleus. In other words, to calculate this function, we need to “add up” the probability densities  $[\psi(r)]^2$  over all points located a distance  $r$  from the nucleus. Figure 6.21 compares the probability density at a point  $[\psi(r)]^2$  with the radial probability function.

Let's examine the difference between probability density and radial probability function more closely. Figure 6.22 shows plots of  $[\psi(r)]^2$  as a function of  $r$  for the 1*s*, 2*s*, and 3*s* orbitals of the hydrogen atom. You will notice that these plots look distinctly different from the radial probability functions shown in Figure 6.19.

As shown in Figure 6.21, the collection of points a distance  $r$  from the nucleus is the surface of a sphere of radius  $r$ . The probability density at *each point* on that spherical surface is  $[\psi(r)]^2$ . To add up all the individual probability densities requires calculus and so is beyond the scope of this text. However, the result of that calculation tells us that the radial probability function is the probability density,  $[\psi(r)]^2$ , multiplied by the surface area of the sphere,  $4\pi r^2$ :

$$\text{Radial probability function at distance } r = 4\pi r^2[\psi(r)]^2$$

Thus, the plots of radial probability function in Figure 6.19 are equal to the plots of  $[\psi(r)]^2$  in Figure 6.22 multiplied by  $4\pi r^2$ . The fact that  $4\pi r^2$  increases rapidly as we move away from the nucleus makes the two sets of plots look very different from each other. For example, the plot of  $[\psi(r)]^2$  for the 3*s* orbital in Figure 6.22 shows that the function generally gets smaller the farther we go from the nucleus. But when we multiply by  $4\pi r^2$ , we see peaks that get larger and larger (up to a certain point) as we move away from the nucleus (Figure 6.19).

▲ **Figure 6.21** Comparing probability density  $[\psi(r)]^2$  and radial probability function  $4\pi r^2[\psi(r)]^2$ .

▲ **Figure 6.22** Probability density  $[\psi(r)]^2$  in the 1*s*, 2*s*, and 3*s* orbitals of hydrogen.

The radial probability functions in Figure 6.19 provide us with the more useful information because they tell us the probability of finding the electron at *all* points a distance  $r$  from the nucleus, not just one particular point.

**Related Exercises:** 6.54, 6.65, 6.66, 6.98

## The *p* Orbitals

Recall that the orbitals for which  $l = 1$  are the *p* orbitals. Each *p* subshell has three orbitals, corresponding to the three allowed values of  $m_l$ :  $-1$ ,  $0$ , and  $1$ . The distribution of electron density for a 2*p* orbital is shown in Figure 6.23(a). The electron density is not distributed spherically as in an *s* orbital. Instead, the density is concentrated in two regions on either side of the nucleus, separated by a node at the nucleus. We say that this dumbbell-shaped orbital has two *lobes*. Recall that we are making no statement of how the electron is moving within the orbital. Figure 6.23(a) portrays only the *averaged* distribution of the electron density in a 2*p* orbital.

Beginning with the  $n = 2$  shell, each shell has three *p* orbitals (Table 6.2), one for each allowed value of  $m_l$ . Thus, there are three 2*p* orbitals, three 3*p* orbitals, and so forth. Each set of *p* orbitals has the dumbbell shapes shown in Figure 6.23(a) for the 2*p* orbitals. For each value of  $n$ , the three *p* orbitals have the same size and shape but differ from one another in spatial orientation. We usually represent *p* orbitals by drawing the shape and orientation of their wave functions, as shown in the contour representations in Figure 6.23(b). It is convenient to label these as  $p_x$ ,  $p_y$ , and  $p_z$  orbitals. The letter subscript indicates the Cartesian axis along which the orbital is oriented. Thus, we see that two

## Go Figure

Each  $p$  orbital has what is called a nodal plane, a plane or sheet where the probability density goes to zero. For which of the orbitals below is the  $yz$  plane a nodal plane?

▲ **Figure 6.23** The  $p$  orbitals. (a) Electron-density distribution of a  $2p$  orbital. (b) Contour representations of the three  $p$  orbitals. The subscript on the orbital label indicates the axis along which the orbital lies.

orbitals with the same value of  $n$  and  $l$ , but different values of  $m_l$ , differ from each other in the way they are oriented in space.\* Like  $s$  orbitals,  $p$  orbitals increase in size as we move from  $2p$  to  $3p$  to  $4p$ , and so forth.

## Give It Some Thought

Consider  $3p_x$  and  $3p_y$  orbitals. Which quantum number(s) is (are) the same for these two orbitals? Which quantum number(s) is (are) different?

## The $d$ and $f$ Orbitals

When  $n$  is 3 or greater, we encounter the  $d$  orbitals (for which  $l = 2$ ). There are five  $3d$  orbitals, five  $4d$  orbitals, and so forth, because in each shell there are five possible values for the  $m_l$  quantum number:  $-2$ ,  $-1$ ,  $0$ ,  $1$ , and  $2$ . The different  $d$  orbitals in a given shell have different shapes and orientations in space, as shown in Figure 6.24. Four of the  $d$ -orbital contour representations have a “four-leaf clover” shape, with four lobes, and each lies primarily in a plane. The  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals lie in the  $xy$ ,  $xz$ , and  $yz$  planes, respectively, with the lobes oriented *between* the axes. The lobes of the  $d_{x^2-y^2}$  orbital also lie in the  $xy$  plane, but the lobes lie *along* the  $x$  and  $y$  axes. The  $d_{z^2}$  orbital looks very different from the other four: It has two lobes along the  $z$  axis and a “doughnut” in the  $xy$  plane. Even though the  $d_{z^2}$  orbital looks different from the other  $d$  orbitals, it has the same energy as the other four  $d$  orbitals. The representations in Figure 6.24 are commonly used for all  $d$  orbitals, regardless of the principal quantum number.

When  $n$  is 4 or greater, there are seven equivalent  $f$  orbitals (for which  $l = 3$ ). The shapes of the  $f$  orbitals are even more complicated than those of the  $d$  orbitals and are not presented here. As you will see in the next section, however, you must be aware of  $f$  orbitals as we consider the electronic structure of atoms in the lower part of the periodic table.

In many instances later in the text, you will find that knowing the number and shapes of atomic orbitals will help you understand chemistry at the molecular level. You will therefore find it useful to memorize the shapes of the  $s$ ,  $p$ , and  $d$  orbitals shown in Figures 6.20, 6.23, and 6.24.

## 6.7 | Many-Electron Atoms

One of our goals in this chapter has been to determine the electronic structures of atoms. So far, we have seen that quantum mechanics leads to an elegant description of the hydrogen atom. This atom, however, has only one electron. How does

\*We cannot make a simple correspondence between the subscripts ( $x$ ,  $y$ , and  $z$ ) and the allowed  $m_l$  values ( $1$ ,  $0$ , and  $-1$ ). To explain why this is so is beyond the scope of an introductory text.

## Go Figure

How many nodal planes, two-dimensional sheets where the probability density goes to zero, are there for the  $d_{xy}$  orbital?

▲ Figure 6.24 Contour representations of the five  $d$  orbitals.

our description change when we consider an atom with two or more electrons (a *many-electron* atom)? To describe such an atom, we must consider the nature of orbitals and their relative energies as well as how the electrons populate the available orbitals.

## Orbitals and Their Energies

We can describe the electronic structure of a many-electron atom by using the orbitals we described for the hydrogen atom in Table 6.2 (p. 230). Thus, the orbitals of a many-electron atom are designated  $1s$ ,  $2p_x$ , and so forth (Table 6.2) and have the same general shapes as the corresponding hydrogen orbitals.

Although the shapes of the orbitals of a many-electron atom are the same as those for hydrogen, the presence of more than one electron greatly changes the energies of the orbitals. In hydrogen, the energy of an orbital depends only on its principal quantum number,  $n$  (Figure 6.18). For instance, in a hydrogen atom, the  $3s$ ,  $3p$ , and  $3d$  subshells all have the same energy. In a many-electron atom, however, the energies of the various subshells in a given shell are *different* because of electron–electron repulsions. To explain why this happens, we must consider the forces between the electrons and how these forces are affected by the shapes of the orbitals. We will, however, forgo this analysis until Chapter 7.

The important idea is this: *In a many-electron atom, for a given value of  $n$ , the energy of an orbital increases with increasing value of  $l$* , as illustrated in Figure 6.25. For example, notice in Figure 6.25 that the  $n = 3$  orbitals increase in energy in the order  $3s < 3p < 3d$ . Notice also that all orbitals of a given subshell (such as the five  $3d$  orbitals) have the same energy, just as they do in the hydrogen atom. Orbitals with the same energy are said to be **degenerate**.

Figure 6.25 is a *qualitative* energy-level diagram; the exact energies of the orbitals and their spacings differ from one atom to another.

## Go Figure

Not all of the orbitals in the  $n = 4$  shell are shown in this figure. Which subshells are missing?

▲ Figure 6.25 General energy ordering of orbitals for a many-electron atom.

### Give It Some Thought

In a many-electron atom, can we predict unambiguously whether the 4s orbital is lower or higher in energy than the 3d orbitals?

## Electron Spin and the Pauli Exclusion Principle

We have now seen that we can use hydrogen-like orbitals to describe many-electron atoms. What, however, determines which orbitals the electrons occupy? That is, how do the electrons of a many-electron atom populate the available orbitals? To answer this question, we must consider an additional property of the electron.

When scientists studied the line spectra of many-electron atoms in great detail, they noticed a very puzzling feature: Lines that were originally thought to be single were actually closely spaced pairs. This meant, in essence, that there were twice as many energy levels as there were “supposed” to be. In 1925, the Dutch physicists George Uhlenbeck (1900–1988) and Samuel Goudsmit (1902–1978) proposed a solution to this dilemma. They postulated that electrons have an intrinsic property, called **electron spin**, that causes each electron to behave as if it were a tiny sphere spinning on its own axis.

By now, it may not surprise you to learn that electron spin is quantized. This observation led to the assignment of a new quantum number for the electron, in addition to  $n$ ,  $l$ , and  $m_l$ , which we have already discussed. This new quantum number, the **spin magnetic quantum number**, is denoted  $m_s$  (the subscript  $s$  stands for *spin*). Two possible values are allowed for  $m_s$ ,  $+\frac{1}{2}$  or  $-\frac{1}{2}$ , which were first interpreted as indicating the two opposite directions in which the electron can spin. A spinning charge produces a magnetic field. The two opposite directions of spin therefore produce oppositely directed magnetic fields (Figure 6.26).<sup>\*</sup> These two opposite magnetic fields lead to the splitting of spectral lines into closely spaced pairs.

Electron spin is crucial for understanding the electronic structures of atoms. In 1925, the Austrian-born physicist Wolfgang Pauli (1900–1958) discovered the principle that governs the arrangement of electrons in many-electron atoms. The **Pauli exclusion principle** states that *no two electrons in an atom can have the same set of four quantum numbers  $n$ ,  $l$ ,  $m_l$ , and  $m_s$* . For a given orbital, the values of  $n$ ,  $l$ , and  $m_l$  are fixed. Thus, if we want to put more than one electron in an orbital *and* satisfy the Pauli exclusion principle, our only choice is to assign different  $m_s$  values to the electrons. Because there are only two such values, we conclude that *an orbital can hold a maximum of two electrons and they must have opposite spins*. This restriction allows us to index the electrons in an atom, giving their quantum numbers and thereby defining the region in space where each electron is most likely to be found. It also provides the key to understanding the remarkable structure of the periodic table of the elements.

▲ **Figure 6.26** Electron spin. The electron behaves as if it were spinning about an axis, thereby generating a magnetic field whose direction depends on the direction of spin. The two directions for the magnetic field correspond to the two possible values for the spin quantum number,  $m_s$ . The magnetic fields that emanate from materials, like iron, arise because there are more electrons with one spin direction than the other.

## 6.8 | Electron Configurations

Armed with knowledge of the relative energies of orbitals and the Pauli exclusion principle, we are in a position to consider the arrangements of electrons in atoms. The way electrons are distributed among the various orbitals of an atom is called the **electron configuration** of the atom.

The most stable electron configuration—the ground state—is that in which the electrons are in the lowest possible energy states. If there were no restrictions on the possible values for the quantum numbers of the electrons, all the electrons would crowd into the 1s orbital because it is the lowest in energy (Figure 6.25). The Pauli exclusion principle

<sup>\*</sup>As we discussed earlier, the electron has both particle-like and wave-like properties. Thus, the picture of an electron as a spinning charged sphere is, strictly speaking, just a useful pictorial representation that helps us understand the two directions of magnetic field that an electron can possess.

## CHEMISTRY AND LIFE Nuclear Spin and Magnetic Resonance Imaging

A major challenge facing medical diagnosis is seeing inside the human body. Until recently, this was accomplished primarily by X-ray technology. X rays do not, however, give well-resolved images of overlapping physiological structures, and sometimes fail to discern diseased or injured tissue. Moreover, because X rays are high-energy radiation, they potentially can cause physiological harm, even in low doses. An imaging technique developed in the 1980s called *magnetic resonance imaging* (MRI) does not have these disadvantages.

The foundation of MRI is a phenomenon called *nuclear magnetic resonance* (NMR), which was discovered in the mid-1940s. Today NMR has become one of the most important spectroscopic methods used in chemistry. NMR is based on the observation that, like electrons, the nuclei of many elements possess an intrinsic spin. Like electron spin, nuclear spin is quantized. For example, the nucleus of  $^1\text{H}$  has two possible magnetic nuclear spin quantum numbers,  $+\frac{1}{2}$  and  $-\frac{1}{2}$ .

A spinning hydrogen nucleus acts like a tiny magnet. In the absence of external effects, the two spin states have the same energy. However, when the nuclei are placed in an external magnetic field,

they can align either parallel or opposed (antiparallel) to the field, depending on their spin. The parallel alignment is lower in energy than the antiparallel one by a certain amount,  $\Delta E$  (Figure 6.27). If the nuclei are irradiated with photons having energy equal to  $\Delta E$ , the spin of the nuclei can be “flipped,” that is, excited from the parallel to the antiparallel alignment. Detection of the flipping of nuclei between the two spin states leads to an NMR spectrum. The radiation used in an NMR experiment is in the radiofrequency range, typically 100 to 900 MHz, which is far less energetic per photon than X rays.

Because hydrogen is a major constituent of aqueous body fluids and fatty tissue, the hydrogen nucleus is the most convenient one for study by MRI. In MRI a person’s body is placed in a strong magnetic field. By irradiating the body with pulses of radiofrequency radiation and using sophisticated detection techniques, medical technicians can image tissue at specific depths in the body, giving pictures with spectacular detail (Figure 6.28). The ability to sample at different depths allows the technicians to construct a three-dimensional picture of the body.

MRI has had such a profound influence on the modern practice of medicine that Paul Lauterbur, a chemist, and Peter Mansfield, a physicist, were awarded the 2003 Nobel Prize in Physiology or Medicine for their discoveries concerning MRI. The major drawback of this technique is expense: The current cost of a new standard MRI instrument for clinical applications is typically \$1.5 million. In the 2000s, a new technique was developed, called *prepolarized MRI*, that requires much less expensive equipment and will lead to an even greater application of this important diagnostic tool.

**Related Exercise: 6.100**

▲ **Figure 6.27 Nuclear spin.** Like electron spin, nuclear spin generates a small magnetic field and has two allowed values. (a) In the absence of an external magnetic field, the two spin states have the same energy. (b) When an external magnetic field is applied, the spin state in which the spin direction is parallel to the direction of the external field is lower in energy than the spin state in which the spin direction is antiparallel to the field direction. The energy difference,  $\Delta E$ , is in the radio frequency portion of the electromagnetic spectrum.

▲ **Figure 6.28 MRI image.** This image of a human head, obtained using magnetic resonance imaging, shows a normal brain, airways, and facial tissues.

tells us, however, that there can be at most two electrons in any single orbital. Thus, *the orbitals are filled in order of increasing energy, with no more than two electrons per orbital*. For example, consider the lithium atom, which has three electrons. (Recall that the number of electrons in a neutral atom equals its atomic number.) The 1s orbital can accommodate two of the electrons. The third one goes into the next lowest-energy orbital, the 2s.

We can represent any electron configuration by writing the symbol for the occupied subshell and adding a superscript to indicate the number of electrons in that subshell. For example, for lithium we write  $1s^2 2s^1$  (read “1s two, 2s one”). We can also show the arrangement of the electrons as

In this representation, which we call an **orbital diagram**, each orbital is denoted by a box and each electron by a half arrow. A half arrow pointing up ( $\uparrow$ ) represents an electron with a positive spin magnetic quantum number ( $m_s = +\frac{1}{2}$ ), and a half arrow pointing down ( $\downarrow$ ) represents an electron with a negative spin magnetic quantum number ( $m_s = -\frac{1}{2}$ ). This pictorial representation of electron spin, which corresponds to the directions of the magnetic fields in Figure 6.26, is quite convenient. Chemists refer to the two possible spin states as “spin-up” and “spin-down” corresponding to the directions of the half arrows.

Electrons having opposite spins are said to be *paired* when they are in the same orbital ( $\uparrow\downarrow$ ). An *unpaired electron* is one not accompanied by a partner of opposite spin. In the lithium atom the two electrons in the 1s orbital are paired and the electron in the 2s orbital is unpaired.

## Hund's Rule

Consider now how the electron configurations of the elements change as we move from element to element across the periodic table.

**Hydrogen** Hydrogen has one electron, which occupies the 1s orbital in its ground state:

The choice of a spin-up electron here is arbitrary; we could equally well show the ground state with one spin-down electron. It is customary, however, to show unpaired electrons with their spins up.

**Helium** The next element, helium, has two electrons. Because two electrons with opposite spins can occupy the same orbital, both of helium's electrons are in the 1s orbital:

The two electrons present in helium complete the filling of the first shell. This arrangement represents a very stable configuration, as is evidenced by the chemical inertness of helium.

**Lithium** The electron configurations of lithium and several elements that follow it in the periodic table are shown in Table 6.3. For the third electron of lithium, the change

**TABLE 6.3 Electron Configurations of Several Lighter Elements**

| Element | Total Electrons | Orbital Diagram              |                              |  |  | Electron Configuration |
|---------|-----------------|------------------------------|------------------------------|--|--|------------------------|
|         |                 | 1s                           | 2s                           | 2p   | 3s                                     |                        |
| Li      | 3               | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow}$           | $\boxed{\phantom{\uparrow\downarrow}}\boxed{\phantom{\uparrow\downarrow}}\boxed{\phantom{\uparrow\downarrow}}$ | $\boxed{\phantom{\uparrow\downarrow}}$ | $1s^2 2s^1$            |
| Be      | 4               | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}$ | $\boxed{\phantom{\uparrow\downarrow}}\boxed{\phantom{\uparrow\downarrow}}\boxed{\phantom{\uparrow\downarrow}}$ | $\boxed{\phantom{\uparrow\downarrow}}$ | $1s^2 2s^2$            |
| B       | 5               | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow}\boxed{\phantom{\uparrow\downarrow}}\boxed{\phantom{\uparrow\downarrow}}$                     | $\boxed{\phantom{\uparrow\downarrow}}$ | $1s^2 2s^2 2p^1$       |
| C       | 6               | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow}\boxed{\uparrow}\boxed{\phantom{\uparrow\downarrow}}$   | $\boxed{\phantom{\uparrow\downarrow}}$ | $1s^2 2s^2 2p^2$       |
| N       | 7               | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow}\boxed{\uparrow}\boxed{\uparrow}$   | $\boxed{\phantom{\uparrow\downarrow}}$ | $1s^2 2s^2 2p^3$       |
| Ne      | 10              | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}$                               | $\boxed{\phantom{\uparrow\downarrow}}$ | $1s^2 2s^2 2p^6$       |
| Na      | 11              | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}$ | $\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}\boxed{\uparrow\downarrow}$                               | $\boxed{\uparrow}$                     | $1s^2 2s^2 2p^6 3s^1$  |

in the principal quantum number from  $n = 1$  for the first two electrons to  $n = 2$  for the third electron represents a large jump in energy and a corresponding jump in the average distance of the electron from the nucleus. In other words, it represents the start of a new shell occupied with electrons. As you can see by examining the periodic table, lithium starts a new row of the table. It is the first member of the alkali metals (group 1A).

**Beryllium and Boron** The element that follows lithium is beryllium; its electron configuration is  $1s^2 2s^2$  (Table 6.3). Boron, atomic number 5, has the electron configuration  $1s^2 2s^2 2p^1$ . The fifth electron must be placed in a  $2p$  orbital because the  $2s$  orbital is filled. Because all three of the  $2p$  orbitals are of equal energy, it does not matter which  $2p$  orbital we place this fifth electron in.

**Carbon** With the next element, carbon, we encounter a new situation. We know that the sixth electron must go into a  $2p$  orbital. However, does this new electron go into the  $2p$  orbital that already has one electron or into one of the other two  $2p$  orbitals?

**Hund's rule** states that when filling degenerate orbitals the lowest energy is attained when the number of electrons having the same spin is maximized.

This means that electrons occupy orbitals singly to the maximum extent possible and that these single electrons in a given subshell all have the same spin magnetic quantum number. Electrons arranged in this way are said to have *parallel spins*. For a carbon atom to achieve its lowest energy, therefore, the two  $2p$  electrons must have the same spin. For this to happen, the electrons must be in different  $2p$  orbitals, as shown in Table 6.3. Thus, a carbon atom in its ground state has two unpaired electrons.

**Nitrogen, Oxygen, Fluorine** Similarly, for nitrogen in its ground state, Hund's rule requires that the three  $2p$  electrons singly occupy each of the three  $2p$  orbitals. This is the only way that all three electrons can have the same spin. For oxygen and fluorine, we place four and five electrons, respectively, in the  $2p$  orbitals. To achieve this, we pair up electrons in the  $2p$  orbitals, as we will see in Sample Exercise 6.7.

Hund's rule is based in part on the fact that electrons repel one another. By occupying different orbitals, the electrons remain as far as possible from one another, thus minimizing electron–electron repulsions.

## Sample Exercise 6.7

### Orbital Diagrams and Electron Configurations

Draw the orbital diagram for the electron configuration of oxygen, atomic number 8. How many unpaired electrons does an oxygen atom possess?

### SOLUTION

**Analyze and Plan** Because oxygen has an atomic number of 8, each oxygen atom has eight electrons. Figure 6.25 shows the ordering of orbitals. The electrons (represented as half arrows) are placed in the orbitals (represented as boxes) beginning with the lowest-energy orbital, the  $1s$ . Each orbital can hold a maximum of two electrons (the Pauli exclusion principle). Because the  $2p$  orbitals are degenerate, we place one electron in each of these orbitals (spin-up) before pairing any electrons (Hund's rule).

**Solve** Two electrons each go into the  $1s$  and  $2s$  orbitals with their spins paired. This leaves four electrons for the three degenerate  $2p$  orbitals. Following Hund's rule, we put one electron into each  $2p$  orbital until all three orbitals have one electron each. The fourth electron is then paired up with one of the three electrons already in a  $2p$  orbital, so that the orbital diagram is

The corresponding electron configuration is written  $1s^2 2s^2 2p^4$ . The atom has two unpaired electrons.

### Practice Exercise 1

How many of the elements in the second row of the periodic table (Li through Ne) will have at least one unpaired electron in their electron configurations?

(a) 3 (b) 4 (c) 5 (d) 6 (e) 7

### Practice Exercise 2

(a) Write the electron configuration for silicon, element 14, in its ground state. (b) How many unpaired electrons does a ground-state silicon atom possess?

|                                 |
|---------------------------------|
| 1A                              |

▲ Figure 6.29 The condensed electron configurations of the alkali metals (group 1A in the periodic table).

## Condensed Electron Configurations

The filling of the  $2p$  subshell is complete at neon (Table 6.3), which has a stable configuration with eight electrons (an *octet*) in the outermost occupied shell. The next element, sodium, atomic number 11, marks the beginning of a new row of the periodic table. Sodium has a single  $3s$  electron beyond the stable configuration of neon. We can therefore abbreviate the electron configuration of sodium as

The symbol  $[\text{Ne}]$  represents the electron configuration of the ten electrons of neon,  $1s^2 2s^2 2p^6$ . Writing the electron configuration as  $[\text{Ne}]3s^1$  focuses attention on the outermost electron of the atom, which is the one largely responsible for how sodium behaves chemically.

We can generalize what we have just done for the electron configuration of sodium. In writing the *condensed electron configuration* of an element, the electron configuration of the nearest noble-gas element of lower atomic number is represented by its chemical symbol in brackets. For lithium, for example, we can write

We refer to the electrons represented by the bracketed symbol as the *noble-gas core* of the atom. More usually, these inner-shell electrons are referred to as the **core electrons**. The electrons given after the noble-gas core are called the *outer-shell electrons*. The outer-shell electrons include the electrons involved in chemical bonding, which are called the **valence electrons**. For the elements with atomic number of 30 or less, all of the outer-shell electrons are valence electrons. By comparing the condensed electron configurations of lithium and sodium, we can appreciate why these two elements are so similar chemically. They have the same type of electron configuration in the outermost occupied shell. Indeed, all the members of the alkali metal group (1A) have a single  $s$  valence electron beyond a noble-gas configuration (Figure 6.29).

## Transition Metals

The noble-gas element argon ( $1s^2 2s^2 2p^6 3s^2 3p^6$ ) marks the end of the row started by sodium. The element following argon in the periodic table is potassium (K), atomic number 19. In all its chemical properties, potassium is clearly a member of the alkali metal group. The experimental facts about the properties of potassium leave no doubt that the outermost electron of this element occupies an  $s$  orbital. But this means that the electron with the highest energy has *not* gone into a  $3d$  orbital, which we might expect it to do. Because the  $4s$  orbital is lower in energy than the  $3d$  orbital (Figure 6.25), the condensed electron configuration of potassium is

Following the complete filling of the  $4s$  orbital (this occurs in the calcium atom), the next set of orbitals to be filled is the  $3d$ . (You will find it helpful as we go along to refer often to the periodic table on the front-inside cover.) Beginning with scandium and extending through zinc, electrons are added to the five  $3d$  orbitals until they are completely filled. Thus, the fourth row of the periodic table is ten elements wider than the two previous rows. These ten elements are known as either **transition elements** or **transition metals**. Note the position of these elements in the periodic table.

In writing the electron configurations of the transition elements, we fill orbitals in accordance with Hund's rule—we add them to the  $3d$  orbitals singly until all five orbitals have one electron each and then place additional electrons in the  $3d$  orbitals with spin pairing until the shell is completely filled. The condensed electron configurations and the corresponding orbital diagram representations of two transition elements are as follows:

Once all the  $3d$  orbitals have been filled with two electrons each, the  $4p$  orbitals begin to be occupied until the completed octet of outer electrons ( $4s^24p^6$ ) is reached with krypton (Kr), atomic number 36, another of the noble gases. Rubidium (Rb) marks the beginning of the fifth row. Refer again to the periodic table on the front-inside cover. Notice that this row is in every respect like the preceding one, except that the value for  $n$  is greater by 1.

### Give It Some Thought

Based on the structure of the periodic table, which becomes occupied first, the  $6s$  orbital or the  $5d$  orbitals?

## The Lanthanides and Actinides

The sixth row of the periodic table begins with Cs and Ba, which have  $[\text{Xe}]6s^1$  and  $[\text{Xe}]6s^2$  configurations, respectively. Notice, however, that the periodic table then has a break, with elements 57–70 placed below the main portion of the table. This break point is where we begin to encounter a new set of orbitals, the  $4f$ .

There are seven degenerate  $4f$  orbitals, corresponding to the seven allowed values of  $m_l$ , ranging from 3 to  $-3$ . Thus, it takes 14 electrons to fill the  $4f$  orbitals completely. The 14 elements corresponding to the filling of the  $4f$  orbitals are known as either the **lanthanide elements** or the **rare earth elements**. These elements are set below the other elements to avoid making the periodic table unduly wide. The properties of the lanthanide elements are all quite similar, and these elements occur together in nature. For many years it was virtually impossible to separate them from one another.

Because the energies of the  $4f$  and  $5d$  orbitals are very close to each other, the electron configurations of some of the lanthanides involve  $5d$  electrons. For example, the elements lanthanum (La), cerium (Ce), and praseodymium (Pr) have the following electron configurations:

Because La has a single  $5d$  electron, it is sometimes placed below yttrium (Y) as the first member of the third series of transition elements; Ce is then placed as the first member of the lanthanides. Based on its chemical properties, however, La can be considered the first element in the lanthanide series. Arranged this way, there are fewer apparent exceptions to the regular filling of the  $4f$  orbitals among the subsequent members of the series.

After the lanthanide series, the third transition element series is completed by the filling of the  $5d$  orbitals, followed by the filling of the  $6p$  orbitals. This brings us to radon (Rn), the heaviest naturally occurring noble-gas element.

The final row of the periodic table begins by filling the  $7s$  orbitals. The **actinide elements**, of which uranium (U, element 92) and plutonium (Pu, element 94) are the best known, are then built up by completing the  $5f$  orbitals. All of the actinide elements are radioactive, and most of them are not found in nature.

## 6.9 | Electron Configurations and the Periodic Table

We just saw that the electron configurations of the elements correspond to their locations in the periodic table. Thus, elements in the same column of the table have related outer-shell (valence) electron configurations. As Table 6.4 shows, for example, all 2A elements have an  $ns^2$  outer configuration, and all 3A elements have an  $ns^2np^1$  outer configuration, with the value of  $n$  increasing as we move down each column.

In Table 6.2 we saw that the total number of orbitals in each shell equals  $n^2$ : 1, 4, 9, or 16. Because we can place two electrons in each orbital, each shell accommodates up

**TABLE 6.4** Electron Configurations of Group 2A and 3A Elements

| Group 2A |                                     |
|----------|-------------------------------------|
| Be       | $[\text{He}]2s^2$                   |
| Mg       | $[\text{Ne}]3s^2$                   |
| Ca       | $[\text{Ar}]4s^2$                   |
| Sr       | $[\text{Kr}]5s^2$                   |
| Ba       | $[\text{Xe}]6s^2$                   |
| Ra       | $[\text{Rn}]7s^2$                   |
| Group 3A |                                     |
| B        | $[\text{He}]2s^22p^1$               |
| Al       | $[\text{Ne}]3s^23p^1$               |
| Ga       | $[\text{Ar}]3d^{10}4s^24p^1$        |
| In       | $[\text{Kr}]4d^{10}5s^25p^1$        |
| Tl       | $[\text{Xe}]4f^{14}5d^{10}6s^26p^1$ |

▲ **Figure 6.30** Regions of the periodic table. The order in which electrons are added to orbitals is read left to right beginning in the top-left corner.

to  $2n^2$  electrons: 2, 8, 18, or 32. We see that the overall structure of the periodic table reflects these electron numbers: Each row of the table has 2, 8, 18, or 32 elements in it. As shown in **Figure 6.30**, the periodic table can be further divided into four blocks based on the filling order of orbitals. On the left are *two* blue columns of elements. These elements, known as the alkali metals (group 1A) and alkaline earth metals (group 2A), are those in which the valence *s* orbitals are being filled. These two columns make up the *s* block of the periodic table.

On the right is a block of *six* pink columns that comprises the *p* block, where the valence *p* orbitals are being filled. The *s* block and the *p* block elements together are the **representative elements**, sometimes called the **main-group elements**.

The orange block in **Figure 6.30** has *ten* columns containing the **transition metals**. These are the elements in which the valence *d* orbitals are being filled and make up the *d* block.

The elements in the two tan rows containing *14* columns are the ones in which the valence *f* orbitals are being filled and make up the *f* block. Consequently, these elements are often referred to as the **f-block metals**. In most tables, the *f* block is positioned below the periodic table to save space:

The number of columns in each block corresponds to the maximum number of electrons that can occupy each kind of subshell. Recall that 2, 6, 10, and 14 are the numbers of electrons that can fill the *s*, *p*, *d*, and *f* subshells, respectively. Thus, the *s* block has 2 columns, the *p* block has 6, the *d* block has 10, and the *f* block has 14. Recall also that 1*s* is the first *s* subshell, 2*p* is the first *p* subshell, 3*d* is the first *d* subshell, and 4*f* is the first *f* subshell, as **Figure 6.30** shows. Using these facts, you can write the electron configuration of an element based merely on its position in the periodic table. Remember: *The periodic table is your best guide to the order in which orbitals are filled.*

Let's use the periodic table to write the electron configuration of selenium (Se, element 34). We first locate Se in the table and then move backward from it through the table, from element 34 to 33 to 32, and so forth, until we come to the noble gas that precedes Se. In this case, the noble gas is argon, Ar, element 18. Thus, the noble-gas core for Se is [Ar]. Our next step is to write symbols for the outer electrons. We do this by moving across period 4 from K, the element following Ar, to Se:

Because K is in the fourth period and the  $s$  block, we begin with the  $4s$  electrons, meaning our first two outer electrons are written  $4s^2$ . We then move into the  $d$  block, which begins with the  $3d$  electrons. (The principal quantum number in the  $d$  block is always one less than that of the preceding elements in the  $s$  block, as seen in Figure 6.30.) Traversing the  $d$  block adds ten electrons,  $3d^{10}$ . Finally, we move into the  $p$  block, whose principal quantum number is always the same as that of the  $s$  block. Counting the squares as we move across the  $p$  block to Se tells us that we need four electrons,  $4p^4$ . The electron configuration for Se is therefore  $[\text{Ar}]4s^23d^{10}4p^4$ . This configuration can also be written with the subshells arranged in order of increasing principal quantum number:  $[\text{Ar}]3d^{10}4s^24p^4$ .

As a check, we add the number of electrons in the  $[\text{Ar}]$  core, 18, to the number of electrons we added to the  $4s$ ,  $3d$ , and  $4p$  subshells. This sum should equal the atomic number of Se, 34:  $18 + 2 + 10 + 4 = 34$ .

### Sample Exercise 6.8

#### Electron Configurations for a Group

What is the characteristic valence electron configuration of the group 7A elements, the halogens?

#### SOLUTION

**Analyze and Plan** We first locate the halogens in the periodic table, write the electron configurations for the first two elements, and then determine the general similarity between the configurations.

**Solve** The first member of the halogen group is fluorine (F, element 9). Moving backward from F, we find that the noble-gas core is  $[\text{He}]$ . Moving from He to the element of next higher atomic number brings us to Li, element 3. Because Li is in the second period of the  $s$  block, we add electrons to the  $2s$  subshell. Moving across this block gives  $2s^2$ . Continuing to move to the right, we enter the  $p$  block. Counting the squares to F gives  $2p^5$ . Thus, the condensed electron configuration for fluorine is

The electron configuration for chlorine, the second halogen, is

From these two examples, we see that the characteristic valence electron configuration of a halogen is  $ns^2np^5$ , where  $n$  ranges from 2 in the case of fluorine to 6 in the case of astatine.

#### Practice Exercise 1

A certain atom has an  $ns^2np^6$  electron configuration in its outermost occupied shell. Which of the following elements could it be? (a) Be (b) Si (c) I (d) Kr (e) Rb

#### Practice Exercise 2

Which group of elements is characterized by an  $ns^2np^2$  electron configuration in the outermost occupied shell?

### Sample Exercise 6.9

#### Electron Configurations from the Periodic Table

(a) Based on its position in the periodic table, write the condensed electron configuration for bismuth, element 83. (b) How many unpaired electrons does a bismuth atom have?

#### SOLUTION

(a) Our first step is to write the noble-gas core. We do this by locating bismuth, element 83, in the periodic table. We then move backward to the nearest noble gas, which is Xe, element 54. Thus, the noble-gas core is  $[\text{Xe}]$ .

Next, we trace the path in order of increasing atomic numbers from Xe to Bi. Moving from Xe to Cs, element 55, we find ourselves in period 6 of the  $s$  block. Knowing the block and the period identifies the subshell in which we begin placing outer electrons,  $6s$ . As we move through the  $s$  block, we add two electrons:  $6s^2$ .

Continued

As we move beyond the  $s$  block, from element 56 to element 57, the curved arrow below the periodic table reminds us that we are entering the  $f$  block. The first row of the  $f$  block corresponds to the  $4f$  subshell. As we move across this block, we add 14 electrons:  $4f^{14}$ .

With element 71, we move into the third row of the  $d$  block. Because the first row of the  $d$  block is  $3d$ , the second row is  $4d$  and the third row is  $5d$ . Thus, as we move through the ten elements of the  $d$  block, from element 71 to element 80, we fill the  $5d$  subshell with ten electrons:  $5d^{10}$ .

Moving from element 80 to element 81 puts us into the  $p$  block in the  $6p$  subshell. (Remember that the principal

quantum number in the  $p$  block is the same as that in the  $s$  block.) Moving across to Bi requires three electrons:  $6p^3$ . The path we have taken is Putting the parts together, we obtain the condensed electron configuration:  $[\text{Xe}]6s^24f^{14}5d^{10}6p^3$ . This configuration can also be written with the subshells arranged in order of increasing principal quantum number:  $[\text{Xe}]4f^{14}5d^{10}6s^26p^3$ .

Finally, we check our result to see if the number of electrons equals the atomic number of Bi, 83: Because Xe has 54 electrons (its atomic number), we have  $54 + 2 + 14 + 10 + 3 = 83$ . (If we had 14 electrons too few, we would realize that we have missed the  $f$  block.)

- (b) We see from the condensed electron configuration that the only partially occupied subshell is  $6p$ . The orbital diagram representation for this subshell is

In accordance with Hund's rule, the three  $6p$  electrons occupy the three  $6p$  orbitals singly, with their spins parallel. Thus, there are three unpaired electrons in the bismuth atom.

#### Practice Exercise 1

A certain atom has a [noble gas] $5s^24d^{10}5p^4$  electron configuration. Which element is it?

- (a) Cd (b) Te (c) Sm (d) Hg (e) More information is needed

#### Practice Exercise 2

Use the periodic table to write the condensed electron configuration for (a) Co (element 27), (b) In (element 49).

Figure 6.31 gives, for all the elements, the ground-state electron configurations for the outer-shell electrons. You can use this figure to check your answers as you practice writing electron configurations. We have written these configurations with orbitals listed in order of increasing principal quantum number. As we saw in Sample Exercise 6.9, the orbitals can also be listed in order of filling, as they would be read off of the periodic table.

Figure 6.31 allow us to reexamine the concept of *valence electrons*. Notice, for example, that as we proceed from Cl ( $[\text{Ne}]3s^23p^5$ ) to Br ( $[\text{Ar}]3d^{10}4s^24p^5$ ) we add a complete subshell of  $3d$  electrons to the electrons beyond the [Ar] core. Although the  $3d$  electrons are outer-shell electrons, they are not involved in chemical bonding and are therefore not considered valence electrons. Thus, we consider only the  $4s$  and  $4p$  electrons of Br to be valence electrons. Similarly, if we compare the electron configurations of Ag (element 47) and Au (element 79), we see that Au has a completely full  $4f^{14}$  subshell beyond its noble-gas core, but those  $4f$  electrons are not involved in bonding. In general, *for representative elements we do not consider the electrons in completely filled d or f subshells to be valence electrons, and for transition elements we do not consider the electrons in a completely filled f subshell to be valence electrons.*

## Anomalous Electron Configurations

The electron configurations of certain elements appear to violate the rules we have just discussed. For example, Figure 6.31 shows that the electron configuration of chromium (element 24) is  $[\text{Ar}]3d^54s^1$  rather than the  $[\text{Ar}]3d^44s^2$  configuration we

A friend tells you that her favorite element has an electron configuration of [noble gas] $6s^24f^{14}5d^6$ . Which element is it?

|  |         |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|--|---------|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--| ▲ **Figure 6.31** Outer-shell electron configurations of the elements.

This anomalous behavior is largely a consequence of the closeness of the  $3d$  and  $4s$  orbital energies. It frequently occurs when there are enough electrons to form precisely half-filled sets of degenerate orbitals (as in chromium) or a completely filled  $d$  subshell (as in copper). There are a few similar cases among the heavier transition metals (those with partially filled  $4d$  or  $5d$  orbitals) and among the  $f$ -block metals. Although these minor departures from the expected are interesting, they are not of great chemical significance.

The elements Ni, Pd, and Pt are all in the same group. By examining the electron configurations for these elements in Figure 6.31, what can you conclude about the relative energies of the  $nd$  and  $(n + 1)s$  orbitals for this group?

## Sample Integrative Exercise

## Putting Concepts Together

Boron, atomic number 5, occurs naturally as two isotopes,  $^{10}\text{B}$  and  $^{11}\text{B}$ , with natural abundances of 19.9% and 80.1%, respectively. (a) In what ways do the two isotopes differ from each other? Does the electronic configuration of  $^{10}\text{B}$  differ from that of  $^{11}\text{B}$ ? (b) Draw the orbital diagram for an atom of  $^{11}\text{B}$ . Which electrons are the valence electrons? (c) Indicate three ways in which the 1s electrons in boron differ from its 2s electrons. (d) Elemental boron reacts with fluorine to form  $\text{BF}_3$ , a gas. Write a balanced chemical equation for the reaction of solid boron with fluorine gas. (e)  $\Delta H_f^\circ$  for  $\text{BF}_3(\text{g})$  is  $-1135.6 \text{ kJ/mol}$ . Calculate the standard enthalpy change in the reaction of boron with fluorine. (f) Will the mass percentage of F be the same in  $^{10}\text{BF}_3$  and  $^{11}\text{BF}_3$ ? If not, why is that the case?

## SOLUTION

(a) The two isotopes of boron differ in the number of neutrons in the nucleus.  (Sections 2.3 and 2.4) Each of the isotopes contains five protons, but  $^{10}\text{B}$  contains five neutrons, whereas  $^{11}\text{B}$  contains six neutrons. The two isotopes of boron have identical electron configurations,  $1s^2 2s^2 2p^1$ , because each has five electrons.

(b) The complete orbital diagram is

The valence electrons are the ones in the outermost occupied shell, the  $2s^2$  and  $2p^1$  electrons. The  $1s^2$  electrons constitute the core electrons, which we represent as  $[\text{He}]$  when we write the condensed electron configuration,  $[\text{He}]2s^2 2p^1$ .

(c) The 1s and 2s orbitals are both spherical, but they differ in three important respects: First, the 1s orbital is lower in energy

than the 2s orbital. Second, the average distance of the 2s electrons from the nucleus is greater than that of the 1s electrons, so the 1s orbital is smaller than the 2s. Third, the 2s orbital has one node, whereas the 1s orbital has no nodes (Figure 6.19).

(d) The balanced chemical equation is

(e)  $\Delta H^\circ = 2(-1135.6) - [0 + 0] = -2271.2 \text{ kJ}$ . The reaction is strongly exothermic.

(f) As we saw in Equation 3.10 (Section 3.3), the mass percentage of an element in a substance depends on the formula weight of the substance. The formula weights of  $^{10}\text{BF}_3$  and  $^{11}\text{BF}_3$  are different because of the difference in the masses of the two isotopes (the isotope masses of  $^{10}\text{B}$  and  $^{11}\text{B}$  are 10.01294 and 11.00931 amu, respectively). The denominators in Equation 3.10 would therefore be different for the two isotopes, whereas the numerators would remain the same.

## Chapter Summary and Key Terms

**WAVELENGTHS AND FREQUENCIES OF LIGHT (INTRODUCTION AND SECTION 6.1)** The **electronic structure** of an atom describes the energies and arrangement of electrons around the atom. Much of what is known about the electronic structure of atoms was obtained by observing the interaction of light with matter.

Visible light and other forms of **electromagnetic radiation** (also known as radiant energy) move through a vacuum at the speed of light,  $c = 2.998 \times 10^8 \text{ m/s}$ . Electromagnetic radiation has both electric and magnetic components that vary periodically in wave-like fashion. The wave characteristics of radiant energy allow it to be described in terms of **wavelength**,  $\lambda$ , and **frequency**,  $\nu$ , which are interrelated:  $\lambda\nu = c$ .

**QUANTIZED ENERGY AND PHOTONS (SECTION 6.2)** Planck proposed that the minimum amount of radiant energy that an object can gain or lose is related to the frequency of the radiation:  $E = h\nu$ . This smallest quantity is called a **quantum** of energy. The constant  $h$  is called the **Planck constant**:  $h = 6.626 \times 10^{-34} \text{ J}\cdot\text{s}$ .

In the quantum theory, energy is quantized, meaning that it can have only certain allowed values. Einstein used the quantum theory to explain the **photoelectric effect**, the emission of electrons from metal surfaces when exposed to light. He proposed that light behaves as if it consists of quantized energy packets called **photons**. Each photon carries energy,  $E = h\nu$ .

**BOHR MODEL OF THE HYDROGEN ATOM (SECTION 6.3)** Dispersion of radiation into its component wavelengths produces a **spectrum**. If the spectrum contains all wavelengths, it is called a **continuous spectrum**; if it contains only certain specific wavelengths, the spectrum is called a **line spectrum**. The radiation emitted by excited hydrogen atoms forms a line spectrum.

Bohr proposed a model of the hydrogen atom that explains its line spectrum. In this model, the energy of the electron in the hydrogen atom depends on the value of a quantum number,  $n$ , called the **principal quantum number**. The value of  $n$  must be a positive integer (1, 2, 3, . . .), and each value of  $n$  corresponds to a different specific energy,  $E_n$ . The energy of the atom increases as  $n$  increases. The lowest energy is achieved for  $n = 1$ ; this is called the **ground state** of the hydrogen atom. Other values of  $n$  correspond to **excited states**. Light is emitted when the electron drops from a higher-energy state to a lower-energy state; light is absorbed to excite the electron from a lower-energy state to a higher one. The frequency of light emitted or absorbed is such that  $h\nu$  equals the difference in energy between two allowed states.

**WAVE BEHAVIOR OF MATTER (SECTION 6.4)** De Broglie proposed that matter, such as electrons, should exhibit wave-like properties. This hypothesis of **matter waves** was proved experimentally by observing the diffraction of electrons. An object has a characteristic wavelength that depends on its **momentum**,  $mv$ :  $\lambda = h/mv$ .

Discovery of the wave properties of the electron led to Heisenberg's **uncertainty principle**, which states that there is an inherent limit to the accuracy with which the position and momentum of a particle can be measured simultaneously.

**QUANTUM MECHANICS AND ORBITALS (SECTION 6.5)** In the quantum-mechanical model of the hydrogen atom, the behavior of the electron is described by mathematical functions called **wave functions**, denoted with the Greek letter  $\psi$ . Each allowed wave function has a precisely known energy, but the location of the electron cannot be determined exactly; rather, the probability of it being at a particular point in space is given by the **probability density**,  $\psi^2$ . The

**electron-density** distribution is a map of the probability of finding the electron at all points in space.

The allowed wave functions of the hydrogen atom are called **orbitals**. An orbital is described by a combination of an integer and a letter, corresponding to values of three quantum numbers. The *principal quantum number*,  $n$ , is indicated by the integers 1, 2, 3, . . . This quantum number relates most directly to the size and energy of the orbital. The *angular momentum quantum number*,  $l$ , is indicated by the letters  $s, p, d, f$ , and so on, corresponding to the values of 0, 1, 2, 3, . . . The  $l$  quantum number defines the shape of the orbital. For a given value of  $n$ ,  $l$  can have integer values ranging from 0 to  $(n - 1)$ . The *magnetic quantum number*,  $m_l$ , relates to the orientation of the orbital in space. For a given value of  $l$ ,  $m_l$  can have integral values ranging from  $-l$  to  $l$ , including 0. Subscripts can be used to label the orientations of the orbitals. For example, the three  $3p$  orbitals are designated  $3p_x$ ,  $3p_y$ , and  $3p_z$ , with the subscripts indicating the axis along which the orbital is oriented.

An electron shell is the set of all orbitals with the same value of  $n$ , such as  $3s$ ,  $3p$ , and  $3d$ . In the hydrogen atom all the orbitals in an electron shell have the same energy. A **subshell** is the set of one or more orbitals with the same  $n$  and  $l$  values; for example,  $3s$ ,  $3p$ , and  $3d$  are each subshells of the  $n = 3$  shell. There is one orbital in an  $s$  subshell, three in a  $p$  subshell, five in a  $d$  subshell, and seven in an  $f$  subshell.

**REPRESENTATIONS OF ORBITALS (SECTION 6.6)** Contour representations are useful for visualizing the shapes of the orbitals. Represented this way,  $s$  orbitals appear as spheres that increase in size as  $n$  increases. The **radial probability function** tells us the probability that the electron will be found at a certain distance from the nucleus. The wave function for each  $p$  orbital has two lobes on opposite sides of the nucleus. They are oriented along the  $x$ ,  $y$ , and  $z$  axes. Four of the  $d$  orbitals appear as shapes with four lobes around the nucleus; the fifth one, the  $d_{z^2}$  orbital, is represented as two lobes along the  $z$  axis and a “doughnut” in the  $xy$  plane. Regions in which the wave function is zero are called **nodes**. There is zero probability that the electron will be found at a node.

**MANY-ELECTRON ATOMS (SECTION 6.7)** In many-electron atoms, different subshells of the same electron shell have different energies. For a given value of  $n$ , the energy of the subshells increases as the value of  $l$  increases:  $ns < np < nd < nf$ . Orbitals within the same subshell are **degenerate**, meaning they have the same energy.

Electrons have an intrinsic property called **electron spin**, which is quantized. The **spin magnetic quantum number**,  $m_s$ , can have two

possible values,  $+\frac{1}{2}$  and  $-\frac{1}{2}$ , which can be envisioned as the two directions of an electron spinning about an axis. The **Pauli exclusion principle** states that no two electrons in an atom can have the same values for  $n$ ,  $l$ ,  $m_l$ , and  $m_s$ . This principle places a limit of two on the number of electrons that can occupy any one atomic orbital. These two electrons differ in their value of  $m_s$ .

**ELECTRON CONFIGURATIONS AND THE PERIODIC TABLE (SECTIONS 6.8 AND 6.9)** The **electron configuration** of an atom describes how the electrons are distributed among the orbitals of the atom. The ground-state electron configurations are generally obtained by placing the electrons in the atomic orbitals of lowest possible energy with the restriction that each orbital can hold no more than two electrons. We depict the arrangement of the electrons pictorially using an **orbital diagram**. When electrons occupy a subshell with more than one degenerate orbital, such as the  $2p$  subshell, **Hund's rule** states that the lowest energy is attained by maximizing the number of electrons with the same electron spin. For example, in the ground-state electron configuration of carbon, the two  $2p$  electrons have the same spin and must occupy two different  $2p$  orbitals.

Elements in any given group in the periodic table have the same type of electron arrangements in their outermost shells. For example, the electron configurations of the halogens fluorine and chlorine are  $[\text{He}]2s^22p^5$  and  $[\text{Ne}]3s^23p^5$ , respectively. The outer-shell electrons are those that lie outside the orbitals occupied in the next lowest noble-gas element. The outer-shell electrons that are involved in chemical bonding are the **valence electrons** of an atom; for the elements with atomic number 30 or less, all of the outer-shell electrons are valence electrons. The electrons that are not valence electrons are called **core electrons**.

The periodic table is partitioned into different types of elements, based on their electron configurations. Those elements in which the outermost subshell is an  $s$  or  $p$  subshell are called the **representative** (or **main-group**) **elements**. Those elements in which a  $d$  subshell is being filled are called the **transition elements** (or **transition metals**). The elements in which the  $4f$  subshell is being filled are called the **lanthanide** (or **rare earth**) **elements**. The actinide elements are those in which the  $5f$  subshell is being filled. The lanthanide and actinide elements are collectively referred to as the **f-block metals**. These elements are shown as two rows of 14 elements below the main part of the periodic table. The structure of the periodic table, summarized in Figure 6.31, allows us to write the electron configuration of an element from its position in the periodic table.

## Learning Outcomes After studying this chapter, you should be able to:

- Calculate the wavelength of electromagnetic radiation given its frequency or its frequency given its wavelength. (Section 6.1)  
*Related Exercises:* 6.19–6.21
- Order the common kinds of radiation in the electromagnetic spectrum according to their wavelengths or energy. (Section 6.1)  
*Related Exercises:* 6.15–6.18
- Explain what photons are and be able to calculate their energies given either their frequency or wavelength. (Section 6.2)  
*Related Exercises:* 6.25, 6.26, 6.29, 6.31
- Explain how line spectra relate to the idea of quantized energy states of electrons in atoms. (Section 6.3)  
*Related Exercises:* 6.36, 6.41, 6.42, 6.44
- Calculate the wavelength of a moving object. (Section 6.4)  
*Related Exercises:* 6.47–6.50
- Explain how the uncertainty principle limits how precisely we can specify the position and the momentum of subatomic particles such as electrons. (Section 6.4) *Related Exercises:* 6.51, 6.52
- Relate the quantum numbers to the number and type of orbitals and recognize the different orbital shapes. (Section 6.5)  
*Related Exercises:* 6.55, 6.57, 6.61, 6.62
- Interpret radial probability function graphs for atomic orbitals. (Section 6.6) *Related Exercises:* 6.53, 6.54, 6.66
- Explain how and why the energies of the orbitals are different in a many-electron atom from those in the hydrogen atom (Section 6.7) *Related Exercises:* 6.67, 6.68
- Draw an energy-level diagram for the orbitals in a many-electron atom and describe how electrons populate the orbitals in the ground state of an atom, using the Pauli exclusion principle and Hund's rule. (Section 6.8)  
*Related Exercises:* 6.11, 6.69
- Use the periodic table to write condensed electron configurations and determine the number of unpaired electrons in an atom. (Section 6.9) *Related Exercises:* 6.75–6.78

## Key Equations

- $\lambda\nu = c$  [6.1] light as a wave:  $\lambda$  = wavelength in meters,  $\nu$  = frequency in  $\text{s}^{-1}$ ,  $c$  = speed of light ( $2.998 \times 10^8 \text{ m/s}$ )
- $E = h\nu$  [6.2] light as a particle (photon):  $E$  = energy of photon in joules,  $h$  = Planck constant ( $6.626 \times 10^{-34} \text{ J}\cdot\text{s}$ ),  $\nu$  = frequency in  $\text{s}^{-1}$
- $E = (-hcR_{\text{H}})\left(\frac{1}{n^2}\right) = (-2.18 \times 10^{-18} \text{ J})\left(\frac{1}{n^2}\right)$  [6.5] energies of the allowed states of the hydrogen atom:  $h$  = Planck constant;  $c$  = speed of light;  $R_{\text{H}}$  = Rydberg constant ( $1.096776 \times 10^7 \text{ m}^{-1}$ );  $n = 1, 2, 3, \dots$  (any positive integer)
- $\lambda = h/mv$  [6.8] matter as a wave:  $\lambda$  = wavelength,  $h$  = Planck constant,  $m$  = mass of object in kg,  $v$  = speed of object in  $\text{m/s}$
- $\Delta x \cdot \Delta(mv) \geq \frac{h}{4\pi}$  [6.9] Heisenberg's uncertainty principle. The uncertainty in position ( $\Delta x$ ) and momentum [ $\Delta(mv)$ ] of an object cannot be zero; the smallest value of their product is  $h/4\pi$

## Exercises

### Visualizing Concepts

- 6.1** The speed of sound in dry air at  $20^\circ\text{C}$  is  $343 \text{ m/s}$  and the lowest frequency sound wave that the human ear can detect is approximately  $20 \text{ Hz}$ . **(a)** What is the wavelength of such a sound wave? **(b)** What would be the frequency of electromagnetic radiation with the same wavelength? **(c)** What type of electromagnetic radiation would that correspond to? [Section 6.1]
- 6.2** A popular kitchen appliance produces electromagnetic radiation with a frequency of  $2450 \text{ MHz}$ . With reference to Figure 6.4, answer the following: **(a)** Estimate the wavelength of this radiation. **(b)** Would the radiation produced by the appliance be visible to the human eye? **(c)** If the radiation is not visible, do photons of this radiation have more or less energy than photons of visible light? **(d)** Which of the following is the appliance likely to be? (i) A toaster oven, (ii) A microwave oven, or (iii) An electric hotplate. [Section 6.1]
- 6.3** The following diagrams represent two electromagnetic waves, drawn on the same scale. **(a)** Which wave has a longer wavelength? **(b)** Which wave has a higher frequency? **(c)** Which wave has a higher energy? [Section 6.2]

- 6.4** Stars do not all have the same temperature. The color of light emitted by stars is characteristic of the light emitted by hot objects. Telescopic photos of three stars are shown below: (i) the Sun, which is classified as a *yellow* star, (ii) *Rigel*, in the constellation Orion, which is classified as a *blue-white* star, and (iii) *Betelgeuse*, also in Orion, which is classified as a *red* star. **(a)** Place these three stars in order of increasing temperature. **(b)** Which of the following principles is relevant to your choice of answer for part (a): The uncertainty principle, the photoelectric effect, blackbody radiation, or line spectra? [Section 6.2]

- 6.5** The familiar phenomenon of a rainbow results from the diffraction of sunlight through raindrops. **(a)** Does the wavelength of light increase or decrease as we proceed outward from the innermost band of the rainbow? **(b)** Does the frequency of light increase or decrease as we proceed outward? [Section 6.3]

- 6.6** A certain quantum-mechanical system has the energy levels shown in the accompanying diagram. The energy levels are indexed by a single quantum number  $n$  that is an integer. **(a)** As drawn, which quantum numbers are involved in the transition that requires the most energy? **(b)** Which quantum numbers are involved in the transition that requires the least energy? **(c)** Based on the drawing, put the following in

**6.14** (a) What is the relationship between the wavelength and the frequency of radiant energy? (b) Ozone in the upper atmosphere absorbs energy in the 210–230-nm range of the spectrum. In what region of the electromagnetic spectrum does this radiation occur?

**6.15** Label each of the following statements as true or false. For those that are false, correct the statement. (a) Visible light is a form of electromagnetic radiation. (b) Ultraviolet light has longer wavelengths than visible light. (c) X rays travel faster than microwaves. (d) Electromagnetic radiation and sound waves travel at the same speed.

**6.16** Determine which of the following statements are false and correct them. (a) The frequency of radiation increases as the wavelength increases. (b) Electromagnetic radiation travels through a vacuum at a constant speed, regardless of wavelength. (c) Infrared light has higher frequencies than visible light. (d) The glow from a fireplace, the energy within a microwave oven, and a foghorn blast are all forms of electromagnetic radiation.

**6.17** Arrange the following kinds of electromagnetic radiation in order of increasing wavelength: infrared, green light, red light, radio waves, X rays, ultraviolet light.

**6.18** List the following types of electromagnetic radiation in order of increasing wavelength: (a) the gamma rays produced by a radioactive nuclide used in medical imaging; (b) radiation from an FM radio station at 93.1 MHz on the dial; (c) a radio signal from an AM radio station at 680 kHz on the dial; (d) the yellow light from sodium vapor streetlights; (e) the red light of a light-emitting diode, such as in a calculator display.

**6.19** (a) What is the frequency of radiation that has a wavelength of  $10\ \mu\text{m}$ , about the size of a bacterium? (b) What is the wavelength of radiation that has a frequency of  $5.50 \times 10^{14}\ \text{s}^{-1}$ ? (c) Would the radiations in part (a) or part (b) be visible to the human eye? (d) What distance does electromagnetic radiation travel in  $50.0\ \mu\text{s}$ ?

**6.20** (a) What is the frequency of radiation whose wavelength is  $0.86\ \text{nm}$ ? (b) What is the wavelength of radiation that has a frequency of  $6.4 \times 10^{11}\ \text{s}^{-1}$ ? (c) Would the radiations in part (a) or part (b) be detected by an X-ray detector? (d) What distance does electromagnetic radiation travel in  $0.38\ \text{ps}$ ?

**6.21** A laser pointer used in a lecture hall emits light at  $650\ \text{nm}$ . What is the frequency of this radiation? Using Figure 6.4, predict the color associated with this wavelength.

**6.22** It is possible to convert radiant energy into electrical energy using photovoltaic cells. Assuming equal efficiency of conversion, would infrared or ultraviolet radiation yield more electrical energy on a per-photon basis?

### Quantized Energy and Photons (Section 6.2)

**6.23** If human height were quantized in 1-foot increments, what would happen to the height of a child as she grows up: (i) The child's height would never change, (ii) the child's height would continuously get greater, (iii) the child's height would increase in "jumps" of 1 foot at a time, or (iv) the child's height would increase in jumps of 6 inches?

**6.24** Einstein's 1905 paper on the photoelectric effect was the first important application of Planck's quantum hypothesis. Describe Planck's original hypothesis, and explain how Einstein made use of it in his theory of the photoelectric effect.

**6.25** (a) Calculate the energy of a photon of electromagnetic radiation whose frequency is  $2.94 \times 10^{14}\ \text{s}^{-1}$ . (b) Calculate the energy of a photon of radiation whose wavelength is  $413\ \text{nm}$ . (c) What wavelength of radiation has photons of energy  $6.06 \times 10^{-19}\ \text{J}$ ?

**6.26** (a) A green laser pointer emits light with a wavelength of  $532\ \text{nm}$ . What is the frequency of this light? (b) What is the energy of one of these photons? (c) The laser pointer emits light because electrons in the material are excited (by a battery) from their ground state to an upper excited state. When the electrons return to the ground state, they lose the excess energy in the form of  $532\text{-nm}$  photons. What is the energy gap between the ground state and excited state in the laser material?

**6.27** (a) Calculate and compare the energy of a photon of wavelength  $3.3\ \mu\text{m}$  with that of wavelength  $0.154\ \text{nm}$ . (b) Use Figure 6.4 to identify the region of the electromagnetic spectrum to which each belongs.

**6.28** An AM radio station broadcasts at  $1010\ \text{kHz}$ , and its FM partner broadcasts at  $98.3\ \text{MHz}$ . Calculate and compare the energy of the photons emitted by these two radio stations.

**6.29** One type of sunburn occurs on exposure to UV light of wavelength in the vicinity of  $325\ \text{nm}$ . (a) What is the energy of a photon of this wavelength? (b) What is the energy of a mole of these photons? (c) How many photons are in a  $1.00\ \text{mJ}$  burst of this radiation? (d) These UV photons can break chemical bonds in your skin to cause sunburn—a form of radiation damage. If the  $325\text{-nm}$  radiation provides exactly the energy to break an average chemical bond in the skin, estimate the average energy of these bonds in  $\text{kJ/mol}$ .

**6.30** The energy from radiation can be used to cause the rupture of chemical bonds. A minimum energy of  $242\ \text{kJ/mol}$  is required to break the chlorine–chlorine bond in  $\text{Cl}_2$ . What is the longest wavelength of radiation that possesses the necessary energy to break the bond? What type of electromagnetic radiation is this?

**6.31** A diode laser emits at a wavelength of  $987\ \text{nm}$ . (a) In what portion of the electromagnetic spectrum is this radiation found? (b) All of its output energy is absorbed in a detector that measures a total energy of  $0.52\ \text{J}$  over a period of  $32\ \text{s}$ . How many photons per second are being emitted by the laser?

**6.32** A stellar object is emitting radiation at  $3.55\ \text{mm}$ . (a) What type of electromagnetic spectrum is this radiation? (b) If a detector is capturing  $3.2 \times 10^8$  photons per second at this wavelength, what is the total energy of the photons detected in  $1.0\ \text{hour}$ ?

**6.33** Molybdenum metal must absorb radiation with a minimum frequency of  $1.09 \times 10^{15}\ \text{s}^{-1}$  before it can eject an electron from its surface via the photoelectric effect. (a) What is the minimum energy needed to eject an electron? (b) What wavelength of radiation will provide a photon of this energy? (c) If molybdenum is irradiated with light of wavelength of  $120\ \text{nm}$ , what is the maximum possible kinetic energy of the emitted electrons?

**6.34** Titanium metal requires a photon with a minimum energy of  $6.94 \times 10^{-19}\ \text{J}$  to emit electrons. (a) What is the minimum frequency of light necessary to emit electrons from titanium via the photoelectric effect? (b) What is the wavelength of this light? (c) Is it possible to eject electrons from titanium metal using visible light? (d) If titanium is irradiated with light of wavelength  $233\ \text{nm}$ , what is the maximum possible kinetic energy of the emitted electrons?

### Bohr's Model; Matter Waves (Sections 6.3 and 6.4)

**6.35** Does the hydrogen atom "expand" or "contract" when an electron is excited from the  $n = 1$  state to the  $n = 3$  state?

**6.36** Classify each of the following statements as either true or false: (a) A hydrogen atom in the  $n = 3$  state can emit light

at only two specific wavelengths, **(b)** a hydrogen atom in the  $n = 2$  state is at a lower energy than one in the  $n = 1$  state, and **(c)** the energy of an emitted photon equals the energy difference of the two states involved in the emission.

**6.37** Is energy emitted or absorbed when the following electronic transitions occur in hydrogen? **(a)** from  $n = 4$  to  $n = 2$ , **(b)** from an orbit of radius  $2.12 \text{ \AA}$  to one of radius  $8.46 \text{ \AA}$ , **(c)** an electron adds to the  $\text{H}^+$  ion and ends up in the  $n = 3$  shell?

**6.38** Indicate whether energy is emitted or absorbed when the following electronic transitions occur in hydrogen: **(a)** from  $n = 2$  to  $n = 6$ , **(b)** from an orbit of radius  $4.76 \text{ \AA}$  to one of radius  $0.529 \text{ \AA}$ , **(c)** from the  $n = 6$  to the  $n = 9$  state.

**6.39** **(a)** Using Equation 6.5, calculate the energy of an electron in the hydrogen atom when  $n = 2$  and when  $n = 6$ . Calculate the wavelength of the radiation released when an electron moves from  $n = 6$  to  $n = 2$ . **(b)** Is this line in the visible region of the electromagnetic spectrum? If so, what color is it?

**6.40** Consider a transition of the electron in the hydrogen atom from  $n = 4$  to  $n = 9$ . **(a)** Is  $\Delta E$  for this process positive or negative? **(b)** Determine the wavelength of light that is associated with this transition. Will the light be absorbed or emitted? **(c)** In which portion of the electromagnetic spectrum is the light in part (b)?

**6.41** The visible emission lines observed by Balmer all involved  $n_f = 2$ . **(a)** Which of the following is the best explanation of why the lines with  $n_f = 3$  are not observed in the visible portion of the spectrum: (i) Transitions to  $n_f = 3$  are not allowed to happen, (ii) transitions to  $n_f = 3$  emit photons in the infrared portion of the spectrum, (iii) transitions to  $n_f = 3$  emit photons in the ultraviolet portion of the spectrum, or (iv) transitions to  $n_f = 3$  emit photons that are at exactly the same wavelengths as those to  $n_f = 2$ . **(b)** Calculate the wavelengths of the first three lines in the Balmer series—those for which  $n_i = 3, 4$ , and  $5$ —and identify these lines in the emission spectrum shown in Figure 6.11.

**6.42** The Lyman series of emission lines of the hydrogen atom are those for which  $n_f = 1$ . **(a)** Determine the region of the electromagnetic spectrum in which the lines of the Lyman series are observed. **(b)** Calculate the wavelengths of the first three lines in the Lyman series—those for which  $n_i = 2, 3$ , and  $4$ .

**6.43** One of the emission lines of the hydrogen atom has a wavelength of  $93.07 \text{ nm}$ . **(a)** In what region of the electromagnetic spectrum is this emission found? **(b)** Determine the initial and final values of  $n$  associated with this emission.

**6.44** The hydrogen atom can absorb light of wavelength  $1094 \text{ nm}$ . **(a)** In what region of the electromagnetic spectrum is this absorption found? **(b)** Determine the initial and final values of  $n$  associated with this absorption.

**6.45** Order the following transitions in the hydrogen atom from smallest to largest frequency of light absorbed:  $n = 3$  to  $n = 6$ ,  $n = 4$  to  $n = 9$ ,  $n = 2$  to  $n = 3$ , and  $n = 1$  to  $n = 2$ .

**6.46** Place the following transitions of the hydrogen atom in order from shortest to longest wavelength of the photon emitted:  $n = 5$  to  $n = 3$ ,  $n = 4$  to  $n = 2$ ,  $n = 7$  to  $n = 4$ , and  $n = 3$  to  $n = 2$ .

**6.47** Use the de Broglie relationship to determine the wavelengths of the following objects: **(a)** an  $85\text{-kg}$  person skiing at  $50 \text{ km/hr}$ , **(b)** a  $10.0\text{-g}$  bullet fired at  $250 \text{ m/s}$ , **(c)** a lithium atom moving at  $2.5 \times 10^5 \text{ m/s}$ , **(d)** an ozone ( $\text{O}_3$ ) molecule in the upper atmosphere moving at  $550 \text{ m/s}$ .

**6.48** Among the elementary subatomic particles of physics is the muon, which decays within a few microseconds after formation. The muon has a rest mass  $206.8$  times that of an electron. Calculate the de Broglie wavelength associated with a muon traveling at  $8.85 \times 10^5 \text{ cm/s}$ .

**6.49** Neutron diffraction is an important technique for determining the structures of molecules. Calculate the velocity of a neutron needed to achieve a wavelength of  $1.25 \text{ \AA}$ . (Refer to the inside cover for the mass of the neutron.)

**6.50** The electron microscope has been widely used to obtain highly magnified images of biological and other types of materials. When an electron is accelerated through a particular potential field, it attains a speed of  $9.47 \times 10^6 \text{ m/s}$ . What is the characteristic wavelength of this electron? Is the wavelength comparable to the size of atoms?

**6.51** Using Heisenberg's uncertainty principle, calculate the uncertainty in the position of **(a)** a  $1.50\text{-mg}$  mosquito moving at a speed of  $1.40 \text{ m/s}$  if the speed is known to within  $\pm 0.01 \text{ m/s}$ ; **(b)** a proton moving at a speed of  $(5.00 \pm 0.01) \times 10^4 \text{ m/s}$ . (The mass of a proton is given in the table of fundamental constants in the inside cover of the text.)

**6.52** Calculate the uncertainty in the position of **(a)** an electron moving at a speed of  $(3.00 \pm 0.01) \times 10^5 \text{ m/s}$ , **(b)** a neutron moving at this same speed. (The masses of an electron and a neutron are given in the table of fundamental constants in the inside cover of the text.) **(c)** Based on your answers to parts (a) and (b), which can we know with greater precision, the position of the electron or of the neutron?

## Quantum Mechanics and Atomic Orbitals (Sections 6.5 and 6.6)

**6.53** Classify the following statements as either true or false: **(a)** In a contour representation of an orbital, such as the one shown here for a  $2p$  orbital, the electron is confined to move about the nucleus on the outer surface of the shape. **(b)** The probability density  $[\psi(r)]^2$  gives the probability of finding the electron at a specific distance from the nucleus.

**6.54** The radial probability function for a  $2s$  orbital is shown here.

Classify the following statements as either true or false: **(a)** There are two maxima in this function because one electron spends most of its time at an approximate distance of  $0.5 \text{ \AA}$  from the nucleus and the other electron spends most of its time at an approximate distance of  $3 \text{ \AA}$  from the nucleus. **(b)** The radial probability function shown here and the probability density  $[\psi(r)]^2$  both go to zero at the same distance from the nucleus, approximately  $1 \text{ \AA}$ . **(c)** For an  $s$  orbital, the number of radial nodes is equal to the principal quantum number,  $n$ .

**6.55** **(a)** For  $n = 4$ , what are the possible values of  $l$ ? **(b)** For  $l = 2$ , what are the possible values of  $m_l$ ? **(c)** If  $m_l = 2$ , what are the possible values for  $l$ ?

**6.56** How many unique combinations of the quantum numbers  $l$  and  $m_l$  are there when **(a)**  $n = 3$ , **(b)**  $n = 4$ ?

- 6.57** Give the numerical values of  $n$  and  $l$  corresponding to each of the following orbital designations: (a)  $3p$ , (b)  $2s$ , (c)  $4f$ , (d)  $5d$ .
- 6.58** Give the values for  $n$ ,  $l$ , and  $m_l$  for (a) each orbital in the  $2p$  subshell, (b) each orbital in the  $5d$  subshell.
- 6.59** A certain orbital of the hydrogen atom has  $n = 4$  and  $l = 2$ . (a) What are the possible values of  $m_l$  for this orbital? (b) What are the possible values of  $m_s$  for the orbital?
- 6.60** A hydrogen atom orbital has  $n = 5$  and  $m_l = -2$ . (a) What are the possible values of  $l$  for this orbital? (b) What are the possible values of  $m_s$  for the orbital?
- 6.61** Which of the following represent impossible combinations of  $n$  and  $l$ ? (a)  $1p$ , (b)  $4s$ , (c)  $5f$ , (d)  $2d$
- 6.62** For the table that follows, write which orbital goes with the quantum numbers. Don't worry about  $x, y, z$  subscripts. If the quantum numbers are not allowed, write "not allowed."

| $n$ | $l$ | $m_l$ | Orbital        |
|-----|-----|-------|----------------|
| 2   | 1   | -1    | $2p$ (example) |
| 1   | 0   | 0     |                |
| 3   | -3  | 2     |                |
| 3   | 2   | -2    |                |
| 2   | 0   | -1    |                |
| 0   | 0   | 0     |                |
| 4   | 2   | 1     |                |
| 5   | 3   | 0     |                |

- 6.63** Sketch the shape and orientation of the following types of orbitals: (a)  $s$ , (b)  $p_z$ , (c)  $d_{xy}$ .
- 6.64** Sketch the shape and orientation of the following types of orbitals: (a)  $p_x$ , (b)  $d_{z^2}$ , (c)  $d_{x^2-y^2}$ .
- 6.65** (a) What are the similarities of and differences between the  $1s$  and  $2s$  orbitals of the hydrogen atom? (b) In what sense does a  $2p$  orbital have directional character? Compare the "directional" characteristics of the  $p_x$  and  $d_{x^2-y^2}$  orbitals. (That is, in what direction or region of space is the electron density concentrated?) (c) What can you say about the average distance from the nucleus of an electron in a  $2s$  orbital as compared with a  $3s$  orbital? (d) For the hydrogen atom, list the following orbitals in order of increasing energy (that is, most stable ones first):  $4f$ ,  $6s$ ,  $3d$ ,  $1s$ ,  $2p$ .
- 6.66** (a) With reference to Figure 6.19, what is the relationship between the number of nodes in an  $s$  orbital and the value of the principal quantum number? (b) Identify the number of nodes; that is, identify places where the electron density is zero, in the  $2p_x$  orbital; in the  $3s$  orbital. (c) What information is obtained from the radial probability functions in Figure 6.19? (d) For the hydrogen atom, list the following orbitals in order of increasing energy:  $3s$ ,  $2s$ ,  $2p$ ,  $5s$ ,  $4d$ .

### Many-Electron Atoms and Electron Configurations (Sections 6.7–6.9)

- 6.67** (a) For an  $\text{He}^+$  ion, do the  $2s$  and  $2p$  orbitals have the same energy? If not, which orbital has a lower energy? (b) If we add one electron to form the He atom, would your answer to part (a) change?
- 6.68** (a) The average distance from the nucleus of a  $3s$  electron in a chlorine atom is smaller than that for a  $3p$  electron. In light of this fact, which orbital is higher in energy? (b) Would you expect it to require more or less energy to remove a  $3s$  electron from the chlorine atom, as compared with a  $2p$  electron?
- 6.69** Two possible electron configurations for an Li atom are shown here. (a) Does either configuration violate the Pauli exclusion principle? (b) Does either configuration violate Hund's rule? (c) In the absence of an external magnetic field, can we say that one electron configuration has a lower energy than the other? If so, which one has the lowest energy?

Configuration A

Configuration B

- 6.70** An experiment called the Stern–Gerlach experiment helped establish the existence of electron spin. In this experiment, a beam of silver atoms is passed through a magnetic field, which deflects half of the silver atoms in one direction and half in the opposite direction. The separation between the two beams increases as the strength of the magnetic field increases. (a) What is the electron configuration for a silver atom? (b) Would this experiment work for a beam of cadmium (Cd) atoms? (c) Would this experiment work for a beam of fluorine (F) atoms?
- 6.71** What is the maximum number of electrons that can occupy each of the following subshells? (a)  $3p$ , (b)  $5d$ , (c)  $2s$ , (d)  $4f$ .
- 6.72** What is the maximum number of electrons in an atom that can have the following quantum numbers? (a)  $n = 3, m_l = -2$ ; (b)  $n = 4, l = 3$ ; (c)  $n = 5, l = 3, m_l = 2$ ; (d)  $n = 4, l = 1, m_l = 0$ .
- 6.73** (a) What are "valence electrons"? (b) What are "core electrons"? (c) What does each box in an orbital diagram represent? (d) What object is represented by the half arrows in an orbital diagram? What does the direction of the arrow signify?
- 6.74** For each element, indicate the number of valence electrons, core electrons, and unpaired electrons in the ground state: (a) nitrogen, (b) silicon, (c) chlorine.
- 6.75** Write the condensed electron configurations for the following atoms, using the appropriate noble-gas core abbreviations: (a) Cs, (b) Ni, (c) Se, (d) Cd, (e) U, (f) Pb.
- 6.76** Write the condensed electron configurations for the following atoms and indicate how many unpaired electrons each has: (a) Mg, (b) Ge, (c) Br, (d) V, (e) Y, (f) Lu.
- 6.77** Identify the specific element that corresponds to each of the following electron configurations and indicate the number of unpaired electrons for each: (a)  $1s^2 2s^2$ , (b)  $1s^2 2s^2 2p^4$ , (c)  $[\text{Ar}] 4s^1 3d^5$ , (d)  $[\text{Kr}] 5s^2 4d^{10} 5p^4$ .
- 6.78** Identify the group of elements that corresponds to each of the following generalized electron configurations and indicate the number of unpaired electrons for each:
- $[\text{noble gas}] ns^2 np^5$
  - $[\text{noble gas}] ns^2 (n-1)d^2$
  - $[\text{noble gas}] ns^2 (n-1)d^{10} np^1$
  - $[\text{noble gas}] ns^2 (n-2)f^6$
- 6.79** The following do not represent valid ground-state electron configurations for an atom either because they violate the Pauli exclusion principle or because orbitals are not filled in order of increasing energy. Indicate which of these two principles is violated in each example. (a)  $1s^2 2s^2 3s^1$ , (b)  $[\text{Xe}] 6s^2 5d^4$  (c)  $[\text{Ne}] 3s^2 3d^5$ .
- 6.80** The following electron configurations represent excited states. Identify the element and write its ground-state condensed electron configuration. (a)  $1s^2 2s^2 2p^4 3s^1$ , (b)  $[\text{Ar}] 4s^1 3d^{10} 4p^2 5p^1$ , (c)  $[\text{Kr}] 5s^2 4d^2 5p^1$ .

## Additional Exercises

**6.81** Consider the two waves shown here, which we will consider to represent two electromagnetic radiations:

- What is the wavelength of wave A? Of wave B?
- What is the frequency of wave A? Of wave B?
- Identify the regions of the electromagnetic spectrum to which waves A and B belong.

**6.82** If you put 120 volts of electricity through a pickle, the pickle will smoke and start glowing orange-yellow. The light is emitted because sodium ions in the pickle become excited; their return to the ground state results in light emission. (a) The wavelength of this emitted light is 589 nm. Calculate its frequency. (b) What is the energy of 1.00 mol of these photons (a mole of photons is called an Einstein)? (c) Calculate the energy gap between the excited and ground states for the sodium ion. (d) If you soaked the pickle for a long time in a different salt solution, such as strontium chloride, would you still observe 589-nm light emission?

**6.83** Certain elements emit light of a specific wavelength when they are burned. Historically, chemists used such emission wavelengths to determine whether specific elements were present in a sample. Characteristic wavelengths for some of the elements are given in the following table:

|    |          |    |          |
|----|----------|----|----------|
| Ag | 328.1 nm | Fe | 372.0 nm |
| Au | 267.6 nm | K  | 404.7 nm |
| Ba | 455.4 nm | Mg | 285.2 nm |
| Ca | 422.7 nm | Na | 589.6 nm |
| Cu | 324.8 nm | Ni | 341.5 nm |

(a) Determine which elements emit radiation in the visible part of the spectrum. (b) Which element emits photons of highest energy? Of lowest energy? (c) When burned, a sample of an unknown substance is found to emit light of frequency  $9.23 \times 10^{14} \text{ s}^{-1}$ . Which of these elements is probably in the sample?

**6.84** In August 2011, the Juno spacecraft was launched from Earth with the mission of orbiting Jupiter, arriving nearly five years later in July of 2016. The distance between the two planets varies depending on where each planet is in its orbit, but at the closest, the distance between Jupiter and Earth is 391 million miles. What is the minimum amount of time it takes for a transmitted signal from Juno to reach the Earth?

**6.85** The rays of the Sun that cause tanning and burning are in the ultraviolet portion of the electromagnetic spectrum. These rays are categorized by wavelength. So-called UV-A radiation has wavelengths in the range of 320–380 nm, whereas UV-B radiation has wavelengths in the range of 290–320 nm. (a) Calculate the frequency of light that has a wavelength of 320 nm. (b) Calculate the energy of a mole of 320-nm photons. (c) Which are more energetic, photons of UV-A radiation or photons of UV-B radiation? (d) The UV-B radiation from the Sun is considered a greater cause of sunburn in humans than is UV-A radiation. Is this observation consistent with your answer to part (c)?

**6.86** The watt is the derived SI unit of power, the measure of energy per unit time:  $1 \text{ W} = 1 \text{ J/s}$ . A semiconductor laser in a CD player has an output wavelength of 780 nm and a power level of 0.10 mW. How many photons strike the CD surface during the playing of a CD 69 minutes in length?

**6.87** Carotenoids are yellow, orange, and red pigments synthesized by plants. The observed color of an object is not the color of light it absorbs but rather the complementary color, as described by a color wheel such as the one shown here. On this wheel, complementary colors are across from each other. (a) Based on this wheel, what color is absorbed most strongly if a plant is orange? (b) If a particular carotenoid absorbs photons at 455 nm, what is the energy of the photon?

**[6.88]** In an experiment to study the photoelectric effect, a scientist measures the kinetic energy of ejected electrons as a function of the frequency of radiation hitting a metal surface. She obtains the following plot. The point labeled " $\nu_0$ " corresponds to light with a wavelength of 542 nm. (a) What is the value of  $\nu_0$  in  $\text{s}^{-1}$ ? (b) What is the value of the work function of the metal in units of kJ/mol of ejected electrons? (c) Note that when the frequency of the light is greater than  $\nu_0$ , the plot shows a straight line with a nonzero slope. What is the slope of this line segment?

**[6.89]** Consider a transition in which the electron of a hydrogen atom is excited from  $n = 1$  to  $n = \infty$ . (a) What is the end result of this transition? (b) What is the wavelength of light that must be absorbed to accomplish this process? (c) What will occur if light with a shorter wavelength than that in part (b) is used to excite the hydrogen atom? (d) How are the results of parts (b) and (c) related to the plot shown in Exercise 6.88?

**6.90** The human retina has three types of receptor cones, each sensitive to a different range of wavelengths of visible light, as shown in this figure (the colors are merely to differentiate the three curves from one another; they do not indicate the actual colors represented by each curve):

(a) Estimate the energies of photons with wavelengths at the maximum for each type of cone. (b) The color of the sky is due to scattering of solar light by the molecules of the atmosphere. Lord Rayleigh was one of the first to study scattering of this kind. He showed that the amount of scattering for very small particles such as molecules is inversely proportional to the fourth power of the wavelength. Estimate the ratio of the scattering efficiency of light at the wavelength of the maximum for the “blue” cones, as compared with that for the “green” cones. (c) Explain why the sky appears blue even though all wavelengths of solar light are scattered by the atmosphere.

**6.91** The series of emission lines of the hydrogen atom for which  $n_i = 3$  is called the *Paschen series*. (a) Determine the region of the electromagnetic spectrum in which the lines of the Paschen series are observed. (b) Calculate the wavelengths of the first three lines in the Paschen series—those for which  $n_i = 4, 5$ , and 6.

**6.92** When the spectrum of light from the Sun is examined in high resolution in an experiment similar to that illustrated in Figure 6.9, dark lines are evident. These are called Fraunhofer lines, after the scientist who studied them extensively in the early nineteenth century. Altogether, about 25,000 lines have been identified in the solar spectrum between 2950 Å and 10,000 Å. The Fraunhofer lines are attributed to absorption of certain wavelengths of the Sun’s “white” light by gaseous elements in the Sun’s atmosphere. (a) Describe the process that causes absorption of specific wavelengths of light from the solar spectrum. (b) To determine which Fraunhofer lines belong to a given element, say, neon, what experiments could a scientist conduct here on Earth?

**6.93** Determine whether each of the following sets of quantum numbers for the hydrogen atom are valid. If a set is not valid, indicate which of the quantum numbers has a value that is not valid:

- (a)  $n = 4, l = 1, m_l = 2, m_s = -\frac{1}{2}$
- (b)  $n = 4, l = 3, m_l = -3, m_s = +\frac{1}{2}$
- (c)  $n = 3, l = 2, m_l = -1, m_s = +\frac{1}{2}$
- (d)  $n = 5, l = 0, m_l = 0, m_s = 0$
- (e)  $n = 2, l = 2, m_l = 1, m_s = +\frac{1}{2}$

**[6.94]** Bohr’s model can be used for hydrogen-like ions—ions that have only one electron, such as  $\text{He}^+$  and  $\text{Li}^{2+}$ . (a) Why is the Bohr model applicable to  $\text{He}^+$  ions but not to neutral He atoms? (b) The ground-state energies of H,  $\text{He}^+$ , and  $\text{Li}^{2+}$  are tabulated as follows:

| Atom or ion         | H                                 | $\text{He}^+$                     | $\text{Li}^{2+}$                  |
|---------------------|-----------------------------------|-----------------------------------|-----------------------------------|
| Ground-state energy | $-2.18 \times 10^{-18} \text{ J}$ | $-8.72 \times 10^{-18} \text{ J}$ | $-1.96 \times 10^{-17} \text{ J}$ |

By examining these numbers, propose a relationship between the ground-state energy of hydrogen-like systems and the nuclear charge,  $Z$ . (c) Use the relationship you derive in part (b) to predict the ground-state energy of the  $\text{C}^{5+}$  ion.

**[6.95]** An electron is accelerated through an electric potential to a kinetic energy of  $2.15 \times 10^{-15} \text{ J}$ . What is its characteristic wavelength? [Hint: Recall that the kinetic energy of a moving object is  $E = \frac{1}{2}mv^2$ , where  $m$  is the mass of the object and  $v$  is the speed of the object.]

**6.96** In the television series *Star Trek*, the transporter beam is a device used to “beam down” people from the *Starship Enterprise* to another location, such as the surface of a planet. The writers of the show put a “Heisenberg compensator” into the transporter beam mechanism. Explain why such a compensator (which is entirely fictional) would be necessary to get around Heisenberg’s uncertainty principle.

**[6.97]** As discussed in the A Closer Look box on “Measurement and the Uncertainty Principle,” the essence of the uncertainty principle is that we can’t make a measurement without

disturbing the system that we are measuring. (a) Why can’t we measure the position of a subatomic particle without disturbing it? (b) How is this concept related to the paradox discussed in the Closer Look box on “Thought Experiments and Schrödinger’s Cat”?

**[6.98]** Consider the discussion of radial probability functions in “A Closer Look” in Section 6.6. (a) What is the difference between the probability density as a function of  $r$  and the radial probability function as a function of  $r$ ? (b) What is the significance of the term  $4\pi r^2$  in the radial probability functions for the  $s$  orbitals? (c) Based on Figures 6.19 and 6.22, make sketches of what you think the probability density as a function of  $r$  and the radial probability function would look like for the  $4s$  orbital of the hydrogen atom.

**[6.99]** For orbitals that are symmetric but not spherical, the contour representations (as in Figures 6.23 and 6.24) suggest where nodal planes exist (that is, where the electron density is zero). For example, the  $p_x$  orbital has a node wherever  $x = 0$ . This equation is satisfied by all points on the  $yz$  plane, so this plane is called a nodal plane of the  $p_x$  orbital. (a) Determine the nodal plane of the  $p_z$  orbital. (b) What are the two nodal planes of the  $d_{xy}$  orbital? (c) What are the two nodal planes of the  $d_{x^2-y^2}$  orbital?

**[6.100]** The Chemistry and Life box in Section 6.7 described the techniques called NMR and MRI. (a) Instruments for obtaining MRI data are typically labeled with a frequency, such as 600 MHz. In what region of the electromagnetic spectrum does a photon with this frequency belong? (b) What is the value of  $\Delta E$  in Figure 6.27 that would correspond to the absorption of a photon of radiation with frequency 450 MHz? (c) When the 450-MHz photon is absorbed, does it change the spin of the electron or the proton on a hydrogen atom?

**[6.101]** Suppose that the spin quantum number,  $m_s$ , could have three allowed values instead of two. How would this affect the number of elements in the first four rows of the periodic table?

**6.102** Using the periodic table as a guide, write the condensed electron configuration and determine the number of unpaired electrons for the ground state of (a) Br, (b) Ga, (c) Hf, (d) Sb, (e) Bi, (f) Sg.

**6.103** Scientists have speculated that element 126 might have a moderate stability, allowing it to be synthesized and characterized. Predict what the condensed electron configuration of this element might be.

**[6.104]** In the experiment shown schematically below, a beam of neutral atoms is passed through a magnetic field. Atoms that have unpaired electrons are deflected in different directions in the magnetic field depending on the value of the electron spin quantum number. In the experiment illustrated, we envision that a beam of hydrogen atoms splits into two beams. (a) What is the significance of the observation that

the single beam splits into two beams? **(b)** What do you think would happen if the strength of the magnet were increased? **(c)** What do you think would happen if the beam of hydrogen atoms were replaced with a beam of helium atoms? Why? **(d)** The relevant experiment was first performed by Otto

Stern and Walter Gerlach in 1921. They used a beam of Ag atoms in the experiment. By considering the electron configuration of a silver atom, explain why the single beam splits into two beams.

## Integrative Exercises

**6.105** Microwave ovens use microwave radiation to heat food. The energy of the microwaves is absorbed by water molecules in food and then transferred to other components of the food. **(a)** Suppose that the microwave radiation has a wavelength of 11.2 cm. How many photons are required to heat 200 mL of coffee from 23 to 60 °C? **(b)** Suppose the microwave's power is 900 W (1 watt = 1 joule-second). How long would you have to heat the coffee in part (a)?

**6.106** The stratospheric ozone (O<sub>3</sub>) layer helps to protect us from harmful ultraviolet radiation. It does so by absorbing ultraviolet light and falling apart into an O<sub>2</sub> molecule and an oxygen atom, a process known as photodissociation.

Use the data in Appendix C to calculate the enthalpy change for this reaction. What is the maximum wavelength a photon can have if it is to possess sufficient energy to cause this dissociation? In what portion of the spectrum does this wavelength occur?

**6.107** The discovery of hafnium, element number 72, provided a controversial episode in chemistry. G. Urbain, a French chemist, claimed in 1911 to have isolated an element number 72 from a sample of rare earth (elements 58–71) compounds. However, Niels Bohr believed that hafnium was more likely to be found along with zirconium than with the rare earths. D. Coster and G. von Hevesy, working in Bohr's laboratory in Copenhagen, showed in 1922 that element 72 was present in a sample of Norwegian zircon, an ore of zirconium. (The name *hafnium* comes from the Latin name for Copenhagen, *Hafnia*.) **(a)** How would you use electron configuration arguments to justify Bohr's prediction? **(b)** Zirconium, hafnium's neighbor in group 4B, can be produced as a metal by reduction of solid ZrCl<sub>4</sub> with molten sodium metal. Write a balanced chemical equation for the reaction. Is this an oxidation-reduction reaction? If yes, what is reduced and what is oxidized? **(c)** Solid zirconium dioxide, ZrO<sub>2</sub>, reacts with chlorine gas in the presence of carbon. The products of the reaction are ZrCl<sub>4</sub> and two gases, CO<sub>2</sub> and CO in the ratio 1:2. Write a balanced chemical equation for the reaction. Starting with a 55.4-g sample of ZrO<sub>2</sub>, calculate the mass of ZrCl<sub>4</sub> formed, assuming

that ZrO<sub>2</sub> is the limiting reagent and assuming 100% yield. **(d)** Using their electron configurations, account for the fact that Zr and Hf form chlorides MCl<sub>4</sub> and oxides MO<sub>2</sub>.

**6.108** **(a)** Account for formation of the following series of oxides in terms of the electron configurations of the elements and the discussion of ionic compounds in Section 2.7: K<sub>2</sub>O, CaO, Sc<sub>2</sub>O<sub>3</sub>, TiO<sub>2</sub>, V<sub>2</sub>O<sub>5</sub>, CrO<sub>3</sub>. **(b)** Name these oxides. **(c)** Consider the metal oxides whose enthalpies of formation (in kJ mol<sup>-1</sup>) are listed here.

| Oxide              | K <sub>2</sub> O(s) | CaO(s) | TiO <sub>2</sub> (s) | V <sub>2</sub> O <sub>5</sub> (s) |
|--------------------|---------------------|--------|----------------------|-----------------------------------|
| $\Delta H_f^\circ$ | -363.2              | -635.1 | -938.7               | -1550.6                           |

Calculate the enthalpy changes in the following general reaction for each case:

(You will need to write the balanced equation for each case and then compute  $\Delta H^\circ$ .) **(d)** Based on the data given, estimate a value of  $\Delta H_f^\circ$  for Sc<sub>2</sub>O<sub>3</sub>(s).

**6.109** The first 25 years of the twentieth century were momentous for the rapid pace of change in scientists' understanding of the nature of matter. **(a)** How did Rutherford's experiments on the scattering of  $\alpha$  particles by a gold foil set the stage for Bohr's theory of the hydrogen atom? **(b)** In what ways is de Broglie's hypothesis, as it applies to electrons, consistent with J. J. Thomson's conclusion that the electron has mass? In what sense is it consistent with proposals preceding Thomson's work that the cathode rays are a wave phenomenon?

**6.110** The two most common isotopes of uranium are <sup>235</sup>U and <sup>238</sup>U. **(a)** Compare the number of protons, the number of electrons, and the number of neutrons in atoms of these two isotopes. **(b)** Using the periodic table in the front-inside cover, write the electron configuration for a U atom. **(c)** Compare your answer to part (b) to the electron configuration given in Figure 6.30. How can you explain any differences between these two electron configurations? **(d)** <sup>238</sup>U undergoes radioactive decay to <sup>234</sup>Th. How many protons, electrons, and neutrons are gained or lost by the <sup>238</sup>U atom during this process? **(e)** Examine the electron configuration for Th in Figure 6.31. Are you surprised by what you find? Explain.

## Design an Experiment

In this chapter, we have learned about the *photoelectric effect* and its impact on the formulation of light as photons. We have also seen that some anomalous electron configurations of the elements are particularly favorable if each atom has one or more half-filled shell, such as the case for the Cr atom with its [Ar]4s<sup>1</sup>3d<sup>5</sup> electron configuration. Let's suppose it is hypothesized that it requires more energy to remove an electron from a metal that has atoms with one or more half-filled shells than from those that do not. **(a)** Design a series of experiments involving the photoelectric effect that would test the

hypothesis. **(b)** What experimental apparatus would be needed to test the hypothesis? It's not necessary that you name actual equipment but rather that you imagine how the apparatus would work—think in terms of the types of measurements that would be needed, and what capability you would need in your apparatus. **(c)** Describe the type of data you would collect and how you would analyze the data to see whether the hypothesis were correct. **(d)** Could your experiments be extended to test the hypothesis for other parts of the periodic table, such as the lanthanide or actinide elements?

7

# PERIODIC PROPERTIES OF THE ELEMENTS

The periodic table is a powerful tool for understanding and predicting the physical and chemical properties of elements. Typically, elements share common characteristics with neighbors that occupy the same column of the periodic table. Sodium, potassium, and rubidium are soft metals that react violently when they come in contact with water. Neon, argon, and krypton are colorless, chemically inert gases. Copper, silver, and gold are highly conductive metals that react slowly, if at all, with air and water.

As we saw in Chapter 6, this behavior arises from repeating patterns of electron configuration. Elements in the same column contain the same number of electrons in their **valence orbitals**—the occupied orbitals that hold the electrons involved in bonding. While elements from the same column tend to have similar properties, every element has its own identity. Nowhere are the differences between elements belonging to the same column more apparent than amongst the group 4A elements: carbon (C), silicon (Si), germanium (Ge), tin (Sn), and lead (Pb). Carbon is a nonmetal that comes in many different forms, including diamond, one of the hardest known substances. Moving to the bottom of group 4A, we find lead, which is a relatively soft metal. Our bodies and those of nearly every living thing on planet Earth are made from molecules that contain carbon, while the toxicity of lead is well documented. In between we find silicon and germanium, both of which have the same arrangement of atoms as diamond and are semiconductors used extensively in integrated circuits and computers. Tin has a split personality in the sense that it behaves as a metal at temperatures above 13 °C ( $\beta$ -Sn or white tin) and as a semiconductor below 13 °C ( $\alpha$ -Sn or gray tin).

In this chapter, we explore several fundamental characteristics of elements. We see how these characteristics change as we move across a row or down a column of the periodic table, which in turn helps us rationalize and predict the physical and chemical properties of the elements.

◀ **THE LIGHTEST ELEMENT** in group 4A, carbon, comes in many different forms including diamond, whose hardness and optical properties make it a highly prized gemstone.

## WHAT'S AHEAD

- 7.1 ▶ Development of the Periodic Table**  
Learn about the discovery and key moments in the development of the periodic table.
- 7.2 ▶ Effective Nuclear Charge**  
Understand the concept of *effective nuclear charge*, the force between the outer or valence electrons and the nucleus, and how it varies throughout the periodic table.
- 7.3 ▶ Sizes of Atoms and Ions** Explore the relative sizes of atoms and ions, both of which follow trends that are related to their placement in the periodic table and the trends in effective nuclear charge.
- 7.4 ▶ Ionization Energy** Learn that *ionization energy* is the energy required to remove one or more electrons from an atom. The periodic trends in ionization energy depend on variations in effective nuclear charge and atomic radii.
- 7.5 ▶ Electron Affinity** Learn that *electron affinity* is the energy released when an electron is added to an atom and understand its periodic trends.
- 7.6 ▶ Metals, Nonmetals, and Metalloids**  
Differentiate the physical and chemical properties of metals from those of nonmetals. The differences in properties arise from the fundamental characteristics of atoms, particularly ionization energy. Metalloids display properties that are intermediate between those of metals and those of nonmetals.
- 7.7 ▶ Trends for Group 1A and Group 2A Metals** Examine some periodic trends in the chemical and physical properties of metals belonging to groups 1A and 2A.
- 7.8 ▶ Trends for Selected Nonmetals**  
Investigate some of the periodic trends in the chemical and physical properties of hydrogen and the elements in groups 6A, 7A, and 8A.

## 7.1 | Development of the Periodic Table

The discovery of chemical elements has been ongoing since ancient times (Figure 7.1). Certain elements, such as gold (Au), appear in nature in elemental form and were thus discovered thousands of years ago. In contrast, some elements, such as technetium (Tc), are radioactive and intrinsically unstable. We know about them only because of technology developed during the twentieth century.

The majority of elements readily form compounds and, consequently, are not found in nature in their elemental form. For centuries, therefore, scientists were unaware of their existence. During the early nineteenth century, advances in chemistry made it easier to isolate elements from their compounds. As a result, the number of known elements more than doubled from 31 in 1800 to 63 by 1865.

As the number of known elements increased, scientists began classifying them. In 1869, Dmitri Mendeleev (1834–1907) in Russia and Lothar Meyer (1830–1895) in Germany published nearly identical classification schemes. Both noted that similar chemical and physical properties recur periodically when the elements are arranged in order of increasing atomic weight. Scientists at that time had no knowledge of atomic numbers. Atomic weights, however, generally increase with increasing atomic number, so both Mendeleev and Meyer fortuitously arranged the elements in nearly the proper sequence.

Although Mendeleev and Meyer came to essentially the same conclusion about the periodicity of elemental properties, Mendeleev is given credit for advancing his ideas more vigorously and stimulating new work. His insistence that elements with similar characteristics be listed in the same column forced him to leave blank spaces in his table.

### Go Figure

Copper, silver, and gold have all been known since ancient times, whereas most of the other metals were not isolated until much later. Can you suggest an explanation?

For example, both gallium (Ga) and germanium (Ge) were unknown to Mendeleev. He boldly predicted their existence and properties, referring to them as *eka-aluminum* (“under” aluminum) and *eka-silicon* (“under” silicon), respectively, after the elements under which they appeared in his table. When these elements were discovered, their properties closely matched those predicted by Mendeleev, as shown in [Table 7.1](#).

In 1913, two years after Rutherford proposed the nuclear model of the atom ([Section 2.2](#)), English physicist Henry Moseley (1887–1915) developed the concept of atomic numbers. Bombarding different elements with high-energy electrons, Moseley found that each element produced X rays of a unique frequency and that the frequency generally increased as the atomic mass increased. He arranged the X-ray frequencies in order by assigning a unique whole number, called an *atomic number*, to each element. Moseley correctly identified the atomic number as the number of protons in the nucleus of the atom. ([Section 2.3](#))

The concept of atomic number clarified some problems in the periodic table of Moseley’s day, which was based on atomic weights. For example, the atomic weight of Ar (atomic number 18) is greater than that of K (atomic number 19), yet the chemical and physical properties of Ar are much more like those of Ne and Kr than like those of Na and Rb. When the elements are arranged in order of increasing atomic number, Ar and K appear in their correct places in the table. Moseley’s studies also made it possible to identify “holes” in the periodic table, which led to the discovery of new elements.

### Give It Some Thought

Looking at the periodic table on the front inside cover, can you find an example other than Ar and K where the order of the elements would be different if the elements were arranged in order of increasing atomic weight?

## 7.2 | Effective Nuclear Charge

Many properties of atoms depend on electron configuration and on how strongly the outer electrons in the atoms are attracted to the nucleus. Coulomb’s law tells us that the strength of the interaction between two electrical charges depends on the magnitudes of the charges and on the distance between them. ([Section 2.3](#)) Thus, the attractive force between an electron and the nucleus depends on the magnitude of the nuclear charge and on the average distance between the nucleus and the electron. The force increases as the nuclear charge increases and decreases as the electron moves farther from the nucleus.

Understanding the attraction between the electron and the nucleus in a hydrogen atom is straightforward because we have only one electron and one proton. In a many-electron atom, however, the situation is more complicated. In addition to the

▲ **Figure 7.2** An analogy for effective nuclear charge. We envision the nucleus as a light bulb, the core electrons as a frosted glass lampshade, and a valence electron as an observer. The amount of light seen by the observer depends on the intensity of the light bulb and the screening by the frosted glass lampshade.

attraction of each electron to the nucleus, each electron experiences the repulsion due to other electrons. These electron–electron repulsions cancel some of the attraction of the electron to the nucleus so that the electron experiences less attraction than it would if the other electrons weren’t there. In essence, each electron in a many-electron atom is *screened* from the nucleus by the other electrons. It therefore experiences a net attraction that is smaller than it would experience in the absence of other electrons.

How can we account for the combination of nuclear attraction and electron repulsions for our electron of interest? The simplest way to do so is to imagine that the electron experiences a net attraction that is the result of the nuclear attraction decreased by the electron–electron repulsions. We call this partially screened nuclear charge the **effective nuclear charge**,  $Z_{\text{eff}}$ . Because the full attractive force of the nucleus has been decreased by the electron repulsions, we see that the effective nuclear charge is always less than the *actual* nuclear charge ( $Z_{\text{eff}} < Z$ ). We can define the amount of screening of the nuclear charge quantitatively by using a *screening constant*,  $S$ , such that

$$Z_{\text{eff}} = Z - S \quad [7.1]$$

where  $S$  is a positive number. For a valence electron, most of the shielding is due to the core electrons, which are much closer to the nucleus. As a result, for the valence electrons in an atom *the value of  $S$  is usually close to the number of core electrons in the atom*. (Electrons in the same valence shell do not screen one another very effectively, but they do affect the value of  $S$  slightly; see “A Closer Look: Effective Nuclear Charge.”)

To understand better the notion of effective nuclear charge, we can use an analogy of a light bulb with a frosted glass shade (Figure 7.2). The light bulb represents the nucleus, and the observer is the electron of interest, which is usually a valence electron. The amount of light that the electron “sees” is analogous to the amount of net nuclear attraction experienced by the electron. The other electrons in the atom, especially the core electrons, act like a frosted glass lampshade, decreasing the amount of light that gets to the observer. If the light bulb gets brighter while the lampshade stays the same ( $Z$  increases), more light is observed. Likewise, if the lampshade gets thicker ( $S$  increases), less light is observed. We will find it helpful to keep this analogy in mind as we discuss trends in effective nuclear charge.

Let’s consider what we would expect for the magnitude of  $Z_{\text{eff}}$  for the sodium atom. Sodium has the electron configuration  $[\text{Ne}]3s^1$ . The nuclear charge is  $Z = 11+$ , and there are 10 core electrons ( $1s^22s^22p^6$ ), which serve as a “lampshade” to screen the nuclear charge “seen” by the  $3s$  electron. Therefore, in the simplest approach, we expect  $S$  to equal 10 and the  $3s$  electron to experience an effective nuclear charge of  $Z_{\text{eff}} = 11 - 10 = 1+$  (Figure 7.3). The situation is more complicated, however, because the  $3s$  electron has a small probability of being very close to the nucleus, in the region occupied by the core electrons. ∞ (Section 6.6) Thus, this electron experiences a greater net attraction than our simple  $S = 10$  model suggests: The actual value of  $Z_{\text{eff}}$  for the  $3s$  electron in Na is  $Z_{\text{eff}} = 2.5+$ . In other words, because there is a small

► **Figure 7.3** Effective nuclear charge. The effective nuclear charge experienced by the  $3s$  electron in a sodium atom depends on the  $11+$  charge of the nucleus and the  $10-$  charge of the core electrons.

## Go Figure

Which electron has a higher probability of being found within  $0.5 \text{ \AA}$  of the nucleus, one in a  $2s$  orbital or one in a  $2p$  orbital? Which orbital,  $2s$  or  $2p$ , will be lower in energy in a multielectron atom?

▲ **Figure 7.4** Comparison of  $1s$ ,  $2s$ , and  $2p$  radial probability functions.

probability that the  $3s$  electron is close to the nucleus, the value of  $S$  in Equation 7.1 changes from 10 to 8.5.

The notion of effective nuclear charge also explains an important effect we noted in Section 6.7: For a many-electron atom, the energies of orbitals with the same  $n$  value increase with increasing  $l$  value. For example, in the carbon atom, whose electron configuration is  $1s^2 2s^2 2p^2$ , the energy of the  $2p$  orbital ( $l = 1$ ) is higher than that of the  $2s$  orbital ( $l = 0$ ), even though both orbitals are in the  $n = 2$  shell (Figure 6.25). This difference in energies is due to the radial probability functions for the orbitals (Figure 7.4). We see first that the  $1s$  electrons are much closer to the nucleus—they serve as an effective “lampshade” for the  $2s$  and  $2p$  electrons. Notice next that the  $2s$  probability function has a small peak fairly close to the nucleus, whereas the  $2p$  probability function does not. As a result, a  $2s$  electron is not screened as much by the core orbitals as is a  $2p$  electron. The greater attraction between the  $2s$  electron and the nucleus leads to a lower energy for the  $2s$  orbital than for the  $2p$  orbital. The same reasoning explains the general trend in orbital energies ( $ns < np < nd$ ) in many-electron atoms.

Finally, let's examine trends in valence-electron  $Z_{\text{eff}}$  values.

*The effective nuclear charge increases from left to right across any period of the periodic table.*

Although the number of core electrons stays the same across the period, the number of protons increases—in our analogy, we are increasing the brightness of the light bulb while keeping the shade the same. The valence electrons added to counterbalance the increasing nuclear charge screen one another ineffectively. Thus,  $Z_{\text{eff}}$  increases steadily. For example, the two core electrons of lithium ( $1s^2 2s^1$ ) screen the  $2s$  valence electron from the  $3+$  nucleus fairly efficiently. Consequently, the valence electron experiences an effective nuclear charge of roughly  $3 - 2 = 1+$ . For beryllium ( $1s^2 2s^2$ ) the effective nuclear charge experienced by each valence electron is larger because here the two core  $1s$  electrons screen a  $4+$  nucleus, and each  $2s$  electron only partially screens the other. Consequently, the effective nuclear charge experienced by each  $2s$  electron is about  $4 - 2 = 2+$ .

Going down a column, the effective nuclear charge experienced by valence electrons changes far less than it does across a period. For example, using our simple estimate for  $S$ , we would expect the effective nuclear charge experienced by the valence electrons in lithium and sodium to be about the same, roughly  $3 - 2 = 1+$  for lithium and  $11 - 10 = 1+$  for sodium. In fact, however, effective nuclear charge increases slightly as we go down a column

## A CLOSER LOOK Effective Nuclear Charge

To get a sense of how effective nuclear charge varies as both nuclear charge and number of electrons increase, consider Figure 7.5. Although the details of how the  $Z_{\text{eff}}$  values in the graph were calculated are beyond the scope of our discussion, the trends are instructive.

The effective nuclear charge felt by the outermost electrons is smaller than that felt by inner electrons because of screening by the inner electrons. In addition, the effective nuclear charge felt by the outermost

electrons does not increase as steeply with increasing atomic number because the valence electrons make a small but nonnegligible contribution to the screening constant  $S$ . The most striking feature associated with the  $Z_{\text{eff}}$  value for the outermost electrons is the sharp drop between the last period 2 element (Ne) and the first period 3 element (Na). This drop reflects the fact that the core electrons are much more effective than the valence electrons at screening the nuclear charge.

Because  $Z_{\text{eff}}$  can be used to understand many physically measurable quantities, it is desirable to have a simple method for estimating it. The value of  $Z$  in Equation 7.1 is known exactly, so the challenge boils down to estimating the value of  $S$ . In the text, we estimated  $S$  very simply by assuming that each core electron contributes 1.00 to  $S$  and the outer electrons contribute nothing. A more accurate approach was developed by John Slater (1900–1976), however, and we can use his approach if we limit ourselves to elements that do not have electrons in  $d$  or  $f$  subshells.

Electrons for which the principal quantum number  $n$  is larger than the value of  $n$  for the electron of interest contribute 0 to the value of  $S$ . Electrons with the same value of  $n$  as the electron of interest contribute 0.35 to the value of  $S$ . Electrons that have principal quantum number  $n - 1$  contribute 0.85, while those with even smaller values of  $n$  contribute 1.00. For example, consider fluorine, which has the ground-state electron configuration  $1s^2 2s^2 2p^5$ . For a valence electron in fluorine, Slater's rules tell us that  $S = (0.35 \times 6) + (0.85 \times 2) = 3.8$ . (Slater's rules ignore the contribution of an electron to itself in screening; therefore, we consider only six  $n = 2$  electrons, not all seven). Thus,  $Z_{\text{eff}} = Z - S = 9 - 3.8 = 5.2+$ , a little lower than the simple estimate of  $9 - 2 = 7+$ .

Values of  $Z_{\text{eff}}$  estimated using the simple method outlined in the text, as well as those estimated with Slater's rules, are plotted in Figure 7.5. While neither of these methods exactly replicates the values of  $Z_{\text{eff}}$  obtained from more sophisticated calculations, both methods effectively capture the periodic variation in  $Z_{\text{eff}}$ . While Slater's approach is more accurate, the method outlined in the text does a reasonably good job of estimating  $Z_{\text{eff}}$  despite its simplicity. For our purposes, therefore, we can assume that the screening constant  $S$  in Equation 7.1 is roughly equal to the number of core electrons.

**Related Exercises:** 7.15, 7.16, 7.31, 7.32, 7.80, 7.81, 7.110

▲ **Figure 7.5** Variations in effective nuclear charge for period 2 and period 3 elements. Moving from one element to the next in the periodic table, the increase in  $Z_{\text{eff}}$  felt by the innermost ( $1s$ ) electrons (red circles) closely tracks the increase in nuclear charge  $Z$  (black line) because these electrons are not screened much. The results of several methods to calculate  $Z_{\text{eff}}$  for valence electrons are shown in other colors.

because the more diffuse core electron cloud is less able to screen the valence electrons from the nuclear charge. In the case of the alkali metals,  $Z_{\text{eff}}$  increases from 1.3+ for lithium, to 2.5+ for sodium, to 3.5+ for potassium.

## Give It Some Thought

Which would you expect to experience a greater effective nuclear charge, a  $2p$  electron of a Ne atom or a  $3s$  electron of a Na atom?

## 7.3 | Sizes of Atoms and Ions

It is tempting to think of atoms as hard, spherical objects. According to the quantum-mechanical model, however, atoms do not have sharply defined boundaries at which the electron distribution becomes zero. ∞ (Section 6.5) Nevertheless, we can define atomic size in several ways, based on the distances between atoms in various situations.

Imagine a collection of argon atoms in the gas phase. When two of these atoms collide, they ricochet apart like colliding billiard balls. This ricocheting happens because the electron clouds of the colliding atoms cannot penetrate each other to any significant extent. The shortest distance separating the two nuclei during such collisions is twice the radii of the atoms. We call this radius the *nonbonding atomic radius* or the *van der Waals radius* (Figure 7.6).

In molecules, the attractive interaction between any two adjacent atoms is what we recognize as a chemical bond. We discuss bonding in Chapters 8 and 9. For now, we need to realize that two bonded atoms are closer together than they would be in a nonbonding collision where the atoms ricochet apart. We can therefore define an atomic radius based on the distance between the nuclei when two atoms are bonded to each other, shown as distance  $d$  in Figure 7.6. The **bonding atomic radius** for any atom in a molecule is equal to half of the bond distance  $d$ . Note from Figure 7.6 that the bonding atomic radius (also known as the *covalent radius*) is smaller than the nonbonding atomic radius. Unless otherwise noted, we mean the bonding atomic radius when we speak of the “size” of an atom.

Although it is very difficult to measure the nonbonding atomic radius of an atom, scientists have developed a variety of techniques for measuring the distances separating nuclei in molecules. From observations of these distances in many molecules, each element can be assigned a bonding atomic radius. For example, in the  $I_2$  molecule, the distance separating the nuclei is observed to be  $2.66 \text{ \AA}$ , which means the bonding atomic radius of an iodine atom in  $I_2$  is  $(2.66 \text{ \AA})/2 = 1.33 \text{ \AA}$ .\* Similarly, the distance separating adjacent carbon nuclei in diamond (a three-dimensional solid network of carbon atoms) is  $1.54 \text{ \AA}$ ; thus, the bonding atomic radius of carbon in diamond is  $0.77 \text{ \AA}$ . By using structural information on more than 30,000 substances, a consistent set of bonding atomic radii of the elements can be defined (Figure 7.7). Note that for the lighter noble gases, the bonding atomic radii must be estimated because there are no known compounds of these elements.

The atomic radii in Figure 7.7 allows us to estimate bond lengths in molecules. For example, the bonding atomic radii for C and Cl are  $0.76 \text{ \AA}$  and  $1.02 \text{ \AA}$ , respectively. In  $CCl_4$  the measured length of the C—Cl bond is  $1.77 \text{ \AA}$ , very close to the sum ( $0.76 + 1.02 \text{ \AA}$ ) of the bonding atomic radii of Cl and C.

▲ Figure 7.6 Distinction between nonbonding and bonding atomic radii within a molecule.

▲ Figure 7.7 Trends in bonding atomic radii for periods 1 through 5.

\*Remember: The angstrom ( $1 \text{ \AA} = 10^{-10} \text{ m}$ ) is a convenient metric unit for atomic measurements of length. It is not an SI unit. The most commonly used SI unit for atomic measurements is the picometer ( $1 \text{ pm} = 10^{-12} \text{ m}$ ;  $1 \text{ \AA} = 100 \text{ pm}$ ).

## Sample Exercise 7.1

## Bond Lengths in a Molecule

Natural gas used in home heating and cooking is odorless. Because natural gas leaks pose the danger of explosion or suffocation, various smelly substances are added to the gas to allow detection of a leak. One such substance is methyl mercaptan,  $\text{CH}_3\text{SH}$ . Use Figure 7.7 to predict the lengths of the  $\text{C—S}$ ,  $\text{C—H}$ , and  $\text{S—H}$  bonds in this molecule.

Methyl mercaptan

## SOLUTION

**Analyze and Plan** We are given three bonds and told to use Figure 7.7 for bonding atomic radii. We will assume that each bond length is the sum of the bonding atomic radii of the two atoms involved.

## Solve

$$\begin{aligned}\text{C—S bond length} &= \text{bonding atomic radius of C} \\ &\quad + \text{bonding atomic radius of S} \\ &= 0.76 \text{ \AA} + 1.05 \text{ \AA} = 1.81 \text{ \AA}\end{aligned}$$

$$\text{C—H bond length} = 0.76 \text{ \AA} + 0.31 \text{ \AA} = 1.07 \text{ \AA}$$

$$\text{S—H bond length} = 1.05 \text{ \AA} + 0.31 \text{ \AA} = 1.36 \text{ \AA}$$

**Check** The experimentally determined bond lengths are  $\text{C—S} = 1.82 \text{ \AA}$ ,  $\text{C—H} = 1.10 \text{ \AA}$ , and  $\text{S—H} = 1.33 \text{ \AA}$ . (In general, the lengths of bonds involving hydrogen show larger deviations from the values predicted from bonding atomic radii than do bonds involving larger atoms.)

**Comment** Notice that our estimated bond lengths are close but not exact matches to the measured bond lengths. Bonding

atomic radii must be used with some caution in estimating bond lengths.

## Practice Exercise 1

Hypothetical elements X and Y form a molecule  $\text{XY}_2$ , in which both Y atoms are bonded to atom X (and not to one another). The  $\text{X—X}$  distance in the elemental form of X is  $2.04 \text{ \AA}$ , and the  $\text{Y—Y}$  distance in elemental Y is  $1.68 \text{ \AA}$ . What would you predict for the  $\text{X—Y}$  distance in the  $\text{XY}_2$  molecule? (a)  $0.84 \text{ \AA}$  (b)  $1.02 \text{ \AA}$  (c)  $1.86 \text{ \AA}$  (d)  $2.70 \text{ \AA}$  (e)  $3.72 \text{ \AA}$

## Practice Exercise 2

Using Figure 7.7, predict which is longer, the  $\text{P—Br}$  bond in  $\text{PBr}_3$  or the  $\text{As—Cl}$  bond in  $\text{AsCl}_3$ .

## Periodic Trends in Atomic Radii

Figure 7.7 shows two interesting trends:

1. *Within each group, bonding atomic radius tends to increase from top to bottom.* This trend results primarily from the increase in the principal quantum number ( $n$ ) of the outer electrons. As we go down a column, the outer electrons have a greater probability of being farther from the nucleus, causing the atomic radius to increase.
2. *Within each period, bonding atomic radius tends to decrease from left to right* (although there are some minor exceptions, such as for Cl to Ar or As to Se). The major factor influencing this trend is the increase in effective nuclear charge  $Z_{\text{eff}}$  across a period. The increasing effective nuclear charge steadily draws the valence electrons closer to the nucleus, causing the bonding atomic radius to decrease.

## Periodic Trends in Ionic Radii

Just as bonding atomic radii can be determined from interatomic distances in molecules, ionic radii can be determined from interatomic distances in ionic compounds. Like the

## Give It Some Thought

In Section 7.2 we said that  $Z_{\text{eff}}$  generally increases when you move down a column of the periodic table, whereas in Chapter 6 we saw that the “size” of an orbital increases as the principal quantum number  $n$  increases. With respect to atomic radii, do these trends work together or against each other? Which effect is larger?

**Sample Exercise 7.2****Predicting Relative Sizes of Atomic Radii**

Referring to the periodic table, arrange (as much as possible) the atoms B, C, Al, and Si in order of increasing size.

**SOLUTION**

**Analyze and Plan** We are given the chemical symbols for four elements and told to use their relative positions in the periodic table

to predict the relative size of their atomic radii. We can use the two periodic trends described in the text to help with this problem.

**Solve**

B and C are in the same period, with C to the right of B. Therefore, we expect the radius of C to be smaller than that of B because radii usually decrease as we move across a period.

$$\text{radius C} < \text{radius B}$$

Al and Si are in the same period, with Si to the right of Al.

$$\text{radius Si} < \text{radius Al}$$

The radius increases as we move down a group with Al and B belonging to the same group, as do C and Si.

$$\begin{aligned} \text{radius B} &< \text{radius Al} \\ \text{radius C} &< \text{radius Si} \end{aligned}$$

Combining these comparisons, we can conclude that C has the smallest radius and Al the largest. Unfortunately, the two periodic trends available to us do not supply enough information to determine the relative sizes of B and Si.

$$\text{radius C} < \text{radius B} \sim \text{radius Si} < \text{radius Al}$$

**Check** Referring back to Figure 7.7, we can obtain numerical values for each atomic radius that allow us to say that the radius of Si is greater than that of B.

$$\text{C} (0.76 \text{ \AA}) < \text{B} (0.84 \text{ \AA}) < \text{Si} (1.11 \text{ \AA}) < \text{Al} (1.21 \text{ \AA})$$

If you examine Figure 7.7 carefully, you will discover that for the *s*- and *p*-block elements the increase in radius moving one element down a column tends to be greater than the increase moving one element left across a row. There are exceptions, however.

**Comment** Note that the trends we have just discussed are for the *s*- and *p*-block elements. As seen in Figure 7.7, the transition elements do not show a regular decrease moving across a period.

**Practice Exercise 1**

By referring to the periodic table, but not to Figure 7.7, place the following atoms in order of increasing bonding atomic radius: N, O, P, Ge.

- (a)  $\text{N} < \text{O} < \text{P} < \text{Ge}$
- (b)  $\text{P} < \text{N} < \text{O} < \text{Ge}$
- (c)  $\text{O} < \text{N} < \text{Ge} < \text{P}$
- (d)  $\text{O} < \text{N} < \text{P} < \text{Ge}$
- (e)  $\text{N} < \text{P} < \text{Ge} < \text{O}$

**Practice Exercise 2**

Arrange Be, C, K, and Ca in order of increasing atomic radius.

size of an atom, the size of an ion depends on its nuclear charge, the number of electrons it possesses, and the orbitals in which the valence electrons reside. When a cation is formed from a neutral atom, electrons are removed from the occupied atomic orbitals that are the most spatially extended from the nucleus. Also, when a cation is formed the number of electron–electron repulsions is reduced. Therefore, *cations are smaller than their parent atoms* (Figure 7.8). The opposite is true of anions. When electrons are added to an atom to form an anion, the increased electron–electron repulsions cause the electrons to spread out more in space. Thus, *anions are larger than their parent atoms*.

**Sample Exercise 7.3****Predicting Relative Sizes of Atomic and Ionic Radii**

Arrange  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and Ca in order of decreasing radius.

**SOLUTION**

Cations are smaller than their parent atoms, and so  $\text{Ca}^{2+} < \text{Ca}$ . Because Ca is below Mg in group 2A,  $\text{Ca}^{2+}$  is larger than  $\text{Mg}^{2+}$ . Consequently,  $\text{Ca} > \text{Ca}^{2+} > \text{Mg}^{2+}$ .

**Practice Exercise 1**

Arrange the following atoms and ions in order of increasing ionic radius: F,  $\text{S}^{2-}$ , Cl, and  $\text{Se}^{2-}$ .

- (a)  $\text{F} < \text{S}^{2-} < \text{Cl} < \text{Se}^{2-}$
- (b)  $\text{F} < \text{Cl} < \text{S}^{2-} < \text{Se}^{2-}$
- (c)  $\text{F} < \text{S}^{2-} < \text{Se}^{2-} < \text{Cl}$
- (d)  $\text{Cl} < \text{F} < \text{Se}^{2-} < \text{S}^{2-}$
- (e)  $\text{S}^{2-} < \text{F} < \text{Se}^{2-} < \text{Cl}$

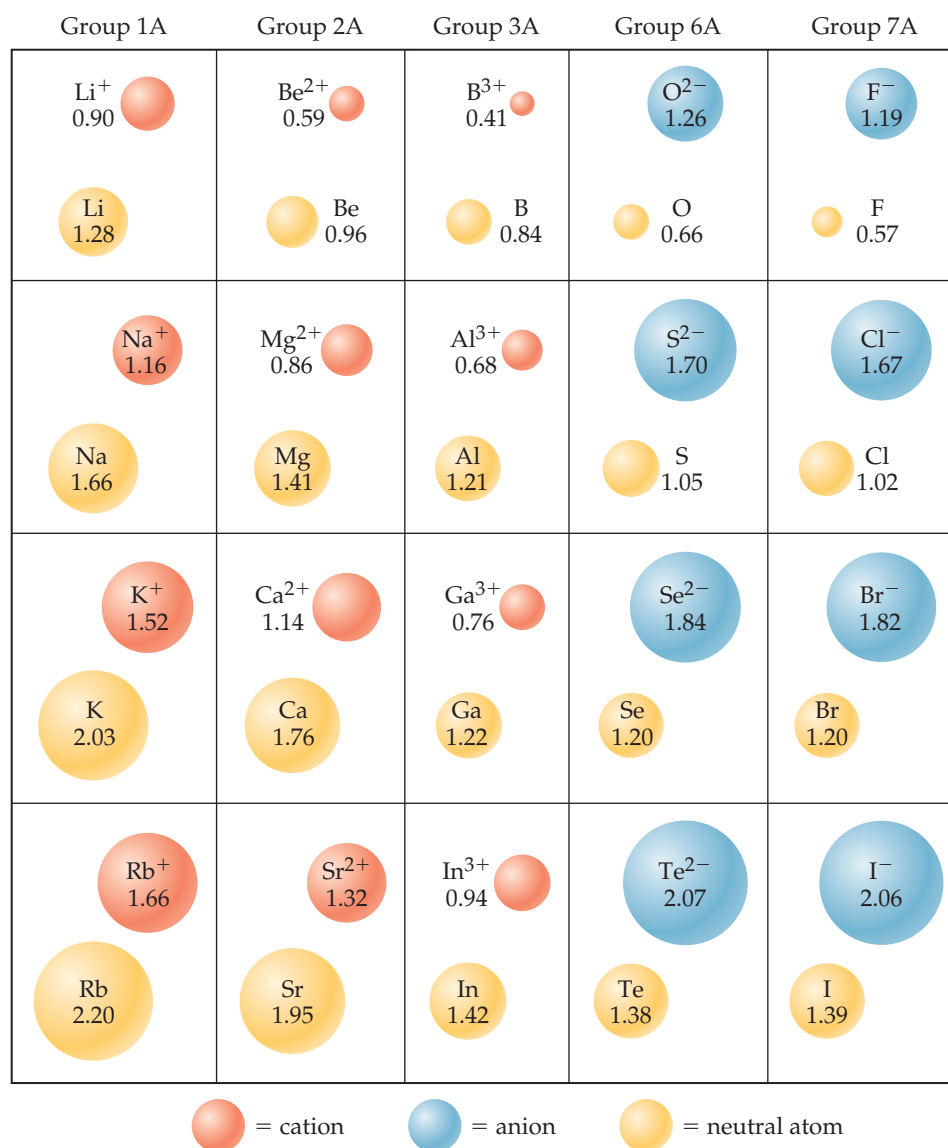

**Practice Exercise 2**

Which of the following atoms and ions is largest:  $\text{S}^{2-}$ , S,  $\text{O}^{2-}$ ?

## Go Figure

How do cations of the same charge change in radius as you move down a column in the periodic table?

▲ **Figure 7.8** Cation and anion size. Radii, in angstroms, of atoms and their ions for five groups of representative elements.

For ions carrying the same charge, ionic radius increases as we move down a column in the periodic table (Figure 7.8). In other words, as the principal quantum number of the outermost occupied orbital of an ion increases, the radius of the ion increases.

An **isoelectronic series** is a group of ions all containing the same number of electrons. For example, each ion in the isoelectronic series  $\text{O}^{2-}$ ,  $\text{F}^-$ ,  $\text{Na}^+$ ,  $\text{Mg}^{2+}$ , and  $\text{Al}^{3+}$  has 10 electrons. In any isoelectronic series, we can list the members in order of increasing atomic number; therefore, the nuclear charge increases as we move through the series. Because the number of electrons remains constant, ionic radius decreases with increasing nuclear charge as the electrons are more strongly attracted to the nucleus:

| Increasing nuclear charge $\longrightarrow$ |              |               |                  |                  |
|---|--------------|---------------|------------------|------------------|
| 8 protons                                   | 9 protons    | 11 protons    | 12 protons       | 13 protons       |
| 10 electrons                                | 10 electrons | 10 electrons  | 10 electrons     | 10 electrons     |
| $\text{O}^{2-}$                             | $\text{F}^-$ | $\text{Na}^+$ | $\text{Mg}^{2+}$ | $\text{Al}^{3+}$ |
| 1.26 Å                                      | 1.19 Å       | 1.16 Å        | 0.86 Å           | 0.68 Å           |
| $\longrightarrow$ Decreasing ionic radius   |              |               |                  |                  |

Notice the positions and atomic numbers of these elements in the periodic table. The nonmetal anions precede the noble gas Ne in the table. The metal cations follow Ne. Oxygen, the largest ion in this isoelectronic series, has the lowest atomic number, 8. Aluminum, the smallest of these ions, has the highest atomic number, 13.

### Sample Exercise 7.4

#### Ionic Radii in an Isoelectronic Series

Arrange the ions  $\text{K}^+$ ,  $\text{Cl}^-$ ,  $\text{Ca}^{2+}$ , and  $\text{S}^{2-}$  in order of decreasing size.

#### SOLUTION

This is an isoelectronic series, with all ions having 18 electrons. In such a series, size decreases as nuclear charge (atomic number) increases. The atomic numbers of the ions are S 16, Cl 17, K 19, Ca 20. Thus, the ions decrease in size in the order  $\text{S}^{2-} > \text{Cl}^- > \text{K}^+ > \text{Ca}^{2+}$ .

#### Practice Exercise 1

Arrange the following ions in order of increasing ionic radius:  $\text{Br}^-$ ,  $\text{Rb}^+$ ,  $\text{Se}^{2-}$ ,  $\text{Sr}^{2+}$ ,  $\text{Te}^{2-}$ .

- (a)  $\text{Sr}^{2+} < \text{Rb}^+ < \text{Br}^- < \text{Se}^{2-} < \text{Te}^{2-}$   
 (b)  $\text{Br}^- < \text{Sr}^{2+} < \text{Se}^{2-} < \text{Te}^{2-} < \text{Rb}^+$   
 (c)  $\text{Rb}^+ < \text{Sr}^{2+} < \text{Se}^{2-} < \text{Te}^{2-} < \text{Br}^-$   
 (d)  $\text{Rb}^+ < \text{Br}^- < \text{Sr}^{2+} < \text{Se}^{2-} < \text{Te}^{2-}$   
 (e)  $\text{Sr}^{2+} < \text{Rb}^+ < \text{Br}^- < \text{Te}^{2-} < \text{Se}^{2-}$

#### Practice Exercise 2

In the isoelectronic series  $\text{Ca}^{2+}$ ,  $\text{Cs}^+$ ,  $\text{Y}^{3+}$ , which ion is largest?

## CHEMISTRY PUT TO WORK Ionic Size and Lithium-Ion Batteries

Ionic size plays a major role in determining the properties of devices that rely on movement of ions, such as batteries. “Lithium-ion” batteries, which have become common energy sources for electronic devices such as cell phones, iPads, laptop computers, and electric vehicles rely in part on the small size of the lithium ion for their operation.

A fully charged battery spontaneously produces an electric current and, therefore, power when its positive and negative electrodes are connected to an electrical load, such as a device to be powered. The positive electrode is called the anode, and the negative electrode is called the cathode. The materials used for the electrodes in lithium-ion batteries are under intense development. Currently, the anode material is graphite, a form of carbon, and the cathode is a transition metal oxide, often lithium cobalt oxide,  $\text{LiCoO}_2$  (Figure 7.9). Between anode and cathode is a *separator*, a porous solid material that allows the passage of lithium ions but not electrons.

When the battery is being charged by an external source, lithium ions migrate through the separator from the cathode to the anode where they insert between the layers of carbon atoms. The ability of an ion to move through a solid increases as the size of the ion decreases and as the charge on the ion decreases. Lithium ions are smaller than most other cations, and they carry only a 1+ charge, which allows them to migrate more readily than other ions can. As an added bonus, lithium is one of the lightest elements, which is attractive for use in electric vehicles. When the battery discharges, the lithium ions move from anode to cathode. To maintain charge balance, electrons simultaneously migrate from anode to cathode through an external circuit, thereby producing electricity.

At the cathode, lithium ions then insert in the oxide material. Again, the small size of lithium ions is an advantage. For every lithium ion that inserts into the lithium cobalt oxide cathode, a  $\text{Co}^{4+}$  ion is reduced to a  $\text{Co}^{3+}$  ion by an electron that has traveled through the external circuit.

The ion migration and the changes in structure that result when lithium

ions enter and leave the electrode materials are complicated. Furthermore, the operation of all batteries generate heat because they are not perfectly efficient. In the case of Li-ion batteries, the heating of the separator material (typically a polymer) has led to problems as the size of the batteries has been scaled larger to increase energy capacity. In a very small number of cases, overheating of Li-ion batteries has caused the batteries to catch fire.

Teams worldwide are trying to discover new cathode and anode materials that will easily accept and release lithium ions without falling apart over many repeated cycles. New separator materials that allow for faster passage of lithium ions with less heat generation are also under development. Some research groups are looking at using sodium ions instead of lithium ions because sodium is far more abundant than lithium, although the larger size of sodium ions poses additional challenges. In the coming years, look for continued advances in battery technology based on alkali metal ions.

**Related Exercise: 7.89**

▲ Figure 7.9 Schematic of a lithium-ion battery.

## 7.4 | Ionization Energy

The ease with which electrons can be removed from an atom or ion has a major impact on chemical behavior. The **ionization energy** of an atom or ion is the minimum energy required to remove an electron from the ground state of the isolated gaseous atom or ion. We first encountered ionization in our discussion of the Bohr model of the hydrogen atom.  (Section 6.3) If the electron in an H atom is excited from  $n = 1$  (the ground state) to  $n = \infty$ , the electron is completely removed from the atom; the atom is *ionized*.

In general, the *first ionization energy*,  $I_1$ , is the energy needed to remove the first electron from a neutral atom. For example, the first ionization energy for the sodium atom is the energy required for the process

The *second ionization energy*,  $I_2$ , is the energy needed to remove the second electron, and so forth, for successive removals of additional electrons. Thus,  $I_2$  for the sodium atom is the energy associated with the process

### Variations in Successive Ionization Energies

The magnitude of the ionization energy tells us how much energy is required to remove an electron; the greater the ionization energy, the more difficult it is to remove an electron. Notice in Table 7.2 that ionization energies for a given element increase as successive electrons are removed:  $I_1 < I_2 < I_3$ , and so forth. This trend makes sense because with each successive removal, an electron is being pulled away from an increasingly positive ion, requiring increasingly more energy.

#### Give It Some Thought

Light can be used to ionize atoms and ions. Which of the two processes shown in Equations 7.2 and 7.3 requires shorter-wavelength radiation?

A second important feature shown in Table 7.2 is the sharp increase in ionization energy that occurs when an inner-shell electron is removed. For example, consider silicon,  $1s^2 2s^2 2p^6 3s^2 3p^2$ . The ionization energies increase steadily from 786 to 4356 kJ/mol for the four electrons in the 3s and 3p subshells. Removal of the fifth electron, which comes from the 2p subshell, requires a great deal more energy: 16,091 kJ/mol. The large increase occurs because the 2p electron is much more likely to be found close to the nucleus than are the four  $n = 3$  electrons, and, therefore, the 2p electron experiences a much greater effective nuclear charge than do the 3s and 3p electrons.

#### Give It Some Thought

Which would you expect to be greater,  $I_1$  for a boron atom or  $I_2$  for a carbon atom?

**TABLE 7.2 Successive Values of Ionization Energies,  $I$ , for the Elements Sodium through Argon (kJ/mol)**

| Element | $I_1$ | $I_2$ | $I_3$ | $I_4$  | $I_5$                   | $I_6$  | $I_7$  |
|---------|-------|-------|-------|--------|-------------------------|--------|--------|
| Na      | 496   | 4562  |       |        |                         |        |        |
| Mg      | 738   | 1451  | 7733  |        | (inner-shell electrons) |        |        |
| Al      | 578   | 1817  | 2745  | 11,577 |                         |        |        |
| Si      | 786   | 1577  | 3232  | 4356   | 16,091                  |        |        |
| P       | 1012  | 1907  | 2914  | 4964   | 6274                    | 21,267 |        |
| S       | 1000  | 2252  | 3357  | 4556   | 7004                    | 8496   | 27,107 |
| Cl      | 1251  | 2298  | 3822  | 5159   | 6542                    | 9362   | 11,018 |
| Ar      | 1521  | 2666  | 3931  | 5771   | 7238                    | 8781   | 11,995 |

Every element exhibits a large increase in ionization energy when the first of its inner-shell electrons is removed. This observation supports the idea that only the outermost electrons are involved in the sharing and transfer of electrons that give rise to chemical bonding and reactions. As we will see when we talk about chemical bonds in Chapters 8 and 9, the inner electrons are too tightly bound to the nucleus to be lost from the atom or even shared with another atom.

### Sample Exercise 7.5

#### Trends in Ionization Energy

Three elements are indicated in the periodic table in the margin. Which one has the largest second ionization energy?

#### SOLUTION

**Analyze and Plan** The locations of the elements in the periodic table allow us to predict the electron configurations. The greatest ionization energies involve removal of core electrons. Thus, we should look first for an element with only one electron in the outermost occupied shell.

**Solve** The red box represents Na, which has one valence electron. The second ionization energy of this element is associated, therefore, with the removal of a core electron. The other elements indicated, S (green) and Ca (blue), have two or more valence electrons. Thus, Na should have the largest second ionization energy.

**Check** A chemistry handbook gives these  $I_2$  values: Ca, 1145 kJ/mol; S, 2252 kJ/mol; Na, 4562 kJ/mol.

#### Practice Exercise 1

The third ionization energy of bromine is the energy required for which of the following processes?

- (a)  $\text{Br}(g) \longrightarrow \text{Br}^+(g) + e^-$     (b)  $\text{Br}^+(g) \longrightarrow \text{Br}^{2+}(g) + e^-$   
 (c)  $\text{Br}(g) \longrightarrow \text{Br}^{2+}(g) + 2e^-$     (d)  $\text{Br}(g) \longrightarrow \text{Br}^{3+}(g) + 3e^-$   
 (e)  $\text{Br}^{2+}(g) \longrightarrow \text{Br}^{3+}(g) + e^-$

#### Practice Exercise 2

Which has the greater third ionization energy, Ca or S?

## Periodic Trends in First Ionization Energies

Figure 7.10 shows, for the first 54 elements, the trends we observe in first ionization energies as we move from one element to another in the periodic table. The important trends are as follows:

1.  $I_1$  generally increases as we move left to right across a period. The alkali metals show the lowest ionization energy in each period, and the noble gases show the highest. There are slight irregularities in this trend that we will discuss shortly.
2.  $I_1$  generally decreases as we move down any column in the periodic table. For example, the ionization energies of the noble gases follow the order  $\text{He} > \text{Ne} > \text{Ar} > \text{Kr} > \text{Xe}$ .
3. The s- and p-block elements show a larger range of  $I_1$  values than do the transition-metal elements. Generally, the ionization energies of the transition metals increase slowly from left to right in a period. The f-block metals (not shown in Figure 7.10) also show only a small variation in the values of  $I_1$ .

In general, smaller atoms have higher ionization energies. The same factors that influence atomic size also influence ionization energies. The energy needed to remove an electron from the outermost occupied shell depends on both the effective nuclear charge and the average distance of the electron from the nucleus. Either increasing the effective nuclear charge or decreasing the distance from the nucleus increases the attraction between the electron and the nucleus. As this attraction increases, it becomes more difficult to remove the electron, and, thus, the ionization energy increases. As we move across a period, there is both an increase in effective nuclear charge and a decrease in atomic radius, causing the ionization energy to increase. As we move down a column, the atomic radius increases, while the effective nuclear charge increases only gradually. The increase in radius dominates, so the attraction between the nucleus and the electron decreases, causing the ionization energy to decrease.

## Go Figure

The value for astatine, At, is missing in this figure. To the nearest 100 kJ/mol, what estimate would you make for the first ionization energy of At?

▲ Figure 7.10 The first ionization energies of the elements in kJ/mol.

## Go Figure

Why is it easier to remove a 2p electron from an oxygen atom than from a nitrogen atom?

▲ Figure 7.11 2p orbital filling in nitrogen and oxygen.

The irregularities in a given period are subtle but still readily explained. For example, the decrease in ionization energy from beryllium ([He]2s<sup>2</sup>) to boron ([He]2s<sup>2</sup>2p<sup>1</sup>), shown in Figure 7.10, occurs because the third valence electron of B must occupy the 2p subshell, which is empty for Be. Recall that the 2p subshell is at a higher energy than the 2s subshell (Figure 6.25). The slight decrease in ionization energy when moving from nitrogen ([He]2s<sup>2</sup>2p<sup>3</sup>) to oxygen ([He]2s<sup>2</sup>2p<sup>4</sup>) is the result of the repulsion of paired electrons in the p<sup>4</sup> configuration (Figure 7.11). Remember that according to Hund's rule, each electron in the p<sup>3</sup> configuration resides in a different p orbital, which minimizes the electron–electron repulsion among the three 2p electrons. ∞ (Section 6.8)

## Electron Configurations of Ions

When electrons are removed from an atom to form a cation, they are always removed first from the occupied orbitals having the largest principal quantum number, *n*. For example, when one electron is removed from a lithium atom (1s<sup>2</sup>2s<sup>1</sup>), it is the 2s<sup>1</sup> electron:

Likewise, when two electrons are removed from Fe ([Ar]4s<sup>2</sup>3d<sup>6</sup>), the 4s<sup>2</sup> electrons are the ones removed:

If an additional electron is removed, forming Fe<sup>3+</sup>, it comes from a 3d orbital because all the orbitals with *n* = 4 are empty:

## Sample Exercise 7.6

### Periodic Trends in Ionization Energy

Referring to the periodic table, arrange the atoms Ne, Na, P, Ar, K in order of increasing first ionization energy.

#### SOLUTION

**Analyze and Plan** We are given the chemical symbols for five elements. To rank them according to increasing first ionization energy, we need to locate each element in the periodic table. We can then use their relative positions and the trends in first ionization energies to predict their order.

**Solve** Ionization energy increases as we move left to right across a period and decreases as we move down a group. Because Na, P, and Ar are in the same period, we expect  $I_1$  to vary in the order  $\text{Na} < \text{P} < \text{Ar}$ . Because Ne is above Ar in group 8A, we expect  $\text{Ar} < \text{Ne}$ . Similarly, K is directly below Na in group 1A, and so we expect  $\text{K} < \text{Na}$ .

From these observations, we conclude that the ionization energies follow the order

**Check** The values shown in Figure 7.10 confirm this prediction.

#### Practice Exercise 1

Consider the following statements about first ionization energies:

- (i) Because the effective nuclear charge for Mg is greater than that for Be, the first ionization energy of Mg is greater than that of Be.
- (ii) The first ionization energy of O is less than that of N because in O we must pair electrons in one of the  $2p$  orbitals.
- (iii) The first ionization energy of Ar is less than that of Ne because a  $3p$  electron in Ar is farther from the nucleus than a  $2p$  electron in Ne.

Which of the statements (i), (ii), and (iii) is or are true?

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

#### Practice Exercise 2

Which has the lowest first ionization energy, B, Al, C, or Si? Which has the highest?

It may seem odd that  $4s$  electrons are removed before  $3d$  electrons in forming transition-metal cations. After all, in writing electron configurations, we added the  $4s$  electrons before the  $3d$  ones. In writing electron configurations for atoms, however, we are going through an imaginary process in which we move through the periodic table from one element to another. In doing so, we are adding both an electron to an orbital and a proton to the nucleus to change the identity of the element. In ionization, we *do not* reverse this process because no protons are being removed. For example, both Ca and  $\text{Ti}^{2+}$  have 20 electrons, but a  $\text{Ti}^{2+}$  ion has more protons than a Ca atom (22 vs. 20). That changes the relative energy levels of the orbitals enough that the two species have different electron configurations:  $\text{Ca}([\text{Ar}]4s^2)$  and  $\text{Ti}^{2+}([\text{Ar}]3d^2)$ .

If there is more than one occupied subshell for a given value of  $n$ , the electrons are first removed from the orbital with the highest value of  $l$ . For example, a tin atom loses its  $5p$  electrons before it loses its  $5s$  electrons:

Electrons added to an atom to form an anion are added to the empty or partially filled orbital having the lowest value of  $n$ . For example, an electron added to a fluorine atom to form the  $\text{F}^-$  ion goes into the one remaining vacancy in the  $2p$  subshell:

### Give It Some Thought

Do  $\text{Cr}^{3+}$  and  $\text{V}^{2+}$  have the same or different electron configurations?

## Sample Exercise 7.7

## Electron Configurations of Ions

Write the electron configurations for (a)  $\text{Ca}^{2+}$ , (b)  $\text{Co}^{3+}$ , and (c)  $\text{S}^{2-}$ .

## SOLUTION

**Analyze and Plan** We are asked to write electron configurations for three ions. To do so, we first write the electron configuration of each parent atom and then remove or add electrons to form the ions. Electrons are first removed from the orbitals having the highest value of  $n$ . They are added to the empty or partially filled orbitals having the lowest value of  $n$ .

## Solve

- (a) Calcium (atomic number 20) has the electron configuration  $[\text{Ar}]4s^2$ . To form a  $2+$  ion, the two outer  $4s$  electrons must be removed, giving an ion that is isoelectronic with Ar:

- (b) Cobalt (atomic number 27) has the electron configuration  $[\text{Ar}]4s^23d^7$ . To form a  $3+$  ion, three electrons must be removed. As discussed in the text, the  $4s$  electrons are removed before the  $3d$  electrons. Consequently, we remove the two  $4s$  electrons and one of the  $3d$  electrons, and the electron configuration for  $\text{Co}^{3+}$  is

- (c) Sulfur (atomic number 16) has the electron configuration  $[\text{Ne}]3s^23p^4$ . To form a  $2-$  ion, two electrons must be added. There is room for two additional electrons in the  $3p$  orbitals. Thus, the  $\text{S}^{2-}$  electron configuration is

**Comment** Remember that many of the common ions of the  $s$ - and  $p$ -block elements, such as  $\text{Ca}^{2+}$  and  $\text{S}^{2-}$ , have the same number of electrons as the closest noble gas. (Section 2.7)

## Practice Exercise 1

The ground-state electron configuration of a Tc atom is  $[\text{Kr}]5s^24d^5$ . What is the electron configuration of a  $\text{Tc}^{3+}$  ion?

- (a)  $[\text{Kr}]4d^4$  (b)  $[\text{Kr}]5s^24d^2$  (c)  $[\text{Kr}]5s^14d^3$  (d)  $[\text{Kr}]5s^24d^8$   
(e)  $[\text{Kr}]4d^{10}$

## Practice Exercise 2

Write the electron configurations for (a)  $\text{Ga}^{3+}$ , (b)  $\text{Cr}^{3+}$ , and (c)  $\text{Br}^-$ .

## 7.5 | Electron Affinity

The first ionization energy of an atom is a measure of the energy change associated with removing an electron from the atom to form a cation. For example, the first ionization energy of  $\text{Cl(g)}$ , 1251 kJ/mol, is the energy change associated with the process

The positive value of the ionization energy means that energy must be put into the atom to remove the electron. *All ionization energies for atoms are positive: Energy must be absorbed to remove an electron.*

Most atoms can also gain electrons to form anions. The energy change that occurs when an electron is added to a gaseous atom is called the **electron affinity** because it measures the attraction, or *affinity*, of the atom for the added electron. For most atoms, energy is *released* when an electron is added. For example, the addition of an electron to a chlorine atom is accompanied by an energy change of  $-349 \text{ kJ/mol}$ , the negative sign indicating that energy is released during the process. We therefore say that the electron affinity of Cl is  $-349 \text{ kJ/mol}$ .\*

It is important to understand the difference between ionization energy and electron affinity:

- Ionization energy measures the energy change when an atom *loses* an electron.
- Electron affinity measures the energy change when an atom *gains* an electron.

\*Two sign conventions are used for electron affinity. In most introductory texts, including this one, the thermodynamic sign convention is used: A negative sign indicates that addition of an electron is an exothermic process, as in the electron affinity for chlorine,  $-349 \text{ kJ/mol}$ . Historically, however, electron affinity has been defined as the energy released when an electron is added to a gaseous atom or ion. Because  $349 \text{ kJ/mol}$  is released when an electron is added to  $\text{Cl(g)}$ , the electron affinity by this convention would be  $+349 \text{ kJ/mol}$ .

The greater the attraction between an atom and an added electron, the more negative the atom's electron affinity. For some elements, such as the noble gases, the electron affinity has a positive value, meaning that the anion is higher in energy than are the separated atom and electron:

The fact that the electron affinity is positive means that an electron will not attach itself to an Ar atom; in other words the  $\text{Ar}^-$  ion is unstable and does not form.

## Periodic Trends in Electron Affinity

The electron affinities for the *s*- and *p*-block elements of the first five periods are shown in Figure 7.12. Notice that the trends are not as evident as they are for ionization energy. The halogens, which are one electron shy of a filled *p* subshell, have the most negative electron affinities. By gaining an electron, a halogen atom forms a stable anion that has a noble-gas configuration (Equation 7.5). The addition of an electron to a noble gas, however, requires that the electron reside in a higher-energy subshell that is empty in the atom (Equation 7.6). Because occupying a higher-energy subshell is energetically unfavorable, the electron affinity is highly positive. The electron affinities of Be and Mg are positive for the same reason; the added electron would reside in a previously empty *p* subshell that is higher in energy.

The electron affinities of the group 5A elements are also interesting. Because these elements have half-filled *p* subshells, the added electron must be put in an orbital that is already occupied, resulting in larger electron–electron repulsions. Consequently, these elements have electron affinities that are either positive (N) or less negative than those of their neighbors to the left (P, As, Sb). Recall that in Section 7.4 we saw a discontinuity in the trends in first ionization energy for the same reason.

Electron affinities do not change greatly as we move down a group (Figure 7.12). With F, for instance, the added electron goes into a *2p* orbital, for Cl a *3p* orbital, for Br a *4p* orbital, and so forth. As we proceed from F to I, therefore, the average distance between the added electron and the nucleus steadily increases, causing the electron–nucleus attraction to decrease. However, the orbital that holds the outermost electron is increasingly spread out, so that as we proceed from F to I, the electron–electron repulsions are also reduced. As a result, the reduction in the electron–nucleus attraction is counterbalanced by the reduction in electron–electron repulsions.

### Go Figure

Why are the electron affinities of the Group 4A elements more negative than those of the Group 5A elements?

### Give It Some Thought

What is the relationship between the value for the first ionization energy of a  $\text{Cl}^-(g)$  ion and the electron affinity of  $\text{Cl}(g)$ ?

## 7.6 | Metals, Nonmetals, and Metalloids

Atomic radii, ionization energies, and electron affinities are properties of individual atoms. With the exception of the noble gases, however, none of the elements exist in nature as individual atoms. To get a broader understanding of the properties of elements, we must also examine periodic trends in properties of samples that involve large collections of atoms.

## Go Figure

How do the periodic trends in metallic character compare to those for ionization energy?

▲ Figure 7.13 Metals, metalloids, and nonmetals.

TABLE 7.3 Characteristic Properties of Metals and Nonmetals

| Metals   | Nonmetals  |
|--|--|
| Have a shiny luster; various colors, although most are silvery | Do not have a luster; various colors                                     |
| Solids are malleable and ductile                               | Solids are usually brittle; some are hard, and some are soft             |
| Good conductors of heat and electricity                        | Poor conductors of heat and electricity                                  |
| Most metal oxides are ionic solids that are basic              | Most nonmetal oxides are molecular substances that form acidic solutions |
| Tend to form cations in aqueous solution                       | Tend to form anions or oxyanions in aqueous solution                     |

The elements can be broadly grouped as metals, nonmetals, and metalloids (Figure 7.13). ∞ (Section 2.5) Some of the distinguishing properties of metals and nonmetals are summarized in Table 7.3.

In the following sections, we explore some common patterns of reactivity across the periodic table. We will examine reactivity for selected nonmetals and metals in more depth in later chapters.

The more an element exhibits the physical and chemical properties of metals, the greater its **metallic character**. As indicated in Figure 7.13, metallic character generally increases as we proceed down a group of the periodic table and decreases as we proceed right across a period. Let's now examine the close relationships that exist between electron configurations and the properties of metals, nonmetals, and metalloids.

▲ Figure 7.14 Metals are shiny, malleable, and ductile.

## Metals

Most metallic elements exhibit the shiny luster we associate with metals (Figure 7.14). Metals conduct heat and electricity. In general, they are malleable (can be pounded into thin sheets) and ductile (can be drawn into wires). All are solids at room temperature except mercury (melting point =  $-39^{\circ}\text{C}$ ), which is a liquid at room temperature. Two metals melt at slightly above room temperature, cesium at  $28.4^{\circ}\text{C}$  and gallium at  $29.8^{\circ}\text{C}$ . At the other extreme, many metals melt at very high temperatures. For example, tungsten, which is used for the filaments of incandescent light bulbs, melts at  $3400^{\circ}\text{C}$ .

*Metals tend to have low ionization energies (Figure 7.10) and therefore tend to form cations relatively easily.* As a result, metals are oxidized (lose electrons) when they undergo

## Go Figure

The red stepped line divides metals from nonmetals. How are common oxidation states divided by this line?

| 1A              | 2A               | Transition metals |                  |                                    |                  |                                      |                                      |                                      |                  |                                     |   | 3A               | 4A                                   | 5A                                   | 6A               | 7A              | 8A |

▲ **Figure 7.15 Representative oxidation states of the elements.** Note that hydrogen exhibits both positive and negative oxidation numbers, +1 and -1.

chemical reactions. Among the fundamental atomic properties (radius, electron configuration, electron affinity, and so forth), first ionization energy is the best indicator of whether an element behaves as a metal or a nonmetal.

**Figure 7.15** shows the oxidation states of representative ions of metals and nonmetals. As noted in Section 2.7, the charge on any alkali metal ion in a compound is always 1+, and that on any alkaline earth metal is always 2+. For atoms belonging to either of these groups, the outer *s* electrons are easily lost, yielding a noble-gas electron configuration. For metals belonging to groups with partially occupied *p* orbitals (groups 3A–7A), cations are formed either by losing only the outer *p* electrons (such as Sn<sup>2+</sup>) or the outer *s* and *p* electrons (such as Sn<sup>4+</sup>). The charge on transition-metal ions does not follow an obvious pattern. One characteristic of the transition metals is their ability to form more than one cation. For example, compounds of Fe<sup>2+</sup> and Fe<sup>3+</sup> are both very common.

## Give It Some Thought

Arsenic forms binary compounds with Cl and with Mg. Will it be in the same oxidation state in these two compounds?

*Compounds made up of a metal and a nonmetal tend to be ionic substances.* For example, most metal oxides and halides are ionic solids. To illustrate, the reaction between nickel metal and oxygen produces nickel oxide, an ionic solid containing Ni<sup>2+</sup> and O<sup>2-</sup> ions:

The oxides are particularly important because of the great abundance of oxygen in our environment.

*Most metal oxides are basic.* Those that dissolve in water react to form metal hydroxides, as in the following examples:

The basicity of metal oxides is due to the oxide ion, which reacts with water:

## Sample Exercise 7.8

### Properties of Metal Oxides

- (a) Would you expect scandium oxide to be a solid, liquid, or gas at room temperature?  
 (b) Write the balanced chemical equation for the reaction of scandium oxide with nitric acid.

### SOLUTION

**Analyze and Plan** We are asked about one physical property of scandium oxide—its state at room temperature—and one chemical property—how it reacts with nitric acid.

#### Solve

- (a) Because scandium oxide is the oxide of a metal, we expect it to be an ionic solid. Indeed it is, with the very high melting point of 2485 °C.  
 (b) In compounds, scandium has a 3+ charge,  $\text{Sc}^{3+}$ , and the oxide ion is  $\text{O}^{2-}$ . Consequently, the formula of scandium oxide is  $\text{Sc}_2\text{O}_3$ . Metal oxides tend to be basic and, therefore, to react with acids to form a salt plus water. In this case, the salt is scandium nitrate,  $\text{Sc}(\text{NO}_3)_3$ :

#### Practice Exercise 1

Suppose that a metal oxide of formula  $\text{M}_2\text{O}_3$  were soluble in water. What would be the major product or products of dissolving the substance in water?

- (a)  $\text{MH}_3(aq) + \text{O}_2(g)$   
 (b)  $\text{M}(s) + \text{H}_2(g) + \text{O}_2(g)$   
 (c)  $\text{M}^{3+}(aq) + \text{H}_2\text{O}_2(aq)$   
 (d)  $\text{M}(\text{OH})_2(aq)$   
 (e)  $\text{M}(\text{OH})_3(aq)$

#### Practice Exercise 2

Write the balanced chemical equation for the reaction between copper(II) oxide and sulfuric acid.

### Go Figure

Would you expect  $\text{NiO}$  to dissolve in an aqueous solution of  $\text{NaNO}_3$ ?

▲ **Figure 7.16** Metal oxides react with acids.  $\text{NiO}$  does not dissolve in water but does react with nitric acid ( $\text{HNO}_3$ ) to give a green solution of  $\text{Ni}(\text{NO}_3)_2$ .

### Go Figure

Do you think sulfur is malleable?

▲ **Figure 7.17** Sulfur, known to the medieval world as “brimstone,” is a nonmetal.

Even metal oxides that are insoluble in water demonstrate their basicity by reacting with acids to form a salt plus water, as illustrated in **Figure 7.16**:

## Nonmetals

Nonmetals can be solid, liquid, or gas. They are not lustrous and generally are poor conductors of heat and electricity. Their melting points are generally lower than those of metals (although diamond, a form of carbon, is an exception and melts at 3570 °C). Under ordinary conditions, seven nonmetals exist as diatomic molecules. Five of these are gases ( $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ ,  $\text{F}_2$ , and  $\text{Cl}_2$ ), one is a liquid ( $\text{Br}_2$ ), and one is a volatile solid ( $\text{I}_2$ ). Excluding the noble gases, the remaining nonmetals are solids that can be either hard, such as diamond, or soft, such as sulfur (**Figure 7.17**).

▲ **Figure 7.18** The reaction of  $\text{CO}_2$  with water containing a bromthymol blue indicator. Initially, the blue color tells us the water is slightly basic. When a piece of solid carbon dioxide (“dry ice”) is added, the color changes to yellow, indicating an acidic solution. The mist is water droplets condensed from the air by cold  $\text{CO}_2$  gas that sublimates off before reacting.

Because of their relatively large, negative electron affinities, nonmetals tend to gain electrons when they react with metals. For example, the reaction of aluminum with bromine produces the ionic compound aluminum bromide:

A nonmetal will typically gain enough electrons to fill its outermost occupied  $p$  subshell, giving a noble-gas electron configuration. For example, the bromine atom gains one electron to fill its  $4p$  subshell:

Compounds composed entirely of nonmetals are typically molecular substances that tend to be gases, liquids, or low melting point solids at room temperature. Examples include the common hydrocarbons we use for fuel (methane,  $\text{CH}_4$ ; propane,  $\text{C}_3\text{H}_8$ ; octane,  $\text{C}_8\text{H}_{18}$ ) and the gases  $\text{HCl}$ ,  $\text{NH}_3$ , and  $\text{H}_2\text{S}$ . Many pharmaceuticals are molecules composed of C, H, N, O, and other nonmetals. For example, the molecular formula for the drug Celebrex® is  $\text{C}_{17}\text{H}_{14}\text{F}_3\text{N}_3\text{O}_2\text{S}$ .

Most nonmetal oxides are acidic, which means that those that dissolve in water form acids:

The reaction of carbon dioxide with water (Figure 7.18) accounts for the acidity of carbonated water and, to some extent, rainwater. Because sulfur is present in oil and coal, combustion of these common fuels produces sulfur dioxide and sulfur trioxide. These substances dissolve in water to produce *acid rain*, a major pollutant in many parts of the world. Like acids, most nonmetal oxides dissolve in basic solutions to form a salt plus water:

### Give It Some Thought

A compound  $\text{ACl}_3$  (A is an element) has a melting point of  $-112^\circ\text{C}$ . Would you expect the compound to be molecular or ionic? If you were told that A is either scandium or phosphorus, which do you think is the more likely choice?

## Sample Exercise 7.9

## Reactions of Nonmetal Oxides

Write a balanced chemical equation for the reaction of solid selenium dioxide,  $\text{SeO}_2(s)$ , with (a) water, (b) aqueous sodium hydroxide.

## SOLUTION

**Analyze and Plan** We note that selenium is a nonmetal. We therefore need to write chemical equations for the reaction of a nonmetal oxide with water and with a base,  $\text{NaOH}$ . Nonmetal oxides are acidic, reacting with water to form an acid and with bases to form a salt and water.

## Solve

- (a) The reaction between selenium dioxide and water is like that between carbon dioxide and water (Equation 7.13):

(It does not matter that  $\text{SeO}_2$  is a solid and  $\text{CO}_2$  is a gas under ambient conditions; the point is that both are water-soluble nonmetal oxides.)

- (b) The reaction with sodium hydroxide is like that in Equation 7.15:

## Practice Exercise 1

Consider the following oxides:  $\text{SO}_2$ ,  $\text{Y}_2\text{O}_3$ ,  $\text{MgO}$ ,  $\text{Cl}_2\text{O}$ ,  $\text{N}_2\text{O}_5$ . How many are expected to form acidic solutions in water?

- (a) 1 (b) 2 (c) 3 (d) 4 (e) 5

## Practice Exercise 2

Write a balanced chemical equation for the reaction of solid tetraphosphorus hexoxide with water.

▲ Figure 7.19 Elemental silicon.

## Metalloids

Metalloids have properties intermediate between those of metals and those of nonmetals. They may have some characteristic metallic properties but lack others. For example, the metalloid silicon *looks* like a metal (Figure 7.19), but it is brittle rather than malleable and does not conduct heat or electricity nearly as well as metals do.

Several metalloids, most notably silicon, are electrical semiconductors and are the principal elements used in integrated circuits and computer chips. One of the reasons metalloids can be used for integrated circuits is that their electrical conductivity is intermediate between that of metals and that of nonmetals. Very pure silicon is an electrical insulator, but its conductivity can be dramatically increased with the addition of specific impurities called *dopants*. This modification provides a mechanism for controlling the electrical conductivity by controlling the chemical composition. We will return to this point in Chapter 12.

## 7.7 | Trends for Group 1A and Group 2A Metals

As we have seen, elements in a given group possess general similarities. However, trends also exist within each group. In this section, we use the periodic table and our knowledge of electron configurations to examine the chemistry of the **alkali metals** and **alkaline earth metals**.

## Group 1A: The Alkali Metals

The alkali metals are soft metallic solids (Figure 7.20). All have characteristic metallic properties, such as a silvery, metallic luster, and high thermal and electrical conductivity. The name *alkali* comes from an Arabic word meaning “ashes.” Many compounds of sodium and potassium, two alkali metals, were isolated from wood ashes by early chemists.

As Table 7.4 shows, the alkali metals have low densities and melting points, and these properties vary in a fairly regular way with increasing atomic number. We see the usual trends as we move down the group, such as increasing atomic radius and decreasing first ionization energy. The alkali metal of any given period has the

▲ Figure 7.20 Sodium, like the other alkali metals, is soft enough to be cut with a knife.

TABLE 7.4 Some Properties of the Alkali Metals

| Element   | Electron Configuration | Melting Point (°C) | Density (g/cm <sup>3</sup> ) | Atomic Radius (Å) | <i>I</i> <sub>1</sub> (kJ/mol) |
|-----------|------------------------|--------------------|------------------------------|-------------------|--------------------------------|
| Lithium   | [He]2s <sup>1</sup>    | 181                | 0.53                         | 1.28              | 520                            |
| Sodium    | [Ne]3s <sup>1</sup>    | 98                 | 0.97                         | 1.66              | 496                            |
| Potassium | [Ar]4s <sup>1</sup>    | 63                 | 0.86                         | 2.03              | 419                            |
| Rubidium  | [Kr]5s <sup>1</sup>    | 39                 | 1.53                         | 2.20              | 403                            |
| Cesium    | [Xe]6s <sup>1</sup>    | 28                 | 1.88                         | 2.44              | 376                            |

lowest *I*<sub>1</sub> value in the period (Figure 7.10), which reflects the relative ease with which its outer *s* electron can be removed. As a result, the alkali metals are all very reactive, readily losing one electron to form ions carrying a 1+ charge. [↔](#) (Section 2.7)

The alkali metals exist in nature only as compounds. Sodium and potassium are relatively abundant in Earth's crust, in seawater, and in biological systems, always as the cations of ionic compounds. All alkali metals combine directly with most non-metals. For example, they react with hydrogen to form hydrides and with sulfur to form sulfides:

where M represents any alkali metal. In hydrides of the alkali metals (LiH, NaH, and so forth), hydrogen is present as H<sup>−</sup>, the **hydride ion**. A hydrogen atom that has *gained* an electron, this ion is distinct from the hydrogen ion, H<sup>+</sup>, formed when a hydrogen atom *loses* its electron.

The alkali metals react vigorously with water, producing hydrogen gas and a solution of an alkali metal hydroxide:

These reactions are very exothermic (Figure 7.21). In many cases, enough heat is generated to ignite the H<sub>2</sub>, producing a fire or sometimes even an explosion, as in the case of K reacting with water. The reaction is even more violent for Rb and, especially, Cs, because their ionization energies are even lower than that of K.

## Go Figure

Would you expect rubidium metal to be more or less reactive with water than potassium metal?

▲ Figure 7.21 The alkali metals react vigorously with water.

▲ **Figure 7.22** Placed in a flame, ions of each alkali metal emit light of a characteristic wavelength.

Recall that the most common ion of oxygen is the oxide ion,  $O^{2-}$ . We would therefore expect that the reaction of an alkali metal with oxygen would produce the corresponding metal oxide. Indeed, reaction of Li metal with oxygen does form lithium oxide:

When dissolved in water,  $\text{Li}_2\text{O}$  and other soluble metal oxides form hydroxide ions from the reaction of  $O^{2-}$  ions with  $\text{H}_2\text{O}$  (Equation 7.10).

The reactions of the other alkali metals with oxygen are more complex than we would anticipate. For example, when sodium reacts with oxygen, the main product is sodium *peroxide*, which contains the  $O_2^{2-}$  ion:

Potassium, rubidium, and cesium react with oxygen to form compounds that contain the  $O_2^-$  ion, which we call the *superoxide ion*. For example, potassium forms potassium superoxide,  $\text{KO}_2$ :

Be aware that the reactions in Equations 7.20 and 7.21 are somewhat unexpected; in most cases, the reaction of oxygen with a metal forms the metal oxide.

As seen from Equations 7.18 through 7.21, the alkali metals are extremely reactive toward water and oxygen. Because of this reactivity, the metals are usually stored submerged in a liquid hydrocarbon, such as mineral oil or kerosene.

Although alkali metal ions are colorless, each emits a characteristic color when placed in a flame (**Figure 7.22**). The ions are reduced to gaseous metal atoms in the flame. The high temperature excites the valence electron from the ground state to a higher-energy orbital, causing the atom to be in an excited state. The atom then emits energy in the form of visible light as the electron falls back into the lower-energy orbital and the atom returns to its ground state. The light emitted is at a specific wavelength for each element, just as we saw earlier for line spectra of hydrogen and sodium. 🔗 (Section 6.3) The characteristic yellow emission of sodium at 589 nm is the basis for sodium vapor lamps (**Figure 7.23**).

### Give It Some Thought

Cesium tends to be the most reactive of the stable alkali metals (francium, Fr, is radioactive and has not been extensively studied). What *atomic* property of Cs is most responsible for its high reactivity?

## Go Figure

If we had potassium vapor lamps, what color would they be?

▲ **Figure 7.23** The characteristic yellow light in a sodium lamp results from excited electrons in the high-energy 3p orbital falling back to the lower-energy 3s orbital.

## Sample Exercise 7.10

## Reactions of an Alkali Metal

Write a balanced equation for the reaction of cesium metal with (a)  $\text{Cl}_2(g)$ , (b)  $\text{H}_2\text{O}(l)$ , (c)  $\text{H}_2(g)$ .

## SOLUTION

**Analyze and Plan** Because cesium is an alkali metal, we expect its chemistry to be dominated by oxidation of the metal to  $\text{Cs}^+$  ions. Further, we recognize that Cs is far down the periodic table, which means it is among the most active of all metals and probably reacts with all three substances.

**Solve** The reaction between Cs and  $\text{Cl}_2$  is a simple combination reaction between a metal and a nonmetal, forming the ionic compound CsCl:

From Equations 7.18 and 7.16, we predict the reactions of cesium with water and hydrogen to proceed as follows:

All three reactions are redox reactions where cesium forms a  $\text{Cs}^+$  ion. The  $\text{Cl}^-$ ,  $\text{OH}^-$ , and  $\text{H}^-$  are all  $1-$  ions, which means the products have 1:1 stoichiometry with  $\text{Cs}^+$ .

## ► Practice Exercise 1

Consider the following three statements about the reactivity of an alkali metal M with oxygen gas:

- (i) Based on their positions in the periodic table, the expected product is the ionic oxide  $\text{M}_2\text{O}$ .
- (ii) Some of the alkali metals produce metal peroxides or metal superoxides when they react with oxygen.
- (iii) When dissolved in water, an alkali metal oxide produces a basic solution.

Which of the statements (i), (ii), and (iii) is or are true?

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

## ► Practice Exercise 2

Write a balanced equation for the expected reaction between potassium metal and elemental sulfur, S(s).

## CHEMISTRY AND LIFE The Improbable Development of Lithium Drugs

Alkali metal ions tend to play an unexciting role in most chemical reactions. As noted in Section 4.2, all salts of the alkali metal ions are soluble in water, and the ions are spectators in most aqueous reactions (except for those involving the alkali metals in their elemental form, such as those in Equations 7.16 through 7.21). However, these ions play an important role in human physiology. Sodium and potassium ions, for example, are major components of blood plasma and intracellular fluid, respectively, with average concentrations of 0.1 M. These electrolytes serve as vital charge carriers in normal cellular

function. In contrast, the lithium ion has no known function in normal human physiology. Since the discovery of lithium in 1817, however, people have believed that salts of the element possessed almost mystical healing powers. There were even claims that lithium ions were an ingredient in ancient “fountain of youth” formulas. In 1927, C. L. Grigg began marketing a soft drink that contained lithium. The original unwieldy name of the beverage was “Bib-Label Lithiated Lemon-Lime Soda,” which was soon changed to the simpler and more familiar name 7UP® (Figure 7.24).

*Continued*

▲ **Figure 7.24 Lithium no more.** The soft drink 7UP® originally contained a lithium salt that was claimed to give the beverage healthful benefits, including “an abundance of energy, enthusiasm, a clear complexion, lustrous hair, and shining eyes!” The lithium was removed from the beverage in the early 1950s, about the time that the antipsychotic action of  $\text{Li}^+$  was discovered.

Because of concerns of the Food and Drug Administration, lithium was removed from 7UP® during the early 1950s. At nearly

the same time, psychiatrists discovered that lithium ions have a remarkable therapeutic effect on the mental condition called *bipolar disorder*. More than 5 million American adults each year suffer from this psychosis, undergoing severe mood swings from deep depression to a manic euphoria. The lithium ion smoothes these mood swings, allowing the bipolar patient to function more effectively in daily life.

The antipsychotic action of  $\text{Li}^+$  was discovered by accident in the 1940s by Australian psychiatrist John Cade (1912–1980) as he was researching the use of uric acid—a component of urine—to treat manic-depressive illness. He administered the acid to manic laboratory animals in the form of its most soluble salt, lithium urate, and found that many of the manic symptoms seemed to disappear. Later studies showed that uric acid has no role in the therapeutic effects observed; rather, the  $\text{Li}^+$  ions were responsible. Because lithium overdose can cause severe side effects in humans, including kidney failure and death, lithium salts were not approved as antipsychotic drugs for humans until 1970. Today  $\text{Li}^+$  is usually administered orally in the form of  $\text{Li}_2\text{CO}_3$ , which is the active ingredient in prescription drugs such as Eskalith®. Lithium drugs are effective for about 70% of bipolar patients who take it.

In this age of sophisticated drug design and biotechnology, the simple lithium ion is still the most effective treatment of this destructive psychiatric disorder. Remarkably, despite intensive research, scientists still do not fully understand the biochemical action of lithium that leads to its therapeutic effects. Because of its similarity to  $\text{Na}^+$ ,  $\text{Li}^+$  is incorporated into blood plasma, where it can affect the behavior of nerve and muscle cells. Because  $\text{Li}^+$  has a smaller radius than  $\text{Na}^+$  (Figure 7.8), the way  $\text{Li}^+$  interacts with molecules in human cells is different from the way  $\text{Na}^+$  interacts with the molecules. Other studies indicate that  $\text{Li}^+$  alters the function of certain neurotransmitters, which might lead to its effectiveness as an antipsychotic drug.

## Group 2A: The Alkaline Earth Metals

Like the alkali metals, the alkaline earth metals are all solids at room temperature and have typical metallic properties (Table 7.5). Compared with the alkali metals, the alkaline earth metals are harder and denser, and melt at higher temperatures.

The first ionization energies of the alkaline earth metals are low but not as low as those of the alkali metals. Consequently, the alkaline earth metals are less reactive than their alkali metal neighbors. As noted in Section 7.4, the ease with which the elements lose electrons decreases as we move across a period and increases as we move down a group. Thus, beryllium and magnesium, the lightest alkaline earth metals, are the least reactive.

The trend of increasing reactivity within the group is shown by the way the alkaline earth metals behave in the presence of water. Beryllium does not react with either water or steam, even when heated red-hot. Magnesium reacts slowly with liquid water and more readily with steam:

Calcium and the elements below it react readily with water at room temperature (although more slowly than the alkali metals adjacent to them in the periodic table). The reaction between calcium and water (Figure 7.25), for example, is

**TABLE 7.5 Some Properties of the Alkaline Earth Metals**

| Element   | Electron Configuration | Melting Point (°C) | Density (g/cm <sup>3</sup> ) | Atomic Radius (Å) | $I_1$ (kJ/mol) |
|-----------|------------------------|--------------------|------------------------------|-------------------|----------------|
| Beryllium | $[\text{He}]2s^2$      | 1287               | 1.85                         | 0.96              | 899            |
| Magnesium | $[\text{Ne}]3s^2$      | 650                | 1.74                         | 1.41              | 738            |
| Calcium   | $[\text{Ar}]4s^2$      | 842                | 1.55                         | 1.76              | 590            |
| Strontium | $[\text{Kr}]5s^2$      | 777                | 2.63                         | 1.95              | 549            |
| Barium    | $[\text{Xe}]6s^2$      | 727                | 3.51                         | 2.15              | 503            |

Equations 7.22 and 7.23 illustrate the dominant pattern in the reactivity of the alkaline earth elements: They tend to lose their two outer *s* electrons and form 2+ ions. For example, magnesium reacts with chlorine at room temperature to form  $\text{MgCl}_2$  and burns with dazzling brilliance in air to give  $\text{MgO}$ :

In the presence of  $\text{O}_2$ , magnesium metal is protected by a thin coating of water-insoluble  $\text{MgO}$ . Thus, even though Mg is high in the activity series  $\infty$  (Section 4.4), it can be incorporated into lightweight structural alloys used in, for example, automobile wheels. The heavier alkaline earth metals (Ca, Sr, and Ba) are even more reactive toward nonmetals than is magnesium.

The heavier alkaline earth ions give off characteristic colors when heated in a hot flame. Strontium salts produce the brilliant red color in fireworks, and barium salts produce the green color.

Like their neighbors sodium and potassium, magnesium and calcium are relatively abundant on Earth and in seawater and are essential for living organisms as cations in ionic compounds. Calcium is particularly important for growth and maintenance of bones and teeth.

### Give It Some Thought

Calcium carbonate,  $\text{CaCO}_3$ , is often used as a dietary calcium supplement for bone health. Although  $\text{CaCO}_3(s)$  is insoluble in water (Table 4.1), it can be taken orally to allow for the delivery of  $\text{Ca}^{2+}(aq)$  ions to the musculoskeletal system. Why is this the case? [Hint: Recall the reactions of metal carbonates discussed in Section 4.3.]

## 7.8 | Trends for Selected Nonmetals

### Hydrogen

We have seen that the chemistry of the alkali metals is dominated by the loss of their outer  $ns^1$  electron to form cations. The  $1s^1$  electron configuration of hydrogen suggests that its chemistry should have some resemblance to that of the alkali metals. The chemistry of hydrogen is much richer and more complex than that of the alkali metals, however, mainly because the ionization energy of hydrogen, 1312 kJ/mol, is higher than any metal and comparable to that of oxygen. As a result, hydrogen is a nonmetal that occurs as a colorless diatomic gas,  $\text{H}_2(g)$ , under most conditions.

The reactivity of hydrogen with nonmetals reflects its much greater tendency to hold on to its electron relative to the alkali metals. Unlike the alkali metals, hydrogen reacts with most nonmetals to form molecular compounds in which its electron is shared with, rather than completely transferred to, the other nonmetal. For example, we have seen that sodium metal reacts vigorously with chlorine gas to produce the ionic compound sodium chloride, in which the outermost sodium electron is completely transferred to a chlorine atom (Figure 2.21):

By contrast, molecular hydrogen reacts with chlorine gas to form hydrogen chloride gas, which consists of  $\text{HCl}$  molecules:

Hydrogen readily forms molecular compounds with other nonmetals, such as the formation of water,  $\text{H}_2\text{O}(l)$ ; ammonia,  $\text{NH}_3(g)$ ; and methane,  $\text{CH}_4(g)$ . The ability of hydrogen to form bonds with carbon is one of the most important aspects of organic chemistry, as will see in later chapters.

We have seen that, particularly in the presence of water, hydrogen does readily form  $\text{H}^+$  ions in which the hydrogen atom has lost its electron.  $\infty$  (Section 4.3) For example,  $\text{HCl}(g)$  dissolves in  $\text{H}_2\text{O}$  to form a solution of hydrochloric acid,  $\text{HCl}(aq)$ , in which the

### Go Figure

What is the cause of the bubbles that are formed? How could you test your answer?

▲ Figure 7.25 Elemental calcium reacts with water.

electron of the hydrogen atom is transferred to the chlorine atom—a solution of hydrochloric acid consists largely of  $\text{H}^+(\text{aq})$  and  $\text{Cl}^-(\text{aq})$  ions stabilized by the  $\text{H}_2\text{O}$  solvent.\* Indeed, the ability of molecular compounds of hydrogen with nonmetals to form acids in water is one of the most important aspects of aqueous chemistry. We will discuss the chemistry of acids and bases in detail later in the text, particularly in Chapter 16.

Finally, as is typical for nonmetals, hydrogen also has the ability to gain an electron from a metal with a low ionization energy. For example, we saw in Equation 7.16 that hydrogen reacts with active metals to form solid metal hydrides that contain the hydride ion,  $\text{H}^-$ . The fact that hydrogen can gain an electron further illustrates that it behaves much more like a nonmetal than an alkali metal.

## Group 6A: The Oxygen Group

As we proceed down group 6A, there is a change from nonmetallic to metallic character (Figure 7.13). Oxygen, sulfur, and selenium are typical nonmetals. Tellurium is a metalloid, and polonium, which is radioactive and quite rare, is a metal. Oxygen is a colorless gas at room temperature; all of the other members of group 6A are solids. Some of the physical properties of the group 6A elements are given in Table 7.6.

As we saw in Section 2.6, oxygen exists in two molecular forms,  $\text{O}_2$  and  $\text{O}_3$ . Because  $\text{O}_2$  is the more common form, people generally mean it when they say “oxygen,” although the name *dioxygen* is more descriptive. The  $\text{O}_3$  form is **ozone**. The two forms of oxygen are examples of *allotropes*, defined as different forms of the same element. About 21% of dry air consists of  $\text{O}_2$  molecules. Ozone is present in very small amounts in the upper atmosphere and in polluted air. It is also formed from  $\text{O}_2$  in electrical discharges, such as in lightning storms:

This reaction is strongly endothermic, telling us that  $\text{O}_3$  is less stable than  $\text{O}_2$ .

Although both  $\text{O}_2$  and  $\text{O}_3$  are colorless and therefore do not absorb visible light,  $\text{O}_3$  absorbs certain wavelengths of ultraviolet light that  $\text{O}_2$  does not. Because of this difference, the presence of ozone in the upper atmosphere is beneficial, filtering out harmful UV light. Ozone and oxygen also have different chemical properties. Ozone, which has a pungent odor, is a powerful oxidizing agent. Because of this property, ozone is sometimes added to water to kill bacteria or used in low levels to help to purify air. However, the reactivity of ozone also makes its presence in polluted air near Earth’s surface detrimental to human health.

Oxygen has a great tendency to attract electrons from other elements (to *oxidize* them). Oxygen in combination with a metal is almost always present as the oxide ion,  $\text{O}^{2-}$ . This ion has a noble-gas configuration and is particularly stable. As shown in Figure 5.14, the formation of nonmetal oxides is also often very exothermic and thus energetically favorable.

In our discussion of the alkali metals, we noted two less common oxygen anions—the peroxide ( $\text{O}_2^{2-}$ ) ion and the superoxide ( $\text{O}_2^-$ ) ion. Compounds of these ions often react to produce an oxide and  $\text{O}_2$ :

**TABLE 7.6 Some Properties of the Group 6A Elements**

| Element   | Electron Configuration              | Melting Point ( $^\circ\text{C}$ ) | Density                | Atomic Radius ( $\text{\AA}$ ) | $I_1$ (kJ/mol) |
|-----------|-------------------------------------|------------------------------------|------------------------|--------------------------------|----------------|
| Oxygen    | $[\text{He}]2s^22p^4$               | −218                               | 1.43 g/L               | 0.66                           | 1314           |
| Sulfur    | $[\text{Ne}]3s^23p^4$               | 115                                | 1.96 g/cm <sup>3</sup> | 1.05                           | 1000           |
| Selenium  | $[\text{Ar}]3d^{10}4s^24p^4$        | 221                                | 4.82 g/cm <sup>3</sup> | 1.20                           | 941            |
| Tellurium | $[\text{Kr}]4d^{10}5s^25p^4$        | 450                                | 6.24 g/cm <sup>3</sup> | 1.38                           | 869            |
| Polonium  | $[\text{Xe}]4f^{14}5d^{10}6s^26p^4$ | 254                                | 9.20 g/cm <sup>3</sup> | 1.40                           | 812            |

\*A more realistic description is one where an  $\text{H}^+$  ion is transferred from  $\text{HCl}$  to  $\text{H}_2\text{O}$  forming  $\text{Cl}^-$  and  $\text{H}_3\text{O}^+$ . We will explore this chemistry in detail in Chapter 16.

For this reason, bottles of aqueous hydrogen peroxide are topped with caps that are able to release the  $\text{O}_2(g)$  produced before the pressure inside becomes too great (Figure 7.26).

After oxygen, the most important member of group 6A is sulfur. This element exists in several allotropic forms, the most common and stable of which is the yellow solid having the molecular formula  $\text{S}_8$ . This molecule consists of an eight-membered ring of sulfur atoms (Figure 7.27). Even though solid sulfur consists of  $\text{S}_8$  rings, we usually write it simply as  $\text{S}(s)$  in chemical equations to simplify the stoichiometric coefficients.

Like oxygen, sulfur has a tendency to gain electrons from other elements to form sulfides, which contain the  $\text{S}^{2-}$  ion. In fact, most sulfur in nature is present as metal sulfides. Sulfur is below oxygen in the periodic table, and the tendency of sulfur to form sulfide anions is not as great as that of oxygen to form oxide ions. As a result, the chemistry of sulfur is more complex than that of oxygen. In fact, sulfur and its compounds (including those in coal and petroleum) can be burned in oxygen. The main product is sulfur dioxide, a major air pollutant:

Below sulfur in group 6A is selenium, Se. This relatively rare element is essential for life in trace quantities, although it is toxic at high doses. There are many allotropes of Se, including several eight-membered ring structures that resemble the  $\text{S}_8$  ring.

The next element in the group is tellurium, Te. Its elemental structure is even more complex than that of Se, consisting of long, twisted chains of Te—Te bonds. Both Se and Te favor the  $-2$  oxidation state, as do O and S.

From O to S to Se to Te, the elements form larger and larger molecules and become increasingly metallic. The thermal stability of group 6A compounds with hydrogen decreases down the column:  $\text{H}_2\text{O} > \text{H}_2\text{S} > \text{H}_2\text{Se} > \text{H}_2\text{Te}$ , with  $\text{H}_2\text{O}$ , water, being the most stable of the series.

## Group 7A: The Halogens

Some of the properties of the group 7A elements, the **halogens**, are given in Table 7.7. Astatine, which is both extremely rare and radioactive, is omitted because many of its properties are not yet known. Even less is known about the recently discovered Tennessine.

Unlike the group 6A elements, all of the halogens that have been characterized are nonmetals. Their melting and boiling points increase with increasing atomic number. Fluorine and chlorine are gases at room temperature, bromine is a liquid, and iodine is a solid. Each element consists of diatomic molecules:  $\text{F}_2$ ,  $\text{Cl}_2$ ,  $\text{Br}_2$ , and  $\text{I}_2$  (Figure 7.28).

### Give It Some Thought

The density of bromine is 1000 times larger than chlorine. What factor do you think plays the biggest role in this dramatic change? (a) The increased mass of a bromine atom. (b) The fact that bromine is a liquid and chlorine a gas. (c) The larger atomic radius of bromine.

The halogens have highly negative electron affinities (Figure 7.12). Thus, it is not surprising that the chemistry of the halogens is dominated by their tendency to gain electrons from other elements to form halide ions,  $\text{X}^-$ . (In many equations, X is used to

## Go Figure

Why are more molecules of  $\text{I}_2$  seen in the molecular view relative to the number of  $\text{Cl}_2$  molecules?

▲ Figure 7.28 The elemental halogens exist as diatomic molecules.

indicate any one of the halogen elements.) Fluorine and chlorine are more reactive than bromine and iodine. In fact, fluorine removes electrons from almost any substance with which it comes into contact, including water, and usually does so very exothermically, as in the following examples:

As a result, fluorine gas is difficult and dangerous to use in the laboratory, requiring specialized equipment.

Chlorine is the most industrially useful of the halogens. It is produced by a process called electrolysis, where an electrical current is used to oxidize chloride anions to molecular chlorine,  $\text{Cl}_2$ . Unlike fluorine, chlorine reacts slowly with water to form relatively stable aqueous solutions of  $\text{HCl}$  and  $\text{HOCl}$  (hypochlorous acid):

Chlorine is often added to drinking water and swimming pools because the  $\text{HOCl}(aq)$  that is generated serves as a disinfectant.

The halogens react directly with most metals to form ionic halides. The halogens also react with hydrogen to form gaseous hydrogen halide compounds:

These compounds are all very soluble in water and dissolve to form the hydrohalic acids. As we discussed in Section 4.3,  $\text{HCl}(aq)$ ,  $\text{HBr}(aq)$ , and  $\text{HI}(aq)$  are strong acids, whereas  $\text{HF}(aq)$  is a weak acid.

## Give It Some Thought

Can you use data in Table 7.7 to estimate the atomic radius and first ionization energy of an astatine atom?

TABLE 7.8 Some Properties of the Noble Gases

| Element | Electron Configuration  | Boiling Point (K) | Density (g/L) | Atomic Radius* (Å) | $I_1$ (kJ/mol) |
|---------|---|-------------------|---------------|--------------------|----------------|
| Helium  | 1s <sup>2</sup>   | 4.2               | 0.18          | 0.28               | 2372           |
| Neon    | [He]2s <sup>2</sup> 2p <sup>6</sup>                                   | 27.1              | 0.90          | 0.58               | 2081           |
| Argon   | [Ne]3s <sup>2</sup> 3p <sup>6</sup>                                   | 87.3              | 1.78          | 1.06               | 1521           |
| Krypton | [Ar]4s <sup>2</sup> 3d <sup>10</sup> 4p <sup>6</sup>                  | 120               | 3.75          | 1.16               | 1351           |
| Xenon   | [Kr]5s <sup>2</sup> 4d <sup>10</sup> 5p <sup>6</sup>                  | 165               | 5.90          | 1.40               | 1170           |
| Radon   | [Xe]6s <sup>2</sup> 4f <sup>14</sup> 5d <sup>10</sup> 6p <sup>6</sup> | 211               | 9.73          | 1.50               | 1037           |

\*Only the heaviest of the noble-gas elements form chemical compounds. Thus, the atomic radii for the lighter noble-gas elements are estimated values.

## Group 8A: The Noble Gases

The group 8A elements, known as the **noble gases**, are all nonmetals that are gases at room temperature. They are all *monatomic* (that is, they consist of single atoms rather than molecules). Some physical properties of the noble-gas elements are listed in Table 7.8. The high radioactivity of radon (Rn, atomic number 86) has limited the study of its reaction chemistry and some of its properties.

The noble gases have completely filled *s* and *p* subshells. All elements of group 8A have large first ionization energies, and we see the expected decrease as we move down the column. Because the noble gases possess such stable electron configurations, they are exceptionally unreactive. In fact, until the early 1960s the elements were called the *inert gases* because they were thought to be incapable of forming chemical compounds. In 1962, Neil Bartlett (1932–2008) at the University of British Columbia reasoned that the ionization energy of Xe might be low enough to allow it to form compounds. For this to happen, Xe would have to react with a substance with an extremely high ability to remove electrons from other substances, such as fluorine. Bartlett synthesized the first noble-gas compound by combining Xe with the fluorine-containing compound PtF<sub>6</sub>. Xenon also reacts directly with F<sub>2</sub>(g) to form the molecular compounds XeF<sub>2</sub>, XeF<sub>4</sub>, and XeF<sub>6</sub>. Krypton has a higher  $I_1$  value than xenon and is therefore less reactive. In fact, only a single stable compound of krypton is known, KrF<sub>2</sub>. In 2000, Finnish scientists reported the first neutral molecule that contains argon, the HArF molecule, which is stable only at low temperatures.

## Sample Integrative Exercise

### Putting Concepts Together

The element bismuth (Bi, atomic number 83) is the heaviest member of group 5A. A salt of the element, bismuth subsalicylate, is the active ingredient in Pepto-Bismol®, an over-the-counter medication for gastric distress.

- Based on values presented in Figure 7.7 and Tables 7.5 and 7.6, what might you expect for the bonding atomic radius of bismuth?
- What accounts for the general increase in atomic radius going down the group 5A elements?
- Another major use of bismuth has been as an ingredient in low-melting metal alloys, such as those used in fire sprinkler systems and in typesetting. The element itself is a brittle white crystalline solid. How do these characteristics fit with the fact that bismuth is in the same periodic group with such nonmetallic elements as nitrogen and phosphorus?
- Bi<sub>2</sub>O<sub>3</sub> is a basic oxide. Write a balanced chemical equation for its reaction with dilute nitric acid. If 6.77 g of Bi<sub>2</sub>O<sub>3</sub> is dissolved in dilute acidic solution to make 0.500 L of solution, what is the molarity of the solution of Bi<sup>3+</sup> ion?
- <sup>209</sup>Bi is the heaviest stable isotope of any element. How many protons and neutrons are present in this nucleus?
- The density of Bi at 25 °C is 9.808 g/cm<sup>3</sup>. How many Bi atoms are present in a cube of the element that is 5.00 cm on each edge? How many moles of the element are present?

Continued

**SOLUTION**

- (a) Bismuth is directly below antimony, Sb, in group 5A. Based on the observation that atomic radii increase as we go down a column, we would expect the radius of Bi to be greater than that of Sb, which is 1.39 Å. We also know that atomic radii generally decrease as we proceed from left to right in a period. Tables 7.5 and 7.6 each give an element in the same period, namely, Ba and Po. We would therefore expect that the radius of Bi is smaller than that of Ba (2.15 Å) and larger than that of Po (1.40 Å). We also see that in other periods, the difference in radius between the neighboring group 5A and group 6A elements is relatively small. We might therefore expect that the radius of Bi is slightly larger than that of Po—much closer to the radius of Po than to the radius of Ba. The tabulated value for the atomic radius on Bi is 1.48 Å, in accord with our expectations.
- (b) The general increase in radius with increasing atomic number in the group 5A elements occurs because additional shells of electrons are being added, with corresponding increases in nuclear charge. The core electrons in each case largely screen the outermost electrons from the nucleus, so the effective nuclear charge does not vary greatly as we go to higher atomic numbers. However, the principal quantum number,  $n$ , of the outermost electrons steadily increases, with a corresponding increase in orbital radius.
- (c) The contrast between the properties of bismuth and those of nitrogen and phosphorus illustrates the general rule that there is a trend toward increased metallic character as we move down in a given group. Bismuth, in fact, is a metal. The increased metallic character occurs because the outermost electrons are more readily lost in bonding, a trend that is consistent with its lower ionization energy.

- (d) Following the procedures described in Section 4.2 for writing molecular and net ionic equations, we have the following:

*Molecular equation:*

*Net ionic equation:*

In the net ionic equation, nitric acid is a strong acid and  $\text{Bi}(\text{NO}_3)_3$  is a soluble salt, so we need to show only the reaction of the solid with the hydrogen ion forming the  $\text{Bi}^{3+}(aq)$  ion and water. To calculate the concentration of the solution, we proceed as follows (Section 4.5):

$$\frac{6.77 \text{ g Bi}_2\text{O}_3}{0.500 \text{ L soln}} \times \frac{1 \text{ mol Bi}_2\text{O}_3}{466.0 \text{ g Bi}_2\text{O}_3} \times \frac{2 \text{ mol Bi}^{3+}}{1 \text{ mol Bi}_2\text{O}_3} = \frac{0.0581 \text{ mol Bi}^{3+}}{\text{L soln}} = 0.0581 \text{ M}$$

- (e) Recall that the atomic number of any element is the number of protons and electrons in a neutral atom of the element.  (Section 2.3) Bismuth is element 83; there are therefore 83 protons in the nucleus. Because the atomic mass number is 209, there are  $209 - 83 = 126$  neutrons in the nucleus.
- (f) We can use the density and the atomic weight to determine the number of moles of Bi, and then use Avogadro's number to convert the result to the number of atoms.  (Sections 1.4 and 3.4) The volume of the cube is  $(5.00)^3 \text{ cm}^3 = 125 \text{ cm}^3$ . Then we have

$$125 \text{ cm}^3 \text{ Bi} \times \frac{9.808 \text{ g Bi}}{1 \text{ cm}^3} \times \frac{1 \text{ mol Bi}}{209.0 \text{ g Bi}} = 5.87 \text{ mol Bi}$$

$$5.87 \text{ mol Bi} \times \frac{6.022 \times 10^{23} \text{ atoms Bi}}{1 \text{ mol Bi}} = 3.53 \times 10^{24} \text{ atoms Bi}$$

## Chapter Summary and Key Terms

**DEVELOPMENT OF THE PERIODIC TABLE (INTRODUCTION AND SECTION 7.1)** The periodic table was first developed by Mendeleev and Meyer on the basis of the similarity in chemical and physical properties exhibited by certain elements. Moseley established that each element has a unique atomic number, which added more order to the periodic table.

We now know that elements in the same column of the periodic table have the same number of electrons in their **valence orbitals**. This similarity in valence electronic structure leads to the similarities among elements in the same group. Differences among elements in the same group arise because their valence orbitals are in different shells.

**EFFECTIVE NUCLEAR CHARGE (SECTION 7.2)** Many properties of atoms depend on the **effective nuclear charge**, which is the portion of the nuclear charge that an outer electron experiences after accounting for repulsions by other electrons in the atom. The core electrons are very effective in screening the outer electrons from the full charge of the nucleus, whereas electrons in the same shell do not screen each other very effectively. Because the actual nuclear charge increases as we progress through a period, the effective nuclear charge experienced by valence electrons increases as we move left to right across a period.

**SIZES OF ATOMS AND IONS (SECTION 7.3)** The size of an atom can be gauged by its **bonding atomic radius**, which is based on measurements of the distances separating atoms in their chemical compounds. In general, atomic radii increase down a column in the periodic table and decrease left to right across a row.

Cations are smaller than their parent atoms; anions are larger than their parent atoms. For ions of the same charge, size increases going down a column of the periodic table. An **isoelectronic series** is a series of ions that has the same number of electrons. For such a series, size decreases with increasing atomic number as the electrons are attracted more strongly to the nucleus as its positive charge increases.

**IONIZATION ENERGY (SECTION 7.4)** The first **ionization energy** of an atom is the minimum energy needed to remove an electron from the atom in the gas phase, forming a cation. The second ionization energy is the energy needed to remove a second electron, and so forth. Ionization energies show a sharp increase after all the valence electrons have been removed because of the much higher effective nuclear charge experienced by the core electrons. The first ionization energies of the elements show periodic trends that are opposite those seen for atomic radii, with smaller atoms having higher first ionization energies. Thus, first ionization energies decrease as we go down a column and increase as we proceed left to right across a row.

We can write electron configurations for ions by first writing the electron configuration of the neutral atom and then removing or adding the appropriate number of electrons. For cations, electrons are removed first from the orbitals of the neutral atom with the largest value of  $n$ . If there are two valence orbitals with the same value of  $n$  (such as 4s and 4p), then the electrons are lost first from the orbital with a higher value of  $l$  (in this case, 4p). For anions, electrons are added to orbitals in the reverse order.

**ELECTRON AFFINITY (SECTION 7.5)** The **electron affinity** of an element is the energy change upon adding an electron to an atom in the gas phase, forming an anion. A negative electron affinity means that energy is released when the electron is added; hence, when the electron affinity is negative the anion is stable. By contrast, a positive electron affinity means that the anion is not stable relative to the separated atom and electron. In general, electron affinities become more negative as we proceed from left to right across the periodic table. The halogens have the most negative electron affinities. The electron affinities of the noble gases are positive because the added electron would have to occupy a new, higher-energy subshell.

**METALS, NONMETALS, AND METALLOIDS (SECTION 7.6)** The elements can be categorized as metals, nonmetals, and metalloids. Most elements are metals; they occupy the left side and the middle of the periodic table. Nonmetals appear in the upper-right section of the table. Metalloids occupy a narrow band between the metals and nonmetals. The tendency of an element to exhibit the properties of metals, called the **metallic character**, increases as we proceed down a column and decreases as we proceed from left to right across a row.

Metals have a characteristic luster, and they are good conductors of heat and electricity. When metals react with nonmetals, the metal atoms are oxidized to cations and ionic substances are generally formed. Most metal oxides are basic; they react with acids to form salts and water.

Nonmetals lack metallic luster and are generally poor conductors of heat and electricity. Several are gases at room temperature. Compounds composed entirely of nonmetals are generally molecular. Nonmetals usually form anions in their reactions with metals. Nonmetal oxides are acidic; they react with bases to form salts and water. Metalloids have properties that are intermediate between those of metals and nonmetals.

**TRENDS FOR GROUP 1A AND 2A METALS (SECTION 7.7)** The periodic properties of the elements can help us understand the properties of groups of the representative elements. The **alkali metals** (group 1A) are soft metals with low densities and low melting points. They have the lowest ionization energies of the elements. As a result, they are very reactive toward nonmetals, easily losing their outer *s* electron to form 1+ ions.

The **alkaline earth metals** (group 2A) are harder and denser, and have higher melting points than the alkali metals. They are also very reactive toward nonmetals, although not as reactive as the alkali metals. The alkaline earth metals readily lose their two outer *s* electrons to form 2+ ions. Both alkali and alkaline earth metals react with hydrogen to form ionic substances that contain the **hydride ion**,  $\text{H}^-$ .

**TRENDS FOR SELECTED NONMETALS (SECTION 7.8)** Hydrogen is a nonmetal with properties that are distinct from any of the groups of the periodic table. It forms molecular compounds with other nonmetals, such as oxygen and the halogens.

Oxygen and sulfur are the most important elements in group 6A. Oxygen is usually found as a diatomic molecule,  $\text{O}_2$ . **Ozone**,  $\text{O}_3$ , is an important allotrope of oxygen. Oxygen has a strong tendency to gain electrons from other elements, thus oxidizing them. In combination with metals, oxygen is usually found as the oxide ion,  $\text{O}^{2-}$ , although salts of the peroxide ion,  $\text{O}_2^{2-}$ , and superoxide ion,  $\text{O}_2^-$ , are sometimes formed. Elemental sulfur is most commonly found as  $\text{S}_8$  molecules. In combination with metals, it is most often found as the sulfide ion,  $\text{S}^{2-}$ .

The **halogens** (group 7A) exist as diatomic molecules. The halogens have the most negative electron affinities of the elements. Thus, their chemistry is dominated by a tendency to form 1- ions, especially in reactions with metals.

The **noble gases** (group 8A) exist as monatomic gases. They are very unreactive because they have completely filled *s* and *p* subshells. Only the heaviest noble gases are known to form compounds, and they do so only with very active nonmetals, such as fluorine.

## Learning Outcomes After studying this chapter, you should be able to:

- Explain the meaning of effective nuclear charge,  $Z_{\text{eff}}$ , and how  $Z_{\text{eff}}$  depends on nuclear charge and electron configuration. (Section 7.2) *Related Exercises:* 7.13–7.15, 7.17
- Use the periodic table to predict the trends in atomic radii, ionic radii, ionization energy, and electron affinity. (Sections 7.2, 7.3, 7.4, and 7.5) *Related Exercises:* 7.26, 7.42, 7.44, 7.53
- Explain how the radius of an atom changes upon losing electrons to form a cation or gaining electrons to form an anion. (Section 7.3) *Related Exercises:* 7.28, 7.33–7.35
- Use the periodic table to determine the electron configurations of ions. (Section 7.3) *Related Exercises:* 7.29, 7.30, 7.45, 7.46
- Predict the trends in ionization energy as successive electrons are removed, including the discontinuous increase that occurs when the ionization corresponds to removing a core electron. (Section 7.4) *Related Exercises:* 7.37–7.39, 7.42
- Explain how electron affinity and ionization energy are related, and how irregularities in the periodic trends for electron affinity can be related to electron configuration. (Section 7.5) *Related Exercises:* 7.53, 7.54, 7.92, 7.95
- Explain the differences in chemical and physical properties of metals and nonmetals, including the basicity of metal oxides and the acidity of nonmetal oxides. (Section 7.6) *Related Exercises:* 7.56, 7.59, 7.60, 7.62
- Explain how atomic properties, such as ionization energy and electron affinity, relate to the chemical reactivity and physical properties of the alkali and alkaline earth metals (groups 1A and 2A). (Section 7.7) *Related Exercises:* 7.67, 7.68
- Write balanced equations for the reactions of the group 1A and 2A metals with water, oxygen, hydrogen, and the halogens. (Sections 7.7 and 7.8) *Related Exercises:* 7.69, 7.70
- List and explain the unique characteristics of hydrogen. (Section 7.7) *Related Exercises:* 7.71, 7.72, 7.99
- Explain how the atomic properties, such as ionization energy and electron affinity, of group 6A, 7A, and 8A elements relate to their chemical reactivity and physical properties. (Section 7.8) *Related Exercises:* 7.73, 7.74, 7.76

## Key Equations

- $Z_{\text{eff}} = Z - S$  [7.1] Estimating effective nuclear charge

## Exercises

### Visualizing Concepts

- 7.1** As discussed in the text, we can draw an analogy between the attraction of an electron to a nucleus and the act of perceiving light from a light bulb through a frosted glass shade, as shown in the illustration.

Using the simple method of estimating effective nuclear charge, Equation 7.1, how does the intensity of the light bulb and/or the thickness of the frosting change in the following cases: **(a)** Moving from boron to carbon? **(b)** Moving from boron to aluminum? [Section 7.2]

- 7.2** Which of these spheres represents F, which represents Br, and which represents  $\text{Br}^-$ ? [Section 7.3]

- 7.3** Consider the  $\text{Mg}^{2+}$ ,  $\text{Cl}^-$ ,  $\text{K}^+$ , and  $\text{Se}^{2-}$  ions. The four spheres below represent these four ions, scaled according to ionic size. **(a)** Without referring to Figure 7.8, match each ion to its appropriate sphere. **(b)** In terms of size, between which of the spheres would you find the (i)  $\text{Ca}^{2+}$  and (ii)  $\text{S}^{2-}$  ions? [Section 7.3]

- 7.4** In the following reaction

which sphere represents a metal and which represents a nonmetal? [Section 7.3]

- 7.5** Consider the  $\text{A}_2\text{X}_4$  molecule depicted here, where A and X are elements. The A—A bond length in this molecule is  $d_1$ , and the four A—X bond lengths are each  $d_2$ . **(a)** In terms of  $d_1$  and  $d_2$ , how could you define the bonding atomic radii of atoms A and X? **(b)** In terms of  $d_1$  and  $d_2$ , what would you predict for the X—X bond length of an  $\text{X}_2$  molecule? [Section 7.3]

- 7.6** Shown below is a qualitative diagram of the atomic orbital energies for an Na atom. The number of orbitals in each subshell is not shown.

- (a)** Are all of the subshells for  $n = 1$ ,  $n = 2$ , and  $n = 3$  shown? If not, what is missing?
- (b)** The 2s and 2p energy levels are different. Which of the following is the best explanation for why this is the case? **(i)** The 2s and 2p energy levels have different energies in the hydrogen atom, so of course they will have different energies in the sodium atom, **(ii)** The energy of the 2p orbital is higher than that of the 2s in all many-electron atoms. **(iii)** The 2s level in Na has electrons in it, whereas the 2p does not.
- (c)** Which of the energy levels holds the highest-energy electron in a sodium atom?
- (d)** A sodium vapor lamp (Figure 7.23) operates by using electricity to excite the highest-energy electron to the next highest-energy level. Light is produced when the excited electron drops back to the lower level. Which two energy levels are involved in this process for the Na atom? [Section 7.7]
- 7.7** Which of the following charts below shows the general periodic trends for each of the following properties of the main-group elements (you can neglect small deviations going either across a row or down a column of the periodic table)? **(1)** Bonding atomic radius, **(2)** first ionization energy, **(3)** effective nuclear charge. [Sections 7.2–7.6]

- 7.8 An element X reacts with  $F_2(g)$  to form the molecular product shown here. (a) Write a balanced equation for this reaction (do not worry about the phases for X and the product). (b) Do you think that X is a metal or nonmetal? [Section 7.6]

### Periodic Table; Effective Nuclear Charge (Sections 7.1 and 7.2)

- 7.9 (a) Evaluate the expressions  $2 \times 1$ ,  $2 \times (1 + 3)$ ,  $2 \times (1 + 3 + 5)$ , and  $2 \times (1 + 3 + 5 + 7)$ . (b) How do the

atomic numbers of the noble gases relate to the numbers from part (a)? (c) What topic discussed in Chapter 6 is the source of the number “2” in the expressions in part (a)?

- 7.10 The prefix *eka-* comes from the Sanskrit word for “one.” Mendeleev used this prefix to indicate that the unknown element was one place away from the known element that followed the prefix. For example, *eka-silicon*, which we now call germanium, is one element below silicon. Mendeleev also predicted the existence of *eka-manganese*, which was not experimentally confirmed until 1937 because this element is radioactive and does not occur in nature. Based on the periodic table shown in Figure 7.1, what do we now call the element Mendeleev called *eka-manganese*?

- 7.11 (a) The five most abundant elements in the Earth’s crust are O, Si, Al, Fe, and Ca. Referring to Figure 7.1, are any of these elements among those known before 1700? If so which ones? (b) Seven of the nine elements known since ancient times are metals. Referring to Table 4.5, are these metals mostly found at the bottom or top of the activity series?

- 7.12 Moseley’s experiments on X rays emitted from atoms led to the concept of atomic numbers. (a) If arranged in order of increasing atomic mass, which element would come after chlorine? (b) Describe two ways in which the properties of this element differ from the other elements in group 8A.

- 7.13 Among elements 1–18, which element or elements have the smallest effective nuclear charge if we use Equation 7.1 to calculate  $Z_{\text{eff}}$ ? Which element or elements have the largest effective nuclear charge?

- 7.14 Which of the following statements about effective nuclear charge for the outermost valence electron of an atom is *incorrect*? (i) The effective nuclear charge can be thought of as the true nuclear charge minus a screening constant due to the other electrons in the atom. (ii) Effective nuclear charge increases going left to right across a row of the periodic table. (iii) Valence electrons screen the nuclear charge more effectively than do core electrons. (iv) The effective nuclear charge shows a sudden decrease when we go from the end of one row to the beginning of the next row of the periodic table. (v) The change in effective nuclear charge going down a column of the periodic table is generally less than that going across a row of the periodic table.

- 7.15 Detailed calculations show that the value of  $Z_{\text{eff}}$  for the outermost electrons in Na and K atoms is 2.51+ and 3.49+, respectively. (a) What value do you estimate for  $Z_{\text{eff}}$  experienced by the outermost electron in both Na and K by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (b) What values do you estimate for  $Z_{\text{eff}}$  using Slater’s rules? (c) Which approach gives a more accurate estimate of  $Z_{\text{eff}}$ ? (d) Does either method of approximation account for the gradual increase in  $Z_{\text{eff}}$  that occurs upon moving down a group? (e) Predict  $Z_{\text{eff}}$  for the outermost electrons in the Rb atom based on the calculations for Na and K.

- 7.16 Detailed calculations show that the value of  $Z_{\text{eff}}$  for the outermost electrons in Si and Cl atoms is 4.29+ and 6.12+, respectively. (a) What value do you estimate for  $Z_{\text{eff}}$  experienced by the outermost electron in both Si and Cl by assuming core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant? (b) What values do you estimate for  $Z_{\text{eff}}$  using Slater’s rules? (c) Which approach gives a more accurate estimate of  $Z_{\text{eff}}$ ? (d) Which method of approximation more accurately accounts for the steady increase in  $Z_{\text{eff}}$  that occurs upon moving left to right across a period? (e) Predict  $Z_{\text{eff}}$  for a valence electron in P, phosphorus, based on the calculations for Si and Cl.

- 7.17 Which will experience the greater effective nuclear charge, the electrons in the  $n = 3$  shell in Ar or the  $n = 3$  shell in Kr? Which will be closer to the nucleus?

- 7.18** Arrange the following atoms in order of increasing effective nuclear charge experienced by the electrons in the  $n = 3$  electron shell: K, Mg, P, Rh, Ti.

### Atomic and Ionic Radii (Section 7.3)

- 7.19** Which quantity must be determined experimentally in order to determine the bonding atomic radius of an atom? (a) The distance from the nucleus where the probability of finding an electron goes to zero. (b) The distance between the nuclei of two atoms that are bonded together. (c) The effective nuclear charge of an atom.
- 7.20** With the exception of helium, the noble gases condense to form solids when they are cooled sufficiently. At temperatures below 83 K, argon forms a close-packed solid whose structure is shown below. (a) What is the apparent radius of an argon atom in solid argon, assuming the atoms touch as shown in this figure? (b) Is this value larger or smaller than the bonding atomic radius estimated for argon in Figure 7.7? (c) Based on this comparison would you say that the atoms are held together by chemical bonds in solid argon?

- 7.21** Tungsten has the highest melting point of any metal in the periodic table: 3422 °C. The distance between W atoms in tungsten metal is 2.74 Å. (a) What is the atomic radius of a tungsten atom in this environment? (This radius is called the *metallic radius*.) (b) If you put tungsten metal under high pressure, predict what would happen to the distance between W atoms.
- 7.22** Which of the following statements about the bonding atomic radii in Figure 7.7 is *incorrect*? (i) For a given period, the radii of the representative elements generally decrease from left to right across a period. (ii) The radii of the representative elements for the  $n = 3$  period are all larger than those of the corresponding elements in the  $n = 2$  period. (iii) For most of the representative elements, the change in radius from the  $n = 2$  to the  $n = 3$  period is greater than the change in radius from  $n = 3$  to  $n = 4$ . (iv) The radii of the transition elements generally increase moving from left to right within a period. (v) The large radii of the Group 1A elements are due to their relatively small effective nuclear charges.
- 7.23** Estimate the As—I bond length from the data in Figure 7.7 and compare your value to the experimental As—I bond length in arsenic triiodide, AsI<sub>3</sub>, 2.55 Å.
- 7.24** The experimental Bi—I bond length in bismuth triiodide, BiI<sub>3</sub>, is 2.81 Å. Based on this value and data in Figure 7.7, predict the atomic radius of Bi.
- 7.25** Using only the periodic table, arrange each set of atoms in order from largest to smallest: (a) K, Li, Cs; (b) Pb, Sn, Si; (c) F, O, N.
- 7.26** Using only the periodic table, arrange each set of atoms in order of increasing radius: (a) Ba, Ca, Na; (b) In, Sn, As; (c) Al, Be, Si.

- 7.27** Identify each statement as true or false: (a) Cations are larger than their corresponding neutral atoms. (b) Li<sup>+</sup> is smaller than Li. (c) Cl<sup>-</sup> is bigger than I<sup>-</sup>.
- 7.28** Explain the following variations in atomic or ionic radii: (a) I<sup>-</sup> > I > I<sup>+</sup> (b) Ca<sup>2+</sup> > Mg<sup>2+</sup> > Be<sup>2+</sup> (c) Fe > Fe<sup>2+</sup> > Fe<sup>3+</sup>
- 7.29** Which neutral atom is isoelectronic with each of the following ions? Ga<sup>3+</sup>, Zr<sup>4+</sup>, Mn<sup>7+</sup>, I<sup>-</sup>, Pb<sup>2+</sup>.
- 7.30** Some ions do not have a corresponding neutral atom that has the same electron configuration. For each of the following ions, identify the neutral atom that has the same number of electrons and determine if this atom has the same electron configuration. (a) Cl<sup>-</sup>, (b) Sc<sup>3+</sup>, (c) Fe<sup>2+</sup>, (d) Zn<sup>2+</sup>, (e) Sn<sup>4+</sup>.
- 7.31** Consider the isoelectronic ions F<sup>-</sup> and Na<sup>+</sup>. (a) Which ion is smaller? (b) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute 0.00 to the screening constant,  $S$ , calculate  $Z_{\text{eff}}$  for the  $2p$  electrons in both ions. (c) Repeat this calculation using Slater's rules to estimate the screening constant,  $S$ . (d) For isoelectronic ions, how are effective nuclear charge and ionic radius related?
- 7.32** Consider the isoelectronic ions Cl<sup>-</sup> and K<sup>+</sup>. (a) Which ion is smaller? (b) Using Equation 7.1 and assuming that core electrons contribute 1.00 and valence electrons contribute nothing to the screening constant,  $S$ , calculate  $Z_{\text{eff}}$  for these two ions. (c) Repeat this calculation using Slater's rules to estimate the screening constant,  $S$ . (d) For isoelectronic ions, how are effective nuclear charge and ionic radius related?
- 7.33** Consider S, Cl, and K and their most common ions. (a) List the atoms in order of increasing size. (b) List the ions in order of increasing size. (c) Explain any differences in the orders of the atomic and ionic sizes.
- 7.34** Arrange each of the following sets of atoms and ions, in order of increasing size: (a) Se<sup>2-</sup>, Te<sup>2-</sup>, Se; (b) Co<sup>3+</sup>, Fe<sup>2+</sup>, Fe<sup>3+</sup>; (c) Ca, Ti<sup>4+</sup>, Sc<sup>3+</sup>; (d) Be<sup>2+</sup>, Na<sup>+</sup>, Ne.
- 7.35** Provide a brief explanation for each of the following: (a) O<sup>2-</sup> is larger than O. (b) S<sup>2-</sup> is larger than O<sup>2-</sup>. (c) S<sup>2-</sup> is larger than K<sup>+</sup>. (d) K<sup>+</sup> is larger than Ca<sup>2+</sup>.
- 7.36** In the ionic compounds LiF, NaCl, KBr, and RbI, the measured cation–anion distances are 2.01 Å (Li–F), 2.82 Å (Na–Cl), 3.30 Å (K–Br), and 3.67 Å (Rb–I), respectively. (a) Predict the cation–anion distance using the values of ionic radii given in Figure 7.8. (b) Calculate the difference between the experimentally measured ion–ion distances and the ones predicted from Figure 7.8. (c) What estimates of the cation–anion distance would you obtain for these four compounds using neutral atom *bonding atomic radii*? Are these estimates as accurate as the estimates using ionic radii?

### Ionization Energies; Electron Affinities (Sections 7.4 and 7.5)

- 7.37** Write equations that show the processes that describe the first, second, and third ionization energies of an aluminum atom. Which process would require the least amount of energy?
- 7.38** Write equations that show the process for (a) the first two ionization energies of lead and (b) the fourth ionization energy of zirconium.
- 7.39** Which element has the highest second ionization energy: Li, K, or Be?
- 7.40** Identify each statement as true or false: (a) Ionization energies are always negative quantities. (b) Oxygen has a larger first ionization energy than fluorine. (c) The second ionization

energy of an atom is always greater than its first ionization energy. **(d)** The third ionization energy is the energy needed to ionize three electrons from a neutral atom.

- 7.41** **(a)** What is the general relationship between the size of an atom and its first ionization energy? **(b)** Which element in the periodic table has the largest ionization energy? Which has the smallest?
- 7.42** **(a)** What is the trend in first ionization energies as one proceeds down the group 7A elements? Explain how this trend relates to the variation in atomic radii. **(b)** What is the trend in first ionization energies as one moves across the fourth period from K to Kr? How does this trend compare with the trend in atomic radii?
- 7.43** Based on their positions in the periodic table, predict which atom of the following pairs will have the smaller first ionization energy: **(a)** Cl, Ar; **(b)** Be, Ca; **(c)** K, Co; **(d)** S, Ge; **(e)** Sn, Te.
- 7.44** For each of the following pairs, indicate which element has the smaller first ionization energy: **(a)** Ti, Ba; **(b)** Ag, Cu; **(c)** Ge, Cl; **(d)** Pb, Sb.
- 7.45** Write the electron configurations for the following ions, and determine which have noble-gas configurations: **(a)**  $\text{Co}^{2+}$ , **(b)**  $\text{Sn}^{2+}$ , **(c)**  $\text{Zr}^{4+}$ , **(d)**  $\text{Ag}^+$ , **(e)**  $\text{S}^{2-}$ .
- 7.46** Write the electron configurations for the following ions, and determine which have noble-gas configurations: **(a)**  $\text{Ru}^{3+}$ , **(b)**  $\text{As}^{3-}$ , **(c)**  $\text{Y}^{3+}$ , **(d)**  $\text{Pd}^{2+}$ , **(e)**  $\text{Pb}^{2+}$ , **(f)**  $\text{Au}^{3+}$ .
- 7.47** Give three examples of ions that have an electron configuration of  $nd^8$  ( $n = 3, 4, 5, \dots$ ).
- 7.48** Give three examples of ions that have an electron configuration of  $nd^6$  ( $n = 3, 4, 5, \dots$ ).
- 7.49** Write an equation for the second electron affinity of chlorine. Would you predict a positive or a negative energy value for this process? Is it possible to directly measure the second electron affinity of chlorine?
- 7.50** If the electron affinity for an element is a negative number, does it mean that the anion of the element is more stable than the neutral atom? Explain.
- 7.51** Would a neutral K atom or a  $\text{K}^+$  ion have a more negative value of electron affinity?
- 7.52** What is the relationship between the ionization energy of an anion with a 1- charge such as  $\text{F}^-$  and the electron affinity of the neutral atom, F?
- 7.53** Consider the first ionization energy of neon and the electron affinity of fluorine. **(a)** Write equations, including electron configurations, for each process. **(b)** These two quantities have opposite signs. Which will be positive, and which will be negative? **(c)** Would you expect the magnitudes of these two quantities to be equal? If not, which one would you expect to be larger?
- 7.54** Consider the following equation:

Which of the following statements are true? **(i)** The energy change for this process is the electron affinity of the  $\text{Ca}^+$  ion. **(ii)** The energy change for this process is the negative of the first ionization energy of the Ca atom. **(iii)** The energy change for this process is the negative of the electron affinity of the Ca atom.

## Properties of Metals and Nonmetals (Section 7.6)

- 7.55** **(a)** Does metallic character increase, decrease, or remain unchanged as one goes from left to right across a row of the periodic table? **(b)** Does metallic character increase, decrease, or remain unchanged as one goes down a column of the periodic table? **(c)** Are the periodic trends in (a) and (b) the same as or different from those for first ionization energy?
- 7.56** You read the following statement about two elements X and Y: One of the elements is a good conductor of electricity, and the other is a semiconductor. Experiments show that the first ionization energy of X is twice as great as that of Y. Which element has the greater metallic character?
- 7.57** Discussing this chapter, a classmate says, "An element that commonly forms a cation is a metal." Do you agree or disagree?
- 7.58** Discussing this chapter, a classmate says, "Since elements that form cations are metals and elements that form anions are nonmetals, elements that do not form ions are metalloids." Do you agree or disagree?
- 7.59** Predict whether each of the following oxides is ionic or molecular:  $\text{SnO}_2$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{CO}_2$ ,  $\text{Li}_2\text{O}$ ,  $\text{Fe}_2\text{O}_3$ ,  $\text{H}_2\text{O}$ .
- 7.60** Some metal oxides, such as  $\text{Sc}_2\text{O}_3$ , do not react with pure water, but they do react when the solution becomes either acidic or basic. Do you expect  $\text{Sc}_2\text{O}_3$  to react when the solution becomes acidic or when it becomes basic? Write a balanced chemical equation to support your answer.
- 7.61** Would you expect manganese(II) oxide,  $\text{MnO}$ , to react more readily with  $\text{HCl}(aq)$  or  $\text{NaOH}(aq)$ ?
- 7.62** Arrange the following oxides in order of increasing acidity:  $\text{CO}_2$ ,  $\text{CaO}$ ,  $\text{Al}_2\text{O}_3$ ,  $\text{SO}_3$ ,  $\text{SiO}_2$ ,  $\text{P}_2\text{O}_5$ .
- 7.63** Chlorine reacts with oxygen to form  $\text{Cl}_2\text{O}_7$ . **(a)** What is the name of this product (see Table 2.6)? **(b)** Write a balanced equation for the formation of  $\text{Cl}_2\text{O}_7(l)$  from the elements. **(c)** Would you expect  $\text{Cl}_2\text{O}_7$  to be more reactive toward  $\text{H}^+(aq)$  or  $\text{OH}^-(aq)$ ? **(d)** If the oxygen in  $\text{Cl}_2\text{O}_7$  is considered to have the -2 oxidation state, what is the oxidation state of the Cl? What is the electron configuration of Cl in this oxidation state?
- [7.64]** An element X reacts with oxygen to form  $\text{XO}_2$  and with chlorine to form  $\text{XCl}_4$ .  $\text{XO}_2$  is a white solid that melts at high temperatures (above  $1000^\circ\text{C}$ ). Under usual conditions,  $\text{XCl}_4$  is a colorless liquid with a boiling point of  $58^\circ\text{C}$ . **(a)**  $\text{XCl}_4$  reacts with water to form  $\text{XO}_2$  and another product. What is the likely identity of the other product? **(b)** Do you think that element X is a metal, nonmetal, or metalloid? **(c)** By using a sourcebook such as the *CRC Handbook of Chemistry and Physics*, try to determine the identity of element X.
- 7.65** Write balanced equations for the following reactions: **(a)** barium oxide with water, **(b)** iron(II) oxide with perchloric acid, **(c)** sulfur trioxide with water, **(d)** carbon dioxide with aqueous sodium hydroxide.
- 7.66** Write balanced equations for the following reactions: **(a)** potassium oxide with water, **(b)** diphosphorus trioxide with water, **(c)** chromium(III) oxide with dilute hydrochloric acid, **(d)** selenium dioxide with aqueous potassium hydroxide.

## Group Trends in Metals and Nonmetals (Sections 7.7 and 7.8)

- 7.67** **(a)** Why is calcium generally more reactive than magnesium? **(b)** Why is calcium generally less reactive than potassium?
- 7.68** Silver and rubidium both form +1 ions, but silver is far less reactive. Suggest an explanation, taking into account the ground-state electron configurations of these elements and their atomic radii.
- 7.69** Write a balanced equation for the reaction that occurs in each of the following cases: **(a)** Potassium metal is exposed to an atmosphere of chlorine gas. **(b)** Strontium oxide is added to water. **(c)** A fresh surface of lithium metal is exposed to oxygen gas. **(d)** Sodium metal reacts with molten sulfur.
- 7.70** Write a balanced equation for the reaction that occurs in each of the following cases: **(a)** Cesium is added to water.

(b) Strontium is added to water. (c) Sodium reacts with oxygen. (d) Calcium reacts with iodine.

**7.71** (a) As described in Section 7.7, the alkali metals react with hydrogen to form hydrides and react with halogens to form halides. Compare the roles of hydrogen and halogens in these reactions. Write balanced equations for the reaction of fluorine with calcium and for the reaction of hydrogen with calcium. (b) What is the oxidation number and electron configuration of calcium in each product?

**7.72** Potassium and hydrogen react to form the ionic compound potassium hydride. (a) Write a balanced equation for this reaction. (b) Use data in Figures 7.10 and 7.12 to determine the energy change in kJ/mol for the following two reactions:

(c) Based on your calculated energy changes in (b), which of these reactions is energetically more favorable (or less unfavorable)? (d) Is your answer to (c) consistent with the description of potassium hydride as containing hydride ions?

**7.73** Compare the elements bromine and chlorine with respect to the following properties: (a) electron configuration, (b) most common ionic charge, (c) first ionization energy, (d) reactivity toward water, (e) electron affinity, (f) atomic radius. Account for the differences between the two elements.

**7.74** Little is known about the properties of astatine, At, because of its rarity and high radioactivity. Nevertheless, it is possible for us to make many predictions about its properties. (a) Do you expect the element to be a gas, liquid, or solid at room temperature? Explain. (b) Would you expect At to be a metal, nonmetal, or metalloid? Explain. (c) What is the chemical formula of the compound it forms with Na?

**7.75** Until the early 1960s, the group 8A elements were called the inert gases. (a) Why was the term *inert gases* dropped? (b) What discovery triggered this change in name? (c) What name is applied to the group now?

**7.76** (a) Why does xenon react with fluorine, whereas neon does not? (b) Using appropriate reference sources, look up the bond lengths of Xe—F bonds in several molecules. How do these numbers compare to the bond lengths calculated from the atomic radii of the elements?

**7.77** Write a balanced equation for the reaction that occurs in each of the following cases: (a) Ozone decomposes to dioxygen. (b) Xenon reacts with fluorine. (Write three different equations.) (c) Sulfur reacts with hydrogen gas. (d) Fluorine reacts with water.

**7.78** Write a balanced equation for the reaction that occurs in each of the following cases: (a) Chlorine reacts with water. (b) Barium metal is heated in an atmosphere of hydrogen gas. (c) Lithium reacts with sulfur. (d) Fluorine reacts with magnesium metal.

## Additional Exercises

**7.79** Consider the stable elements through lead ( $Z = 82$ ). In how many instances are the atomic weights of the elements out of order relative to the atomic numbers of the elements?

**[7.80]** Figure 7.4 shows the radial probability distribution functions for the 2s orbitals and 2p orbitals. (a) Which orbital, 2s or 2p, has more electron density close to the nucleus? (b) How would you modify Slater's rules to adjust for the difference in electronic penetration of the nucleus for the 2s and 2p orbitals?

**7.81** (a) If the core electrons were totally effective at screening the valence electrons and the valence electrons provided no screening for each other, what would be the effective nuclear charge acting on the 3s and 3p valence electrons in P? (b) Repeat these calculations using Slater's rules. (c) Detailed calculations indicate that the effective nuclear charge is 5.6+ for the 3s electrons and 4.9+ for the 3p electrons. Why are the values for the 3s and 3p electrons different? (d) If you remove a single electron from a P atom, which orbital will it come from?

**7.82** As we move across a period of the periodic table, why do the sizes of the transition elements change more gradually than those of the representative elements?

**7.83** In the series of group 5A hydrides, of general formula  $\text{MH}_3$ , the measured bond distances are P—H, 1.419 Å; As—H, 1.519 Å; Sb—H, 1.707 Å. (a) Compare these values with those estimated by use of the atomic radii in Figure 7.7. (b) Explain the steady increase in M—H bond distance in this series in terms of the electron configurations of the M atoms.

**7.84** In Table 7.8, the bonding atomic radius of neon is listed as 0.58 Å, whereas that for xenon is listed as 1.40 Å. A classmate of yours states that the value for Xe is more realistic than the one for Ne. Is she correct? If so, what is the basis for her statement?

**7.85** The As—As bond length in elemental arsenic is 2.48 Å. The Cl—Cl bond length in  $\text{Cl}_2$  is 1.99 Å. (a) Based on these data, what is the predicted As—Cl bond length in arsenic trichloride,  $\text{AsCl}_3$ , in which each of the three Cl atoms is bonded to the As atom? (b) What bond length is predicted for  $\text{AsCl}_3$ , using the atomic radii in Figure 7.7?

**7.86** The following observations are made about two hypothetical elements A and B: The A—A and B—B bond lengths in the elemental forms of A and B are 2.36 and 1.94 Å, respectively. A and B react to form the binary compound  $\text{AB}_2$ , which has a linear structure (that is  $\angle \text{B—A—B} = 180^\circ$ ). Based on these statements, predict the separation between the two B nuclei in a molecule of  $\text{AB}_2$ .

**7.87** Elements in group 7A in the periodic table are called the halogens; elements in group 6A are called the chalcogens. (a) What is the most common oxidation state of the chalcogens compared to the halogens? (b) For each of the following periodic properties, state whether the halogens or the chalcogens have larger values: atomic radii, ionic radii of the most common oxidation state, first ionization energy, second ionization energy.

**7.88** Note from the following table that there is a significant increase in atomic radius upon moving from Y to La, whereas the radii of Zr to Hf are the same. Suggest an explanation for this effect.

| Atomic Radii (Å) |      |    |      |
|------------------|------|----|------|
| Sc               | 1.70 | Ti | 1.60 |
| Y                | 1.90 | Zr | 1.75 |
| La               | 2.07 | Hf | 1.75 |

**[7.89]** (a) Which ion is smaller,  $\text{Co}^{3+}$  or  $\text{Co}^{4+}$ ? (b) In a lithium-ion battery that is discharging to power a device, for every  $\text{Li}^+$  that inserts into the lithium cobalt oxide electrode, a  $\text{Co}^{4+}$  ion must be reduced to a  $\text{Co}^{3+}$  ion to balance charge. Using

the *CRC Handbook of Chemistry and Physics* or other standard reference, find the ionic radii of  $\text{Li}^+$ ,  $\text{Co}^{3+}$ , and  $\text{Co}^{4+}$ . Order these ions from smallest to largest. (c) Will the lithium cobalt oxide cathode expand or contract as lithium ions are inserted? (d) Lithium is not nearly as abundant as sodium. If sodium ion batteries were developed that function in the same manner as lithium ion batteries, do you think “sodium cobalt oxide” would still work as the electrode material? Explain. (e) If you don’t think cobalt would work as the redox-active partner ion in the sodium version of the electrode, suggest an alternative metal ion and explain your reasoning.

- [7.90] The ionic substance strontium oxide,  $\text{SrO}$ , forms from the reaction of strontium metal with molecular oxygen. The arrangement of the ions in solid  $\text{SrO}$  is analogous to that in solid  $\text{NaCl}$ :

(a) Write a balanced equation for the formation of  $\text{SrO}(s)$  from its elements. (b) Based on the ionic radii in Figure 7.8, predict the length of the side of the cube in the figure (the distance from the center of an atom at one corner to the center of an atom at a neighboring corner). (c) The density of  $\text{SrO}$  is  $5.10 \text{ g/cm}^3$ . Given your answer to part (b), how many formula units of  $\text{SrO}$  are contained in the cube shown here?

- 7.91 Explain the variation in the ionization energies of carbon, as displayed in this graph:

- 7.92 Group 4A elements have much more negative electron affinities than their neighbors in groups 3A and 5A (see Figure 7.12). Which of the following statements best explains this observation? (i) The group 4A elements have much higher first ionization energies than their neighbors in groups 3A and 5A. (ii) The addition of an electron to a group 4A element leads to a half-filled  $np^3$  outer electron configuration. (iii) The group 4A elements have unusually large atomic radii. (iv) The group 4A elements are easier to vaporize than are the group 3A and 5A elements.
- 7.93 In the chemical process called *electron transfer*, an electron is transferred from one atom or molecule to another. (We will talk about electron transfer extensively in Chapter 20.) A simple electron transfer reaction is

In terms of the ionization energy and electron affinity of atom A, what is the energy change for this reaction? For a representative nonmetal such as chlorine, is this process exothermic? For a representative metal such as sodium, is this process exothermic?

- 7.94 (a) Use orbital diagrams to illustrate what happens when an oxygen atom gains two electrons. (b) Why does  $\text{O}^{3-}$  not exist?
- [7.95] Use electron configurations to explain the following observations: (a) The first ionization energy of phosphorus is greater than that of sulfur. (b) The electron affinity of nitrogen is lower (less negative) than those of both carbon and oxygen. (c) The second ionization energy of oxygen is greater than the first ionization energy of fluorine. (d) The third ionization energy of manganese is greater than those of both chromium and iron.
- 7.96 Identify two ions that have the following ground-state electron configurations: (a)  $[\text{Ar}]$ , (b)  $[\text{Ar}]3d^5$ , (c)  $[\text{Kr}]5s^24d^{10}$ .
- 7.97 Which of the following chemical equations is connected to the definitions of (a) the first ionization energy of oxygen, (b) the second ionization energy of oxygen, and (c) the electron affinity of oxygen?
- (i)  $\text{O}(g) + e^- \longrightarrow \text{O}^-(g)$  (ii)  $\text{O}(g) \longrightarrow \text{O}^+(g) + e^-$   
 (iii)  $\text{O}(g) + 2e^- \longrightarrow \text{O}^{2-}(g)$  (iv)  $\text{O}(g) \longrightarrow \text{O}^{2+}(g) + 2e^-$   
 (v)  $\text{O}^+(g) \longrightarrow \text{O}^{2+}(g) + e^-$
- 7.98 The electron affinities, in kJ/mol, for the group 1B and group 2B metals are as follows:

|            |           |
|------------|-----------|
| Cu<br>−119 | Zn<br>> 0 |
| Ag<br>−126 | Cd<br>> 0 |
| Au<br>−223 | Hg<br>> 0 |

(a) Why are the electron affinities of the group 2B elements greater than zero? (b) Why do the electron affinities of the group 1B elements become more negative as we move down the group? [Hint: Examine the trends in the electron affinities of other groups as we proceed down the periodic table.]

- 7.99 Hydrogen is an unusual element because it behaves in some ways like the alkali metal elements and in other ways like nonmetals. Its properties can be explained in part by its electron configuration and by the values for its ionization energy and electron affinity. (a) Explain why the electron affinity of hydrogen is much closer to the values for the alkali elements than for the halogens. (b) Is the following statement true? “Hydrogen has the smallest bonding atomic radius of any element that forms chemical compounds.” If not, correct it. If it is, explain in terms of electron configurations. (c) Explain why the ionization energy of hydrogen is closer to the values for the halogens than for the alkali metals. (d) The hydride ion is  $\text{H}^-$ . Write out the process corresponding to the first ionization energy of the hydride ion. (e) How does the process in part (d) compare to the process for the electron affinity of a neutral hydrogen atom?

- [7.100] The first ionization energy of the oxygen molecule is the energy required for the following process:

The energy needed for this process is  $1175 \text{ kJ/mol}$ , very similar to the first ionization energy of Xe. Would you expect  $\text{O}_2$  to react with  $\text{F}_2$ ? If so, suggest a product or products of this reaction.

- [7.101] It is possible to define *metallic character* as we do in this book and base it on the reactivity of the element and the ease with which it loses electrons. Alternatively, one could measure

how well electricity is conducted by each of the elements to determine how “metallic” the elements are. On the basis of conductivity, there is not much of a trend in the periodic table: Silver is the most conductive metal, and manganese the least. Look up the first ionization energies of silver and manganese; which of these two elements would you call more metallic based on the way we define it in this book?

- 7.102** Which of the following is the expected product of the reaction of K(s) and H<sub>2</sub>(g)? (i) KH(s), (ii) K<sub>2</sub>H(s), (iii) KH<sub>2</sub>(s), (iv) K<sub>2</sub>H<sub>2</sub>(s), or (v) K(s) and H<sub>2</sub>(g) will not react with one another.
- 7.103** Elemental cesium reacts more violently with water than does elemental sodium. Which of the following best explains this difference in reactivity? (i) Sodium has greater metallic character than does cesium. (ii) The first ionization energy of cesium is less than that of sodium. (iii) The electron affinity of sodium is smaller than that of cesium. (iv) The effective nuclear charge for cesium is less than that of sodium. (v) The atomic radius of cesium is smaller than that of sodium.
- 7.104** (a) One of the alkali metals reacts with oxygen to form a solid white substance. When this substance is dissolved in water, the solution gives a positive test for hydrogen peroxide, H<sub>2</sub>O<sub>2</sub>. When the solution is tested in a burner flame, a lilac-purple flame is produced. What is the likely identity of the metal? (b) Write a balanced chemical equation for the reaction of the white substance with water.
- 7.105** Zinc in its 2+ oxidation state is an essential metal ion for life. Zn<sup>2+</sup> is found bound to many proteins that are involved in biological processes, but unfortunately Zn<sup>2+</sup> is hard to detect by common chemical methods. Therefore, scientists who are interested in studying Zn<sup>2+</sup>-containing proteins frequently substitute Cd<sup>2+</sup> for Zn<sup>2+</sup>, since Cd<sup>2+</sup> is easier to detect. (a) On the basis of the properties of the elements and ions discussed in this chapter and their positions in the periodic table, describe the pros and cons of using Cd<sup>2+</sup> as a Zn<sup>2+</sup> substitute. (b) Proteins that speed up (catalyze) chemical reactions are called *enzymes*. Many enzymes are required for proper metabolic reactions in the body. One problem with using Cd<sup>2+</sup> to replace Zn<sup>2+</sup> in enzymes is that Cd<sup>2+</sup> substitution can decrease or even eliminate enzymatic activity. Can you suggest

a different metal ion that might replace Zn<sup>2+</sup> in enzymes instead of Cd<sup>2+</sup>? Justify your answer.

- [7.106]** A historian discovers a nineteenth-century notebook in which some observations, dated 1822, were recorded on a substance thought to be a new element. Here are some of the data recorded in the notebook: “Ductile, silver-white, metallic looking. Softer than lead. Unaffected by water. Stable in air. Melting point: 153 °C. Density: 7.3 g/cm<sup>3</sup>. Electrical conductivity: 20% that of copper. Hardness: About 1% as hard as iron. When 4.20 g of the unknown is heated in an excess of oxygen, 5.08 g of a white solid is formed. The solid could be sublimed by heating to over 800 °C.” (a) Using information in the text and the *CRC Handbook of Chemistry and Physics*, and making allowances for possible variations in numbers from current values, identify the element reported. (b) Write a balanced chemical equation for the reaction with oxygen. (c) Judging from Figure 7.1, might this nineteenth-century investigator have been the first to discover a new element?

- 7.107** In April 2010, a research team reported that it had made Element 117. This discovery was confirmed in 2012 by additional experiments. Write the ground-state electron configuration for Element 117 and estimate values for its first ionization energy, electron affinity, atomic size, and common oxidation state based on its position in the periodic table.

- 7.108** We will see in Chapter 12 that semiconductors are materials that conduct electricity better than nonmetals but not as well as metals. The only two elements in the periodic table that are technologically useful semiconductors are silicon and germanium. Integrated circuits in computer chips today are based on silicon. Compound semiconductors are also used in the electronics industry. Examples are gallium arsenide, GaAs; gallium phosphide, GaP; cadmium sulfide, CdS; and cadmium selenide, CdSe. (a) What is the relationship between the compound semiconductors’ compositions and the positions of their elements on the periodic table relative to Si and Ge? (b) Workers in the semiconductor industry refer to “II–VI” and “III–V” materials, using Roman numerals. Can you identify which compound semiconductors are II–VI and which are III–V? (c) Suggest other compositions of compound semiconductors based on the positions of their elements in the periodic table.

## Integrative Exercises

- [7.109]** Moseley established the concept of atomic number by studying X rays emitted by the elements. The X rays emitted by some of the elements have the following wavelengths:

| Element | Wavelength (Å) |
|---------|----------------|
| Ne      | 14.610         |
| Ca      | 3.358          |
| Zn      | 1.435          |
| Zr      | 0.786          |
| Sn      | 0.491          |

- (a) Calculate the frequency,  $\nu$ , of the X rays emitted by each of the elements, in Hz. (b) Plot the square root of  $\nu$  versus the atomic number of the element. What do you observe about the plot? (c) Explain how the plot in part (b) allowed Moseley to predict the existence of undiscovered elements. (d) Use the result from part (b) to predict the X-ray wavelength emitted by iron. (e) A particular element emits X rays with a wavelength of 0.980 Å. What element do you think it is?

- [7.110]** (a) Write the electron configuration for Li and estimate the effective nuclear charge experienced by the valence electron. (b) The energy of an electron in a one-electron atom or ion

equals  $(-2.18 \times 10^{-18} \text{ J}) \left( \frac{Z^2}{n^2} \right)$ , where  $Z$  is the nuclear charge and  $n$  is the principal quantum number of the electron. Estimate the first ionization energy of Li. (c) Compare the result of your calculation with the value reported in Table 7.4 and explain the difference. (d) What value of the effective nuclear charge gives the proper value for the ionization energy? Does this agree with your explanation in part (c)?

- [7.111]** One way to measure ionization energies is ultraviolet photoelectron spectroscopy (PES), a technique based on the photoelectric effect.  (Section 6.2) In PES, monochromatic light is directed onto a sample, causing electrons to be emitted. The kinetic energy of the emitted electrons is measured. The difference between the energy of the photons and the kinetic energy of the electrons corresponds to the energy needed to remove the electrons (that is, the ionization energy). Suppose that a PES experiment is performed in which mercury vapor is irradiated with ultraviolet light of wavelength 58.4 nm. (a) What is the energy of a photon of this light, in joules? (b) Write an equation that shows the process corresponding to the first ionization energy of Hg. (c) The kinetic energy of the emitted electrons is measured to be  $1.72 \times 10^{-18} \text{ J}$ . What is the first ionization energy of Hg, in

kJ/mol? **(d)** Using Figure 7.10, determine which of the halogen elements has a first ionization energy closest to that of mercury.

- 7.112** Mercury in the environment can exist in oxidation states 0, +1, and +2. One major question in environmental chemistry research is how to best measure the oxidation state of mercury in natural systems; this is made more complicated by the fact that mercury can be reduced or oxidized on surfaces differently than it would be if it were free in solution. XPS, X-ray photoelectron spectroscopy, is a technique related to PES (see Exercise 7.111), but instead of using ultraviolet light to eject valence electrons, X rays are used to eject core electrons. The energies of the core electrons are different for different oxidation states of the element. In one set of experiments, researchers examined mercury contamination of minerals in water. They measured the XPS signals that corresponded to electrons ejected from mercury's 4f orbitals at 105 eV, from an X-ray source that provided 1253.6 eV of energy ( $1 \text{ eV} = 1.602 \times 10^{-19} \text{ J}$ ). The oxygen on the mineral surface gave emitted electron energies at 531 eV, corresponding to the 1s orbital of oxygen. Overall the researchers concluded that oxidation states were +2 for Hg and -2 for O. **(a)** Calculate the wavelength of the X rays used in this experiment. **(b)** Compare the energies of the 4f electrons in mercury and the 1s electrons in oxygen from these data to the first ionization energies of mercury and oxygen from the data in this chapter. **(c)** Write out the ground-state electron configurations for  $\text{Hg}^{2+}$  and  $\text{O}^{2-}$ ; which electrons are the valence electrons in each case?

**[7.113]** When magnesium metal is burned in air (Figure 3.6), two products are produced. One is magnesium oxide, MgO. The other is the product of the reaction of Mg with molecular nitrogen, magnesium nitride. When water is added to magnesium nitride, it reacts to form magnesium oxide and ammonia gas. **(a)** Based on the charge of the nitride ion (Table 2.5), predict the formula of magnesium nitride. **(b)** Write a balanced equation for the reaction of magnesium nitride with water. What is the driving force for this reaction? **(c)** In an experiment, a piece of magnesium ribbon is burned in air in a crucible. The mass of the mixture of MgO and magnesium nitride after burning is 0.470 g. Water is added to the

crucible, further reaction occurs, and the crucible is heated to dryness until the final product is 0.486 g of MgO. What was the mass percentage of magnesium nitride in the mixture obtained after the initial burning? **(d)** Magnesium nitride can also be formed by reaction of the metal with ammonia at high temperature. Write a balanced equation for this reaction. If a 6.3-g Mg ribbon reacts with 2.57 g  $\text{NH}_3(\text{g})$  and the reaction goes to completion, which component is the limiting reactant? What mass of  $\text{H}_2(\text{g})$  is formed in the reaction? **(e)** The standard enthalpy of formation of solid magnesium nitride is  $-461.08 \text{ kJ/mol}$ . Calculate the standard enthalpy change for the reaction between magnesium metal and ammonia gas.

- 7.114** **(a)** The measured Bi—Br bond length in bismuth tribromide,  $\text{BiBr}_3$ , is 2.63 Å. Based on this value and the data in Figure 7.8, predict the atomic radius of Bi. **(b)** Bismuth tribromide is soluble in acidic solution. It is formed by treating solid bismuth(III) oxide with aqueous hydrobromic acid. Write a balanced chemical equation for this reaction. **(c)** While bismuth(III) oxide is soluble in acidic solutions, it is insoluble in basic solutions such as  $\text{NaOH}(\text{aq})$ . Based on these properties, is bismuth characterized as a metallic, metalloid, or nonmetallic element? **(d)** Treating bismuth with fluorine gas forms  $\text{BiF}_3$ . Use the electron configuration of Bi to explain the formation of a compound with this formulation. **(e)** While it is possible to form  $\text{BiF}_3$  in the manner just described, pentahalides of bismuth are not known for the other halogens. Explain why the pentahalide might form with fluorine but not with the other halogens. How does the behavior of bismuth relate to the fact that xenon reacts with fluorine to form compounds but not with the other halogens?

- 7.115** Potassium superoxide,  $\text{KO}_2$ , is often used in oxygen masks (such as those used by firefighters) because  $\text{KO}_2$  reacts with  $\text{CO}_2$  to release molecular oxygen. Experiments indicate that 2 mol of  $\text{KO}_2(\text{s})$  react with each mole of  $\text{CO}_2(\text{g})$ . **(a)** The products of the reaction are  $\text{K}_2\text{CO}_3(\text{s})$  and  $\text{O}_2(\text{g})$ . Write a balanced equation for the reaction between  $\text{KO}_2(\text{s})$  and  $\text{CO}_2(\text{g})$ . **(b)** Indicate the oxidation number for each atom involved in the reaction in part (a). What elements are being oxidized and reduced? **(c)** What mass of  $\text{KO}_2(\text{s})$  is needed to consume 18.0 g  $\text{CO}_2(\text{g})$ ? What mass of  $\text{O}_2(\text{g})$  is produced during this reaction?

## Design an Experiment

In this chapter we have seen that the reaction of potassium metal with oxygen leads to a product that we might not expect, namely, potassium superoxide,  $\text{KO}_2(\text{s})$ . Let's design some experiments to learn more about this unusual product.

**(a)** One of your team members proposes that the capacity to form a superoxide such as  $\text{KO}_2$  is related to a low value for the first ionization energy. How would you go about testing this hypothesis for the metals of group 1A? What other periodic property of the alkali metals might be considered as a factor favoring superoxide formation?

**(b)**  $\text{KO}_2(\text{s})$  is the active ingredient in many breathing masks used by firefighters because it can be used as a source of  $\text{O}_2(\text{g})$ . In principle,  $\text{KO}_2(\text{s})$  can react with both major components of human

breath,  $\text{H}_2\text{O}(\text{g})$  and  $\text{CO}_2(\text{g})$ , to produce  $\text{O}_2(\text{g})$  and other products (all of which follow the expected patterns of reactivity we have seen). Predict the other products in these reactions and design experiments to determine whether  $\text{KO}_2(\text{s})$  does actually react with both  $\text{H}_2\text{O}(\text{g})$  and  $\text{CO}_2(\text{g})$ .

**(c)** Propose an experiment to determine whether either of the reactions in part (b) is more important in the operation of a firefighter's breathing mask.

**(d)** The reaction of  $\text{K}(\text{s})$  and  $\text{O}_2(\text{g})$  leads to a mixture of  $\text{KO}_2(\text{s})$  and  $\text{K}_2\text{O}(\text{s})$ . Use ideas presented in this exercise to design an experiment to determine the percentages of  $\text{KO}_2(\text{s})$  and  $\text{K}_2\text{O}(\text{s})$  in the product mixture that results from the reaction of  $\text{K}(\text{s})$  with excess  $\text{O}_2(\text{g})$ .

8

# BASIC CONCEPTS OF CHEMICAL BONDING

Whenever two atoms or ions are strongly held together, we say there is a **chemical bond** between them. There are three general types of chemical bonds: *ionic*, *covalent*, and *metallic*. These three types of bonds are in the substances illustrated in **Figure 8.1**: We add table salt to water using a stainless steel spoon.

Table salt is sodium chloride, NaCl, which consists of sodium ions, Na<sup>+</sup>, and chloride ions, Cl<sup>-</sup>. The structure is held together by **ionic bonds**, which are due to the electrostatic attractions between oppositely charged ions. The water consists mainly of H<sub>2</sub>O molecules. The hydrogen and oxygen atoms are bonded to one another through **covalent bonds**, in which molecules are formed by the sharing of electrons between atoms. The spoon consists mainly of iron metal, in which Fe atoms are connected to one another by **metallic bonds**, which are formed by electrons that are relatively free to move from one atom to another. These different substances—NaCl, H<sub>2</sub>O, and Fe metal—behave as they do because of the ways in which their constituent atoms are connected to one another. For example, NaCl readily dissolves in water, but Fe metal does not.

What determines the type of bonding in any substance? How do the characteristics of these bonds give rise to different physical and chemical properties? The keys to answering the first question are found in the electronic structure of the atoms involved, as discussed in Chapters 6 and 7. In this chapter and the next, we examine the relationship between the electronic structure of atoms and the ionic and covalent chemical bonds they form. We will discuss metallic bonding in Chapter 12.

◀ **GIANT CRYSTALS.** These gypsum crystals, large enough for people to walk on, are composed of CaSO<sub>4</sub>·2H<sub>2</sub>O. The ionic bonding between calcium and sulfate ions at the atomic scale leads to the characteristic crystal shape at the human scale.

## WHAT'S AHEAD

- 8.1 ▶ Lewis Symbols and the Octet Rule** Learn about the three main types of chemical bonds: *ionic*, *covalent*, and *metallic*. In evaluating bonding, *Lewis symbols* provide a useful shorthand for keeping track of valence electrons. We learn that atoms usually follow the *octet rule*.
- 8.2 ▶ Ionic Bonding** Explore ionic substances, substances in which atoms are held together by the electrostatic attractions between ions of opposite charge. Analyze the energetics of forming ionic substances and describe the *lattice energy* of these substances.
- 8.3 ▶ Covalent Bonding** Examine the bonding in molecular substances, in which atoms bond by sharing one or more electron pairs. In general, the electrons are shared in such a way that each atom attains an octet of electrons.
- 8.4 ▶ Bond Polarity and Electronegativity** Learn that *electronegativity* is the ability of an atom in a compound to attract electrons to itself. In general, electron pairs are shared unequally between atoms with different electronegativities, leading to *polar covalent bonds*.
- 8.5 ▶ Drawing Lewis Structures** Learn that *Lewis structures* are a simple yet powerful way of predicting covalent bonding patterns in molecules. In addition to the octet rule, see how the concept of *formal charge* can be used to identify the dominant Lewis structure.
- 8.6 ▶ Resonance Structures** Learn that in some cases, more than one equivalent Lewis structure can be drawn for a molecule or polyatomic ion. The bonding description in such cases is a blend of two or more *resonance structures*.
- 8.7 ▶ Exceptions to the Octet Rule** Recognize that the octet rule is more of a guideline than an absolute rule. Exceptions to the rule include molecules with an odd number of electrons, molecules where large differences in electronegativity prevent an atom from completing its octet, and molecules where an element from period 3 or below in the periodic table attains more than an octet of electrons.
- 8.8 ▶ Strengths and Lengths of Covalent Bonds** Observe that bond strengths and lengths vary with the number of shared electron pairs as well as other factors.

## 8.1 | Lewis Symbols and the Octet Rule

### Go Figure

If the white powder were sugar,  $C_{12}H_{22}O_{11}$ , how would we have to change this picture?

▲ **Figure 8.1** Ionic, covalent, and metallic bonds. The three different substances shown here are held together by different types of chemical bonds.

The electrons involved in chemical bonding are the *valence electrons*, which, for most atoms, are those in the outermost occupied shell. ∞ (Section 6.8) The American chemist G. N. Lewis (1875–1946) suggested a simple way of showing the valence electrons in an atom and tracking them during bond formation, using what are now known as either *Lewis electron-dot symbols* or simply Lewis symbols.

The **Lewis symbol** for an element consists of the element’s chemical symbol plus a dot for each valence electron. Sulfur, for example, has the electron configuration  $[Ne]3s^23p^4$  and therefore six valence electrons. Its Lewis symbol is

The dots are placed on the four sides of the symbol—top, bottom, left, and right—and each side can accommodate up to two electrons. All four sides are equivalent, which means that the choice of sides for placement of two electrons rather than one electron is arbitrary. In general, we spread out the dots as much as possible. In the Lewis symbol for S, for instance, we prefer the dot arrangement shown rather than the arrangement having two electrons on three of the sides and none on the fourth.

The electron configurations and Lewis symbols for the main-group elements of periods 2 and 3 are shown in **Figure 8.2**. Notice that the number of valence electrons in any representative element is the same as the element’s group number. For example, the Lewis symbols for oxygen and sulfur, members of group 6A, both show six dots.

### Give It Some Thought

Are all these Lewis symbols for Cl correct?

### The Octet Rule

Atoms often gain, lose, or share electrons to achieve the same number of electrons as the noble gas closest to them in the periodic table. The noble gases have very stable electron arrangements, as evidenced by their high ionization energies, low affinity for additional electrons, and general lack of chemical reactivity. ∞ (Section 7.8) Because all the noble gases except He have eight valence electrons, many atoms undergoing reactions end up with eight valence electrons. This observation has led to a guideline known as the **octet rule**: *Atoms tend to gain, lose, or share electrons until they are surrounded by eight valence electrons.*

An octet of electrons consists of full *s* and *p* subshells in an atom. In a Lewis symbol, an octet is shown as four pairs of valence electrons arranged around the element symbol, as in the Lewis symbols for Ne and Ar in Figure 8.2. There are exceptions to the octet rule, as we will see in Section 8.7, but it provides a useful framework for introducing many

| Group                  | 1A         | 2A         | 3A             | 4A             | 5A             | 6A             | 7A             | 8A             |

|                        | $[Ne]3s^1$ | $[Ne]3s^2$ | $[Ne]3s^23p^1$ | $[Ne]3s^23p^2$ | $[Ne]3s^23p^3$ | $[Ne]3s^23p^4$ | $[Ne]3s^23p^5$ | $[Ne]3s^23p^6$ |
|                        | Na·        | ·Mg·       | ·Al·           | ·Si·           | ·P·            | ·S·            | ·Cl·           | ·Ar·           |

▲ **Figure 8.2** Lewis symbols.

important concepts of bonding. The octet rule mostly applies to atoms that have *s* and *p* valence electrons; compounds of the transition metals, having valence *d* electrons, will be examined in Chapter 23.

## 8.2 | Ionic Bonding

Ionic substances generally result from the interaction of metals on the left side of the periodic table with nonmetals on the right side (excluding the noble gases, group 8A). For example, when sodium metal, Na(s), is brought into contact with chlorine gas, Cl<sub>2</sub>(g), a violent reaction ensues (Figure 8.3). The product of this very exothermic reaction is sodium chloride, NaCl(s):

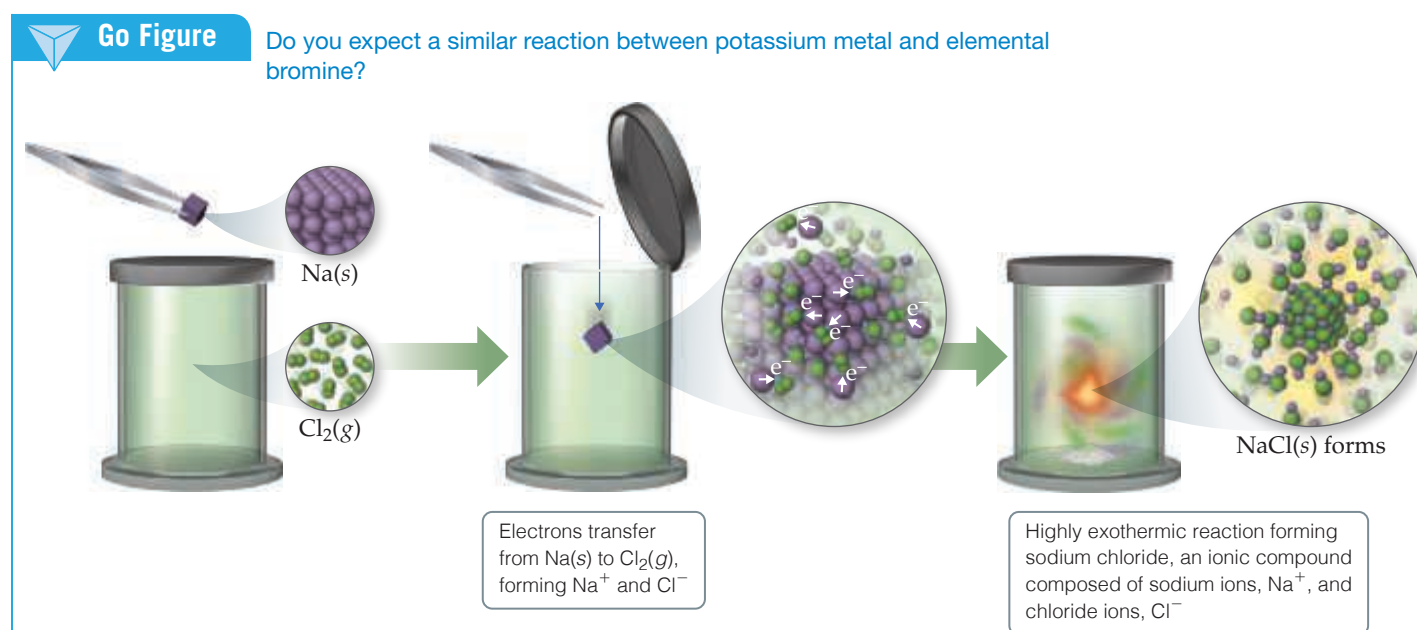

Sodium chloride is composed of Na<sup>+</sup> and Cl<sup>−</sup> ions arranged in a three-dimensional array (Figure 8.4).

The formation of Na<sup>+</sup> from Na and Cl<sup>−</sup> from Cl<sub>2</sub> indicates that an electron has been lost by a sodium atom and gained by a chlorine atom—we say there has been an *electron transfer* from the Na atom to the Cl atom. Two of the atomic properties discussed in Chapter 7 give us an indication of how readily electron transfer occurs: ionization energy, which indicates how easily an electron can be removed from an atom; and electron affinity, which measures how much an atom wants to gain an electron. (Sections 7.4 and 7.5) Electron transfer to form oppositely charged ions occurs when one atom readily gives up an electron (low ionization energy) and another atom readily gains an electron (high electron affinity). Thus, NaCl is a typical ionic compound because it consists of a metal of low ionization energy and a nonmetal of high electron affinity. Using Lewis electron-dot symbols (and showing a chlorine atom rather than the Cl<sub>2</sub> molecule), we can represent this reaction as

The arrow indicates the transfer of an electron from the Na atom to the Cl atom. Each ion has an octet of electrons, the Na<sup>+</sup> octet being the 2s<sup>2</sup>2p<sup>6</sup> electrons that lie below the single 3s valence electron of the Na atom. We have put a bracket around the chloride ion to emphasize that all eight electrons are located on it.

▲ Figure 8.3 Reaction of sodium metal with chlorine gas to form the ionic compound sodium chloride.

### Go Figure

If no color key were provided, how would you know which color ball represented  $\text{Na}^+$  and which represented  $\text{Cl}^-$ ?

▲ **Figure 8.4** The crystal structure of sodium chloride.

Ionic substances possess several characteristic properties. They are usually brittle substances with high melting points. They are usually crystalline. Furthermore, ionic crystals often can be cleaved; that is, they break apart along smooth, flat surfaces. These characteristics result from electrostatic forces that maintain the ions in a rigid, well-defined, three-dimensional arrangement such as that shown in Figure 8.4.

## Energetics of Ionic Bond Formation

The formation of sodium chloride from sodium and chlorine is *very* exothermic, as indicated by the large negative enthalpy of formation value given in Equation 8.1,  $\Delta H_f^\circ = -410.9 \text{ kJ}$ . Appendix C shows that the heat of formation of other ionic substances is also quite negative. What factors make the formation of ionic compounds so exothermic?

In Equation 8.2, we represented the formation of NaCl as the transfer of an electron from Na to Cl. Recall from Section 7.4 that the loss of electrons from an atom is always an endothermic process. Removing an electron from  $\text{Na(g)}$  to form  $\text{Na}^+(\text{g})$  for instance, requires  $496 \text{ kJ/mol}$ . Recall from Section 7.5 that when a nonmetal gains an electron, the process is generally exothermic, as seen from the negative electron affinities of the elements. Adding an electron to  $\text{Cl(g)}$ , for example, releases  $349 \text{ kJ/mol}$ . From the magnitudes of these energies, we can see that the transfer of an electron from an Na atom to a Cl atom would not be exothermic—the overall process would be an endothermic process that requires  $496 - 349 = 147 \text{ kJ/mol}$ . This endothermic process corresponds to the formation of sodium and chloride ions that are infinitely far apart—in other words, the positive energy change assumes that the ions do not interact with each other, which is quite different from the situation in ionic solids.

The principal reason ionic compounds are stable is the attraction between ions of opposite charge. This attraction draws the ions together, releasing energy and causing many ions to form a solid array, or lattice, such as that shown in Figure 8.4. A measure of how much stabilization results from arranging oppositely charged ions in an ionic solid is given by the **lattice energy**, which is *the energy required to completely separate one mole of a solid ionic compound into its gaseous ions*.

To envision this process for NaCl, imagine that the structure in Figure 8.4 expands from within, so that the distances between the ions increase until the ions are very far apart. This process requires  $788 \text{ kJ/mol}$ , which is the value of the lattice energy:

Notice that this process is highly endothermic. The reverse process—the coming together of  $\text{Na}^+(\text{g})$  and  $\text{Cl}^-(\text{g})$  to form  $\text{NaCl(s)}$ —is therefore highly exothermic ( $\Delta H = -788 \text{ kJ/mol}$ ).

**Table 8.1** lists the lattice energies for a number of ionic compounds. The large positive values indicate that the ions are strongly attracted to one another in ionic solids.

**TABLE 8.1** Lattice Energies for Some Ionic Compounds

| Compound | Lattice Energy (kJ/mol) | Compound          | Lattice Energy (kJ/mol) |
|----------|-------------------------|-------------------|-------------------------|
| LiF      | 1030                    | MgCl <sub>2</sub> | 2526                    |
| LiCl     | 834                     | SrCl <sub>2</sub> | 2127                    |
| LiI      | 730                     |                   |                         |
| NaF      | 910                     | MgO               | 3795                    |
| NaCl     | 788                     | CaO               | 3414                    |
| NaBr     | 732                     | SrO               | 3217                    |
| NaI      | 682                     |                   |                         |
| KF       | 808                     | ScN               | 7547                    |
| KCl      | 701                     |                   |                         |
| KBr      | 671                     |                   |                         |
| CsCl     | 657                     |                   |                         |
| CsI      | 600                     |                   |                         |

The energy released by the attraction between ions of unlike charge more than makes up for the endothermic nature of ionization energies, making the formation of ionic compounds an exothermic process. The strong attractions also cause most ionic materials to be hard and brittle with high melting points—for example, NaCl melts at 801 °C.

### Give It Some Thought

If you were to perform the reaction  $\text{KCl(s)} \longrightarrow \text{K}^{\text{+}}(\text{g}) + \text{Cl}^{\text{−}}(\text{g})$ , would energy be released?

The magnitude of the lattice energy of an ionic solid depends on the charges of the ions, their sizes, and their arrangement in the solid. We saw in Section 5.1 that the electrostatic potential energy of two interacting charged particles is given by

$$E_{\text{el}} = \frac{\kappa Q_1 Q_2}{d} \quad [8.4]$$

In this equation  $Q_1$  and  $Q_2$  are the charges on the particles in Coulombs, with their signs;  $d$  is the distance between their centers in meters; and  $\kappa$  is a constant,  $8.99 \times 10^9 \text{ J}\cdot\text{m}/\text{C}^2$ . Equation 8.4 indicates that the attractive interaction between two oppositely charged ions increases as the magnitudes of their charges increase and as the distance between their centers decreases. Thus, *for a given arrangement of ions, the lattice energy increases as the charges on the ions increase and as their radii decrease*. The variation in the magnitude of lattice energies depends more on ionic charge than on ionic radius because ionic radii vary over only a limited range compared to charges.

### Sample Exercise 8.1

#### Magnitudes of Lattice Energies

Without consulting Table 8.1, arrange the ionic compounds NaF, CsI, and CaO in order of increasing lattice energy.

#### SOLUTION

**Analyze** From the formulas for three ionic compounds, we must determine their relative lattice energies.

**Plan** We need to determine the charges and relative sizes of the ions in the compounds. We then use Equation 8.4 qualitatively to determine the relative energies, knowing that **(a)** the larger the ionic charges, the greater the energy and **(b)** the farther apart the ions are, the lower the energy.

**Solve** NaF consists of  $\text{Na}^+$  and  $\text{F}^-$  ions, CsI of  $\text{Cs}^+$  and  $\text{I}^-$  ions, and CaO of  $\text{Ca}^{2+}$  and  $\text{O}^{2-}$  ions. Because the product  $Q_1 Q_2$  appears in the numerator of Equation 8.4, the lattice energy increases dramatically when the charges increase. Thus, we expect the lattice energy of CaO, which has 2+ and 2− ions, to be the greatest of the three.

The ionic charges are the same in NaF and CsI. The difference in their lattice energies thus depends on the difference in the distance between ions in the lattice. Because ionic size increases as we go down a group in the periodic table  $\infty$  (Section 7.3), we know

that  $\text{Cs}^+$  is larger than  $\text{Na}^+$  and  $\text{I}^-$  is larger than  $\text{F}^-$ . Therefore, the distance between  $\text{Na}^+$  and  $\text{F}^-$  ions in NaF is less than the distance between the  $\text{Cs}^+$  and  $\text{I}^-$  ions in CsI. As a result, the lattice energy of NaF should be greater than that of CsI. In order of increasing energy, therefore, we have  $\text{CsI} < \text{NaF} < \text{CaO}$ .

**Check** Table 8.1 confirms our predicted order is correct.

#### Practice Exercise 1

Without looking at Table 8.1, predict which one of the following orderings of lattice energy is correct for these ionic compounds.

- (a)**  $\text{NaCl} > \text{MgO} > \text{CsI} > \text{ScN}$  **(b)**  $\text{ScN} > \text{MgO} > \text{NaCl} > \text{CsI}$   
**(c)**  $\text{NaCl} > \text{CsI} > \text{ScN} > \text{CaO}$  **(d)**  $\text{MgO} > \text{NaCl} > \text{ScN} > \text{CsI}$   
**(e)**  $\text{ScN} > \text{CsI} > \text{NaCl} > \text{MgO}$

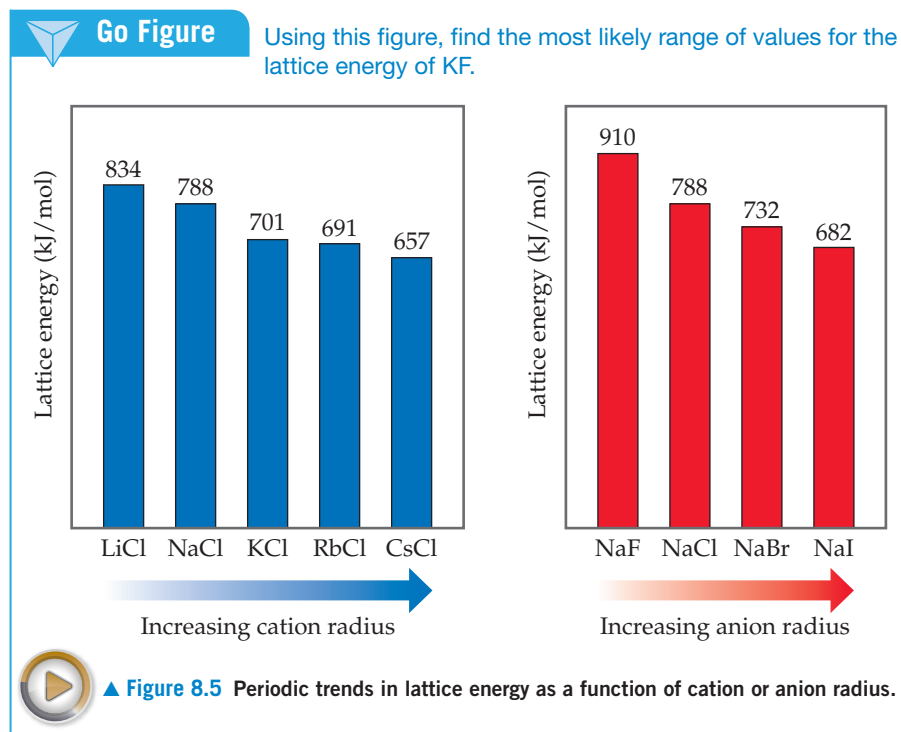

#### Practice Exercise 2

Which substance do you expect to have the greatest lattice energy:  $\text{MgF}_2$ ,  $\text{CaF}_2$ , or  $\text{ZrO}_2$ ?

Because lattice energy decreases as distance between ions increases, lattice energies follow trends that parallel those in ionic radius shown in Figure 7.8. In particular, because ionic radius increases as we go down a group of the periodic table, we find that, for a

given type of ionic compound, lattice energy decreases as we go down a group. **Figure 8.5** illustrates this trend for the alkali chlorides MCl (M = Li, Na, K, Rb, Cs) and the sodium halides NaX (X = F, Cl, Br, I).

## Electron Configurations of Ions of the s- and p-Block Elements

The energetics of ionic bond formation helps explain why many ions tend to have noble-gas electron configurations. For example, sodium readily loses one electron to form  $\text{Na}^+$ , which has the same electron configuration as Ne:

Even though lattice energy increases with increasing ionic charge, we never find ionic compounds that contain  $\text{Na}^{2+}$  ions. The second electron removed would have to come from an inner shell of the sodium atom, and removing electrons from an inner shell requires a very large amount of energy. [∞ \(Section 7.4\)](#) The increase in lattice energy is not enough to compensate for the energy needed to remove an inner-shell electron. Thus, sodium and the other group 1A metals are found in ionic substances only as 1+ ions.

Similarly, adding electrons to nonmetals is either exothermic or only slightly endothermic as long as the electrons are added to the valence shell. Thus, a Cl atom easily adds an electron to form  $\text{Cl}^-$ , which has the same electron configuration as Ar:

To form a  $\text{Cl}^{2-}$  ion, the second electron would have to be added to the next higher shell of the Cl atom, an addition that is energetically very unfavorable. Therefore, we never observe  $\text{Cl}^{2-}$  ions in ionic compounds. We thus expect ionic compounds of the representative metals from groups 1A, 2A, and 3A to contain 1+, 2+, and 3+ cations, respectively, and we usually expect ionic compounds of the representative nonmetals of groups 5A, 6A, and 7A to contain 3−, 2−, and 1− anions, respectively.

## A CLOSER LOOK Calculation of Lattice Energies: The Born–Haber Cycle

Lattice energies cannot be determined directly by experiment. They can, however, be calculated by envisioning the formation of an ionic compound as occurring in a series of well-defined steps. We can then use Hess's law (Section 5.6) to combine the steps in a way that gives the lattice energy for the compound. By so doing, we construct a **Born–Haber cycle**, a thermochemical cycle named after the German scientists Max Born (1882–1970) and Fritz Haber (1868–1934), who introduced it to analyze the factors contributing to the stability of ionic compounds.

Let's use NaCl as an example. In Equation 8.3, which defines lattice energy, NaCl(s) is the reactant, and the gas-phase ions Na<sup>+</sup>(g) and Cl<sup>−</sup>(g) are the products. This equation is our target as we apply Hess's Law.

In seeking a set of other equations that can be added up to give our target equation, we can use the heat of formation for NaCl (Section 5.7):

Of course, we will have to turn this equation around so that we have NaCl(s) as the reactant as we do in the equation for the lattice energy. We can use two other equations to arrive at our target, as shown below:

Step 2 involves the formation of sodium ion from solid sodium, which is just the heat of formation for sodium gas and the first ionization energy for sodium (Appendix C and Figure 7.10 list numbers for these processes):

The sum of these two processes gives us the required energy for Step 2 (above), which is 604 kJ.

Similarly, for Step 3, we have to create chlorine atoms, and then anions, from the Cl<sub>2</sub> molecule, in two steps. The enthalpy changes for these two steps are the sum of the enthalpy of formation of Cl(g) and the electron affinity of chlorine, EA(Cl):

The sum of these two processes gives us the required energy for Step 3 (above), which is −227 kJ.

Finally, when we put it all together, we have:

This process is described as a “cycle” because it corresponds to the scheme in Figure 8.6, which shows how all the quantities we have just calculated are related. The sum of all the blue “up” arrow energies has to be equal to the sum of all the red “down” arrow energies in this cycle. Born and Haber recognized that if we know the value of every quantity in the cycle except the lattice energy, we can calculate it from this cycle.

**Related Exercises: 8.28–8.30, 8.83**

▲ **Figure 8.6** Born–Haber cycle for formation of NaCl. This Hess's law representation shows the energetic relationships in the formation of the ionic solid from its elements.

## Transition Metal Ions

Because ionization energies increase rapidly for each successive electron removed, the lattice energies of ionic compounds are generally large enough to compensate for the loss of up to only three electrons from atoms. Thus, we find cations with charges of 1+, 2+, or 3+ in ionic compounds. Most transition metals, however, have more than three electrons beyond a noble-gas core. Silver, for example, has a [Kr]4d<sup>10</sup>5s<sup>1</sup> electron configuration. Metals of group 1B (Cu, Ag, Au) often occur as 1+ ions (as in CuBr and AgCl). In forming Ag<sup>+</sup>, the 5s electron is lost, leaving a completely filled 4d subshell. As in this example, transition metals generally do not form ions that have a noble-gas configuration. The octet rule, although useful, is clearly limited in scope.

## Sample Exercise 8.2

## Charges on Ions

Predict the ion generally formed by (a) Sr, (b) S, (c) Al.

## SOLUTION

**Analyze** We must decide how many electrons are most likely to be gained or lost by atoms of Sr, S, and Al.

**Plan** In each case, we can use the element's position in the periodic table to predict whether the element forms a cation or an anion. We can then use its electron configuration to determine the most likely ion formed.

**Solve**

- (a) Strontium is a metal in group 2A and therefore forms a cation. Its electron configuration is  $[\text{Kr}]5s^2$ , and so we expect that the two valence electrons will be lost to give an  $\text{Sr}^{2+}$  ion.
- (b) Sulfur is a nonmetal in group 6A and will thus tend to be found as an anion. Its electron configuration ( $[\text{Ne}]3s^23p^4$ )

is two electrons short of a noble-gas configuration. Thus, we expect that sulfur will form  $\text{S}^{2-}$  ions.

- (c) Aluminum is a metal in group 3A. We therefore expect it to form  $\text{Al}^{3+}$  ions.

**Check** The ionic charges we predict here are confirmed in Tables 2.4 and 2.5.

## ► Practice Exercise 1

Which of these elements is most likely to form ions with a 2+ charge?

- (a) Li (b) Ca (c) O (d) P (e) Cl

## ► Practice Exercise 2

Predict the charges on the ions formed when magnesium reacts with nitrogen.

Recall from Section 7.4 that when a positive ion forms from an atom, electrons are always lost first from the subshell having the largest value of  $n$ . Thus, *in forming ions, transition metals lose the valence-shell s electrons first, then as many d electrons as required to reach the charge of the ion*. For instance, in forming  $\text{Fe}^{2+}$  from Fe, which has the electron configuration  $[\text{Ar}]3d^64s^2$ , the two 4s electrons are lost, leading to an  $[\text{Ar}]3d^6$  configuration. Removal of an additional electron gives  $\text{Fe}^{3+}$ , whose electron configuration is  $[\text{Ar}]3d^5$ .

## Give It Some Thought

Which element forms a 3+ ion that has the electron configuration  $[\text{Kr}]4d^6$ ?

## 8.3 | Covalent Bonding

The vast majority of chemical substances do not have the characteristics of ionic materials. Most of the substances with which we come into daily contact—such as water—tend to be gases, liquids, or solids with low melting points. Many, such as gasoline, vaporize readily. Many are pliable in their solid forms—for example, plastic bags and wax.

For the very large class of substances that do not behave like ionic substances, we need a different model to describe the bonding between atoms. G. N. Lewis reasoned that atoms might acquire a noble-gas electron configuration by sharing electrons with other atoms. A chemical bond formed by sharing a pair of electrons is a *covalent bond*.

The hydrogen molecule,  $\text{H}_2$ , provides the simplest example of a covalent bond. When two hydrogen atoms are close to each other, the two positively charged nuclei repel each other, the two negatively charged electrons repel each other, and the nuclei and electrons attract each other, as shown in Figure 8.7(a). Because the molecule is stable, we know that the attractive forces must overcome the repulsive ones. Let's take a closer look at the attractive forces that hold this molecule together.

By using quantum mechanical methods analogous to those used for atoms in Section 6.5, we can calculate the distribution of electron density in molecules. Such a calculation for  $\text{H}_2$  shows that the attractions between the nuclei and the electrons cause electron density to concentrate between the nuclei, as shown in Figure 8.7(b). As a result, the overall electrostatic interactions are attractive. Thus, the atoms in  $\text{H}_2$  are held together principally because the two positive nuclei are attracted to the concentration of negative charge between them. In essence, the shared pair of electrons in any covalent bond acts as a kind of “glue” to bind atoms together.

### Give It Some Thought

Ionizing an  $\text{H}_2$  molecule to  $\text{H}_2^+$  changes the strength of the bond. Based on the description of covalent bonding given previously, do you expect the  $\text{H}-\text{H}$  bond in  $\text{H}_2^+$  to be weaker or stronger than the  $\text{H}-\text{H}$  bond in  $\text{H}_2$ ?

## Lewis Structures

The formation of covalent bonds can be represented with Lewis symbols. The formation of the  $\text{H}_2$  molecule from two H atoms, for example, can be represented as

In forming the covalent bond, each hydrogen atom acquires a second electron, achieving the stable, two-electron, noble-gas electron configuration of helium.

Formation of a covalent bond between two Cl atoms to give a  $\text{Cl}_2$  molecule can be represented in a similar way:

By sharing the bonding electron pair, each chlorine atom has eight electrons (an octet) in its valence shell, thus achieving the noble-gas electron configuration of argon.

The structures shown here for  $\text{H}_2$  and  $\text{Cl}_2$  are **Lewis structures**, or *Lewis dot structures*. While these structures show circles to indicate electron sharing, the more common convention is to show each shared electron pair or **bonding pair**, as a line and any unshared electron pairs (also called **lone pairs** or **nonbonding pairs**) as dots. Written this way, the Lewis structures for  $\text{H}_2$  and  $\text{Cl}_2$  are

For nonmetals, the number of valence electrons in a neutral atom is the same as the group number. Therefore, one might predict that 7A elements, such as F, would form one covalent bond to achieve an octet; 6A elements, such as O, would form two covalent bonds; 5A elements, such as N, would form three; and 4A elements, such as C, would form four. These predictions are borne out in many compounds, as in, for example, the compounds with hydrogen of the nonmetals of the second row of the periodic table:

### Go Figure

What would happen to the concentration of electron density between the nuclei in (b) if you pulled the nuclei further apart?

▲ **Figure 8.7** The covalent bond in  $\text{H}_2$ . (a) The attractions and repulsions among electrons and nuclei in the hydrogen molecule. (b) Electron distribution in the  $\text{H}_2$  molecule.

### Sample Exercise 8.3

#### Lewis Structure of a Compound

Given the Lewis symbols for nitrogen and fluorine in Figure 8.2, predict the formula of the stable binary compound (a compound composed of two elements) formed when nitrogen reacts with fluorine and draw its Lewis structure.

#### SOLUTION

**Analyze** The Lewis symbols for nitrogen and fluorine reveal that nitrogen has five valence electrons and fluorine has seven.

**Plan** We need to find a combination of the two elements that results in an octet of electrons around each atom. Nitrogen requires three additional electrons to complete its octet, and fluorine requires one. Sharing a pair of electrons between one N atom and one F atom will result in an octet of electrons for fluorine but not for nitrogen. We therefore need to figure out a way to get two more electrons for the N atom.

**Solve** Nitrogen must share a pair of electrons with three fluorine atoms to complete its octet. Thus, the binary compound these two elements form must be  $\text{NF}_3$ :

**Check** The Lewis structure in the center shows that each atom is surrounded by an octet of electrons. Once you are accustomed to thinking of each line in a Lewis structure as representing *two* electrons, you can just as easily use the structure on the right to check for octets.

#### Practice Exercise 1

Which of these molecules has the same number of shared electron pairs as unshared electron pairs?

(a) HCl (b)  $\text{H}_2\text{S}$  (c)  $\text{PF}_3$  (d)  $\text{CCl}_2\text{F}_2$  (e)  $\text{Br}_2$

#### Practice Exercise 2

Compare the Lewis symbol for neon with the Lewis structure for methane,  $\text{CH}_4$ . How many valence electrons are in each structure? How many bonding pairs and how many nonbonding pairs does each structure have?

## Multiple Bonds

A shared electron pair constitutes a single covalent bond, generally referred to simply as a **single bond**. In many molecules, atoms attain complete octets by sharing more than one pair of electrons. When two electron pairs are shared by two atoms, two lines are drawn in the Lewis structure, representing a **double bond**. In carbon dioxide, for example, bonding occurs between carbon, with four valence electrons, and oxygen, with six:

As the diagram shows, each oxygen atom acquires an octet by sharing two electron pairs with carbon. In the case of  $\text{CO}_2$ , carbon acquires an octet by sharing two electron pairs with each of the two oxygen atoms; each double bond involves four electrons.

A **triple bond** corresponds to the sharing of three pairs of electrons, such as in the  $\text{N}_2$  molecule:

Because each nitrogen atom has five valence electrons, three electron pairs must be shared to achieve the octet configuration.

The properties of  $\text{N}_2$  are in complete accord with its Lewis structure. Nitrogen is a diatomic gas with exceptionally low reactivity that results from the very stable nitrogen–nitrogen bond. The nitrogen atoms are separated by only 1.10 Å. The short separation distance between the two N atoms is a result of the triple bond between the atoms. From studies of the structures of many different substances in which nitrogen atoms share one or two electron pairs, we have learned that the

average distance between bonded nitrogen atoms varies with the number of shared electron pairs:

As a general rule, the length of the bond between two atoms decreases as the number of shared electron pairs increases. We will explore this point in greater detail in Section 8.8.

### Give It Some Thought

The C—O bond length in carbon monoxide, CO, is 1.13 Å, whereas the C—O bond length in CO<sub>2</sub> is 1.24 Å. Without drawing a Lewis structure, do you think that CO contains a single, double, or triple bond?

## 8.4 | Bond Polarity and Electronegativity

When two identical atoms bond, as in Cl<sub>2</sub> or H<sub>2</sub>, the electron pairs must be shared equally. When two atoms from opposite sides of the periodic table bond, such as NaCl, there is relatively little sharing of electrons, which means that NaCl is best described as an ionic compound composed of Na<sup>+</sup> and Cl<sup>−</sup> ions. The 3s electron of the Na atom is, in effect, transferred completely to chlorine. The bonds that are found in most substances fall somewhere between these extremes.

**Bond polarity** is a measure of how equally or unequally the electrons in any covalent bond are shared. A **nonpolar covalent bond** is one in which the electrons are shared equally, as in Cl<sub>2</sub> and N<sub>2</sub>. In a **polar covalent bond**, one of the atoms exerts a greater attraction for the bonding electrons than the other. If the difference in relative ability to attract electrons is large enough, an ionic bond is formed.

### Electronegativity

We use a quantity called electronegativity to estimate whether a given bond is nonpolar covalent, polar covalent, or ionic.

**Electronegativity** is defined as the ability of an atom *in a molecule* to attract electrons to itself.

The greater an atom's electronegativity, the greater its ability to attract electrons to itself. The electronegativity of an atom in a molecule is related to the atom's ionization energy and electron affinity, which are properties of isolated atoms. An atom with a very negative electron affinity and a high ionization energy both attracts electrons from other atoms and resists having its electrons attracted away; therefore, it is highly electronegative.

Electronegativity values can be based on a variety of properties, not just ionization energy and electron affinity. The American chemist Linus Pauling (1901–1994) developed the first and most widely used electronegativity scale, which is based on thermochemical data. As [Figure 8.8](#) shows, there is generally an increase in electronegativity from left to right across a period—that is, from the most metallic to the most nonmetallic elements. With some exceptions (especially in the transition metals), electronegativity decreases with increasing atomic number in a group. This is what we expect because we know that ionization energies decrease with increasing atomic number in a group and electron affinities do not change very much.

You do not need to memorize electronegativity values. Instead, you should know the periodic trends so that you can predict which of two elements is more electronegative.

### Give It Some Thought

How does the *electronegativity* of an element differ from its *electron affinity*?

## Electronegativity and Bond Polarity

We can use the difference in electronegativity between two atoms to gauge the polarity of the bond the atoms form. Consider these three fluorine-containing compounds:

|                              | $F_2$             | HF                | LiF               |
|------------------------------|-------------------|-------------------|-------------------|
| Electronegativity difference | $4.0 - 4.0 = 0$   | $4.0 - 2.1 = 1.9$ | $4.0 - 1.0 = 3.0$ |
| Type of bond                 | Nonpolar covalent | Polar covalent    | Ionic             |

In  $F_2$  the electrons are shared equally between the fluorine atoms and, thus, the covalent bond is *nonpolar*. A nonpolar covalent bond results when the electronegativities of the bonded atoms are equal.

In HF the fluorine atom has a greater electronegativity than the hydrogen atom, with the result that the electrons are shared unequally—the bond is *polar*. In general, a polar covalent bond results when the atoms differ in electronegativity. In HF the more electronegative fluorine atom attracts electron density away from the less electronegative hydrogen atom, leaving a partial positive charge on the hydrogen atom and a partial negative charge on the fluorine atom. We can represent this charge distribution as

The  $\delta+$  and  $\delta-$  (read “delta plus” and “delta minus”) symbolize the partial positive and negative charges, respectively. In a polar bond, these numbers are less than the full charges of the ions.

In LiF the electronegativity difference is very large, meaning that the electron density is shifted far toward F. The resulting bond is therefore most accurately described as *ionic*. Thus, if we considered the bond in LiF to be fully ionic, we could say  $\delta+$  for Li is  $1+$  and  $\delta-$  for F is  $1-$ . If two atoms differ in electronegativity by more than 2.0, many chemists would consider their bond to be an ionic bond.

The shift of electron density toward the more electronegative atom in a bond can be seen from the results of calculations of electron-density distributions. For the three species in our example, the calculated electron-density distributions are shown

◀ **Figure 8.9** Electron-density distribution. This computer-generated rendering shows the calculated electron-density distribution on the surface of the  $F_2$ , HF, and LiF molecules.

in **Figure 8.9**. You can see that in  $F_2$  the distribution is symmetrical, in HF the electron density is clearly shifted toward fluorine, and in LiF the shift is even greater. These examples illustrate, therefore, that *the greater the difference in electronegativity between two atoms, the more polar their bond*.

## Sample Exercise 8.4

### Bond Polarity

In each case, which bond is more polar? (a) B—Cl or C—Cl, (b) P—F or P—Cl. Indicate in each case which atom has the partial negative charge.

### SOLUTION

**Analyze** We are asked to determine relative bond polarities, given nothing but the atoms involved in the bonds.

**Plan** Because we are not asked for quantitative answers, we can use the periodic table and our knowledge of electronegativity trends to answer the question.

### Solve

(a) The chlorine atom is common to both bonds. Therefore, we just need to compare the electronegativities of B and C. Because boron is to the left of carbon in the periodic table, we predict that boron has the lower electronegativity. Chlorine, being on the right side of the table, has high electronegativity. The more polar bond will be the one between the atoms with the biggest differences in electronegativity. Consequently, the B—Cl bond is more polar; the chlorine atom carries the partial negative charge because it has a higher electronegativity.

(b) In this example, phosphorus is common to both bonds, and so we just need to compare the electronegativities of F and Cl. Because fluorine is above chlorine in the periodic table, it should be more electronegative and will form the more polar

bond with P. The higher electronegativity of fluorine means that it will carry the partial negative charge.

### Check

- (a) Using Figure 8.8: The difference in the electronegativities of chlorine and boron is  $3.0 - 2.0 = 1.0$ ; the difference between the electronegativities of chlorine and carbon is  $3.0 - 2.5 = 0.5$ . Hence, the B—Cl bond is more polar, as we had predicted.
- (b) Using Figure 8.8: The difference in the electronegativities of chlorine and phosphorus is  $3.0 - 2.1 = 0.9$ ; the difference between the electronegativities of fluorine and phosphorus is  $4.0 - 2.1 = 1.9$ . Hence, the P—F bond is more polar, as we had predicted.

### Practice Exercise 1

Which of the following bonds is the most polar?

- (a) H—F (b) H—I (c) Se—F (d) N—P (e) Ga—Cl

### Practice Exercise 2

Which of the following bonds is most polar: S—Cl, S—Br, Se—Cl, or Se—Br?

## Dipole Moments

The difference in electronegativity between H and F leads to a polar covalent bond in the HF molecule. As a consequence, there is a concentration of negative charge on the more electronegative F atom, leaving the less electronegative H atom at the positive end of the molecule. A molecule such as HF, in which the centers of positive and negative charge do not coincide, is a **polar molecule**. Thus, we describe both bonds and entire molecules as being polar and nonpolar.

We can indicate the polarity of the HF molecule in two ways:

### Go Figure

If the charged particles are moved closer together, does  $\mu$  increase, decrease, or stay the same?

Dipole moment  $\mu = Qr$

▲ **Figure 8.10** Dipole and dipole moment. When charges of equal magnitude and opposite sign  $Q+$  and  $Q-$  are separated by a distance  $r$ , a dipole is produced.

In the notation on the right, the arrow denotes the shift in electron density toward the fluorine atom. The crossed end of the arrow can be thought of as a plus sign designating the positive end of the molecule.

Polarity helps determine many properties we observe at the macroscopic level in the laboratory and in everyday life. Polar molecules align themselves with respect to one another, with the negative end of one molecule and the positive end of another attracting each other. Polar molecules are likewise attracted to ions. The negative end of a polar molecule is attracted to a positive ion, and the positive end is attracted to a negative ion. These interactions account for many properties of liquids, solids, and solutions, as you will see in Chapters 11, 12, and 13. Charge separation within molecules plays an important role in energy conversion processes such as photosynthesis and in solar cells.

How can we quantify the polarity of a molecule? Whenever two electrical charges of equal magnitude but opposite sign are separated by a distance, a **dipole** is established. The quantitative measure of the magnitude of a dipole is called its **dipole moment**, denoted with the Greek letter mu,  $\mu$ . If two equal and opposite charges  $Q+$  and  $Q-$  are separated by a distance  $r$ , as in **Figure 8.10**, the magnitude of the dipole moment is the product of  $Q$  and  $r$ :

$$\mu = Qr \quad [8.10]$$

This expression tells us that the dipole moment increases as the magnitude of  $Q$  increases and as  $r$  increases. The larger the dipole moment, the more polar the bond. For a nonpolar molecule, such as  $F_2$ , the dipole moment is zero because there is no charge separation.

### Give It Some Thought

Chlorine monofluoride, ClF, and iodine monofluoride, IF, are *interhalogen* compounds—compounds that contain bonds between different halogen elements. Which of these molecules has the larger dipole moment?

Dipole moments are experimentally measurable and are usually reported in *debyes* (D), a unit that equals  $3.34 \times 10^{-30}$  coulomb-meters (C·m). For molecules, we usually measure charge in units of the electronic charge  $e$ ,  $1.60 \times 10^{-19}$  C, and distance in angstroms. This means we need to convert units whenever we want to report a dipole moment in debyes. Suppose that two charges  $1+$  and  $1-$  (in units of  $e$ ) are separated by  $1.00 \text{ \AA}$ . The dipole moment produced is

$$\mu = Qr = (1.60 \times 10^{-19} \text{ C})(1.00 \text{ \AA}) \left( \frac{10^{-10} \text{ m}}{1 \text{ \AA}} \right) \left( \frac{1 \text{ D}}{3.34 \times 10^{-30} \text{ C}\cdot\text{m}} \right) = 4.79 \text{ D}$$

Measurement of the dipole moments can provide us with valuable information about the charge distributions in molecules, as illustrated in Sample Exercise 8.5.

### Sample Exercise 8.5

#### Dipole Moments of Diatomic Molecules

The bond length in the HCl molecule is  $1.27 \text{ \AA}$ . (a) Calculate the dipole moment, in debyes, that results if the charges on the H and Cl atoms were  $1+$  and  $1-$  respectively. (b) The experimentally measured dipole moment of HCl(g) is  $1.08 \text{ D}$ . What magnitude of charge, in units of  $e$ , on the H and Cl atoms leads to this dipole moment?

### SOLUTION

**Analyze and Plan** We are asked in part (a) to calculate the dipole moment of HCl that would result if there were a full charge transferred from H to Cl. We can use Equation 8.10 to obtain this result.

In part (b), we are given the actual dipole moment for the molecule and will use that value to calculate the actual partial charges on the H and Cl atoms.

**Solve**

- (a) The charge on each atom is the electronic charge,  $e = 1.60 \times 10^{-19} \text{ C}$ . The separation is  $1.27 \text{ \AA}$ . The dipole moment is therefore:

$$\mu = Qr = (1.60 \times 10^{-19} \text{ C})(1.27 \text{ \AA}) \left( \frac{10^{-10} \text{ m}}{1 \text{ \AA}} \right) \left( \frac{1 \text{ D}}{3.34 \times 10^{-30} \text{ C}\cdot\text{m}} \right) = 6.08 \text{ D}$$

- (b) We know the value of  $\mu$ ,  $1.08 \text{ D}$ , and the value of  $r$ ,  $1.27 \text{ \AA}$ . We want to calculate the value of  $Q$ :

$$Q = \frac{\mu}{r} = \frac{(1.08 \text{ D}) \left( \frac{3.34 \times 10^{-30} \text{ C}\cdot\text{m}}{1 \text{ D}} \right)}{(1.27 \text{ \AA}) \left( \frac{10^{-10} \text{ m}}{1 \text{ \AA}} \right)} = 2.84 \times 10^{-20} \text{ C}$$

We can readily convert this charge to units of  $e$ :

$$\text{Charge in } e = (2.84 \times 10^{-20} \text{ C}) \left( \frac{1e}{1.60 \times 10^{-19} \text{ C}} \right) = 0.178e$$

Thus, the experimental dipole moment indicates that the charge separation in the HCl molecule is:

Because the experimental dipole moment is less than that calculated in part (a), the charges on the atoms are much less than a full electronic charge. We could have anticipated this because the H—Cl bond is polar covalent rather than ionic.

**Practice Exercise 1**

What is the dipole moment for HF (bond length  $0.917 \text{ \AA}$ ), assuming that the bond is completely ionic?

- (a)  $0.917 \text{ D}$  (b)  $1.91 \text{ D}$  (c)  $2.75 \text{ D}$  (d)  $4.39 \text{ D}$  (e)  $7.37 \text{ D}$

**Practice Exercise 2**

The dipole moment of chlorine monofluoride, ClF(g), is  $0.88 \text{ D}$ . The bond length of the molecule is  $1.63 \text{ \AA}$ . (a) Which atom is expected to have the partial negative charge? (b) What is the charge on that atom in units of  $e$ ?

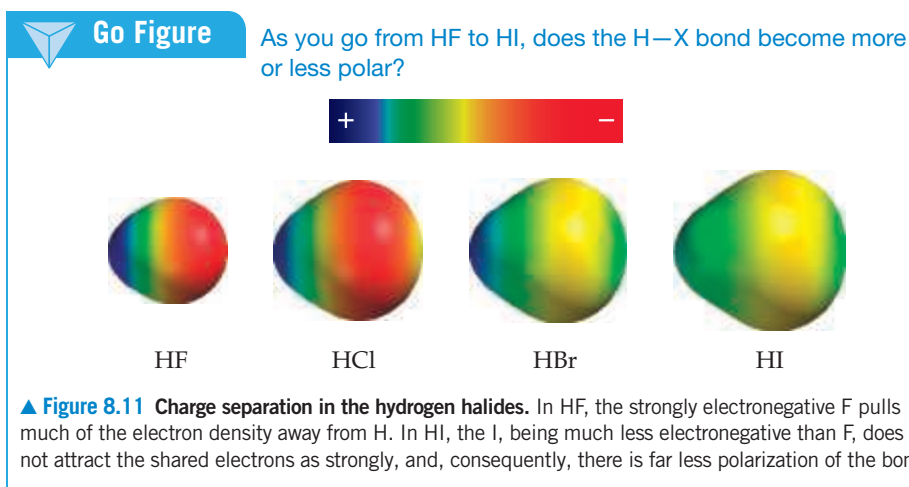

Table 8.2 presents the bond lengths and dipole moments of the hydrogen halides. Notice that as we proceed from HF to HI, the electronegativity difference decreases and the bond length increases. The first effect decreases the amount of charge separated and causes the dipole moment to decrease from HF to HI, even though the bond length is increasing. Calculations identical to those used in Sample Exercise 8.5 show that the charges on the atoms decrease from  $0.41+$  and  $0.41-$  in HF to  $0.057+$  and  $0.057-$  in HI. We can visualize the varying degree of electronic charge shift in these substances from computer-generated renderings based on calculations of electron distribution, as shown in Figure 8.11. For these molecules, the change in the electronegativity difference has a greater effect on the dipole moment than does the change in bond length.

**Give It Some Thought**

The bond between carbon and hydrogen is one of the most important types of bonds in chemistry. The length of an H—C bond is approximately  $1.1 \text{ \AA}$ . Based on this distance and differences in electronegativity, do you expect the dipole moment of an individual H—C bond to be larger or smaller than that of an H—I bond?

**TABLE 8.2 Bond Lengths, Electronegativity Differences, and Dipole Moments of the Hydrogen Halides**

| Compound | Bond Length ( $\text{\AA}$ ) | Electronegativity Difference | Dipole Moment (D) |
|----------|------------------------------|------------------------------|-------------------|
| HF       | 0.92                         | 1.9                          | 1.82              |
| HCl      | 1.27                         | 0.9                          | 1.08              |
| HBr      | 1.41                         | 0.7                          | 0.82              |
| HI       | 1.61                         | 0.4                          | 0.44              |

Before leaving this section, let's return to the LiF molecule in Figure 8.9. Under standard conditions, LiF exists as an ionic solid with an arrangement of atoms analogous to the sodium chloride structure shown in Figure 8.4. However, it is possible to generate LiF *molecules* by vaporizing the ionic solid at high temperature. The molecules have a dipole moment of 6.28 D and a bond distance of 1.53 Å. From these values we can calculate the charge on lithium and fluorine to be 0.857+ and 0.857−, respectively. This bond is extremely polar, and the presence of such large charges strongly favors the formation of an extended ionic lattice in which each lithium ion is surrounded by fluoride ions and vice versa. But even here, the experimentally determined charges on the ions are still not 1+ and 1−. This tells us that even in ionic compounds, there is still some covalent contribution to the bonding.

## Comparing Ionic and Covalent Bonding

To understand the interactions responsible for chemical bonding, it is advantageous to treat ionic and covalent bonding separately. That is the approach taken in this chapter, as well as in most other undergraduate-level chemistry texts. In reality, however, there is a continuum between the extremes of ionic and covalent bonding. This lack of a well-defined separation between the two types of bonding may seem unsettling or confusing at first.

The simple models of ionic and covalent bonding presented in this chapter go a long way toward understanding and predicting the structures and properties of chemical compounds. When covalent bonding is dominant, we expect compounds to exist as molecules,\* having all the properties we associate with molecular substances, such as relatively low melting and boiling points and nonelectrolyte behavior when dissolved in water. When ionic bonding is dominant, we expect the compounds to be brittle, high-melting solids with extended lattice structures, exhibiting strong electrolyte behavior when dissolved in water.

Naturally, there are exceptions to these general characterizations, some of which we examine later in the book. Nonetheless, the ability to quickly categorize the predominant bonding interactions in a substance as covalent or ionic imparts considerable insight into the properties of that substance. The question then becomes the best way to recognize which type of bonding dominates.

The simplest approach is to assume that the interaction between a metal and a nonmetal is ionic and that between two nonmetals is covalent. While this classification scheme is reasonably predictive, there are far too many exceptions to use it blindly. For example, tin is a metal and chlorine is a nonmetal, but SnCl<sub>4</sub> is a molecular substance that exists as a colorless liquid at room temperature. It freezes at −33 °C and boils at 114 °C. The characteristics of SnCl<sub>4</sub> are not those typical of an ionic substance. Is there a more predictable way of determining what type of bonding is prevalent in a compound? A more sophisticated approach is to use the difference in electronegativity as the main criterion for determining whether ionic or covalent bonding will be dominant. This

\* There are some exceptions to this statement, such as network solids, including diamond, silicon, and germanium, where an extended structure is formed even though the bonding is clearly covalent. These substances are discussed in Section 12.7.

approach correctly predicts the bonding in  $\text{SnCl}_4$  to be polar covalent based on an electronegativity difference of 1.2 and at the same time correctly predicts the bonding in  $\text{NaCl}$  to be predominantly ionic based on an electronegativity difference of 2.1.

Evaluating bonding based on electronegativity difference is a useful system, but it has one shortcoming. The electronegativity values given in Figure 8.8 do not take into account changes in bonding that accompany changes in the oxidation state of the metal. For example, Figure 8.8 gives the electronegativity difference between manganese and oxygen as  $3.5 - 1.5 = 2.0$ , which falls in the range where the bonding is normally considered ionic (the electronegativity difference for  $\text{NaCl}$  is  $3.0 - 0.9 = 2.1$ ). Therefore, it is not surprising to learn that manganese(II) oxide,  $\text{MnO}$ , is a green solid that melts at  $1842^\circ\text{C}$  and has the same crystal structure as  $\text{NaCl}$ .

However, the bonding between manganese and oxygen is not always ionic. Manganese(VII) oxide,  $\text{Mn}_2\text{O}_7$ , is a green liquid that freezes at  $5.9^\circ\text{C}$ , an indication that covalent rather than ionic bonding dominates. The change in the oxidation state of manganese is responsible for the change in bonding. In general, as the oxidation state of a metal increases, so does the degree of covalent bonding. When the oxidation state of the metal is highly positive (roughly speaking, +4 or larger), we can expect significant covalency in the bonds it forms with nonmetals. Thus, metals in high oxidation states form molecular substances, such as  $\text{Mn}_2\text{O}_7$ , or polyatomic ions, such as  $\text{MnO}_4^-$  and  $\text{CrO}_4^{2-}$ , rather than ionic compounds.

### Give It Some Thought

You have a yellow solid that melts at  $41^\circ\text{C}$  and boils at  $131^\circ\text{C}$  and a green solid that melts at  $2320^\circ\text{C}$ . If you are told that one of them is  $\text{Cr}_2\text{O}_3$  and the other is  $\text{OsO}_4$ , which one do you expect to be the yellow solid?

## 8.5 | Drawing Lewis Structures

Lewis structures can help us understand the bonding in many compounds and are frequently used when discussing the properties of molecules. For this reason, drawing Lewis structures is an important skill that you should practice.

### How to Draw Lewis Structures

- 1. Sum the valence electrons from all atoms, taking into account overall charge.** Use the periodic table to help you determine the number of valence electrons in each atom. For an anion, add one electron to the total for each negative charge. For a cation, subtract one electron from the total for each positive charge. Do not worry about keeping track of which electrons come from which atoms. Only the total number is important.
- 2. Write the symbols for the atoms, show which atoms are attached to which, and connect them with a single bond (a line, representing two electrons).** Chemical formulas are often written in the order in which the atoms are connected in the molecule or ion. The formula  $\text{HCN}$ , for example, tells you that the carbon atom is bonded to the H and to the N. In many polyatomic molecules and ions, the central atom is usually written first, as in  $\text{CO}_3^{2-}$  and  $\text{SF}_4$ . Remember that the central atom is generally less electronegative than the atoms surrounding it. In other cases, you may need more information before you can draw the Lewis structure.
- 3. Complete the octets around all the atoms bonded to the central atom.** Keep in mind that a hydrogen atom has only a single pair of electrons around it.
- 4. Place any remaining electrons on the central atom, even if doing so results in more than an octet of electrons around the atom.**
- 5. If there are not enough electrons to give the central atom an octet, try multiple bonds.** Use one or more of the unshared pairs of electrons on the atoms bonded to the central atom to form double or triple bonds.

The following examples of this procedure will help you put it into practice.

**Sample Exercise 8.6****Drawing a Lewis Structure**

Draw the Lewis structure for phosphorus trichloride,  $\text{PCl}_3$ .

**SOLUTION**

**Analyze and Plan** We are asked to draw a Lewis structure from a molecular formula. Our plan is to follow the five-step procedure just described.

**Solve** First, we sum the valence electrons. Phosphorus (group 5A) has five valence electrons, and each chlorine (group 7A) has seven. The total number of valence electrons is therefore

$$5 + (3 \times 7) = 26$$

Second, we arrange the atoms to show which atom is connected to which, and we draw a single bond between them. There are various ways the atoms might be arranged. It helps to know, though, that in binary compounds the first element in the chemical formula is generally surrounded by the remaining atoms. So we proceed to draw a skeleton structure in which a single bond connects the P atom to each Cl atom:

(It is not crucial that the Cl atoms be to the left of, right of, and below the P atom—any structure that shows each of the three Cl atoms bonded to P will work.)

Third, we add Lewis electron dots to complete the octets on the atoms bonded to the central atom. Completing the octets around each

Cl atom accounts for 24 electrons (remember, each line in our structure represents *two* electrons):

Fourth, recalling that our total number of electrons is 26, we place the remaining two electrons on the central atom, P, which completes its octet:

This structure gives each atom an octet, so we stop at this point. (In checking for octets, remember to count a single bond as two electrons.)

**Practice Exercise 1**

Which of these molecules has a Lewis structure with a central atom having no nonbonding electron pairs?

(a)  $\text{CO}_2$  (b)  $\text{H}_2\text{S}$  (c)  $\text{PF}_3$  (d)  $\text{SiF}_4$  (e) more than one of a, b, c, d

**Practice Exercise 2**

(a) How many valence electrons should appear in the Lewis structure for  $\text{CH}_2\text{Cl}_2$ ?  
(b) Draw the Lewis structure.

**Sample Exercise 8.7****Lewis Structure with a Multiple Bond**

Draw the Lewis structure for HCN.

**SOLUTION**

Hydrogen has one valence electron, carbon (group 4A) has four, and nitrogen (group 5A) has five. The total number of valence electrons is, therefore,  $1 + 4 + 5 = 10$ . In principle, there are different ways in which we might choose to arrange the atoms. Because hydrogen can accommodate only one electron pair, it always has only one single bond associated with it. Therefore,  $\text{C}-\text{H}-\text{N}$  is an impossible arrangement. The remaining two possibilities are  $\text{H}-\text{C}-\text{N}$  and  $\text{H}-\text{N}-\text{C}$ . The first is the arrangement found experimentally. You might have guessed this because the formula is written with the atoms in this order, and carbon is less electronegative than nitrogen. Thus, we begin with the skeleton structure

The two bonds account for four electrons. The H atom can have only two electrons associated with it, and so we will not add any more electrons to it. If we place the remaining six electrons around N to give it an octet, we do not achieve an octet on C:

We therefore try a double bond between C and N, using one of the unshared pairs we placed on N. Again we end up with fewer than eight electrons on C, and so we next try a triple bond. This structure gives an octet around both C and N:

The octet rule is satisfied for the C and N atoms, and the H atom has two electrons around it. This is a correct Lewis structure.

**Practice Exercise 1**

Draw the Lewis structure(s) for the molecule with the chemical formula  $\text{C}_2\text{H}_3\text{N}$ , where the N is connected to only one other atom. How many double bonds are there in the correct Lewis structure?

(a) zero (b) one (c) two (d) three (e) four

**Practice Exercise 2**

Draw the Lewis structure for (a)  $\text{NO}^+$  ion, (b)  $\text{C}_2\text{H}_4$ .

## Sample Exercise 8.8

### Lewis Structure for a Polyatomic Ion

Draw the Lewis structure for the  $\text{BrO}_3^-$  ion.

#### SOLUTION

Bromine (group 7A) has seven valence electrons, and oxygen (group 6A) has six. We must add one more electron to our sum to account for the  $1-$  charge of the ion. The total number of valence electrons is, therefore,  $7 + (3 \times 6) + 1 = 26$ . For oxyanions— $\text{SO}_4^{2-}$ ,  $\text{NO}_3^-$ ,  $\text{CO}_3^{2-}$ , and so forth—the oxygen atoms surround the central nonmetal atom. After arranging the O atoms around the Br atom, drawing single bonds, and distributing the unshared electron pairs, we have

Notice that the Lewis structure for an ion is written in brackets and the charge is shown outside the brackets at the upper right.

#### Practice Exercise 1

How many nonbonding electron pairs are there in the Lewis structure of the peroxide ion,  $\text{O}_2^{2-}$ ?

(a) 7 (b) 6 (c) 5 (d) 4 (e) 3

#### Practice Exercise 2

Draw the Lewis structure for (a)  $\text{ClO}_2^-$ , (b)  $\text{PO}_4^{3-}$ .

## Formal Charge and Alternative Lewis Structures

When we draw a Lewis structure, we are describing how the electrons are distributed in a molecule or polyatomic ion. In some instances, we can draw two or more valid Lewis structures for a molecule that all obey the octet rule. All of these structures can be thought of as contributing to the *actual* arrangement of the electrons in the molecule, but not all of them will contribute to the same extent. How do we decide which one of several Lewis structures is the most important? One approach is to do some “bookkeeping” of the valence electrons to determine the *formal charge* of each atom in each Lewis structure. The **formal charge** of any atom in a molecule is the charge the atom would have if each bonding electron pair in the molecule were shared equally between its two atoms.

### How to Calculate the Formal Charges of Atoms in Lewis Structures

1. All unshared (nonbonding) electrons are assigned to the atom on which they are found.
2. For any bond—single, double, or triple—*half* of the bonding electrons are assigned to each atom in the bond.
3. The formal charge of each atom is calculated by subtracting the number of electrons assigned to the atom from the number of valence electrons in the neutral atom:

$$\text{Formal charge} = \text{valence electrons} - \frac{1}{2}(\text{bonding electrons}) - \text{nonbonding electrons} \quad [8.11]$$

Let's practice by calculating the formal charges for the atoms in the cyanide ion,  $\text{CN}^-$ , which has the Lewis structure

The neutral C atom has four valence electrons. There are six electrons in the cyanide triple bond and two nonbonding electrons on C. We calculate the formal charge on C as  $4 - \frac{1}{2}(6) - 2 = -1$ . For N, the valence electron count is five; there are six electrons in the cyanide triple bond, and two nonbonding electrons on the N. The formal charge on N is  $5 - \frac{1}{2}(6) - 2 = 0$ . We can draw the whole ion with its formal charges as

Notice that the sum of the formal charges equals the overall charge on the ion,  $1-$ . The formal charges on a neutral molecule must add to zero, whereas those on an ion add to give the charge on the ion.

If we can draw several Lewis structures for a molecule, the concept of formal charge can help us decide which is the most important, which we shall call the *dominant* Lewis structure. One Lewis structure for CO<sub>2</sub>, for instance, has two double bonds. However, we can also satisfy the octet rule by drawing a Lewis structure having one single bond and one triple bond. Calculating formal charges in these structures, we have

|                                |  |   |   |  |   |    |
|--------------------------------|--|---|---|--|---|----|
|                                | $\ddot{\text{O}}=\text{C}=\ddot{\text{O}}$ |   |   | $:\ddot{\text{O}}-\text{C}\equiv\text{O}:$ |   |    |
| Valence electrons:             | 6  | 4 | 6 | 6  | 4 | 6  |
| –(Electrons assigned to atom): | 6  | 4 | 6 | 7  | 4 | 5  |
| Formal charge:                 | 0  | 0 | 0 | –1   | 0 | +1 |

Note that in both cases the formal charges add up to zero, as they must because CO<sub>2</sub> is a neutral molecule. So, which is the dominant structure? As a general rule, when more than one Lewis structure is possible, we will use the following guidelines to choose the dominant one:

#### How to Identify the Dominant Lewis Structure

1. The dominant Lewis structure is generally the one in which the atoms bear formal charges closest to zero.
2. A Lewis structure in which any negative charges reside on the more electronegative atoms is generally more dominant than one that has negative charges on the less electronegative atoms.

Thus, the first Lewis structure of CO<sub>2</sub> is the dominant one because the atoms carry no formal charges and so satisfy the first guideline. The other Lewis structure shown (and the similar one that has a triple bond to the left O and a single bond to the right O) contribute to the actual structure to a much smaller extent.

Although the concept of formal charge helps us to arrange alternative Lewis structures in order of importance, it is important to remember that *formal charges do not represent real charges on atoms*. These charges are just a bookkeeping convention. The actual charge distributions in molecules and ions are determined not by formal charges but by a number of other factors, including electronegativity differences between atoms.

#### Give It Some Thought

Suppose a Lewis structure for a neutral fluorine-containing molecule results in a formal charge of +1 on the fluorine atom. What conclusion would you draw?

### Sample Exercise 8.9

#### Lewis Structures and Formal Charges

Three possible Lewis structures for the thiocyanate ion, NCS<sup>–</sup>, are

- Determine the formal charges in each structure.
- Based on the formal charges, which Lewis structure is the dominant one?

#### SOLUTION

- (a) Neutral N, C, and S atoms have five, four, and six valence electrons, respectively. We can determine the formal charges in the three structures by using the rules we just discussed:

As they must, the formal charges in all three structures sum to 1–, the overall charge of the ion.

- (b) The dominant Lewis structure generally produces formal charges of the smallest magnitude (guideline 1). That eliminates the left structure as the dominant one. Further, as discussed in Section 8.4, N is more

electronegative than C or S. Therefore, we expect any negative formal charge to reside on the N atom (guideline 2). For these two reasons, the middle Lewis structure is the dominant one for  $\text{NCS}^-$ .

### Practice Exercise 1

The sulfate ion,  $\text{SO}_4^{2-}$ , can be drawn in many ways. If you minimize formal charge on the sulfur, how many  $\text{S}=\text{O}$

double bonds should you draw in the Lewis structure?  
(a) 0 (b) 1 (c) 2 (d) 3 (e) 4

### Practice Exercise 2

The cyanate ion,  $\text{NCO}^-$ , has three possible Lewis structures. (a) Draw these three structures and assign formal charges in each. (b) Which Lewis structure is dominant?

## A CLOSER LOOK Oxidation Numbers, Formal Charges, and Actual Partial Charges

In Chapter 4 we introduced the rules for assigning *oxidation numbers* to atoms. The concept of electronegativity is the basis of these numbers. An atom's oxidation number is the charge the atom would have if its bonds were completely ionic. That is, in determining oxidation number, all shared electrons are counted with the more electronegative atom. For example, consider the Lewis structure of  $\text{HCl}$  in Figure 8.12(a). To assign oxidation numbers, both electrons in the covalent bond between the atoms are assigned to the more electronegative Cl atom. This procedure gives Cl eight valence electrons, one more than in the neutral atom. Thus, its oxidation number is  $-1$ . Hydrogen has no valence electrons when they are counted this way, giving it an oxidation number of  $+1$ .

In assigning formal charges to the atoms in  $\text{HCl}$  [Figure 8.12(b)], we ignore electronegativity; the electrons in bonds are assigned equally to the two bonded atoms. In this case Cl has seven assigned electrons, the same as that of the neutral Cl atom, and H has one assigned electron. Thus, the formal charges of both Cl and H in this compound are 0.

Neither oxidation number nor formal charge gives an accurate depiction of the actual charges on atoms because oxidation numbers overstate the role of electronegativity and formal charges ignore it. It seems reasonable that electrons in covalent bonds should be apportioned according to the relative electronegativities of the bonded atoms. Figure 8.8 (page 310) shows that Cl has an electronegativity of 3.0, while the electronegativity value of H is 2.1. The

more electronegative Cl atom might therefore be expected to have roughly  $3.0/(3.0 + 2.1) = 0.59$  of the electrical charge in the bonding pair, whereas the H atom would have  $2.1/(3.0 + 2.1) = 0.41$  of the charge. Because the bond consists of two electrons, the Cl atom's share is  $0.59 \times 2e = 1.18e$ , or  $0.18e$  more than the neutral Cl atom. This gives rise to a partial negative charge of  $0.18-$  on Cl and therefore a partial positive charge of  $0.18+$  on H. (Notice again that we place the plus and minus signs *before* the magnitude in writing oxidation numbers and formal charges but *after* the magnitude in writing actual charges.)

The dipole moment of  $\text{HCl}$  gives an experimental measure of the partial charge on each atom. In Sample Exercise 8.5 we saw that the dipole moment of  $\text{HCl}$  corresponds to a partial charge of  $0.178+$  on H and  $0.178-$  on Cl, in remarkably good agreement with our simple approximation based on electronegativities. Although our approximation method provides ballpark numbers for the magnitude of charge on atoms, the relationship between electronegativities and charge separation is generally more complicated. As we have already seen, computer programs employing quantum-mechanical principles have been developed to obtain more accurate estimates of the partial charges on atoms, even in complex molecules. A computer-graphical representation of the calculated charge distribution in  $\text{HCl}$  is shown in Figure 8.12(c).

## 8.6 | Resonance Structures

We sometimes encounter molecules and ions in which the experimentally determined arrangement of atoms is not adequately described by a single dominant Lewis structure. Consider ozone,  $\text{O}_3$ , which is a bent molecule with two equal  $\text{O}-\text{O}$  bond lengths

### Go Figure

What feature of this structure suggests that the two outer O atoms are in some way equivalent to each other?

▲ Figure 8.13 Molecular structure of ozone.

(Figure 8.13). Because each oxygen atom contributes 6 valence electrons, the ozone molecule has 18 valence electrons. This means the Lewis structure must have one O—O single bond and one O=O double bond to attain an octet about each atom:

However, this single structure cannot by itself be dominant because it requires that one O—O bond be different from the other, contrary to the observed structure—we would expect the O=O double bond to be shorter than the O—O single bond. In drawing the Lewis structure, however, we could just as easily have put the O=O bond on the left:

### Go Figure

Is the electron density consistent with equal contributions from the two resonance structures for  $\text{O}_3$ ? Explain.

Notice that the electron density is distributed symmetrically across the molecule.

▲ Figure 8.14 Resonance. Describing a molecule as a blend of different resonance structures is similar to describing a paint color as a blend of primary colors. (a) Green paint is a blend of blue and yellow. We cannot describe green as a single primary color. (b) The ozone molecule is a blend of two resonance structures. We cannot describe the ozone molecule in terms of a single Lewis structure.

There is no reason for one of these Lewis structures to be dominant because they are equally valid representations of the molecule. The placement of the atoms in these two alternative but completely equivalent Lewis structures is the same, but the placement of the electrons is different; we call Lewis structures of this sort **resonance structures**. To describe the structure of ozone properly, we write both resonance structures and use a double-headed arrow to indicate that the real molecule is described by an average of the two:

To understand why certain molecules require more than one resonance structure, we can draw an analogy to mixing paint (Figure 8.14). Blue and yellow are both primary colors of paint pigment. An equal blend of blue and yellow pigments produces green pigment. We cannot describe green paint in terms of a single primary color, yet it still has its own identity. Green paint does not oscillate between its two primary colors: It is not blue part of the time and yellow the rest of the time. Similarly, molecules such as ozone cannot be described as oscillating between the two individual Lewis structures shown previously—there are two equivalent dominant Lewis structures that contribute equally to the actual structure of the molecule.

The actual arrangement of the electrons in molecules such as  $\text{O}_3$  must be considered as a blend of two (or more) Lewis structures. By analogy to the green paint, the molecule has its own identity separate from the individual resonance structures. For example, the ozone molecule always has two equivalent O—O bonds whose lengths are intermediate between the lengths of an oxygen–oxygen single bond and an oxygen–oxygen double bond. Another way of looking at it is to say that the rules for drawing Lewis structures do not allow us to have a single dominant structure for the ozone molecule. For example, there are no rules for drawing half-bonds. We can get around this limitation by drawing two equivalent Lewis structures that, when averaged, amount to something very much like what is observed experimentally.

### Give It Some Thought

The O—O bonds in ozone can be described as “one and a half bonds.” Does this suggest that the bond lengths in ozone are longer or shorter than those in the  $\text{O}_2$  molecule?

As an additional example of resonance structures, consider the nitrate ion,  $\text{NO}_3^-$ , for which three equivalent Lewis structures can be drawn:

Notice that the arrangement of atoms is the same in each structure—only the placement of electrons differs. In writing resonance structures, the same atoms must be bonded to each other in all structures, so that the only differences are in the arrangements of electrons. All three  $\text{NO}_3^-$  Lewis structures are equally dominant and taken together adequately describe the ion, in which all three N—O bond lengths are the same.

### Give It Some Thought

Predict whether the N—O bonds in  $\text{NO}_3^-$  are stronger or weaker than the N—O bond in  $\text{NO}^+$ .

For some molecules or ions, all possible Lewis structures may not be equivalent; in other words, one or more resonance structures are more dominant than others. We will encounter examples of this as we proceed.

## Resonance in Benzene

Resonance is an important concept in describing the bonding in organic molecules, particularly *aromatic* organic molecules, a category that includes the hydrocarbon *benzene*,  $\text{C}_6\text{H}_6$ . The six C atoms are bonded in a hexagonal ring, and one H atom is bonded to each C atom. We can write two equivalent dominant Lewis structures for benzene, each of which satisfies the octet rule. These two structures are in resonance:

Note that the double bonds are in different places in the two structures. Each of these resonance structures shows three carbon-carbon single bonds and three carbon-carbon double bonds. However, experimental data show that all six C—C bonds are of equal length, 1.40 Å, intermediate between the typical bond lengths for a C—C single bond (1.54 Å) and a C=C double bond (1.34 Å). Each of the C—C bonds in benzene can be thought of as a blend of a single bond and a double bond (**Figure 8.15**).

Benzene is commonly represented by omitting the hydrogen atoms and showing only the carbon-carbon framework with the vertices unlabeled. In this convention, the resonance in the molecule is represented either by two structures separated by a double-headed arrow or by a shorthand notation in which we draw a hexagon with a circle inside:

The shorthand notation reminds us that benzene is a blend of two resonance structures—it emphasizes that the C=C double bonds cannot be assigned to specific edges of the hexagon. Chemists use both representations of benzene interchangeably.

The bonding arrangement in benzene confers special stability to the molecule. As a result, millions of organic compounds contain the six-membered ring characteristic of

### Go Figure

What is the significance of the dashed bonds in this ball-and-stick model?

▲ **Figure 8.15** Benzene, an “aromatic” organic compound. The benzene molecule is a regular hexagon of carbon atoms with a hydrogen atom bonded to each one. The dashed lines represent the blending of two equivalent resonance structures, leading to C—C bonds that are intermediate between single and double bonds.

benzene. Many of these compounds are important in biochemistry, in pharmaceuticals, and in the production of modern materials.

### Give It Some Thought

Each Lewis structure of benzene has three C=C double bonds. Another hydrocarbon containing three C=C double bonds is *hexatriene*, C<sub>6</sub>H<sub>8</sub>. A Lewis structure of hexatriene is

Experiments show that three of the C—C bonds in hexatriene are shorter than the other two. Does this data suggest that hexatriene exhibits resonance structures?

## Sample Exercise 8.10

### Resonance Structures

Which is predicted to have the shorter sulfur–oxygen bonds, SO<sub>3</sub> or SO<sub>3</sub><sup>2−</sup>?

#### SOLUTION

The sulfur atom has six valence electrons, as does oxygen. Thus, SO<sub>3</sub> contains 24 valence electrons. In writing the Lewis structure, we see that three equivalent resonance structures can be drawn:

As with NO<sub>3</sub><sup>−</sup> the actual structure of SO<sub>3</sub> is an equal blend of all three. Thus, each S—O bond length should be about one-third of the way between the length of a single bond and the length of a double bond. That is, S—O should be shorter than single bonds but not as short as double bonds.

The SO<sub>3</sub><sup>2−</sup> ion has 26 electrons, which leads to a dominant Lewis structure in which all the S—O bonds are single:

Our analysis of the Lewis structures thus far leads us to conclude that SO<sub>3</sub> should have the shorter S—O bonds and SO<sub>3</sub><sup>2−</sup> the longer ones. This conclusion is correct: The experimentally measured S—O bond lengths are 1.42 Å in SO<sub>3</sub> and 1.51 Å in SO<sub>3</sub><sup>2−</sup>.

#### Practice Exercise 1

Which of these statements about resonance is true?

- When you draw resonance structures, it is permissible to alter the way atoms are connected.
- The nitrate ion has one long N—O bond and two short N—O bonds.
- “Resonance” refers to the idea that molecules are resonating rapidly between different bonding patterns.
- The cyanide ion has only one dominant resonance structure.
- All of the above are true.

#### Practice Exercise 2

Draw two equivalent resonance structures for the formate ion, HCO<sub>2</sub><sup>−</sup>.

## 8.7 | Exceptions to the Octet Rule

The octet rule is so simple and useful in introducing the basic concepts of bonding that you might assume it is always obeyed. In Section 8.2, however, we noted its limitation in dealing with ionic compounds of the transition metals. The rule also fails in many situations involving covalent bonding. These exceptions to the octet rule are of three main types:

- Molecules and polyatomic ions containing an odd number of electrons
- Molecules and polyatomic ions in which an atom has fewer than an octet of valence electrons
- Molecules and polyatomic ions in which an atom has more than an octet of valence electrons

## Odd Number of Electrons

In the vast majority of molecules and polyatomic ions, the total number of valence electrons is even, and complete pairing of electrons occurs. However, in a few molecules and polyatomic ions, such as  $\text{ClO}_2$ ,  $\text{NO}$ ,  $\text{NO}_2$ , and  $\text{O}_2^-$ , the number of valence electrons is odd. Complete pairing of these electrons is impossible, and an octet around each atom cannot be achieved. For example,  $\text{NO}$  contains  $5 + 6 = 11$  valence electrons. The two most important Lewis structures for this molecule are

### Give It Some Thought

Which of the Lewis structures for  $\text{NO}$  is dominant based on analysis of the formal charges?

## Less Than an Octet of Valence Electrons

A second type of exception occurs when there are fewer than eight valence electrons around an atom in a molecule or polyatomic ion. This situation is also relatively rare (with the exception of hydrogen and helium as we have already discussed), and is most often encountered in compounds of boron and beryllium. As an example, let's consider boron trifluoride,  $\text{BF}_3$ . If we follow the first steps of our procedure for drawing Lewis structures, we obtain the structure

which has only six electrons around the boron atom. The formal charge is zero on both B and F, and we could complete the octet around boron by forming a double bond (recall that if there are not enough electrons to give the central atom an octet, a multiple bond may be the answer). In so doing, we see that there are three equivalent resonance structures (the formal charges are shown in red):

Each of these structures forces a fluorine atom to share additional electrons with the boron atom, which is inconsistent with the high electronegativity of fluorine. In fact, the formal charges tell us that this is an unfavorable situation. In each structure, the F atom involved in the  $\text{B}=\text{F}$  double bond has a formal charge of  $+1$ , while the less electronegative B atom has a formal charge of  $-1$ . Thus, the resonance structures containing a  $\text{B}=\text{F}$  double bond are less important than the one in which there are fewer than an octet of valence electrons around boron:

We usually represent  $\text{BF}_3$  solely by the dominant resonance structure, in which there are only six valence electrons around boron. The chemical behavior of  $\text{BF}_3$  is consistent with this representation. In particular,  $\text{BF}_3$  reacts energetically with molecules having an unshared pair of electrons that can be used to form a bond with boron, as, for example, in the reaction

In the stable compound  $\text{NH}_3\text{BF}_3$ , boron has an octet of valence electrons.

### More Than an Octet of Valence Electrons

The third and largest class of exceptions consists of molecules or polyatomic ions in which there are more than eight electrons in the valence shell of an atom. When we draw the Lewis structure for  $\text{PF}_5$ , for example, we are forced to place ten electrons around the central phosphorus atom:

Molecules and ions with more than an octet of electrons around the central atom are often called *hypervalent*. Other examples of hypervalent species are  $\text{SF}_4$ ,  $\text{AsF}_6^-$ , and  $\text{ICl}_4^-$ . The corresponding molecules with a second-period atom as the central atom, such as  $\text{NCl}_5$  and  $\text{OF}_4$ , do *not* exist.

Hypervalent molecules are formed only for central atoms from period 3 and below in the periodic table. The principal reason for their formation is the relatively larger size of the central atom. For example, a P atom is large enough that five F (or even five Cl) atoms can be bonded to it without being too crowded. By contrast, an N atom is too small to accommodate five atoms bonded to it. Because size is a factor, hypervalent molecules occur most often when the central atom is bonded to the smallest and most electronegative atoms—F, Cl, and O.

The notion that a valence shell can contain more than eight electrons is also consistent with the presence of unfilled *nd* orbitals in atoms from period 3 and below. [\(Section 6.8\)](#) By comparison, in elements of the second period, only the *2s* and *2p* valence orbitals are available for bonding. However, theoretical work on the bonding in molecules such as  $\text{PF}_5$  and  $\text{SF}_6$  suggests that the presence of unfilled *3d* orbitals in P and S has a relatively minor impact on the formation of hypervalent molecules. Most chemists now believe that the larger size of the atoms from periods 3 through 6 is more important to explain hypervalency than is the presence of unfilled *d* orbitals.

### Sample Exercise 8.11

#### Lewis Structure for an Ion with More Than an Octet of Electrons

Draw the Lewis structure for  $\text{ICl}_4^-$ .

#### SOLUTION

Iodine (group 7A) has seven valence electrons. Each chlorine atom (group 7A) also has seven. An extra electron is added to account for the  $1-$  charge of the ion. Therefore, the total number of valence electrons is  $7 + (4 \times 7) + 1 = 36$ .

The I atom is the central atom in the ion. Putting eight electrons around each Cl atom (including a pair of electrons between I and each Cl to represent the single bond between these atoms) requires  $8 \times 4 = 32$  electrons.

We are thus left with  $36 - 32 = 4$  electrons to be placed on the larger iodine:

Iodine has 12 valence electrons around it, four more than needed for an octet.

#### Practice Exercise 1

In which of these molecules or ions is there only one lone pair of electrons on the central sulfur atom?

(a)  $\text{SF}_4$  (b)  $\text{SF}_6$  (c)  $\text{SOF}_4$  (d)  $\text{SF}_2$  (e)  $\text{SO}_4^{2-}$

#### Practice Exercise 2

(a) Which of the following atoms is never found with more than an octet of valence electrons around it? S, C, P, Br, I.

(b) Draw the Lewis structure for  $\text{XeF}_2$ .

Finally, there are Lewis structures where you might have to choose between satisfying the octet rule and obtaining the most favorable formal charges by using more than an octet of electrons. For example, consider these Lewis structures for the phosphate ion,  $\text{PO}_4^{3-}$ :

The formal charges on the atoms are shown in red. In the left structure, the P atom obeys the octet rule. In the right structure, however, the P atom has five electron pairs, leading to smaller formal charges on the atoms. (You should be able to see that there are three additional resonance structures for the Lewis structure on the right.)

Chemists are still debating which of these two structures is dominant for  $\text{PO}_4^{3-}$ . Recent theoretical calculations based on quantum mechanics suggest to some researchers that the left structure is the dominant one. Other researchers claim that the bond lengths in the ion are more consistent with the right structure being dominant. This disagreement is a convenient reminder that, in general, multiple Lewis structures can contribute to the actual electron distribution in an atom or molecule.

## 8.8 | Strengths and Lengths of Covalent Bonds

The stability of a molecule is related to the strengths of its covalent bonds. We saw in Chapter 5 that we can measure the average bond enthalpy of many single bonds (Table 5.4). Table 5.4 is repeated here as [Table 8.3](#). As you might expect, Table 8.3 shows that multiple bonds are generally stronger than single bonds.

**TABLE 8.3** Average Bond Enthalpies (kJ/mol)

| Single Bonds   |      |      |     |      |     |       |     |
|----------------|------|------|-----|------|-----|-------|-----|
| C—H            | 413  | N—H  | 391 | O—H  | 463 | F—F   | 155 |
| C—C            | 348  | N—N  | 163 | O—O  | 146 |       |     |
| C—N            | 293  | N—O  | 201 | O—F  | 190 | Cl—F  | 253 |
| C—O            | 358  | N—F  | 272 | O—Cl | 203 | Cl—Cl | 242 |
| C—F            | 485  | N—Cl | 200 | O—I  | 234 |       |     |
| C—Cl           | 328  | N—Br | 243 |      |     | Br—F  | 237 |
| C—Br           | 276  |      |     | S—H  | 339 | Br—Cl | 218 |

|                |      | H—Cl | 431 | S—Br | 218 | I—Cl  | 208 |
| Si—H           | 323  | H—Br | 366 | S—S  | 266 | I—Br  | 175 |
| Si—Si          | 226  | H—I  | 299 |      |     | I—I   | 151 |
| Si—C           | 301  |      |     |      |     |       |     |
| Si—O           | 368  |      |     |      |     |       |     |
| Si—Cl          | 464  |      |     |      |     |       |     |
| Multiple Bonds |      |      |     |      |     |       |     |
| C=C            | 614  | N=N  | 418 | O=O  | 495 |       |     |
| C≡C            | 839  | N≡N  | 941 |      |     |       |     |
| C=N            | 615  | N=O  | 607 | S=O  | 523 |       |     |
| C≡N            | 891  |      |     | S=S  | 418 |       |     |
| C=O            | 799  |      |     |      |     |       |     |
| C≡O            | 1072 |      |     |      |     |       |     |

Just as we can define an average bond enthalpy, we can also define an average bond length for a number of common bonds (Table 8.4). Of particular interest is the relationship, in any atom pair, among bond enthalpy, bond length, and number of bonds between the atoms. For example, we can use data in Tables 8.3 and 8.4 to compare the bond lengths and bond enthalpies of carbon–carbon single, double, and triple bonds:

|                     |                     |                          |
|---------------------|---------------------|--------------------------|
| $\text{C}-\text{C}$ | $\text{C}=\text{C}$ | $\text{C}\equiv\text{C}$ |
| 1.54 Å              | 1.34 Å              | 1.20 Å                   |
| 348 kJ/mol          | 614 kJ/mol          | 839 kJ/mol               |

**TABLE 8.4 Average Bond Lengths for Some Single, Double, and Triple Bonds**

| Bond                     | Bond Length (Å) | Bond                     | Bond Length (Å) |
|--------------------------|-----------------|--------------------------|-----------------|
| $\text{C}-\text{C}$      | 1.54            | $\text{N}-\text{N}$      | 1.47            |
| $\text{C}=\text{C}$      | 1.34            | $\text{N}=\text{N}$      | 1.24            |
| $\text{C}\equiv\text{C}$ | 1.20            | $\text{N}\equiv\text{N}$ | 1.10            |
| $\text{C}-\text{N}$      | 1.43            | $\text{N}-\text{O}$      | 1.36            |
| $\text{C}=\text{N}$      | 1.38            | $\text{N}=\text{O}$      | 1.22            |
| $\text{C}\equiv\text{N}$ | 1.16            |                          |                 |
|                          |                 | $\text{O}-\text{O}$      | 1.48            |
| $\text{C}-\text{O}$      | 1.43            | $\text{O}=\text{O}$      | 1.21            |
| $\text{C}=\text{O}$      | 1.23            |                          |                 |
| $\text{C}\equiv\text{O}$ | 1.13            |                          |                 |

As the number of bonds between the carbon atoms increases, the bond length decreases and the bond enthalpy increases. That is, the carbon atoms are held more closely and more tightly together. In general, *as the number of bonds between two atoms increases, the bond grows shorter and stronger*. This trend is illustrated in Figure 8.16 for N—N single, double, and triple bonds.

### Go Figure

Predict the N—N bond enthalpy for an N—N bond that has resonance forms that include equal contributions from single and double N—N bonds.

▲ **Figure 8.16** Bond strength versus bond length for N—N bonds.

## Sample Integrative Exercise

### Putting Concepts Together

Phosgene, a substance used in poisonous gas warfare during World War I, is so named because it was first prepared by the action of sunlight on a mixture of carbon monoxide and chlorine gases. Its name comes from the Greek words *phos* (light) and *genes* (born of). Phosgene has the following elemental composition: 12.14% C, 16.17% O, and 71.69% Cl by mass. Its molar mass is 98.9 g/mol. (a) Determine the molecular formula of this compound. (b) Draw three Lewis structures for the molecule that satisfy the octet rule for each atom. (The Cl and O atoms bond to C.) (c) Using formal charges, determine which Lewis structure is the dominant one. (d) Using average bond enthalpies, estimate  $\Delta H$  for the formation of gaseous phosgene from  $\text{CO}(g)$  and  $\text{Cl}_2(g)$ .

### SOLUTION

- (a) The empirical formula of phosgene can be determined from its elemental composition. (Section 3.5) Assuming 100 g of the compound and calculating the number of moles of C, O, and Cl in this sample, we have:

$$(12.14 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 1.011 \text{ mol C}$$

$$(16.17 \text{ g O}) \left( \frac{1 \text{ mol O}}{16.00 \text{ g O}} \right) = 1.011 \text{ mol O}$$

$$(71.69 \text{ g Cl}) \left( \frac{1 \text{ mol Cl}}{35.45 \text{ g Cl}} \right) = 2.022 \text{ mol Cl}$$

The ratio of the number of moles of each element, obtained by dividing each number of moles by the smallest quantity, indicates that there is one C and one O for each two Cl in the empirical formula,  $\text{COCl}_2$ .

The molar mass of the empirical formula is  $12.01 + 16.00 + 2(35.45) = 98.91 \text{ g/mol}$ , the same as the molar mass of the molecule. Thus,  $\text{COCl}_2$  is the molecular formula.

- (b) Carbon has four valence electrons, oxygen has six, and chlorine has seven, giving  $4 + 6 + 2(7) = 24$  electrons for the Lewis structures. Drawing a Lewis structure with all single bonds does not give the central carbon atom an octet. Using multiple bonds, we find that three structures satisfy the octet rule:

- (c) Calculating the formal charges on each atom gives:

The first structure is expected to be the dominant one because it has the lowest formal charges on each atom. Indeed, the molecule is usually represented by this single Lewis structure.

- (d) Writing the chemical equation in terms of the Lewis structures of the molecules, we have:

Thus, the reaction involves breaking a  $\text{C}\equiv\text{O}$  bond and a  $\text{Cl}-\text{Cl}$  bond and forming a  $\text{C}=\text{O}$  bond and two  $\text{C}-\text{Cl}$  bonds. Using bond enthalpies from Table 8.3, we have:

$$\begin{aligned} \Delta H &= [D(\text{C}\equiv\text{O}) + D(\text{Cl}-\text{Cl})] - [D(\text{C}=\text{O}) + 2D(\text{C}-\text{Cl})] \\ &= [1072 \text{ kJ} + 242 \text{ kJ}] - [799 \text{ kJ} + 2(328 \text{ kJ})] = -141 \text{ kJ} \end{aligned}$$

Notice that the reaction is exothermic. Nevertheless, energy is needed from sunlight or another source for the reaction to begin, as is the case for the combustion of  $\text{H}_2(g)$  and  $\text{O}_2(g)$  to form  $\text{H}_2\text{O}(g)$ .

## Chapter Summary and Key Terms

### CHEMICAL BONDS, LEWIS SYMBOLS, AND THE OCTET RULE (INTRODUCTION AND SECTION 8.1)

In this chapter, we have focused on the interactions that lead to the formation of **chemical bonds**. We classify these bonds into three broad groups: **ionic bonds**, which result from the electrostatic forces that exist between ions of opposite charge; **covalent bonds**, which result from the sharing of electrons by two atoms; and **metallic bonds**, which result from a delocalized sharing of electrons in metals. The formation of bonds involves interactions of the outermost electrons of atoms, their valence electrons. The valence electrons of an atom can be represented by electron-dot symbols, called **Lewis symbols**. The tendencies of atoms to gain, lose, or share their valence electrons often follow the **octet rule**, which says that the atoms in molecules or ions (usually) have eight valence electrons.

**IONIC BONDING (SECTION 8.2)** Ionic bonding results from the transfer of electrons from one atom to another, leading to the formation of a three-dimensional lattice of charged particles. The stabilities of ionic substances result from the strong electrostatic attractions between an ion and the surrounding ions of opposite charge. The magnitude of these interactions is measured by the **lattice energy**, which is the energy needed to separate an ionic lattice into gaseous ions. Lattice energy increases with increasing charge on the ions and with decreasing distance between the ions. The **Born–Haber cycle** is a useful thermochemical cycle in which we use Hess’s law to calculate the lattice energy as the sum of several steps in the formation of an ionic compound.

**COVALENT BONDING (SECTION 8.3)** A covalent bond results from the sharing of valence electrons between atoms. We can represent the electron distribution in molecules by means of **Lewis structures**, which indicate how many valence electrons are involved in forming bonds and how many remain as **nonbonding electron pairs** (or **lone pairs**). The octet rule helps determine how many bonds will be formed between two atoms. The sharing of one pair of electrons produces a **single bond**; the sharing of two or three pairs of electrons between two atoms produces **double** or **triple bonds**, respectively. Double and triple bonds are examples of multiple bonding between atoms. The bond length decreases as the number of bonds between the atoms increases.

**BOND POLARITY AND ELECTRONEGATIVITY (SECTION 8.4)** In covalent bonds, the electrons may not necessarily be shared equally between two atoms. **Bond polarity** helps describe unequal sharing of electrons in a bond. In a **nonpolar covalent bond**, the electrons in the bond are shared equally by the two atoms; in a **polar covalent bond**, one of the atoms exerts a greater attraction for the electrons than the other.

**Electronegativity** is a numerical measure of the ability of an atom to compete with other atoms for the electrons shared between them. Fluorine is the most electronegative element, meaning it has the greatest ability to attract electrons from other atoms. Electronegativity values range from 0.7 for Cs to 4.0 for F. Electronegativity

generally increases from left to right in a row of the periodic table and decreases going down a column. The difference in the electronegativities of bonded atoms can be used to determine the polarity of a bond. The greater the electronegativity difference, the more polar the bond.

A **polar molecule** is one whose centers of positive and negative charge do not coincide. Thus, a polar molecule has a positive side and a negative side. This separation of charge produces a **dipole**, the magnitude of which is given by the **dipole moment**, which is measured in debyes (D). Dipole moments increase with increasing amount of charge separated and increasing distance of separation. Any diatomic molecule  $X-Y$  in which  $X$  and  $Y$  have different electronegativities is a polar molecule.

Most bonding interactions lie between the extremes of covalent and ionic bonding. While it is generally true that the bonding between a metal and a nonmetal is predominantly ionic, exceptions to this guideline are not uncommon when the difference in electronegativity of the atoms is relatively small or when the oxidation state of the metal becomes large.

### DRAWING LEWIS STRUCTURES AND RESONANCE STRUCTURES (SECTIONS 8.5 AND 8.6)

If we know which atoms are connected to one another, we can draw Lewis structures for molecules and ions by a simple procedure. Once we do so, we can determine the **formal charge** of each atom in a Lewis structure, which is the charge that the atom would have if all atoms had the same electronegativity. In general, the dominant Lewis structure will have low formal charges, with any negative formal charges residing on more electronegative atoms.

Sometimes a single dominant Lewis structure is inadequate to represent a particular molecule (or ion). In such situations, we describe the molecule by using two or more **resonance structures** for the molecule. The molecule is envisioned as a blend of these multiple resonance structures. Resonance structures are important in describing the bonding in molecules such as ozone,  $O_3$ , and the organic molecule benzene,  $C_6H_6$ .

**EXCEPTIONS TO THE OCTET RULE (SECTION 8.7)** The octet rule is not obeyed in all cases. Exceptions occur when (a) a molecule has an odd number of electrons, (b) it is not possible to complete an octet around an atom without forcing an unfavorable distribution of electrons, or (c) a large atom is surrounded by a sufficiently large number of small electronegative atoms that it has more than an octet of electrons around it. Lewis structures with more than an octet of electrons are observed for atoms in the third row and beyond in the periodic table.

### STRENGTHS AND LENGTHS OF COVALENT BONDS (SECTION 8.8)

The average strengths and lengths of many common covalent bonds can be measured. Average bond enthalpies for multiple bonds are generally larger than those of single bonds. The average bond length between two atoms decreases as the number of bonds between the atoms increases, consistent with the bond being stronger as the number of bonds increases.

## Learning Outcomes After studying this chapter, you should be able to:

- Write Lewis symbols for atoms and ions. (Section 8.1)  
*Related Exercises: 8.13, 8.14, 8.19, 8.20*
- Define lattice energy and be able to arrange compounds in order of increasing lattice energy based on the charges and sizes of the ions involved. (Section 8.2) *Related Exercises: 8.21–8.24*
- Use atomic electron configurations and the octet rule to draw Lewis structures for molecules. (Section 8.3)  
*Related Exercises: 8.35, 8.36, 8.47, 8.48*
- Use electronegativity differences to identify nonpolar covalent, polar covalent, and ionic bonds. (Section 8.4) *Related Exercises: 8.37–8.40*
- Calculate charge separation in diatomic molecules based on the experimentally measured dipole moment and bond length. (Section 8.4) *Related Exercises: 8.43, 8.44*
- Calculate formal charges from Lewis structures and use those formal charges to identify the dominant Lewis structure for a molecule or ion. (Section 8.5) *Related Exercises: 8.49–8.52*
- Recognize molecules where resonance structures are needed to describe the bonding and draw the dominant resonance structures. (Section 8.6) *Related Exercises: 8.53–8.56*
- Recognize exceptions to the octet rule and draw accurate Lewis structures even when the octet rule is not obeyed. (Section 8.7) *Related Exercises: 8.63, 8.64*
- Predict the relationship between bond type (single, double, and triple), bond strength (or enthalpy), and bond length. (Section 8.8) *Related Exercises: 8.71–8.74*

## Key Equations

- $E_{\text{el}} = \frac{\kappa Q_1 Q_2}{d}$  [8.4] The potential energy of two interacting charges
- $\mu = Qr$  [8.10] The dipole moment of two charges of equal magnitude but opposite sign, separated by a distance  $r$
- Formal charge = valence electrons –  $\frac{1}{2}$  (bonding electrons) – nonbonding electrons [8.11] The definition of formal charge

## Exercises

### Visualizing Concepts

**8.1** For each of these Lewis symbols, indicate the group in the periodic table in which the element X belongs: [Section 8.1]

**8.2** Illustrated are four ions — A, B, X, and Y— showing their relative ionic radii. The ions shown in red carry positive charges: a 2+ charge for A and a 1+ charge for B. Ions shown in blue carry negative charges: a 1– charge for X and a 2– charge for Y. (a) Which combinations of these ions produce ionic compounds where there is a 1:1 ratio of cations and anions? (b) Among the combinations in part (a), which leads to the ionic compound having the largest lattice energy? [Section 8.2]

**8.3** A portion of a two-dimensional “slab” of NaCl(s) is shown here (see Figure 8.2) in which the ions are numbered. (a) Which colored balls must represent sodium ions? (b) Which colored balls must represent chloride ions? (c) Consider ion 5. How many attractive electrostatic interactions are shown for it? (d) Consider ion 5. How many repulsive interactions are shown for it? (e) Is the sum of the attractive interactions in part (c) larger or smaller than the sum of the repulsive interactions in part (d)? (f) If this pattern of ions was extended indefinitely in two dimensions, would the lattice energy be positive or negative? [Section 8.2]

- 8.4** The orbital diagram that follows shows the valence electrons for a  $2+$  ion of an element. **(a)** What is the element? **(b)** What is the electron configuration of an atom of this element? [Section 8.2]

- 8.5** In the Lewis structure shown here, A, D, E, Q, X, and Z represent elements in the first two rows of the periodic table. Identify all six elements so that the formal charges of all atoms are zero. [Section 8.3]

- 8.6** Incomplete Lewis structures for the nitrous acid molecule,  $\text{HNO}_2$ , and the nitrite ion,  $\text{NO}_2^-$ , are shown here. **(a)** Complete each Lewis structure by adding electron pairs as needed. **(b)** Is the formal charge on N the same or different in these two species? **(c)** Would either  $\text{HNO}_2$  or  $\text{NO}_2^-$  be expected to exhibit resonance? **(d)** Would you expect the  $\text{N}=\text{O}$  bond in  $\text{HNO}_2$  to be longer, shorter, or the same length as the  $\text{N}-\text{O}$  bonds in  $\text{NO}_2^-$ ? [Sections 8.5 and 8.6]

- 8.7** The partial Lewis structure that follows is for a hydrocarbon molecule. In the full Lewis structure, each carbon atom satisfies the octet rule, and there are no unshared electron pairs in the molecule. The carbon-carbon bonds are labeled 1, 2, and 3. **(a)** How many hydrogen atoms are in the molecule? **(b)** Rank the carbon-carbon bonds in order of increasing bond length. **(c)** Which carbon-carbon bond is the strongest one? [Sections 8.3 and 8.8]

- 8.8** Consider the Lewis structure for the polyatomic oxyanion shown here, where X is an element from the third period (Na – Ar). By changing the overall charge,  $n$ , from  $1-$  to  $2-$  to  $3-$  we get three different polyatomic ions. For each of these ions **(a)** identify the central atom, X; **(b)** determine the formal charge of the central atom, X; **(c)** draw a Lewis structure that makes the formal charge on the central atom equal to zero. [Sections 8.5, 8.6, and 8.7]

## Lewis Symbols (Section 8.1)

- 8.9** **(a)** True or false: An element's number of valence electrons is the same as its atomic number. **(b)** How many valence electrons does a nitrogen atom possess? **(c)** An atom has the electron configuration  $1s^2 2s^2 2p^6 3s^2 3p^2$ . How many valence electrons does the atom have?
- 8.10** **(a)** True or false: The hydrogen atom is most stable when it has a full octet of electrons. **(b)** How many electrons must a sulfur atom gain to achieve an octet in its valence shell? **(c)** If an atom has the electron configuration  $1s^2 2s^2 2p^3$ , how many electrons must it gain to achieve an octet?
- 8.11** Consider the element silicon, Si. **(a)** Write its electron configuration. **(b)** How many valence electrons does a silicon atom have? **(c)** Which subshells hold the valence electrons?
- 8.12** **(a)** Write the electron configuration for the element titanium, Ti. How many valence electrons does this atom possess? **(b)** Hafnium, Hf, is also found in group 4B. Write the electron configuration for Hf. **(c)** Ti and Hf behave as though they possess the same number of valence electrons. Which of the subshells in the electron configuration of Hf behave as valence orbitals? Which behave as core orbitals?
- 8.13** Write the Lewis symbol for atoms of each of the following elements: **(a)** Al, **(b)** Br, **(c)** Ar, **(d)** Sr.
- 8.14** What is the Lewis symbol for each of the following atoms or ions? **(a)** K, **(b)** As, **(c)**  $\text{Sn}^{2+}$ , **(d)**  $\text{N}^{3-}$ .

## Ionic Bonding (Section 8.2)

- 8.15** **(a)** Using Lewis symbols, diagram the reaction between magnesium and oxygen atoms to give the ionic substance  $\text{MgO}$ . **(b)** How many electrons are transferred? **(c)** Which atom loses electrons in the reaction?
- 8.16** **(a)** Use Lewis symbols to represent the reaction that occurs between Ca and F atoms. **(b)** What is the chemical formula of the most likely product? **(c)** How many electrons are transferred? **(d)** Which atom loses electrons in the reaction?
- 8.17** Predict the chemical formula of the ionic compound formed between the following pairs of elements: **(a)** Al and F, **(b)** K and S, **(c)** Y and O, **(d)** Mg and N.
- 8.18** Which ionic compound is expected to form from combining the following pairs of elements? **(a)** barium and fluorine, **(b)** cesium and chlorine, **(c)** lithium and nitrogen, **(d)** aluminum and oxygen.
- 8.19** Write the electron configuration for each of the following ions, and determine which ones possess noble-gas configurations: **(a)**  $\text{Sr}^{2+}$ , **(b)**  $\text{Ti}^{2+}$ , **(c)**  $\text{Se}^{2-}$ , **(d)**  $\text{Ni}^{2+}$ , **(e)**  $\text{Br}^-$ , **(f)**  $\text{Mn}^{3+}$ .
- 8.20** Write electron configurations for the following ions, and determine which have noble-gas configurations: **(a)**  $\text{Cd}^{2+}$ , **(b)**  $\text{P}^{3-}$ , **(c)**  $\text{Zr}^{4+}$ , **(d)**  $\text{Ru}^{3+}$ , **(e)**  $\text{As}^{3-}$ , **(f)**  $\text{Ag}^+$ .
- 8.21** **(a)** Is lattice energy usually endothermic or exothermic? **(b)** Write the chemical equation that represents the process of lattice energy for the case of NaCl. **(c)** Would you expect salts like NaCl, which have singly charged ions, to have larger or smaller lattice energies compared to salts like  $\text{CaO}$  which are composed of doubly-charged ions?

- 8.22** NaCl and KF have the same crystal structure. The only difference between the two is the distance that separates cations and anions. **(a)** The lattice energies of NaCl and KF are given in Table 8.1. Based on the lattice energies, would you expect the Na—Cl or the K—F distance to be longer? **(b)** Use the ionic radii given in Figure 7.8 to estimate the Na—Cl and K—F distances.
- 8.23** The substances NaF and CaO are isoelectronic (have the same number of valence electrons). **(a)** What are the charges on each of the cations in each compound? **(b)** What are the charges of each of the anions in each compound? **(c)** Without looking up lattice energies, which compound is predicted to have the larger lattice energy? **(d)** Using the lattice energies in Table 8.1, predict the lattice energy of ScN.
- 8.24** **(a)** Does the lattice energy of an ionic solid increase or decrease (i) as the charges of the ions increase, (ii) as the sizes of the ions increase? **(b)** Arrange the following substances not listed in Table 8.1 according to their expected lattice energies, listing them from lowest lattice energy to the highest: MgS, KI, GaN, LiBr.
- 8.25** Consider the ionic compounds KF, NaCl, NaBr, and LiCl. **(a)** Use ionic radii (Figure 7.8) to estimate the cation–anion distance for each compound. **(b)** Based on your answer to part (a), arrange these four compounds in order of decreasing lattice energy. **(c)** Check your predictions in part (b) with the experimental values of lattice energy from Table 8.1. Are the predictions from ionic radii correct?
- 8.26** Which of the following trends in lattice energy is due to differences in ionic radii? **(a)**  $\text{NaCl} > \text{RbBr} > \text{CsBr}$ , **(b)**  $\text{BaO} > \text{KF}$ , **(c)**  $\text{SrO} > \text{SrCl}_2$ .
- 8.27** Energy is required to remove two electrons from Ca to form  $\text{Ca}^{2+}$ , and energy is required to add two electrons to O to form  $\text{O}^{2-}$ . Yet CaO is stable relative to the free elements. Which statement is the best explanation? **(a)** The lattice energy of CaO is large enough to overcome these processes. **(b)** CaO is a covalent compound, and these processes are irrelevant. **(c)** CaO has a higher molar mass than either Ca or O. **(d)** The enthalpy of formation of CaO is small. **(e)** CaO is stable to atmospheric conditions.
- 8.28** List the individual steps used in constructing a Born–Haber cycle for the formation of  $\text{BaI}_2$  from the elements. Which of the steps would you expect to be exothermic?
- 8.29** Use data from Appendix C, Figure 7.10, and Figure 7.12 to calculate the lattice energy of RbCl.
- 8.30** **(a)** Based on the lattice energies of  $\text{MgCl}_2$  and  $\text{SrCl}_2$  given in Table 8.1, what is the range of values that you would expect for the lattice energy of  $\text{CaCl}_2$ ? **(b)** Using data from Appendix C, Figure 7.11, Figure 7.13, and the value of the second ionization energy for Ca, 1145 kJ/mol, calculate the lattice energy of  $\text{CaCl}_2$ .

### Covalent Bonding, Electronegativity, and Bond Polarity (Sections 8.3 and 8.4)

- 8.31** **(a)** State whether or not the bonding in each substance is likely to be covalent: (i) iron, (ii) sodium chloride, (iii) water, (iv) oxygen, (v) argon. **(b)** A substance XY, formed from two different elements, boils at  $-33^\circ\text{C}$ . Is XY likely to be a covalent or an ionic substance?
- 8.32** Which of these elements are unlikely to form covalent bonds? S, H, K, Ar, Si.
- 8.33** Using Lewis symbols and Lewis structures, diagram the formation of  $\text{SiCl}_4$  from Si and Cl atoms, showing valence-shell electrons. **(a)** How many valence electrons does Si have initially? **(b)** How many valence electrons does each Cl have initially? **(c)** How many valence electrons surround the Si in the  $\text{SiCl}_4$  molecule? **(d)** How many valence electrons surround each Cl in the  $\text{SiCl}_4$  molecule? **(e)** How many bonding pairs of electrons are in the  $\text{SiCl}_4$  molecule?
- 8.34** Use Lewis symbols and Lewis structures to diagram the formation of  $\text{PF}_3$  from P and F atoms, showing valence-shell electrons. **(a)** How many valence electrons does P have initially? **(b)** How many valence electrons does each F have initially? **(c)** How many valence electrons surround the P in the  $\text{PF}_3$  molecule? **(d)** How many valence electrons surround each F in the  $\text{PF}_3$  molecule? **(e)** How many bonding pairs of electrons are in the  $\text{PF}_3$  molecule?
- 8.35** **(a)** Construct a Lewis structure for  $\text{O}_2$  in which each atom achieves an octet of electrons. **(b)** How many bonding electrons are in the structure? **(c)** Would you expect the O—O bond in  $\text{O}_2$  to be shorter or longer than the O—O bond in compounds that contain an O—O single bond? Explain.
- 8.36** **(a)** Construct a Lewis structure for hydrogen peroxide,  $\text{H}_2\text{O}_2$ , in which each atom achieves an octet of electrons. **(b)** How many bonding electrons are between the two oxygen atoms? **(c)** Do you expect the O—O bond in  $\text{H}_2\text{O}_2$  to be longer or shorter than the O—O bond in  $\text{O}_2$ ? Explain.
- 8.37** Which of the following statements about electronegativity is false? **(a)** Electronegativity is the ability of an atom in a molecule to attract electron density toward itself. **(b)** Electronegativity is the same thing as electron affinity. **(c)** The numerical values for electronegativity have no units. **(d)** Fluorine is the most electronegative element. **(e)** Cesium is the least electronegative element.
- 8.38** **(a)** What is the trend in electronegativity going from left to right in a row of the periodic table? **(b)** How do electronegativity values generally vary going down a column in the periodic table? **(c)** True or false: The most easily ionizable elements are the most electronegative.
- 8.39** Using only the periodic table as your guide, select the most electronegative atom in each of the following sets: **(a)** Na, Mg, K, Ca; **(b)** P, S, As, Se; **(c)** Be, B, C, Si; **(d)** Zn, Ge, Ga, As.
- 8.40** By referring only to the periodic table, select **(a)** the most electronegative element in group 6A; **(b)** the least electronegative element in the group Al, Si, P; **(c)** the most electronegative element in the group Ga, P, Cl, Na; **(d)** the element in the group K, C, Zn, F that is most likely to form an ionic compound with Ba.
- 8.41** Which of the following bonds are polar? **(a)** B—F, **(b)** Cl—Cl, **(c)** Se—O, **(d)** H—I. Which is the more electronegative atom in each polar bond?
- 8.42** Arrange the bonds in each of the following sets in order of increasing polarity: **(a)** C—F, O—F, Be—F; **(b)** O—Cl, S—Br, C—P; **(c)** C—S, B—F, N—O.
- 8.43** **(a)** From the data in Table 8.2, calculate the effective charges on the H and Br atoms of the HBr molecule in units of the electronic charge,  $e$ . **(b)** If you were to put HBr under very high pressure, so its bond length decreased significantly, would its dipole moment increase, decrease, or stay the same, if you assume that the effective charges on the atoms do not change?

**8.44** The iodine monobromide molecule, IBr, has a bond length of 2.49 Å and a dipole moment of 1.21 D. (a) Which atom of the molecule is expected to have a negative charge? (b) Calculate the effective charges on the I and Br atoms in IBr in units of the electronic charge,  $e$ .

**8.45** In the following pairs of binary compounds, determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (a) SiF<sub>4</sub> and LaF<sub>3</sub>, (b) FeCl<sub>2</sub> and ReCl<sub>6</sub>, (c) PbCl<sub>4</sub> and RbCl.

**8.46** In the following pairs of binary compounds, determine which one is a molecular substance and which one is an ionic substance. Use the appropriate naming convention (for ionic or molecular substances) to assign a name to each compound: (a) TiCl<sub>4</sub> and CaF<sub>2</sub>, (b) ClF<sub>3</sub> and VF<sub>3</sub>, (c) SbCl<sub>5</sub> and AlF<sub>3</sub>.

### Lewis Structures; Resonance Structures (Sections 8.5 and 8.6)

**8.47** Draw Lewis structures for the following: (a) SiH<sub>4</sub>, (b) CO, (c) SF<sub>2</sub>, (d) H<sub>2</sub>SO<sub>4</sub> (H is bonded to O), (e) ClO<sub>2</sub><sup>-</sup>, (f) NH<sub>2</sub>OH.

**8.48** Write Lewis structures for the following: (a) H<sub>2</sub>CO (both H atoms are bonded to C), (b) H<sub>2</sub>O<sub>2</sub>, (c) C<sub>2</sub>F<sub>6</sub> (contains a C—C bond), (d) AsO<sub>3</sub><sup>3-</sup>, (e) H<sub>2</sub>SO<sub>3</sub> (H is bonded to O), (f) NH<sub>2</sub>Cl.

**8.49** Which one of these statements about formal charge is true? (a) Formal charge is the same as oxidation number. (b) To draw the best Lewis structure, you should minimize formal charge. (c) Formal charge takes into account the different electronegativities of the atoms in a molecule. (d) Formal charge is most useful for ionic compounds. (e) Formal charge is used in calculating the dipole moment of a diatomic molecule.

**8.50** (a) Draw the dominant Lewis structure for the phosphorus trifluoride molecule, PF<sub>3</sub>. (b) Determine the oxidation numbers of the P and F atoms. (c) Determine the formal charges of the P and F atoms.

**8.51** Write Lewis structures that obey the octet rule for each of the following, and assign oxidation numbers and formal charges to each atom: (a) OCS, (b) SOCl<sub>2</sub> (S is the central atom), (c) BrO<sub>3</sub><sup>-</sup>, (d) HClO<sub>2</sub> (H is bonded to O).

**8.52** For each of the following molecules or ions of sulfur and oxygen, write a single Lewis structure that obeys the octet rule, and calculate the oxidation numbers and formal charges on all the atoms: (a) SO<sub>2</sub>, (b) SO<sub>3</sub>, (c) SO<sub>3</sub><sup>2-</sup>. (d) Arrange these molecules/ions in order of increasing S—O bond length.

**8.53** (a) Draw the best Lewis structure(s) for the nitrite ion, NO<sub>2</sub><sup>-</sup>. (b) With what allotrope of oxygen is it isoelectronic? (c) What would you predict for the lengths of the bonds in NO<sub>2</sub><sup>-</sup> relative to N—O single bonds and double bonds?

**8.54** Consider the formate ion, HCO<sub>2</sub><sup>-</sup>, which is the anion formed when formic acid loses an H<sup>+</sup> ion. The H and the two O atoms are bonded to the central C atom. (a) Draw the best Lewis structure(s) for this ion. (b) Are resonance structures needed to describe the structure? (c) Would you predict that the C—O bond lengths in the formate ion would be longer or shorter relative to those in CO<sub>2</sub>?

**8.55** Predict the ordering, from shortest to longest, of the bond lengths in CO, CO<sub>2</sub>, and CO<sub>3</sub><sup>2-</sup>.

**8.56** Based on Lewis structures, predict the ordering, from shortest to longest, of N—O bond lengths in NO<sup>+</sup>, NO<sub>2</sub><sup>-</sup>, and NO<sub>3</sub><sup>-</sup>.

**8.57** True or false: (a) The C—C bonds in benzene are all the same length and correspond to typical single C—C bond lengths. (b) The C—C bond in acetylene, HCCH, is longer than the average C—C bond length in benzene.

**[8.58]** Mothballs are composed of naphthalene, C<sub>10</sub>H<sub>8</sub>, a molecule that consists of two six-membered rings of carbon fused along an edge, as shown in this incomplete Lewis structure:

(a) Draw all of the resonance structures of naphthalene. How many are there? (b) Do you expect the C—C bond lengths in the molecule to be similar to those of C—C single bonds, C=C double bonds, or intermediate between C—C single and C=C double bonds? (c) Not all of the C—C bond lengths in naphthalene are equivalent. Based on your resonance structures, how many C—C bonds in the molecule do you expect to be shorter than the others?

### Exceptions to the Octet Rule (Section 8.7)

**8.59** (a) Which of these compounds is an exception to the octet rule: carbon dioxide, water, ammonia, phosphorus trifluoride, or arsenic pentafluoride? (b) Which of these compounds or ions is an exception to the octet rule: borohydride (BH<sub>4</sub><sup>-</sup>), borazine (B<sub>3</sub>N<sub>3</sub>H<sub>6</sub>, which is analogous to benzene with alternating B and N in the ring), or boron trichloride?

**8.60** Fill in the blank with the appropriate numbers for both electrons and bonds (considering that single bonds are counted as one, double bonds as two, and triple bonds as three).

- (a) Fluorine has \_\_\_\_\_ valence electrons and makes \_\_\_\_\_ bond(s) in compounds.  
 (b) Oxygen has \_\_\_\_\_ valence electrons and makes \_\_\_\_\_ bond(s) in compounds.  
 (c) Nitrogen has \_\_\_\_\_ valence electrons and makes \_\_\_\_\_ bond(s) in compounds.  
 (d) Carbon has \_\_\_\_\_ valence electrons and makes \_\_\_\_\_ bond(s) in compounds.

**8.61** Draw the dominant Lewis structures for these chlorine-oxygen molecules/ions: ClO, ClO<sup>-</sup>, ClO<sub>2</sub><sup>-</sup>, ClO<sub>3</sub><sup>-</sup>, ClO<sub>4</sub><sup>-</sup>. Which of these do not obey the octet rule?

**8.62** For Group 3A–7A elements in the third row of the periodic table and beyond, the octet rule is often not obeyed. A friend of yours says this is because these heavier elements are more likely to make double or triple bonds. Another friend of yours says that this is because the heavier elements are larger and can make bonds to more than four atoms at a time. Which friend is more correct?

**8.63** Draw the Lewis structures for each of the following ions or molecules. Identify those in which the octet rule is not obeyed; state which atom in each compound does not follow the octet rule; and state, for those atoms, how many electrons surround these atoms: (a) PH<sub>3</sub>, (b) AlH<sub>3</sub>, (c) N<sub>3</sub><sup>-</sup>, (d) CH<sub>2</sub>Cl<sub>2</sub>, (e) SnF<sub>6</sub><sup>2-</sup>.

**8.64** Draw the Lewis structures for each of the following molecules or ions. Identify instances where the octet rule is not obeyed; state which atom in each compound does not follow the octet rule; and state how many electrons surround these atoms: (a) NO, (b) BF<sub>3</sub>, (c) ICl<sub>2</sub><sup>−</sup>, (d) OPBr<sub>3</sub> (the P is the central atom), (e) XeF<sub>4</sub>.

**8.65** In the vapor phase, BeCl<sub>2</sub> exists as a discrete molecule. (a) Draw the Lewis structure of this molecule, using only single bonds. Does this Lewis structure satisfy the octet rule? (b) What other resonance structures are possible that satisfy the octet rule? (c) On the basis of the formal charges, which Lewis structure is expected to be dominant for BeCl<sub>2</sub>?

**8.66** (a) Describe the molecule xenon trioxide, XeO<sub>3</sub>, using four possible Lewis structures, one each with zero, one, two, or three Xe—O double bonds. (b) Do any of these resonance structures satisfy the octet rule for every atom in the molecule? (c) Do any of the four Lewis structures have multiple resonance structures? If so, how many resonance structures do you find? (d) Which of the Lewis structures in part (a) yields the most favorable formal charges for the molecule?

**8.67** There are many Lewis structures you could draw for sulfuric acid, H<sub>2</sub>SO<sub>4</sub> (each H is bonded to an O). (a) What Lewis structure(s) would you draw to satisfy the octet rule? (b) What Lewis structure(s) would you draw to minimize formal charge?

**8.68** Some chemists believe that satisfaction of the octet rule should be the top criterion for choosing the dominant Lewis structure of a molecule or ion. Other chemists believe that achieving the best formal charges should be the top criterion. Consider the dihydrogen phosphate ion, H<sub>2</sub>PO<sub>4</sub><sup>−</sup>, in which the H atoms are bonded to O atoms. (a) What is the predicted dominant Lewis structure if satisfying the octet rule is the top criterion? (b) What is the predicted dominant Lewis structure if achieving the best formal charges is the top criterion?

### Strengths and Lengths of Covalent Bonds (Section 8.8)

**8.69** Using Table 8.3, estimate ΔH for each of the following gas-phase reactions (note that lone pairs on atoms are not shown):

**8.70** Using Table 8.3, estimate ΔH for the following gas-phase reactions:

**8.71** State whether each of these statements is true or false. (a) The longer the bond, the larger the bond enthalpy. (b) C—C bonds are stronger than C—H bonds. (c) A typical single bond length is in the 5–10 Å range. (d) If you break a chemical bond, energy is released. (e) Energy is stored in chemical bonds.

**8.72** State whether each of these statements is true or false. (a) A carbon–carbon triple bond is shorter than a carbon–carbon single bond. (b) There are exactly six bonding electrons in the O<sub>2</sub> molecule. (c) The C—O bond in carbon monoxide is longer than the C—O bond in carbon dioxide. (d) The O—O bond in ozone is shorter than the O—O bond in O<sub>2</sub>. (e) The more electronegative the atom, the more bonds it makes to other atoms.

**8.73** We can define average bond enthalpies and bond lengths for ionic bonds, just like we have for covalent bonds. Which ionic bond is predicted to be stronger, Na—Cl or Ca—O?

**8.74** We can define average bond enthalpies and bond lengths for ionic bonds, just like we have for covalent bonds. Which ionic bond is predicted to have the smaller bond enthalpy, Li—F or Cs—F?

**8.75** A *carbene* is a compound that has a carbon bonded to two atoms and a lone pair remaining on the carbon. Many carbenes are very reactive. (a) Draw the Lewis structure for the simplest carbene, H<sub>2</sub>C. (b) Predict the length of the carbon–carbon bond you would expect if two H<sub>2</sub>C molecules reacted with each other by a combination reaction.

**8.76** Draw the Lewis structure for NO<sup>+</sup>. Is the nitrogen–oxygen bond in NO<sup>+</sup> longer, shorter, or the same length as the nitrogen–oxygen bond in NO? Explain.

## Additional Exercises

- 8.77** A new compound is made that has a C—C bond length of 1.15 Å. Is this bond likely to be a single, double, or triple C—C bond?
- 8.78** A new compound is made that has an N—N bond length of 1.26 Å. Is this bond likely to be a single, double, or triple N—N bond?
- 8.79** Consider the lattice energies of the following Group 2A compounds: BeH<sub>2</sub>, 3205 kJ/mol; MgH<sub>2</sub>, 2791 kJ/mol; CaH<sub>2</sub>, 2410 kJ/mol; SrH<sub>2</sub>, 2250 kJ/mol; BaH<sub>2</sub>, 2121 kJ/mol. (a) What is the oxidation number of H in these compounds? (b) Assuming that all of these compounds have the same three-dimensional arrangement of ions in the solid, which of these compounds has the shortest cation–anion distance? (c) Consider BeH<sub>2</sub>. Does it require 3205 kJ of energy to break one mole of the solid into its ions, or does breaking up one mole of solid into its ions release 3205 kJ of energy? (d) The lattice energy of ZnH<sub>2</sub> is 2870 kJ/mol. Considering the trend in lattice enthalpies in the Group 2A compounds, predict which Group 2A element is most similar in ionic radius to the Zn<sup>2+</sup> ion.
- 8.80** Based on data in Table 8.1, estimate (within 30 kJ/mol) the lattice energy for (a) LiBr, (b) CsBr, (c) CaCl<sub>2</sub>.
- 8.81** An ionic substance of formula MX has a lattice energy of  $6 \times 10^3$  kJ/mol. Is the charge on the ion M likely to be 1+, 2+, or 3+? Explain.
- [8.82]** The ionic compound CaO crystallizes with the same structure as sodium chloride (Figure 8.3). (a) In this structure, how many O<sup>2−</sup> are in contact with each Ca<sup>2+</sup> ion (*Hint*: Remember the pattern of ions shown in Figure 8.3 repeats over and over again in all three directions.) (b) Would energy be consumed or released if a crystal of CaO was converted to a collection of widely separated Ca—O ion pairs? (c) From the ionic radii given in Figure 7.8, calculate the potential energy of a single Ca—O ion pair that is just touching (the magnitude of electronic charge is given on the inside back cover). (d) Calculate the energy of a mole of such pairs. How does this compare to the lattice energy of CaO? (e) What factor do you think accounts for most of the discrepancy between the energies in part (d)—the bonding in CaO is more covalent than ionic, or the electrostatic interactions in a crystal lattice are more complicated than those in a single ion pair?
- 8.83** Construct a Born–Haber cycle for the formation of the hypothetical compound NaCl<sub>2</sub>, where the sodium ion has a 2+ charge (the second ionization energy for sodium is given in Table 7.2). (a) How large would the lattice energy need to be for the formation of NaCl<sub>2</sub> to be exothermic? (b) If we were to estimate the lattice energy of NaCl<sub>2</sub> to be roughly equal to that of MgCl<sub>2</sub> (2326 kJ/mol from Table 8.1), what value would you obtain for the standard enthalpy of formation,  $\Delta H_f^\circ$ , of NaCl<sub>2</sub>?
- 8.84** A classmate of yours is convinced that he knows everything about electronegativity. (a) In the case of atoms X and Y having different electronegativities, he says, the diatomic molecule X—Y must be polar. Is your classmate correct? (b) Your classmate says that the farther the two atoms are apart in a bond, the larger the dipole moment will be. Is your classmate correct?
- 8.85** Consider the collection of nonmetallic elements O, P, Te, I, and B. (a) Which two would form the most polar single bond? (b) Which two would form the longest single bond? (c) Which two would be likely to form a compound of formula XY<sub>2</sub>? (d) Which combinations of elements would likely yield a compound of empirical formula X<sub>2</sub>Y<sub>3</sub>?
- 8.86** The substance chlorine monoxide, ClO(g), is important in atmospheric processes that lead to depletion of the ozone layer. The ClO molecule has an experimental dipole moment of 1.24 D, and the Cl—O bond length is 1.60 Å. (a) Determine the magnitude of the charges on the Cl and O atoms in units of the electronic charge, *e*. (b) Based on the electronegativities of the elements, which atom would you expect to have a partial negative charge in the ClO molecule? (c) Using formal charges as a guide, propose the dominant Lewis structure for the molecule. (d) The anion ClO<sup>−</sup> exists. What is the formal charge on the Cl for the best Lewis structure for ClO<sup>−</sup>?
- [8.87]** (a) Using the electronegativities of Br and Cl, estimate the partial charges on the atoms in the Br—Cl molecule. (b) Using these partial charges and the atomic radii given in Figure 7.8, estimate the dipole moment of the molecule. (c) The measured dipole moment of BrCl is 0.57 D. If you assume the bond length in BrCl is the sum of the atomic radii, what are the partial charges on the atoms in BrCl using the experimental dipole moment?
- 8.88** A major challenge in implementing the “hydrogen economy” is finding a safe, lightweight, and compact way of storing hydrogen for use as a fuel. The hydrides of light metals are attractive for hydrogen storage because they can store a high weight percentage of hydrogen in a small volume. For example, NaAlH<sub>4</sub> can release 5.6% of its mass as H<sub>2</sub> upon decomposing to NaH(s), Al(s), and H<sub>2</sub>(g). NaAlH<sub>4</sub> possesses both covalent bonds, which hold polyatomic anions together, and ionic bonds. (a) Write a balanced equation for the decomposition of NaAlH<sub>4</sub>. (b) Which element in NaAlH<sub>4</sub> is the most electronegative? Which one is the least electronegative? (c) Based on electronegativity differences, predict the identity of the polyatomic anion. Draw a Lewis structure for this ion. (d) What is the formal charge on hydrogen in the polyatomic ion?
- 8.89** Although I<sub>3</sub><sup>−</sup> is a known ion, F<sub>3</sub><sup>−</sup> is not. (a) Draw the Lewis structure for I<sub>3</sub><sup>−</sup> (it is linear, not a triangle). (b) One of your classmates says that F<sub>3</sub><sup>−</sup> does not exist because F is too electronegative to make bonds with another atom. Give an example that proves your classmate is wrong. (c) Another classmate says F<sub>3</sub><sup>−</sup> does not exist because it would violate the octet rule. Is this classmate possibly correct? (d) Yet another classmate says F<sub>3</sub><sup>−</sup> does not exist because F is too small to make bonds to more than one atom. Is this classmate possibly correct?
- 8.90** Calculate the formal charge on the indicated atom in each of the following molecules or ions: (a) the central oxygen atom in O<sub>3</sub>, (b) phosphorus in PF<sub>6</sub><sup>−</sup>, (c) nitrogen in NO<sub>2</sub>, (d) iodine in ICl<sub>3</sub>, (e) chlorine in HClO<sub>4</sub> (hydrogen is bonded to O).
- 8.91** The hypochlorite ion, ClO<sup>−</sup>, is the active ingredient in bleach. The perchlorate ion, ClO<sub>4</sub><sup>−</sup>, is a main component of rocket propellants. Draw Lewis structures for both ions.

(a) What is the formal charge of Cl in the hypochlorite ion? (b) What is the formal charge of Cl in the perchlorate ion, assuming the Cl—O bonds are all single bonds? (c) What is the oxidation number of Cl in the hypochlorite ion? (d) What is the oxidation number of Cl in the perchlorate ion, assuming the Cl—O bonds are all single bonds? (e) In a redox reaction, which ion would you expect to be more easily reduced?

**8.92** The following three Lewis structures can be drawn for  $\text{N}_2\text{O}$ :

(a) Using formal charges, which of these three resonance forms is likely to be the most important? (b) The N—N bond length in  $\text{N}_2\text{O}$  is 1.12 Å, slightly longer than a typical N≡N bond; and the N—O bond length is 1.19 Å, slightly shorter than a typical N=O bond (see Table 8.4). Based on these data, which resonance structure best represents  $\text{N}_2\text{O}$ ?

**[8.93]** (a) Triazine,  $\text{C}_3\text{H}_3\text{N}_3$ , is like benzene except that in triazine every other C—H group is replaced by a nitrogen atom.

Draw the Lewis structure(s) for the triazine molecule. (b) Estimate the carbon–nitrogen bond distances in the ring.

**[8.94]** *Ortho*-Dichlorobenzene,  $\text{C}_6\text{H}_4\text{Cl}_2$ , is obtained when two of the adjacent hydrogen atoms in benzene are replaced with Cl atoms. A skeleton of the molecule is shown here. (a) Complete a Lewis structure for the molecule using bonds and electron pairs as needed. (b) Are there any resonance structures for the molecule? If so, sketch them. (c) Are the resonance structures in (a) and (b) equivalent to one another as they are in benzene?

## Integrative Exercises

**8.95** Consider the hypothetical molecule  $\text{B}-\text{A}=\text{B}$ . Are the following statements true or false? (a) This molecule cannot exist. (b) If resonance was important, the molecule would have identical A–B bond lengths.

**8.96** An important reaction for the conversion of natural gas to other useful hydrocarbons is the conversion of methane to ethane.

In practice, this reaction is carried out in the presence of oxygen, which converts the hydrogen produced into water.

Use Table 8.3 to estimate  $\Delta H$  for these two reactions. Why is the conversion of methane to ethane more favorable when oxygen is used?

**8.97** Two compounds are isomers if they have the same chemical formula but different arrangements of atoms. Use Table 8.3 to estimate  $\Delta H$  for each of the following gas-phase isomerization reactions and indicate which isomer has the lower enthalpy.

**8.98** The  $\text{Ti}^{2+}$  ion is isoelectronic with the Ca atom. (a) Write the electron configurations of  $\text{Ti}^{2+}$  and Ca. (b) Calculate the number of unpaired electrons for Ca and for  $\text{Ti}^{2+}$ . (c) What charge would Ti have to be isoelectronic with  $\text{Ca}^{2+}$ ?

**8.99** (a) Draw the Lewis structure for hydrogen peroxide,  $\text{H}_2\text{O}_2$ . (b) What is the weakest bond in hydrogen peroxide? (c) Hydrogen peroxide is sold commercially as an aqueous solution in brown bottles to protect it from light. Calculate the longest wavelength of light that has sufficient energy to break the weakest bond in hydrogen peroxide.

- 8.100** The electron affinity of oxygen is  $-141 \text{ kJ/mol}$ , corresponding to the reaction

The lattice energy of  $\text{K}_2\text{O(s)}$  is  $2238 \text{ kJ/mol}$ . Use these data along with data in Appendix C and Figure 7.10 to calculate the “second electron affinity” of oxygen, corresponding to the reaction

- 8.101** You and a partner are asked to complete a lab entitled “Oxides of Ruthenium” that is scheduled to extend over two lab periods. The first lab, which is to be completed by your partner, is devoted to carrying out compositional analysis. In the second lab, you are to determine melting points. Upon going to lab you find two unlabeled vials, one containing a soft yellow substance and the other a black powder. You also find the following notes in your partner’s notebook—*Compound 1*: 76.0% Ru and 24.0% O (by mass), *Compound 2*: 61.2% Ru and 38.8% O (by mass). (a) What is the empirical formula for Compound 1? (b) What is the empirical formula for Compound 2? Upon determining the melting points of these two compounds, you find that the yellow compound melts at  $25^\circ\text{C}$ , while the black powder does not melt up to the maximum temperature of your apparatus,  $1200^\circ\text{C}$ . (c) What is the identity of the yellow compound? (d) What is the identity of the black compound? (e) Which compound is molecular? (f) Which compound is ionic?
- 8.102** One scale for electronegativity is based on the concept that the electronegativity of any atom is proportional to the ionization energy of the atom minus its electron affinity:  $\text{electronegativity} = k(I - EA)$ , where  $k$  is a proportionality constant. (a) How does this definition explain why the electronegativity of F is greater than that of Cl, even though Cl has the greater electron affinity? (b) Why are both ionization energy and electron affinity relevant to the notion of electronegativity? (c) By using data in Chapter 7, determine the value of  $k$  that would lead to an electronegativity of 4.0 for F under this definition. (d) Use your result from part (c) to determine the electronegativities of Cl and O using this scale. (e) Another scale for electronegativity defines electronegativity as the average of an atom’s first ionization energy and its electron affinity. Using this scale, calculate the electronegativities for the halogens, and scale them so that fluorine has an electronegativity of 4.0. On this scale, what is Br’s electronegativity?
- 8.103** The compound chloral hydrate, known in detective stories as knockout drops, is composed of 14.52% C, 1.83% H, 64.30% Cl, and 13.35% O by mass, and has a molar mass of  $165.4 \text{ g/mol}$ . (a) What is the empirical formula of this substance? (b) What is the molecular formula of this substance? (c) Draw the Lewis structure of the molecule, assuming that the Cl atoms bond to a single C atom and that there are a C—C bond and two C—O bonds in the compound.
- 8.104** Barium azide is 62.04% Ba and 37.96% N. Each azide ion has a net charge of  $1^-$ . (a) Determine the chemical formula of the azide ion. (b) Write three resonance structures for the azide ion. (c) Which structure is most important? (d) Predict the bond lengths in the ion.
- 8.105** Acetylene ( $\text{C}_2\text{H}_2$ ) and nitrogen ( $\text{N}_2$ ) both contain a triple bond, but they differ greatly in their chemical properties. (a) Write the Lewis structures for the two substances. (b) By

referring to Appendix C, look up the enthalpies of formation of acetylene and nitrogen. Which compound is more stable? (c) Write balanced chemical equations for the complete oxidation of  $\text{N}_2$  to form  $\text{N}_2\text{O}_5(\text{g})$  and of acetylene to form  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ . (d) Calculate the enthalpy of oxidation per mole for  $\text{N}_2$  and for  $\text{C}_2\text{H}_2$  (the enthalpy of formation of  $\text{N}_2\text{O}_5(\text{g})$  is  $11.30 \text{ kJ/mol}$ ). (e) Both  $\text{N}_2$  and  $\text{C}_2\text{H}_2$  possess triple bonds with quite high bond enthalpies (Table 8.3). Calculate the enthalpy of hydrogenation per mole for both compounds: acetylene plus  $\text{H}_2$  to make methane,  $\text{CH}_4$ ; nitrogen plus  $\text{H}_2$  to make ammonia,  $\text{NH}_3$ .

- 8.106** Under special conditions, sulfur reacts with anhydrous liquid ammonia to form a binary compound of sulfur and nitrogen. The compound is found to consist of 69.6% S and 30.4% N. Measurements of its molecular mass yield a value of  $184.3 \text{ g/mol}$ . The compound occasionally detonates on being struck or when heated rapidly. The sulfur and nitrogen atoms of the molecule are joined in a ring. All the bonds in the ring are of the same length. (a) Calculate the empirical and molecular formulas for the substance. (b) Write Lewis structures for the molecule, based on the information you are given. (Hint: You should find a relatively small number of dominant Lewis structures.) (c) Predict the bond distances between the atoms in the ring. (Note: The S—S distance in the  $\text{S}_8$  ring is  $2.05 \text{ \AA}$ .) (d) The enthalpy of formation of the compound is estimated to be  $480 \text{ kJ/mol}^{-1}$ .  $\Delta H_f^\circ$  of  $\text{S(g)}$  is  $222.8 \text{ kJ/mol}$ . Estimate the average bond enthalpy in the compound.
- 8.107** A common form of elemental phosphorus is the tetrahedral  $\text{P}_4$  molecule, where all four phosphorus atoms are equivalent:

At room temperature phosphorus is a solid. (a) Are there any lone pairs of electrons in the  $\text{P}_4$  molecule? (b) How many P—P bonds are there in the molecule? (c) Draw a Lewis structure for a linear  $\text{P}_4$  molecule that satisfies the octet rule. Does this molecule have resonance structures? (d) On the basis of formal charges, which is more stable, the linear molecule or the tetrahedral molecule?

- 8.108** Formic acid has the chemical formula  $\text{HCOOH}$ . It is a colorless liquid that has a density of  $1.220 \text{ g/mL}$ . (a) The carbon atom in formic acid is bound to one H and both O’s. Draw the Lewis structure for formic acid, showing resonance if present. (b) Formic acid can react with  $\text{NaOH}$  in aqueous solution to produce the formate ion,  $\text{HCOO}^-$ . Write the balanced chemical equation for this reaction. (c) Draw the Lewis structure of the formate ion, showing resonance if present. (d) How many milliliters of a  $0.100 \text{ M}$  solution of  $\text{NaOH}$  would it take to completely react with  $0.785 \text{ mL}$  of formic acid?
- 8.109** Ammonia reacts with boron trifluoride to form a stable compound, as we saw in Section 8.7. (a) Draw the Lewis structure of the ammonia–boron trifluoride reaction product. (b) The B—N bond is obviously more polar than the

C—C bond. Draw the charge distribution you expect on the B—N bond within the molecule (using the delta plus and delta minus symbols mentioned in Section 8.4). (c) Boron trichloride also reacts with ammonia in a similar way to the trifluoride. Predict whether the B—N bond in the trichloride reaction product would be more or less polar than the B—N bond in the trifluoride product, and justify your reasoning.

**8.110** Ammonium chloride,  $\text{NH}_4\text{Cl}$ , is a very soluble salt in water. (a) Draw the Lewis structures of the ammonium and chloride ions. (b) Is there an N—Cl bond in solid ammonium chloride? (c) If you dissolve 14 g of ammonium chloride in 500.0 mL of water, what is the molar concentration of the solution? (d) How many grams of silver nitrate do you need to add to the solution in part (c) to precipitate all of the chloride as silver chloride?

## Design an Experiment

You have learned that the resonance of benzene,  $\text{C}_6\text{H}_6$ , gives the compound special stability.

(a) By using data in Appendix C, compare the heat of combustion of 1.0 mol  $\text{C}_6\text{H}_6(\text{g})$  to the heat of combustion of 3.0 mol acetylene,  $\text{C}_2\text{H}_2(\text{g})$ . Which has the greater fuel value, 1.0 mol  $\text{C}_6\text{H}_6(\text{g})$  or 3.0 mol  $\text{C}_2\text{H}_2(\text{g})$ ? Are your calculations consistent with benzene being especially stable? (b) Repeat part (a), with the appropriate molecules, for toluene ( $\text{C}_6\text{H}_5\text{CH}_3$ ), a derivative of benzene that has a  $-\text{CH}_3$  group in place of one H. (c) Another reaction you can use to compare molecules is *hydrogenation*, the reaction of a carbon–carbon double bond with  $\text{H}_2$  to make a C—C single bond and two C—H single bonds. The experimental heat of hydrogenation of benzene to make cyclohexane ( $\text{C}_6\text{H}_{12}$ , a six-membered ring with 6 C—C single bonds and 12 C—H bonds) is 208 kJ/mol. The experimental heat of hydrogenation of cyclohexene ( $\text{C}_6\text{H}_{10}$ , a six-membered ring with one C=C double bond, 5 C—C single bonds, and 10 C—H bonds)

to make cyclohexane is 120 kJ/mol. Show how these data can provide you with an estimate of the *resonance stabilization energy* of benzene. (d) Are the bond lengths or angles in benzene, compared to other hydrocarbons, sufficient to decide if benzene exhibits resonance and is especially stable? Discuss. (e) Consider cyclooctatetraene,  $\text{C}_8\text{H}_8$ , which has the octagonal structure shown below.

Cyclooctatetraene

What experiments or calculations could you perform to determine whether cyclooctatetraene exhibits resonance?

9

(*S*)-naproxen

(*R*)-naproxen

# MOLECULAR GEOMETRY AND BONDING THEORIES

Lewis structures help us understand the compositions of molecules and their covalent bonds. However, Lewis structures do not show one of the most important aspects of molecules—their overall shapes. The shape and size of molecules—sometimes referred to as *molecular architecture*—are defined by the angles and distances between the nuclei of the component atoms.

The shape and size of a molecule of a substance, together with the strength and polarity of its bonds, largely determine the properties of that substance. Some of the most dramatic examples of the important roles of molecular architecture are seen in biochemical reactions. Drugs are examples of molecules in which small changes in the three-dimensional arrangement of atoms have huge consequences. In the chapter-opening image, we see two different molecules: their trade names are (*S*)-naproxen and (*R*)-naproxen. They have the same chemical formula and even the same number of the same kind of chemical bonds; but if you look closely, the positions of an H and a CH<sub>3</sub> group are reversed in one compared to the other. The (*S*) compound is prescribed to treat patients who experience the pain of arthritis; the (*R*) compound has no beneficial effects in humans and, in fact, causes liver poisoning. These compounds belong to a special class of structural isomers called *enantiomers* that we will learn more about in Chapter 24. Much effort in the pharmaceutical industry goes into making, separating, and purifying one isomer of a compound from other isomers.

◀ **SHAPE MATTERS.** These two compounds at first glance appear identical. But a very small change at one carbon atom makes one compound an anti-pain medication and the other a liver toxin.

## WHAT'S AHEAD

- 9.1 ► **Molecular Shapes** Draw three-dimensional structures of molecules.
- 9.2 ► **The VSEPR Model** Predict molecular geometries using the *valence-shell electron-pair repulsion*, or *VSEPR*, model, which is based on Lewis structures and the repulsions between regions of high electron density.
- 9.3 ► **Molecular Shape and Molecular Polarity** Determine whether a molecule is *polar* or *nonpolar* by analyzing its geometry and the types of bonds it contains.
- 9.4 ► **Covalent Bonding and Orbital Overlap** Explore how electrons are shared between atoms in a covalent bond. In *valence-bond theory*, the bonding electrons are visualized as originating in atomic orbitals on two atoms. A covalent bond is formed when these orbitals overlap.
- 9.5 ► **Hybrid Orbitals** Examine how the orbitals of one atom mix with one another, or *hybridize*, to create *hybrid orbitals*.
- 9.6 ► **Multiple Bonds** Learn how atomic orbitals overlap in multiple ways to produce *sigma* and *pi* bonds between atoms. Single bonds consist of one sigma bond; multiple bonds involve one sigma and one or more pi bonds. Examine the geometric arrangements of these bonds and how they are exemplified in organic compounds.
- 9.7 ► **Molecular Orbitals** Examine a more sophisticated treatment of bonding called *molecular orbital theory*, which introduces the concepts of *bonding* and *antibonding molecular orbitals*.
- 9.8 ► **Bonding in Period 2 Diatomic Molecules** Extend the concepts of molecular orbital theory to construct *energy-level diagrams* for second-row diatomic molecules.

In this chapter, our first goal is to understand the relationship between two-dimensional Lewis structures and three-dimensional molecular shapes. We will see the intimate relationship between the number of electrons in a molecule and the overall shape it adopts. Armed with this knowledge, we can examine more closely the nature of covalent bonds. The lines used to depict bonds in Lewis structures provide important clues about the orbitals that molecules use in bonding. By examining these orbitals, we can gain a greater understanding of the behavior of molecules. Mastering the material in this chapter will help you in later discussions of the physical and chemical properties of substances.

## 9.1 | Molecular Shapes

In Chapter 8 we used Lewis structures to account for the formulas of covalent compounds. [Section 8.5](#) Lewis structures, however, do not indicate the shapes of molecules; they simply show the number and types of bonds. For example, the Lewis structure of  $\text{CCl}_4$  tells us only that four Cl atoms are bonded to a central C atom:

The Lewis structure is drawn with the atoms all in the same plane. As shown in [Figure 9.1](#), however, the actual three-dimensional arrangement has the Cl atoms at the corners of a *tetrahedron*, a geometric object with four corners and four faces, each an equilateral triangle.

The shape of a molecule is determined by its **bond angles**, the angles made by the lines joining the nuclei of the atoms in the molecule. The bond angles of a molecule, together with the bond lengths [Section 8.8](#), define the shape and size of the molecule. In [Figure 9.1](#), you should be able to see that there are six  $\text{Cl—C—Cl}$  bond angles in  $\text{CCl}_4$ , all of which have the same value. That bond angle,  $109.5^\circ$ , is characteristic of a tetrahedron. In addition, all four  $\text{C—Cl}$  bonds are of the same length ( $1.78 \text{ \AA}$ ). Thus, the shape and size of  $\text{CCl}_4$  are completely described by stating that the molecule is tetrahedral with  $\text{C—Cl}$  bonds of length  $1.78 \text{ \AA}$ . To draw the three-dimensional structure of a molecule on paper, chemists use a convention shown in [Figure 9.1](#): Regular lines imply the bond is in the plane of the paper, a heavy wedge is used to show that the bond is coming out of the paper toward you, and the dashed line is used to show that the bond is pointing away from you, through the back of the paper.

▲ **Figure 9.1** Tetrahedral shape of  $\text{CCl}_4$ .

## Go Figure

Which of these structures is not planar?

▲ Figure 9.2 Shapes of AB<sub>2</sub> and AB<sub>3</sub> molecules.

We begin our discussion of molecular shapes with molecules (and ions) that, like CCl<sub>4</sub>, have a single central atom bonded to two or more atoms of the same type. Such molecules have the general formula AB<sub>*n*</sub> in which the central atom A is bonded to *n* B atoms. Both CO<sub>2</sub> and H<sub>2</sub>O are AB<sub>2</sub> molecules, for example, whereas SO<sub>3</sub> and NH<sub>3</sub> are AB<sub>3</sub> molecules, and so on.

The number of shapes possible for AB<sub>*n*</sub> molecules depends on the value of *n*. Those commonly found for AB<sub>2</sub> and AB<sub>3</sub> molecules are shown in Figure 9.2. An AB<sub>2</sub> molecule must be either *linear* (bond angle = 180°) or *bent* (bond angle ≠ 180°). For AB<sub>3</sub> molecules, the two most common shapes place the B atoms at the corners of an equilateral triangle. If the A atom lies in the same plane as the B atoms, the shape is called *trigonal planar*. If the A atom lies above the plane of the B atoms, the shape is called *trigonal pyramidal* (a pyramid with an equilateral triangle as its base). Some AB<sub>3</sub> molecules, such as ClF<sub>3</sub>, are *T-shaped*, a relatively unusual shape shown in Figure 9.2. The atoms lie in one plane with two B—A—B angles of about 90°, and a third angle close to 180°.

Quite remarkably, the shapes of most AB<sub>*n*</sub> molecules can be derived from just five basic geometric arrangements, shown in Figure 9.3. All of these are highly symmetric arrangements of the *n* B atoms around the central A atom. We have already seen the first three shapes: linear, trigonal planar, and tetrahedral. The trigonal bipyramid shape for

## Go Figure

Which of these molecular shapes do you expect for the SF<sub>6</sub> molecule?▲ Figure 9.3 Shapes allowing maximum distances between B atoms in AB<sub>*n*</sub> molecules.

### Go Figure

In going from the tetrahedral shape to the bent shape, does it matter which two of the atoms we choose to remove?

▲ Figure 9.4 Derivatives of the tetrahedral molecular shape.

$AB_5$  can be thought of as a trigonal planar  $AB_3$  arrangement with two additional atoms, one above and one below the equilateral triangle. The octahedral shape for  $AB_6$  has all six B atoms at the same distance from atom A with  $90^\circ$  B—A—B angles between all neighboring B atoms. Its symmetric shape (and its name) is derived from the *octahedron*, with eight faces, all of which are equilateral triangles.

You may have noticed that some of the shapes we have already discussed are *not* among the five shapes in Figure 9.3. For example, in Figure 9.2, neither the bent shape of the  $SO_2$  molecule nor the trigonal pyramidal shape of the  $NF_3$  molecule is among the shapes in Figure 9.3. However, as we soon will see, we can derive additional shapes, such as bent and trigonal pyramidal, by starting with one of our five basic arrangements. Starting with a tetrahedron, for example, we can remove atoms successively from the vertices, as shown in Figure 9.4. When an atom is removed from one vertex of a tetrahedron, the remaining  $AB_3$  fragment has a trigonal-pyramidal geometry. When a second atom is removed, the remaining  $AB_2$  fragment has a bent geometry.

Why do most  $AB_n$  molecules have shapes related to those shown in Figure 9.3? Can we predict these shapes? When A is a representative element (one from the *s* block or *p* block of the periodic table), we can answer these questions by using the **valence-shell electron-pair repulsion (VSEPR) model**. Although the name is rather imposing, the model is quite simple. It has useful predictive capabilities, as we will see in Section 9.2.

### Give It Some Thought

In addition to tetrahedral, another common shape for  $AB_4$  molecules is *square planar*. All five atoms lie in the same plane, with the B atoms at the corners of a square and the A atom at the center of the square. Which shape in Figure 9.3 could lead to a square-planar shape upon removal of one or more atoms?

## 9.2 | The VSEPR Model

Imagine tying two identical balloons together at their ends. As shown in Figure 9.5, the two balloons naturally orient themselves to point away from each other; that is, they try to “get out of each other’s way” as much as possible. If we add a third balloon, the balloons orient themselves toward the vertices of an equilateral triangle, and if we add a fourth balloon, they adopt a tetrahedral shape. We see that an optimum geometry exists for each number of balloons.

In some ways, the electrons in molecules behave like these balloons. We have seen that a single covalent bond is formed between two atoms when a pair of electrons occupies the space between the atoms.  (Section 8.3) A *bonding pair* of electrons thus defines a region in which the electrons are most likely to be found. We will refer to such a region as an **electron domain**. Likewise, a *nonbonding pair* (or *lone pair*) of electrons,

which was also discussed in Section 8.3, defines an electron domain that is located principally on one atom. For example, the Lewis structure of  $\text{NH}_3$  has four electron domains around the central nitrogen atom (three bonding pairs, represented as usual by short lines, and one nonbonding pair, represented by dots):

Each multiple bond in a molecule also constitutes a single electron domain. Thus, the following resonance structure for  $\text{O}_3$  has three electron domains around the central oxygen atom (a single bond, a double bond, and a nonbonding pair of electrons):

In general, *each nonbonding pair, single bond, or multiple bond produces a single electron domain around the central atom in a molecule.*

### Give It Some Thought

Suppose a particular  $\text{AB}_3$  molecule has the resonance structure

Does this structure follow the octet rule? How many electron domains are there around the A atom?

The VSEPR model is based on the idea that electron domains are negatively charged and therefore repel one another. Like the balloons in Figure 9.5, electron domains try to stay out of one another's way.

*The best arrangement of a given number of electron domains is the one that minimizes the repulsions among them.*

In fact, the analogy between electron domains and balloons is so close that the same preferred geometries are found in both cases. Like the balloons in Figure 9.5, two electron domains orient *linearly*, three domains orient in a *trigonal-planar* fashion, and four orient *tetrahedrally*. These arrangements, together with those for five- and six-electron domains, are summarized in Table 9.1. If you compare the geometries in Table 9.1 with those in Figure 9.3, you will see that they are the same.

*The shapes of different  $\text{AB}_n$  molecules or ions depend on the number of electron domains surrounding the central atom.*

The arrangement of electron domains about the central atom of an  $\text{AB}_n$  molecule or ion is called its **electron-domain geometry**. In contrast, the **molecular geometry** is the arrangement of *only the atoms* in a molecule or ion—any nonbonding pairs in the molecule are *not* part of the description of the molecular geometry.

## Applying the VSEPR Model to Determine Molecular Shapes

In determining the shape of any molecule, we first use the VSEPR model to predict the electron-domain geometry. From knowing how many of the domains are due to nonbonding pairs, we can then predict the molecular geometry. When all the electron domains in a molecule arise from bonds, the molecular geometry is identical to the electron-domain geometry. When, however, one or more domains involve nonbonding pairs of electrons, we must remember that *the molecular geometry involves only electron domains due to bonds* even though the nonbonding pairs contribute to the electron-domain geometry.

**TABLE 9.1** Electron-Domain Geometries as a Function of Number of Electron Domains

| Number of Electron Domains* | Arrangement of Electron Domains  | Electron Domain Geometry | Predicted Bond Angles |
|-----------------------------|--|--------------------------|-----------------------|
| 2                           |    | Linear                   | 180°                  |
| 3                           |    | Trigonal planar          | 120°                  |
| 4                           |    | Tetrahedral              | 109.5°                |
| 5                           |   | Trigonal bipyramidal     | 120°<br>90°           |
| 6                           |  | Octahedral               | 90°                   |

\*The number of electron domains is sometimes called the *coordination number* of the atom.

#### How to Predict the Shapes of Molecules and Ions Using the VSEPR Model

1. Draw the Lewis structure of the molecule or ion  (Section 8.5), and count the number of electron domains around the central atom. Each nonbonding electron pair, each single bond, each double bond, and each triple bond counts as one electron domain.
2. Determine the *electron-domain geometry* by arranging the electron domains about the central atom so that the repulsions among them are minimized, as shown in Table 9.1.
3. Use the arrangement of the bonded atoms to determine the *molecular geometry*.

**Table 9.2** summarizes the possible molecular geometries when an  $AB_n$  molecule has four or fewer electron domains about A. These geometries are important because they include all the shapes usually seen in molecules or ions that obey the octet rule.

**TABLE 9.2** Electron-Domain and Molecular Geometries for Two, Three, and Four Electron Domains around a Central Atom

| Number of Electron Domains | Electron-Domain Geometry   | Bonding Domains | Nonbonding Domains | Molecular Geometry   | Example  |
|----------------------------|--|-----------------|--------------------|--|--|
| 2                          | <br>Linear          | 2               | 0                  | <br>Linear               | $\ddot{\text{O}}=\text{C}=\ddot{\text{O}}$   |
| 3                          | <br>Trigonal planar | 3               | 0                  | <br>Trigonal planar      | $\begin{array}{c} \text{:}\ddot{\text{F}}\text{:} \\   \\ \text{:}\ddot{\text{B}}\text{:} \\   \\ \text{:}\ddot{\text{F}}\text{:} \end{array}$                     |
|                            |  | 2               | 1                  | <br>Bent                 | $\left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\    \\ \text{:}\ddot{\text{N}}\text{:} \\   \\ \text{:}\ddot{\text{O}}\text{:} \end{array} \right]^{-}$ |
| 4                          | <br>Tetrahedral     | 4               | 0                  | <br>Tetrahedral          | $\begin{array}{c} \text{H} \\   \\ \text{H}-\text{C}-\text{H} \\   \\ \text{H} \end{array}$  |
|                            |  | 3               | 1                  | <br>Trigonal pyramidal | $\begin{array}{c} \text{:}\ddot{\text{N}}\text{:} \\   \\ \text{H}-\text{N}-\text{H} \\   \\ \text{H} \end{array}$   |
|                            |  | 2               | 2                  | <br>Bent               | $\begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\   \\ \text{H}-\text{O}-\text{H} \end{array}$  |

Figure 9.6 shows how to use the three steps in the VSEPR model to predict the geometry of the  $\text{NH}_3$  molecule. The three bonds and one nonbonding pair in the Lewis structure tell us we have four electron domains. Thus, from Table 9.1, the electron-domain

◀ **Figure 9.6** Determining the molecular geometry of  $\text{NH}_3$ .

geometry of  $\text{NH}_3$  is tetrahedral. We know from the Lewis structure that one electron domain is due to a nonbonding pair, which occupies one of the four vertices of the tetrahedron. In determining the molecular geometry, we consider only the three  $\text{N}-\text{H}$  bond domains, which leads to a trigonal pyramidal geometry. The situation is just like the middle drawing in Figure 9.4 in which removing one atom from a tetrahedral molecule results in a trigonal pyramidal molecule. Notice that the tetrahedral arrangement of the four electron domains leads us to predict the trigonal-pyramidal molecular geometry.

Because the trigonal-pyramidal molecular geometry is based on a tetrahedral electron-domain geometry, the ideal bond angles are  $109.5^\circ$ . As we will soon see, bond angles deviate from ideal values when the surrounding atoms and electron domains are not identical.

As one more example, let's determine the shape of the  $\text{CO}_2$  molecule. Its Lewis structure reveals two electron domains (each one a double bond) around the central carbon:

Two electron domains orient in a linear electron-domain geometry (Table 9.1). Because neither domain is a nonbonding pair of electrons, the molecular geometry is also linear, and the  $\text{O}-\text{C}-\text{O}$  bond angle is  $180^\circ$ .

## Sample Exercise 9.1

### Using the VSEPR Model

Use the VSEPR model to predict the molecular geometry of (a)  $\text{O}_3$ , (b)  $\text{SnCl}_3^-$ .

### SOLUTION

**Analyze** We are given the molecular formulas of a molecule and a polyatomic ion, both conforming to the general formula  $\text{AB}_n$  and both having a central atom from the  $p$  block of the periodic table. (Notice that for  $\text{O}_3$ , the A and B atoms are all oxygen atoms.)

**Plan** To predict the molecular geometries, we draw their Lewis structures and count electron domains around the central atom to get the electron-domain geometry. We then obtain the molecular geometry from the arrangement of the domains that are due to bonds.

### Solve

(a) We can draw two resonance structures for  $\text{O}_3$ :

Because of resonance, the bonds between the central O atom and the outer O atoms are of equal length. In both resonance structures, the central O atom is bonded to the two outer O atoms and has one nonbonding pair. Thus, there are three electron domains about the central O atoms. (Remember that a double bond counts as a single electron domain.) The arrangement of three electron domains is trigonal planar (Table 9.1). Two of the domains are from bonds, and one is due to a nonbonding pair. So, the molecular geometry is bent with an ideal bond angle of  $120^\circ$  (Table 9.2).

**Comment** As this example illustrates, when a molecule exhibits resonance, any one of the resonance structures can be used to predict the molecular geometry.

(b) The Lewis structure for  $\text{SnCl}_3^-$  is:

The central Sn atom is bonded to the three Cl atoms and has one nonbonding pair; thus, we have four electron domains, meaning a tetrahedral electron-domain geometry (Table 9.1) with one vertex occupied by a nonbonding pair of electrons. A tetrahedral electron-domain geometry with three bonding and one nonbonding domains leads to a trigonal-pyramidal molecular geometry (Table 9.2).

### Practice Exercise 1

Consider the following  $\text{AB}_3$  molecules and ions:  $\text{PCl}_3$ ,  $\text{SO}_3$ ,  $\text{AlCl}_3$ ,  $\text{SO}_3^{2-}$ , and  $\text{CH}_3^+$ . How many of these molecules and ions do you predict to have a trigonal-planar molecular geometry? (a) 1 (b) 2 (c) 3 (d) 4 (e) 5

### Practice Exercise 2

Predict the electron-domain and molecular geometries for (a)  $\text{SeCl}_2$ , (b)  $\text{CO}_3^{2-}$ .

## Effect of Nonbonding Electrons and Multiple Bonds on Bond Angles

We can refine the VSEPR model to explain slight distortions from the ideal geometries summarized in Table 9.2. For example, consider methane ( $\text{CH}_4$ ), ammonia ( $\text{NH}_3$ ), and water ( $\text{H}_2\text{O}$ ). All three have a tetrahedral electron-domain geometry, but their bond angles differ slightly:

Notice that the bond angles decrease as the number of nonbonding electron pairs increases. A bonding pair of electrons is attracted by both nuclei of the bonded atoms, but a nonbonding pair is attracted primarily by only one nucleus. Because a nonbonding pair experiences less nuclear attraction, its electron domain is spread out more in space than is the electron domain for a bonding pair (Figure 9.7). Nonbonding electron pairs therefore take up more space than bonding pairs; in essence, they act as larger and fatter balloons in our analogy of Figure 9.5. As a result, *electron domains for nonbonding electron pairs exert greater repulsive forces on adjacent electron domains and tend to compress bond angles*.

Because multiple bonds contain a higher electronic-charge density than single bonds, multiple bonds also represent enlarged electron domains. Consider the Lewis structure of *phosgene*,  $\text{Cl}_2\text{CO}$ :

Because three electron domains surround the central atom, we might expect a trigonal-planar geometry with  $120^\circ$  bond angles. The double bond, however, seems to act much like a nonbonding pair of electrons, reducing the  $\text{Cl}-\text{C}-\text{Cl}$  bond angle to  $111.4^\circ$ :

In general, *electron domains for multiple bonds exert a greater repulsive force on adjacent electron domains than do electron domains for single bonds*.

### Give It Some Thought

One resonance structure of the nitrate ion is

The bond angles in this ion are  $120^\circ$ . Is this observation consistent with the preceding discussion of the effect of multiple bonds on bond angles?

▲ Figure 9.7 Relative volumes occupied by bonding and nonbonding electron domains.

## Molecules with Expanded Valence Shells

Atoms from period 3 and beyond may be surrounded by more than four electron pairs. (Section 8.7) Molecules with five or six electron domains around the central atom have molecular geometries based on either a *trigonal-bipyramidal* (five domains) or *octahedral* (six domains) electron-domain geometry (Table 9.3).

The most stable electron-domain geometry for five electron domains is the trigonal bipyramid (two trigonal pyramids sharing a base). Unlike the other arrangements we

**TABLE 9.3 Electron-Domain and Molecular Geometries for Five and Six Electron Domains around a Central Atom**

| Number of Electron Domains | Electron-Domain Geometry  | Bonding Domains | Nonbonding Domains | Molecular Geometry  | Example        |
|----------------------------|---|-----------------|--------------------|---|----------------|
| 5                          | <br>Trigonal bipyramidal | 5               | 0                  | <br>Trigonal bipyramidal | $\text{PCl}_5$ |
|                            |   | 4               | 1                  | <br>Seesaw               | $\text{SF}_4$  |
|                            |   | 3               | 2                  | <br>T-shaped             | $\text{ClF}_3$ |
|                            |   | 2               | 3                  | <br>Linear              | $\text{XeF}_2$ |
| 6                          | <br>Octahedral         | 6               | 0                  | <br>Octahedral         | $\text{SF}_6$  |
|                            |   | 5               | 1                  | <br>Square pyramidal   | $\text{BrF}_5$ |
|                            |   | 4               | 2                  | <br>Square planar      | $\text{XeF}_4$ |

have seen, the electron domains in a trigonal bipyramid can point toward two geometrically distinct types of positions. Two domains point toward *axial positions*, and three point toward *equatorial positions* (Figure 9.8). Each axial domain makes a  $90^\circ$  angle with any equatorial domain. Each equatorial domain makes a  $120^\circ$  angle with either of the other two equatorial domains and a  $90^\circ$  angle with either axial domain.

Suppose a molecule has five electron domains, and there are one or more nonbonding pairs. Will the domains from the nonbonding pairs occupy axial or equatorial positions? To answer this question, we must determine which location minimizes repulsion between domains. Repulsion between two domains is much greater when they are situated  $90^\circ$  from each other than when they are at  $120^\circ$ . An equatorial domain is  $90^\circ$  from only two other domains (the axial domains), but an axial domain is  $90^\circ$  from *three* other domains (the equatorial domains). Hence, an equatorial domain experiences less repulsion than an axial domain. Because the domains from nonbonding pairs exert larger repulsions than those from bonding pairs, nonbonding domains *always* occupy the equatorial positions in a trigonal bipyramid.

### Give It Some Thought

It might seem that a square-planar geometry of four electron domains around a central atom would be more favorable than a tetrahedron. Can you rationalize why the tetrahedron is preferred, based on angles between electron domains?

The most stable electron-domain geometry for six electron domains is the *octahedron*. An octahedron is a polyhedron with six vertices and eight faces, each an equilateral triangle. An atom with six electron domains around it can be visualized as being at the center of the octahedron with the electron domains pointing toward the six vertices, as shown in Table 9.3. All the bond angles are  $90^\circ$ , and all six vertices are equivalent. Therefore, if an atom has five bonding electron domains and one nonbonding domain, we can put the nonbonding domain at any of the six vertices of the octahedron. The result is always a *square-pyramidal* molecular geometry. When there are two nonbonding electron domains, however, their repulsions are minimized by pointing them toward opposite sides of the octahedron, producing a *square-planar* molecular geometry, as shown in Table 9.3.

### Go Figure

What is the bond angle formed by an axial atom, the central atom, and any equatorial atom?

▲ **Figure 9.8** In a trigonal-bipyramidal geometry, there are two types of positions for the outer atoms.

## Sample Exercise 9.2

### Molecular Geometries of Molecules with Expanded Valence Shells

Use the VSEPR model to predict the molecular geometry of (a)  $\text{SF}_4$ , (b)  $\text{IF}_5$ .

### SOLUTION

**Analyze** The molecules are of the  $\text{AB}_n$  type with a central *p*-block atom.

**Plan** We first draw Lewis structures and then use the VSEPR model to determine the electron-domain geometry and molecular geometry.

### Solve

(a) The Lewis structure for  $\text{SF}_4$  is:

The sulfur has five electron domains around it: four from the  $\text{S}-\text{F}$  bonds and one from the nonbonding pair. Each domain points toward a vertex of a trigonal bipyramid. The domain from the nonbonding pair will point toward an equatorial position. The four bonds point toward the remaining four positions, resulting in a molecular geometry that is described as seesaw-shaped:

**Comment** The experimentally observed structure is shown on the right. We can infer that the nonbonding electron domain occupies an equatorial position, as predicted. The axial and equatorial S—F bonds are slightly bent away from the nonbonding domain, suggesting that the bonding domains are “pushed” by the nonbonding domain, which exerts a greater repulsion (Figure 9.7).

### Solve

(b) The Lewis structure of  $\text{IF}_5$  is:

The iodine has six electron domains around it, one of which is nonbonding. The electron-domain geometry is therefore octahedral, with one position occupied by the nonbonding pair, and the molecular geometry is *square pyramidal* (Table 9.3):

**Comment** Because the nonbonding domain is larger than the bonding domains, we predict that the four F atoms in the base of the pyramid will be tipped up slightly toward the top F atom. Experimentally, we find that the angle between the base atoms and the top F atom is  $82^\circ$ , smaller than the ideal  $90^\circ$  angle of an octahedron.

### Practice Exercise 1

A certain  $\text{AB}_4$  molecule has a square-planar molecular geometry. Which of the following statements about the molecule is or are true?

- (i) The molecule has four electron domains about the central atom A.
- (ii) The  $\text{B—A—B}$  angles between neighboring B atoms are  $90^\circ$ .
- (iii) The molecule has two nonbonding pairs of electrons on atom A.

- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

### Practice Exercise 2

Predict the electron-domain and molecular geometries of (a)  $\text{BrF}_3$ , (b)  $\text{SF}_5^+$ .

## Shapes of Larger Molecules

Although the molecules and ions we have considered contain only a single central atom, the VSEPR model can be extended to more complex molecules. Consider the acetic acid molecule:

We can use the VSEPR model to predict the geometry about each carbon atom:

| Number of electron domains | 4             | 3               | 4             |
|----------------------------|---------------|-----------------|---------------|
| Electron-domain geometry   | Tetrahedral   | Trigonal planar | Tetrahedral   |

## Go Figure

In the actual structure of acetic acid, which bond angle is expected to be the smallest?

Electron-domain geometry tetrahedral,  
molecular geometry tetrahedral

Electron-domain geometry trigonal planar,  
molecular geometry trigonal planar

Electron-domain geometry tetrahedral,  
molecular geometry bent

▲ **Figure 9.9** The electron-domain and molecular geometries around the three central atoms of acetic acid,  $\text{CH}_3\text{COOH}$ .

The C on the left has four electron domains (all bonding), so the electron-domain and molecular geometries around that atom are both tetrahedral. The central C has three electron domains (counting the double bond as one domain), making both the electron-domain and the molecular geometries trigonal planar. The O on the right has four electron domains (two bonding, two nonbonding), so its electron-domain geometry is tetrahedral and its molecular geometry is bent. The bond angles about the central C atom and the O atom are expected to deviate slightly from the ideal values of  $120^\circ$  and  $109.5^\circ$  because of the spatial demands of multiple bonds and nonbonding electron pairs.

Our analysis of the acetic acid molecule is shown in **Figure 9.9**.

## Sample Exercise 9.3

## Predicting Bond Angles

Eyedrops for dry eyes usually contain a water-soluble polymer called *poly(vinyl alcohol)*, which is based on the unstable organic molecule *vinyl alcohol*:

Predict the approximate values for the  $\text{H}-\text{O}-\text{C}$  and  $\text{O}-\text{C}-\text{C}$  bond angles in vinyl alcohol.

## SOLUTION

**Analyze** We are given a Lewis structure and asked to determine two bond angles.

**Plan** To predict a bond angle, we determine the number of electron domains surrounding the middle atom in the angle. The ideal angle corresponds to the electron-domain geometry around the atom. The angle will be compressed somewhat by nonbonding electrons or multiple bonds.

**Solve** In  $\text{H}-\text{O}-\text{C}$ , the O atom has four electron domains (two bonding, two nonbonding). The electron-domain geometry around O is therefore tetrahedral, which gives an ideal angle of  $109.5^\circ$ . The  $\text{H}-\text{O}-\text{C}$  angle is compressed somewhat by the nonbonding pairs, so we expect this angle to be slightly less than  $109.5^\circ$ .

To predict the  $\text{O}-\text{C}-\text{C}$  bond angle, we examine the middle atom in the angle. In the molecule, there are three atoms bonded to this C atom and no nonbonding pairs, and so it has three electron domains about it. The predicted electron-domain geometry is trigonal planar, resulting in an ideal bond angle of  $120^\circ$ . Because of the larger size of the  $\text{C}=\text{C}$  domain, the bond angle should be slightly greater than  $120^\circ$ .

## Practice Exercise 1

The atoms of the compound methylhydrazine,  $\text{CH}_6\text{N}_2$ , which is used as a rocket propellant, are connected as follows (note that lone pairs are not shown):

What do you predict for the ideal values of the  $\text{C}-\text{N}-\text{N}$  and  $\text{H}-\text{N}-\text{H}$  angles, respectively?

- (a)  $109.5^\circ$  and  $109.5^\circ$  (b)  $109.5^\circ$  and  $120^\circ$  (c)  $120^\circ$  and  $109.5^\circ$  (d)  $120^\circ$  and  $120^\circ$  (e) None of the above

## Practice Exercise 2

Predict the  $\text{H}-\text{C}-\text{H}$  and  $\text{C}-\text{C}-\text{C}$  bond angles in propyne:

## 9.3 | Molecular Shape and Molecular Polarity

Now that we have a sense of the shapes that molecules adopt and why they do so, we will return to some topics that we first discussed in Section 8.4, namely, *bond polarity* and *dipole moments*. Recall that bond polarity is a measure of how equally the electrons in a bond are shared between the two atoms of the bond. As the difference in electronegativity between the two atoms increases, so does the bond polarity.  $\infty$  (Section 8.4) We saw that the dipole moment of a diatomic molecule is a measure of the amount of charge separation in the molecule.

For a molecule consisting of more than two atoms, *the dipole moment depends on both the polarities of the individual bonds and the geometry of the molecule*. For each bond in the molecule, we consider the **bond dipole**, which is the dipole moment due only to the two atoms in that bond. Consider the linear  $\text{CO}_2$  molecule, for example. As shown in Figure 9.10(a), each  $\text{C}=\text{O}$  bond is polar, and because the  $\text{C}=\text{O}$  bonds are identical, the bond dipoles are equal in magnitude. A plot of the molecule's electron density clearly shows that the individual bonds are polar, but what can we say about the *overall* dipole moment of the molecule?

Bond dipoles and dipole moments are *vector quantities*; that is, they have both a magnitude and a direction. The dipole moment of a polyatomic molecule is the vector sum of its bond dipoles. Both the magnitudes *and* the directions of the bond dipoles must be considered when summing vectors. The two bond dipoles in  $\text{CO}_2$ , although equal in magnitude, are opposite in direction. Adding them is the same as adding two numbers that are equal in magnitude but opposite in sign, such as  $100 + (-100)$ . The bond dipoles, like the numbers, “cancel” each other. Therefore, the dipole moment of  $\text{CO}_2$  is zero, even though the individual bonds are polar. The geometry of the molecule dictates that the overall dipole moment be zero, making  $\text{CO}_2$  a *nonpolar* molecule.

Now let's consider  $\text{H}_2\text{O}$ , a bent molecule with two polar bonds (Figure 9.10(b)). Again, the two bonds are identical, and the bond dipoles are equal in magnitude. Because

▲ **Figure 9.10**  $\text{CO}_2$ , a nonpolar molecule, and  $\text{H}_2\text{O}$ , a polar molecule. The numbers are electronegativity values for these two atoms.

the molecule is bent, however, the bond dipoles do not directly oppose each other and therefore do not cancel. Hence, the  $\text{H}_2\text{O}$  molecule has an overall nonzero dipole moment (measured dipole moment,  $\mu = 1.85 \text{ D}$ ) and is therefore a *polar* molecule. The oxygen atom carries a partial negative charge, and the hydrogen atoms each have a partial positive charge, as shown in Figure 9.10(b).

### Give It Some Thought

The molecule  $\text{O}=\text{C}=\text{S}$  is linear and has a Lewis structure analogous to that of  $\text{CO}_2$ . Would you expect this molecule to be nonpolar?

Figure 9.11 shows some examples of polar and nonpolar molecules, all with polar bonds. The molecules in which the central atom is symmetrically surrounded by identical atoms ( $\text{BF}_3$  and  $\text{CCl}_4$ ) are nonpolar. For  $\text{AB}_n$  molecules in which all the B atoms are the same, certain symmetrical shapes—linear ( $\text{AB}_2$ ), trigonal planar ( $\text{AB}_3$ ), tetrahedral and square planar ( $\text{AB}_4$ ), trigonal bipyramidal ( $\text{AB}_5$ ), and octahedral ( $\text{AB}_6$ )—must lead to nonpolar molecules even though the individual bonds might be polar.

▲ **Figure 9.11** Polar and nonpolar molecules containing polar bonds. The numbers are electronegativity values.

### Sample Exercise 9.4

#### Polarity of Molecules

Predict whether these molecules are polar or nonpolar: (a)  $\text{BrCl}$ , (b)  $\text{SO}_2$ , (c)  $\text{SF}_6$ .

#### SOLUTION

**Analyze** We are given three molecular formulas and asked to predict whether the molecules are polar.

**Plan** A molecule containing only two atoms is polar if the atoms differ in electronegativity. The polarity of a molecule containing three or more atoms depends on both the molecular geometry and the individual bond polarities. Thus, we must draw a Lewis structure for each molecule containing three or more atoms and determine its molecular geometry. We then use electronegativity values to determine the direction of the bond dipoles. Finally, we see whether the bond dipoles cancel to give a nonpolar molecule or reinforce each other to give a polar one.

#### Solve

- (a) Chlorine is more electronegative than bromine. All diatomic molecules with polar bonds are polar molecules. Consequently,  $\text{BrCl}$  is polar, with chlorine carrying the partial negative charge:

The measured dipole moment  $\mu$  of  $\text{BrCl}$  is  $0.57 \text{ D}$ .

- (b) Because oxygen is more electronegative than sulfur,  $\text{SO}_2$  has polar bonds. Three resonance forms can be written:

For each of these, the VSEPR model predicts a bent molecular geometry. Because the molecule is bent, the bond dipoles do not cancel, and the molecule is polar:

Experimentally, the dipole moment  $\mu$  of  $\text{SO}_2$  is  $1.63 \text{ D}$ .

Continued

- (c) Fluorine is more electronegative than sulfur, so the bond dipoles point toward fluorine. For clarity, only one S—F dipole is shown. The six S—F bonds are arranged octahedrally around the central sulfur:

Because the octahedral molecular geometry is symmetrical, the bond dipoles cancel, and the molecule is nonpolar, meaning that  $\mu = 0$ .

### Practice Exercise 1

Consider an  $AB_3$  molecule in which A and B differ in electronegativity. You are told that the molecule has an overall dipole moment of zero. Which of the following could be the molecular geometry of the molecule?

- (a) Trigonal pyramidal (b) Trigonal planar  
(c) T-shaped (d) Tetrahedral  
(e) More than one of the above

### Practice Exercise 2

Determine whether the following molecules are polar or nonpolar: (a)  $SF_4$ , (b)  $SiCl_4$ .

## 9.4 | Covalent Bonding and Orbital Overlap

The VSEPR model provides a simple means for predicting molecular geometries but does not explain why bonds exist between atoms. In developing theories of covalent bonding, chemists have approached the problem from another direction, using quantum mechanics. How can we use atomic orbitals to explain bonding and to account for molecular geometries? The marriage of Lewis's notion of electron-pair bonds and the idea of atomic orbitals leads to a model of chemical bonding, called **valence-bond theory**, in which bonding electron pairs are concentrated in the regions between atoms, and nonbonding electron pairs lie in directed regions of space. By extending this approach to include the ways in which atomic orbitals can mix with one another, we obtain an explanatory picture that corresponds to the VSEPR model.

In Lewis theory, covalent bonding occurs when atoms share electrons because the sharing concentrates electron density between the nuclei. In valence-bond theory, we visualize the buildup of electron density between two nuclei as occurring when a valence atomic orbital of one atom shares space, or *overlaps*, with a valence atomic orbital of another atom. The overlap of orbitals allows two electrons of opposite spin to share the space between the nuclei, forming a covalent bond.

**Figure 9.12** shows three examples of how valence-bond theory describes the coming together of two atoms to form a molecule. In the example of the formation of  $H_2$ , each hydrogen atom has a single electron in a  $1s$  orbital. As the orbitals overlap, electron density is concentrated between the nuclei. Because the electrons in the overlap region are simultaneously attracted to both nuclei, they hold the atoms together, forming a covalent bond.

The idea of orbital overlap producing a covalent bond applies equally well to other molecules. In  $HCl$ , for example, chlorine has the electron configuration  $[Ne]3s^23p^5$ . All the valence orbitals of chlorine are full except one  $3p$  orbital, which contains a single electron. This  $3p$  electron pairs with the single  $1s$  electron of  $H$  to form the covalent bond that holds  $HCl$  together (Figure 9.12). Because the other two chlorine  $3p$  orbitals are already each filled with a pair of electrons, they do not participate in the bonding to hydrogen. Likewise, we can explain the covalent bond in  $Cl_2$  in terms of the overlap of the singly occupied  $3p$  orbital of one  $Cl$  atom with the singly occupied  $3p$  orbital of another.

There is always an optimum distance between the two nuclei in any covalent bond. **Figure 9.13** shows how the potential energy of a system consisting of two  $H$  atoms changes as the atoms come together to form an  $H_2$  molecule. When the atoms are infinitely far apart, they do not “feel” each other and so the energy approaches zero. As the distance between the atoms decreases, the overlap between their  $1s$  orbitals increases. Because of the resulting increase in electron density between the nuclei, the potential energy of the system decreases. That is, the strength of the bond increases, as shown by the decrease in the potential energy of the two-atom system. However, Figure 9.13 also shows that the energy increases sharply when the distance between the two hydrogen nuclei is less than  $0.74 \text{ \AA}$ . The increase in potential energy of the system, which becomes significant at short internuclear distances, is due mainly to the electrostatic repulsion between the nuclei. The internuclear distance at the minimum of the potential-energy curve (in

**Figure 9.12** Covalent bonds in  $H_2$ ,  $HCl$ , and  $Cl_2$  result from overlap of atomic orbitals.

this example, at 0.74 Å) corresponds to the bond length of the molecule. The potential energy at this minimum corresponds to the bond strength. Thus, the observed bond length is the distance at which the attractive forces between unlike charges (electrons and nuclei) are balanced by the repulsive forces between like charges (electron–electron and nucleus–nucleus).

## 9.5 | Hybrid Orbitals

The VSEPR model, simple as it is, does a surprisingly good job at predicting molecular shape, despite the fact that it has no obvious relationship to the filling and shapes of atomic orbitals. For example, we would like to understand how to account for the tetrahedral arrangement of C—H bonds in methane in terms of the  $2s$  and  $2p$  orbitals of the central carbon atom, which are not directed toward the apices of a tetrahedron. How can we reconcile the notion that covalent bonds are formed from overlap of atomic orbitals with the molecular geometries that come from the VSEPR model?

To begin with, we recall that atomic orbitals are mathematical functions that come from the quantum-mechanical model for atomic structure. [Section 6.5](#) To explain molecular geometries, we often assume that the atomic orbitals on an atom (usually the central atom) mix to form new orbitals called **hybrid orbitals**. The shape of any hybrid orbital is different from the shapes of the original atomic orbitals. The process of mixing atomic orbitals is a mathematical operation called **hybridization**. The total number of atomic orbitals on an atom remains constant, so the number of hybrid orbitals on an atom equals the number of atomic orbitals that are mixed.

As we examine the common types of hybridization, notice the connection between the type of hybridization and some of the molecular geometries predicted by the VSEPR model: linear, bent, trigonal planar, and tetrahedral.

### $sp$ Hybrid Orbitals

To illustrate the process of hybridization, consider the  $\text{BeF}_2$  molecule, which has the Lewis structure

The VSEPR model predicts that  $\text{BeF}_2$  is linear with two identical  $\text{Be}-\text{F}$  bonds, in accord with experiment. How can we use valence-bond theory to describe the bonding? The electron configuration of F ( $1s^2 2s^2 2p^5$ ) indicates an unpaired electron in a  $2p$  orbital. This electron can be paired with an unpaired Be electron to form a polar covalent bond. Which orbitals on the Be atom, however, overlap with those on the F atoms to form the  $\text{Be}-\text{F}$  bonds?

The orbital diagram for a ground-state Be atom is

Because it has no unpaired electrons, the Be atom in its ground state cannot bond with the fluorine atoms. The Be atom could form two bonds, however, by envisioning that we “promote” one of the  $2s$  electrons to a  $2p$  orbital:

The Be atom now has two unpaired electrons and can therefore form two polar covalent bonds with F atoms. The two bonds would not be identical, however, because a Be  $2s$  orbital would be used to form one of the bonds and a  $2p$  orbital would be used to form the other. Therefore, although the promotion of an electron allows two  $\text{Be}-\text{F}$  bonds to form, we still have not explained the structure of  $\text{BeF}_2$ .

We can solve this dilemma by “mixing” the  $2s$  orbital with one  $2p$  orbital to generate two new orbitals, as shown in Figure 9.14. Like  $p$  orbitals, each new orbital has two lobes. Unlike  $p$  orbitals, however, one lobe is much larger than the other. The two new orbitals are identical in shape, but their large lobes point in opposite directions. These two new orbitals, which are shown in purple in Figure 9.14, are hybrid orbitals. Because we have hybridized one  $s$  and one  $p$  orbital, we call each hybrid an  $sp$  hybrid orbital. *According to the valence-bond model, a linear arrangement of electron domains implies  $sp$  hybridization.*

For the Be atom of  $\text{BeF}_2$ , we write the orbital diagram for the formation of two  $sp$  hybrid orbitals as

The electrons in the  $sp$  hybrid orbitals can form bonds with the two fluorine atoms (Figure 9.15). Because the  $sp$  hybrid orbitals are equivalent but point in opposite directions,  $\text{BeF}_2$  has two identical bonds and a linear geometry. We have used one of the  $2p$  orbitals in making the hybrids; the remaining two  $2p$  atomic orbitals of Be remain unhybridized and are vacant. Remember also that each fluorine atom has two other valence  $p$  atomic orbitals, each containing one nonbonding electron pair. Those atomic orbitals are omitted from Figure 9.15 to keep the illustration simpler.

▲ Figure 9.14 Formation of  $sp$  hybrid orbitals.

◀ **Figure 9.15** Formation of two equivalent Be—F bonds in  $\text{BeF}_2$ .

### Give It Some Thought

What is the orientation of the two unhybridized  $p$  orbitals on Be with respect to the two Be—F bonds?

## $sp^2$ and $sp^3$ Hybrid Orbitals

Whenever we mix a certain number of atomic orbitals, we get the same number of hybrid orbitals. Each hybrid orbital is equivalent to the others but points in a different direction. Thus, mixing one  $2s$  and one  $2p$  atomic orbital yields two equivalent  $sp$  hybrid orbitals that point in opposite directions (Figure 9.14). Other combinations of atomic orbitals can be hybridized to obtain different geometries, such as  $sp^2$  and  $sp^3$ .

In  $\text{BF}_3$ , for example, mixing the  $2s$  and two of the  $2p$  atomic orbitals yields three equivalent  $sp^2$  (pronounced “ $s$ - $p$ -two”) hybrid orbitals (Figure 9.16). The three  $sp^2$  hybrid orbitals lie in the same plane,  $120^\circ$  apart from one another. They are used to make three equivalent bonds with the three fluorine atoms, leading to the trigonal-planar molecular geometry of  $\text{BF}_3$ . Notice that an unfilled  $2p$  atomic orbital remains unhybridized; it is oriented perpendicular to the plane defined by the three  $sp^2$  hybrid orbitals, with one lobe above and one below the plane. This unhybridized orbital will be important when we discuss double bonds in Section 9.6.

An  $s$  atomic orbital can mix with all three  $p$  atomic orbitals in the same subshell. For example, the carbon atom in  $\text{CH}_4$  forms four equivalent bonds with the four hydrogen

### Go Figure

What is the angle formed between the large lobes of the three  $sp^2$  hybrid orbitals?

▲ **Figure 9.16** Formation of  $sp^2$  hybrid orbitals.

## Go Figure

Which of the  $p$  orbitals do you think contributes the most in the mixing that leads to the right-most  $sp^3$  hybrid orbital in the second row of the figure?

▲ **Figure 9.17** Formation of  $sp^3$  hybrid orbitals.

atoms. We envision this process as resulting from the mixing of the  $2s$  and all three  $2p$  atomic orbitals of carbon to create four equivalent  $sp^3$  (pronounced “ $s$ - $p$ -three”) hybrid orbitals. Each  $sp^3$  hybrid orbital has a large lobe that points toward one vertex of a tetrahedron (**Figure 9.17**). These hybrid orbitals can be used to form two-electron bonds by overlap with the atomic orbitals of another atom, such as H. Using valence-bond theory, we can describe the bonding in  $\text{CH}_4$  as the overlap of four equivalent  $sp^3$  hybrid orbitals on C with the  $1s$  orbitals of the four H atoms to form four equivalent bonds.

## Give It Some Thought

In an  $sp^2$  hybridized atom, we saw that there was one unhybridized  $2p$  orbital. How many unhybridized  $2p$  orbitals remain on an atom that has  $sp^3$  hybrid orbitals?

The idea of hybridization is also used to describe the bonding in molecules containing nonbonding pairs of electrons. In  $\text{H}_2\text{O}$ , for example, the electron-domain geometry around the central O atom is approximately tetrahedral (**Figure 9.18**). Thus, the four electron pairs can be envisioned as occupying  $sp^3$  hybrid orbitals. Two of the hybrid orbitals contain nonbonding pairs of electrons, and the other two form bonds with the hydrogen atoms.

## Go Figure

Does it matter which of the two  $sp^3$  hybrid orbitals are used to hold the two nonbonding electron pairs?

▲ Figure 9.18 Hybrid orbital description of  $\text{H}_2\text{O}$ .

## Hypervalent Molecules

So far our discussion of hybridization has extended only to period 2 elements, specifically carbon, nitrogen, and oxygen. The elements of period 3 and beyond introduce a new consideration because in many of their compounds these elements are **hypervalent**—they have more than an octet of electrons around the central atom. (Section 8.7) We saw in Section 9.2 that the VSEPR model works well to predict the geometries of hypervalent molecules such as  $\text{PCl}_5$ ,  $\text{SF}_6$ , or  $\text{BrF}_5$ . But can we extend the use of hybrid orbitals to describe the bonding in these molecules? In short, the answer is no; hybrid orbitals should not be used for hypervalent molecules. Let's examine the reasons.

The valence-bond model we developed for period 2 elements works well for compounds of period 3 elements so long as we have no more than an octet of electrons in the valence-shell orbitals. Thus, for example, it is appropriate to discuss the bonding in  $\text{PF}_3$  or  $\text{H}_2\text{Se}$  in terms of hybridized  $s$  and  $p$  orbitals on the central atom.

For compounds with more than an octet, we could imagine increasing the number of hybrid orbitals formed by including valence-shell  $d$  orbitals. For example, for  $\text{SF}_6$  we could envision mixing in two sulfur  $3d$  orbitals in addition to the  $3s$  and three  $3p$  orbitals to make a total of six hybrid orbitals. However, the sulfur  $3d$  orbitals are substantially higher in energy than the  $3s$  and  $3p$  orbitals, so the amount of energy needed to form the six hybrid orbitals is greater than the amount returned by forming bonds with the six fluorine atoms. Theoretical calculations suggest that the sulfur  $3d$  orbitals do not participate to a significant degree in the bonding between sulfur and the six fluorine atoms, and that it would not be valid to describe the bonding in  $\text{SF}_6$  in terms of six hybrid orbitals. The more detailed bonding model needed to discuss the bonding in  $\text{SF}_6$  and other hypervalent molecules requires a treatment beyond the scope of a general chemistry text. Fortunately, the VSEPR model, which explains the geometrical properties of such molecules in terms of electrostatic repulsions, does a good job of predicting their geometries.

This discussion reminds us that models in science are not reality but rather are our attempts to describe aspects of reality that we have been able to measure, such as bond distances, bond energies, molecular geometries, and so on. A model may work well up to a certain point but not beyond it, as is the case for hybrid orbitals. The hybrid orbital model for period 2 elements has proven very useful and is an essential part of any modern discussion of bonding and molecular geometry in organic chemistry. When it comes to molecules such as  $\text{SF}_6$ , however, we encounter the limitations of the model.

## Hybrid Orbital Summary

Overall, hybrid orbitals provide a convenient model for using valence-bond theory to describe covalent bonds in molecules that have an octet or less of electrons around

the central atom and in which the molecular geometry conforms to the electron-domain geometry predicted by the VSEPR model. While the concept of hybrid orbitals has limited predictive value, when we know the electron-domain geometry, we can employ hybridization to describe the atomic orbitals used by the central atom in bonding.

#### How to Describe the Hybrid Orbitals Used by an Atom in Bonding

1. Draw the *Lewis structure* for the molecule or ion.
2. Use the VSEPR model to determine the electron-domain geometry around the central atom.
3. Specify the *hybrid orbitals* needed to accommodate the electron pairs based on their geometric arrangement (Table 9.4).

These steps are illustrated in Figure 9.19, which shows how the hybridization at N in  $\text{NH}_3$  is determined.

**TABLE 9.4 Geometric Arrangements Characteristic of Hybrid Orbital Sets**

| Atomic Orbital Set | Hybrid Orbital Set | Geometry   | Examples   |
|--------------------|--------------------|--|--|
| $s, p$             | Two $sp$           | <br>180°<br>Linear           | $\text{BeF}_2$ , $\text{HgCl}_2$                                       |
| $s, p, p$          | Three $sp^2$       | <br>120°<br>Trigonal planar | $\text{BF}_3$ , $\text{SO}_3$  |
| $s, p, p, p$       | Four $sp^3$        | <br>109.5°<br>Tetrahedral  | $\text{CH}_4$ , $\text{NH}_3$ , $\text{H}_2\text{O}$ , $\text{NH}_4^+$ |

#### Go Figure

How would we modify the figure if we were looking at  $\text{PH}_3$  rather than  $\text{NH}_3$ ?

**▲ Figure 9.19 Hybrid orbital description of bonding in  $\text{NH}_3$ .** Note the comparison with Figure 9.6. Here we focus on the hybrid orbitals used to make bonds and to hold nonbonding electron pairs.

## Sample Exercise 9.5

### Describing the Hybridization of a Central Atom

Describe the orbital hybridization around the central atom in  $\text{NH}_2^-$ .

#### SOLUTION

**Analyze** We are given the chemical formula for a polyatomic anion and asked to describe the type of hybrid orbitals surrounding the central atom.

**Plan** To determine the central atom hybrid orbitals, we must know the electron-domain geometry around the atom. Thus, we draw the Lewis structure to determine the number of electron domains around the central atom. The hybridization conforms to the number and geometry of electron domains around the central atom as predicted by the VSEPR model.

**Solve** The Lewis structure is

Because there are four electron domains around N, the electron-domain geometry is tetrahedral. The hybridization that gives a tetrahedral electron-domain geometry is  $sp^3$  (Table 9.4). Two of the  $sp^3$  hybrid orbitals contain nonbonding pairs of electrons, and the other two are used to make bonds with the hydrogen atoms.

#### Practice Exercise 1

For which of the following molecules or ions does the following description apply? “The bonding can be explained using a set of  $sp^2$  hybrid orbitals on the central atom, with one of the hybrid orbitals holding a nonbonding pair of electrons.”

- (a)  $\text{CO}_2$
- (b)  $\text{H}_2\text{S}$
- (c)  $\text{O}_3$
- (d)  $\text{CO}_3^{2-}$
- (e) More than one of the above

#### Practice Exercise 2

Predict the electron-domain geometry and hybridization of the central atom in  $\text{SO}_3^{2-}$ .

## 9.6 | Multiple Bonds

In the covalent bonds we have considered thus far, the electron density is concentrated along the line connecting the nuclei (the *internuclear axis*). The line joining the two nuclei passes through the middle of the overlap region, forming a type of covalent bond called a **sigma ( $\sigma$ ) bond**. Examples of sigma bond formation include:

- the overlap of two  $s$  orbitals; one from each H in  $\text{H}_2$  (Figure 9.12),
- the overlap of an H  $s$  orbital and a Cl  $p$  orbital in  $\text{HCl}$  (Figure 9.12),
- the overlap of two  $p$  orbitals; one from each Cl in  $\text{Cl}_2$  (Figure 9.12),
- the overlap of an F  $p$  orbital and a Be  $sp$  hybrid orbital in  $\text{BeF}_2$  (Figure 9.15).

To describe multiple bonding, we must consider a second kind of bond, this one the result of overlap between two  $p$  orbitals oriented perpendicularly to the internuclear axis (Figure 9.20). The sideways overlap of  $p$  orbitals produces what is called a **pi ( $\pi$ ) bond**. A  $\pi$  bond is one in which the overlap regions lie above and below the internuclear axis. Unlike a  $\sigma$  bond, in a  $\pi$  bond the electron density is not concentrated on the internuclear axis. Although it is not evident in Figure 9.20, the sideways orientation of  $p$  orbitals in a  $\pi$  bond makes for weaker overlap. As a result,  $\pi$  bonds are generally weaker than  $\sigma$  bonds.

▲ **Figure 9.20** Comparison of  $\sigma$  and  $\pi$  bonds. Note that the two regions of overlap in the  $\pi$  bond, above and below the internuclear axis, constitute a single  $\pi$  bond.

In almost all cases, single bonds are  $\sigma$  bonds. A double bond consists of one  $\sigma$  bond and one  $\pi$  bond, and a triple bond consists of one  $\sigma$  bond and two  $\pi$  bonds:

▲ **Figure 9.21** Trigonal-planar molecular geometry of ethylene. The double bond is made up of one  $\text{C}-\text{C}$   $\sigma$  bond and one  $\text{C}-\text{C}$   $\pi$  bond.

Consider ethylene ( $\text{C}_2\text{H}_4$ ), which has a  $\text{C}=\text{C}$  double bond. As illustrated by the ball-and-stick model of **Figure 9.21**, the three bond angles about each carbon are all approximately  $120^\circ$ , suggesting that each carbon atom uses  $sp^2$  hybrid orbitals (Figure 9.16) to form  $\sigma$  bonds with the other carbon and with two hydrogens. Because carbon has four valence electrons, after  $sp^2$  hybridization one electron in each carbon remains in the unhybridized  $2p$  orbital. Note that this unhybridized  $2p$  orbital is directed perpendicular to the plane that contains the three  $sp^2$  hybrid orbitals.

Let's go through the steps of building the bonds in the ethylene molecule. Each  $sp^2$  hybrid orbital on a carbon atom contains one electron. **Figure 9.22** shows how we can first

### Go Figure

Why is it important that the  $sp^2$  hybrid orbitals of the two carbon atoms lie in the same plane?

▲ **Figure 9.22** Hybrid orbital bonding in ethylene.

envision forming the C—C  $\sigma$  bond by the overlap of two  $sp^2$  hybrid orbitals, one on each carbon atom. Two electrons are used in forming the C—C  $\sigma$  bond. Next, the C—H  $\sigma$  bonds are formed by overlap of the remaining  $sp^2$  hybrid orbitals on the C atoms with the 1s orbitals on each H atom. We use eight more electrons to form these four C—H bonds. Thus, 10 of the 12 valence electrons in the  $C_2H_4$  molecule are used to form five  $\sigma$  bonds.

The remaining two valence electrons reside in the unhybridized 2p orbitals, one electron on each carbon. These two orbitals can overlap sideways with each other, as shown in Figure 9.22. The resulting electron density is concentrated above and below the C—C bond axis: It is a  $\pi$  bond (Figure 9.20). Thus, the C=C double bond in ethylene consists of one  $\sigma$  bond and one  $\pi$  bond.

Although we cannot experimentally observe a  $\pi$  bond directly (all we can observe are the positions of the atoms), the structure of ethylene provides strong support for its presence. First, the C—C bond length in ethylene (1.34 Å) is much shorter than in compounds with C—C single bonds (1.54 Å), consistent with the presence of a stronger C=C double bond. Second, all six atoms in  $C_2H_4$  lie in the same plane. The p orbitals on each C atom that make up the  $\pi$  bond can achieve a good overlap only when the two  $CH_2$  fragments lie in the same plane. Because  $\pi$  bonds require that portions of a molecule be planar, they can introduce rigidity into molecules.

Triple bonds can also be explained using hybrid orbitals. Acetylene ( $C_2H_2$ ), for example, is a linear molecule containing a triple bond:  $H-C\equiv C-H$ . The linear geometry suggests that each carbon atom uses  $sp$  hybrid orbitals to form  $\sigma$  bonds with the other carbon and one hydrogen. Each carbon atom thus has two unhybridized 2p orbitals at right angles to each other and to the axis of the  $sp$  hybrid set (Figure 9.23). Thus, there are *two* p orbitals remaining on an  $sp$ -hybridized carbon atom. These p orbitals overlap to form a pair of  $\pi$  bonds. The triple bond in acetylene therefore consists of one  $\sigma$  bond and two  $\pi$  bonds.

**Go Figure**

Based on the models of bonding in ethylene and acetylene, which molecule should have the greater carbon—carbon bond strength?

**Figure 9.23** Formation of two  $\pi$  bonds in acetylene,  $C_2H_2$ .

## Give It Some Thought

The molecule called *diazine* has the formula  $N_2H_2$  and the Lewis structure

Do you expect diazine to be a linear molecule (all four atoms on the same line)? If not, do you expect the molecule to be planar (all four atoms in the same plane)?

Although it is possible to make  $\pi$  bonds from  $d$  orbitals, the only  $\pi$  bonds we will consider are those formed by the overlap of  $p$  orbitals. These  $\pi$  bonds can form only if unhybridized  $p$  orbitals are present on the bonded atoms. Therefore, only atoms having  $sp$  or  $sp^2$  hybridization can form  $\pi$  bonds. Further, double and triple bonds (and hence  $\pi$  bonds) are more common in molecules made up of period 2 atoms, especially C, N, and O. Larger atoms, such as S, P, and Si, form  $\pi$  bonds less readily.

## Sample Exercise 9.6

Describing  $\sigma$  and  $\pi$  Bonds in a Molecule

Formaldehyde has the Lewis structure

Describe how the bonds in formaldehyde are formed in terms of overlaps of hybrid and unhybridized orbitals.

## SOLUTION

**Analyze** We are asked to describe the bonding in formaldehyde in terms of hybrid orbitals.

**Plan** Single bonds are  $\sigma$  bonds, and double bonds consist of one  $\sigma$  bond and one  $\pi$  bond. The ways in which these bonds form can be deduced from the molecular geometry, which we predict using the VSEPR model.

**Solve** The C atom has three electron domains around it, which suggests a trigonal-planar geometry with bond angles of about  $120^\circ$ . This geometry implies  $sp^2$  hybrid orbitals on C (Table 9.4). These hybrids are used to make the two C—H and one C—O  $\sigma$  bonds to C. There remains an unhybridized  $2p$  orbital on carbon, perpendicular to the plane of the three  $sp^2$  hybrids.

The O atom also has three electron domains around it, and so we assume it has  $sp^2$  hybridization as well. One of these hybrid orbitals participates in the C—O  $\sigma$  bond, while the other two hold the two nonbonding electron pairs of the O atom. Like the C atom, therefore, the O atom has a  $p$  orbital that is perpendicular to the plane of the molecule. The two  $p$  orbitals overlap to form a C—O  $\pi$  bond (Figure 9.24).

▲ Figure 9.24 Formation of  $\sigma$  and  $\pi$  bonds in formaldehyde,  $H_2CO$ .

## Practice Exercise 1

We have just arrived at a bonding description for the formaldehyde molecule. Which of the following statements about the molecule is or are true?

- (i) Two of the electrons in the molecule are used to make the  $\pi$  bond in the molecule.
- (ii) Six of the electrons in the molecule are used to make the  $\sigma$  bonds in the molecule.
- (iii) The C—O bond length in formaldehyde should be shorter than that in methanol,  $H_3COH$ .
- (a) Only one of the statements is true.
- (b) Statements (i) and (ii) are true.
- (c) Statements (i) and (iii) are true.
- (d) Statements (ii) and (iii) are true.
- (e) All three statements are true.

## Practice Exercise 2

- (a) Predict the bond angles around each carbon atom in acetonitrile:

- (b) Describe the hybridization at each carbon atom, and
- (c) determine the number of  $\sigma$  and  $\pi$  bonds in the molecule.

## Resonance Structures, Delocalization, and $\pi$ Bonding

In the molecules we have discussed thus far in this section, the bonding electrons are *localized*. By this we mean that the  $\sigma$  and  $\pi$  electrons are associated totally with the two atoms that form the bond. In many molecules, however, we cannot adequately describe the bonding as being entirely localized. This situation arises particularly in molecules that have two or more resonance structures involving  $\pi$  bonds.

One molecule that cannot be described with localized  $\pi$  bonds is benzene ( $\text{C}_6\text{H}_6$ ), which has two resonance structures:  (Section 8.6)

Benzene has a total of 30 valence electrons. To describe the bonding in benzene using hybrid orbitals, we first choose a hybridization scheme consistent with the geometry of the molecule. Because each carbon is surrounded by three atoms at  $120^\circ$  angles, the appropriate hybrid set is  $sp^2$ . Six localized C—C  $\sigma$  bonds and six localized C—H  $\sigma$  bonds are formed from the  $sp^2$  hybrid orbitals, as shown in Figure 9.25(a). Thus, 24 of the valence electrons are used to form the  $\sigma$  bonds in the molecule.

### Go Figure

What are the two kinds of  $\sigma$  bonds found in benzene?

▲ **Figure 9.25**  $\sigma$  and  $\pi$  bond networks in benzene,  $\text{C}_6\text{H}_6$ . (a) The  $\sigma$  bond framework. (b) The  $\pi$  bonds are formed from overlap of the unhybridized  $2p$  orbitals on the six carbon atoms.

Because the hybridization at each C atom is  $sp^2$ , there is one  $p$  orbital on each C atom, each oriented perpendicular to the plane of the molecule. The situation is very much like that in ethylene except we now have six  $p$  orbitals arranged in a ring [Figure 9.25(b)]. The remaining six valence electrons occupy these six  $p$  orbitals, one per orbital.

We could envision using the  $p$  orbitals to form three localized  $\pi$  bonds. As shown in Figure 9.26, there are two equivalent ways to make these localized bonds, each corresponding to one resonance structure. However, a representation that reflects *both* resonance structures has the six  $\pi$  electrons “smeared out” among all six carbon atoms, as shown on the right in Figure 9.26. Notice how this smeared representation corresponds

◀ **Figure 9.26** Delocalized  $\pi$  bonds in benzene.

to the circle-in-a-hexagon drawing we often use to represent benzene. This model leads us to predict that all the carbon-carbon bond lengths will be identical, with a bond length between that of a C—C single bond (1.54 Å) and that of a C=C double bond (1.34 Å). This prediction is consistent with the observed carbon-carbon bond length in benzene (1.40 Å).

Because we cannot describe the  $\pi$  bonds in benzene as individual bonds between neighboring atoms, we say that benzene has a six-electron  $\pi$  system **delocalized** among the six carbon atoms. Delocalization of the electrons in its  $\pi$  bonds gives benzene a special stability. Electron delocalization in  $\pi$  bonds is also responsible for the color of many organic molecules. A final important point to remember about delocalized  $\pi$  bonds is the constraint they place on the geometry of a molecule. For optimal overlap of the  $p$  orbitals, all the atoms involved in a delocalized  $\pi$  bonding network should lie in the same plane. This restriction imparts a certain rigidity to the molecule that is absent in molecules containing only  $\sigma$  bonds (see the “Chemistry and Life” box on vision).

If you take a course in organic chemistry, you will see many examples of how electron delocalization influences the properties of organic molecules.

## Sample Exercise 9.7

### Delocalized Bonding

Describe the bonding in the nitrate ion,  $\text{NO}_3^-$ . Does this ion have delocalized  $\pi$  bonds?

#### SOLUTION

**Analyze** Given the chemical formula for a polyatomic anion, we are asked to describe the bonding and determine whether the ion has delocalized  $\pi$  bonds.

**Plan** Our first step is to draw Lewis structures. Multiple resonance structures involving the placement of the double bonds in different locations would suggest that the  $\pi$  component of the double bonds is delocalized.

**Solve** In Section 8.6 we saw that  $\text{NO}_3^-$  has three resonance structures:

In each structure, the electron-domain geometry at nitrogen is trigonal planar, which implies  $sp^2$  hybridization of the N atom. It is helpful when considering delocalized  $\pi$  bonding to consider atoms with lone pairs that are bonded to the central atom to be  $sp^2$  hybridized as well. Thus, we can envision that each of the O atoms in the anion has three  $sp^2$  hybrid orbitals in the plane of the ion. Each of the four atoms has an unhybridized  $p$  orbital oriented perpendicular to the plane of the ion.

The  $\text{NO}_3^-$  ion has 24 valence electrons. We can first use the  $sp^2$  hybrid orbitals on the four atoms to construct the three N—O  $\sigma$  bonds. That uses all of the  $sp^2$  hybrids on the N atom and one  $sp^2$  hybrid on each O atom. Each of the two remaining  $sp^2$  hybrids on each O atom is used to hold a nonbonding pair of electrons. Thus, for any of the resonance structures, we have the following arrangement in the plane of the ion:

Notice that we have accounted for a total of 18 electrons—6 in the three N—O  $\sigma$  bonds, and 12 as nonbonding pairs on the O atoms. The remaining six electrons will reside in the  $\pi$  system of the ion.

The four  $p$  orbitals—one on each of the four atoms—are used to build the  $\pi$  system. For any one of the three resonance structures shown, we might imagine a single localized N—O  $\pi$  bond formed by the overlap of the  $p$  orbital on N and a  $p$  orbital on one of the O atoms. The remaining two O atoms have nonbonding pairs in their  $p$  orbitals. Thus, for each of the resonance structures, we have the situation shown in Figure 9.27. Because each resonance structure contributes equally to the observed structure of  $\text{NO}_3^-$ , however, we represent the  $\pi$  bonding as delocalized over the three N—O bonds, as shown in the figure. We see that the  $\text{NO}_3^-$  ion has a six-electron  $\pi$  system delocalized among the four atoms in the ion.

▲ Figure 9.27 Localized and delocalized representations of the six-electron  $\pi$  system in  $\text{NO}_3^-$ .

#### Practice Exercise 1

How many electrons are in the  $\pi$  system of the ozone molecule,  $\text{O}_3$ ?

(a) 2 (b) 4 (c) 6 (d) 14 (e) 18

#### Practice Exercise 2

Which of these species have delocalized bonding:  $\text{SO}_2$ ,  $\text{SO}_3$ ,  $\text{SO}_3^{2-}$ ,  $\text{H}_2\text{CO}$ ,  $\text{NH}_4^+$ ?

## General Conclusions about $\sigma$ and $\pi$ Bonding

On the basis of the examples we have seen, we can draw a few helpful conclusions for using hybrid orbitals to describe molecular structures:

- Every pair of bonded atoms shares one or more pairs of electrons. Each bond line we draw in a Lewis structures represents two shared electrons. In every  $\sigma$  bond one pair of electrons is localized in the space between the atoms. The appropriate set of hybrid orbitals used to form the  $\sigma$  bonds between an atom and its neighbors is determined by the observed geometry of the molecule. The correlation between the set of hybrid orbitals and the geometry about an atom is given in Table 9.4.
- Because the electrons in  $\sigma$  bonds are localized in the region between two bonded atoms, they do not make a significant contribution to the bonding between any other two atoms.
- When atoms share more than one pair of electrons, one pair is used to form a  $\sigma$  bond; the additional pairs form  $\pi$  bonds. The centers of charge density in a  $\pi$  bond lie above and below the internuclear axis.
- Molecules can have  $\pi$  systems that extend over more than two bonded atoms. Electrons in extended  $\pi$  systems are said to be “delocalized.” We can determine the number of electrons in the  $\pi$  system of a molecule using the procedures we discussed in this section.

## CHEMISTRY AND LIFE The Chemistry of Vision

Vision begins when light is focused by the lens of the eye onto the retina, the layer of cells lining the interior of the eyeball. The retina contains *photoreceptor* cells called rods and cones (Figure 9.28). The rods are sensitive to dim light and are used in night vision. The cones are sensitive to colors. The tops of the rods and cones contain a molecule called *rhodopsin*, which consists of a protein, *opsin*, bonded to a reddish purple pigment called *retinal*. Structural changes around a double bond in the retinal portion of the molecule trigger a series of chemical reactions that result in vision.

We know that a double bond between two atoms is stronger than a single bond between those same two atoms (Table 8.3). We are now in a position to appreciate another aspect of double bonds: They introduce rigidity into molecules.

Consider the C—C double bond in ethylene. Imagine rotating one —CH<sub>2</sub> group in ethylene relative to the other —CH<sub>2</sub> group, as pictured in Figure 9.29. This rotation destroys the overlap of the *p* orbitals, breaking the  $\pi$  bond, a process that requires considerable energy. Thus, the presence of a double bond restricts bond rotation

▲ **Figure 9.28** Inside the eye. A color-enhanced scanning electron micrograph of the rods and cones in the retina of the human eye.

▲ **Figure 9.29** Rotation about the carbon—carbon double bond in ethylene breaks the  $\pi$  bond.

in a molecule. In contrast, molecules can rotate almost freely around the bond axis in single ( $\sigma$ ) bonds because this motion has no effect on the orbital overlap for a  $\sigma$  bond. Rotation allows molecules with single bonds to twist and fold almost as if their atoms were attached by hinges.

Our vision depends on the rigidity of double bonds in retinal. In its normal form, retinal is held rigid by its double bonds. Light entering the eye is absorbed by rhodopsin, and it is the energy of that light which is used to break the  $\pi$ -bond portion of the double bond shown in red in Figure 9.30. Breaking the double bond allows rotation around the bond axis, changing the geometry of the retinal molecule. The retinal then separates from the opsin, triggering the reactions that produce a nerve impulse that the brain interprets as the sensation of vision. It takes as few as five closely spaced molecules reacting in this fashion to produce the sensation of vision. Thus, only five photons of light are necessary to stimulate the eye.

The retinal slowly reverts to its original form and reattaches to the opsin. The slowness of this process helps explain why intense bright light causes temporary blindness. The light causes all the retinal to separate from opsin, leaving no molecules to absorb light.

*Continued*

▲ **Figure 9.30** The rhodopsin molecule, the chemical basis of vision. When rhodopsin absorbs visible light, the  $\pi$  component of the double bond shown in red breaks, allowing rotation that produces a change in molecular geometry before the  $\pi$  bond re-forms. The hexagonal part of the structure is a short-hand way of drawing C—C bonds with attendant H's.

### Give It Some Thought

When two atoms are bonded by a triple bond, what is the hybridization of the orbitals that make up the  $\sigma$ -bond component of the bond?

## 9.7 | Molecular Orbitals

While valence-bond theory helps explain some of the relationships among Lewis structures, atomic orbitals, and molecular geometries, it does not explain all aspects of bonding. It is not successful, for example, in describing the excited states of molecules, which we must understand to explain how molecules absorb light, giving them color.

Some aspects of bonding are better explained by a more sophisticated model called **molecular orbital theory**. In Chapter 6 we saw that electrons in atoms can be described by wave functions, which we call atomic orbitals. In a similar way, molecular orbital theory describes the electrons in molecules by using specific wave functions, each of which is called a **molecular orbital (MO)**.

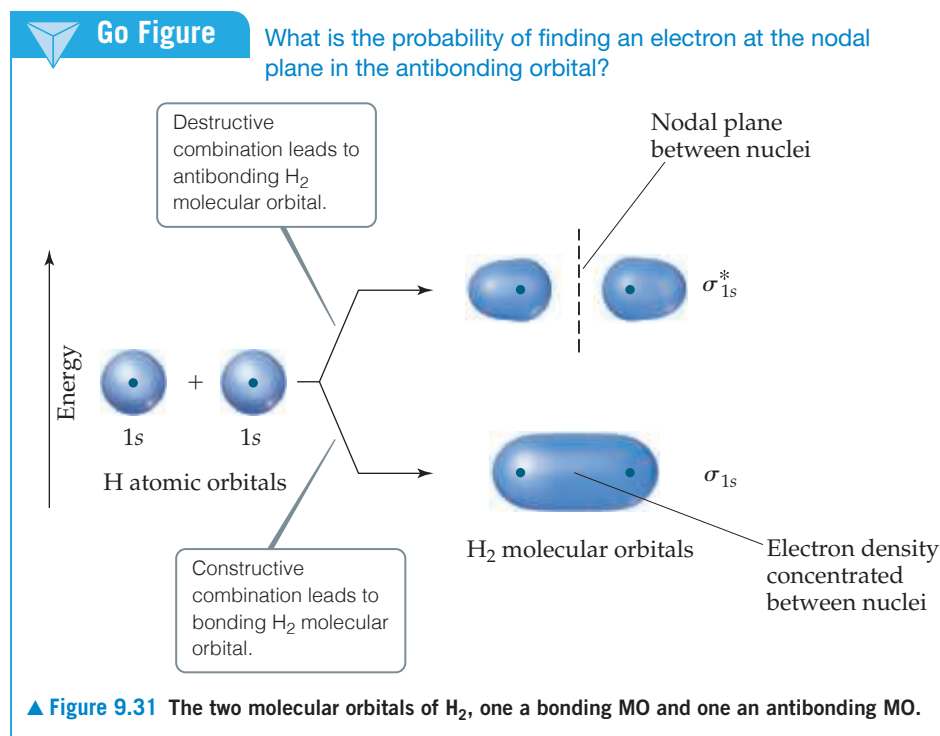

Molecular orbitals have many of the same characteristics as atomic orbitals. For example, an MO can hold a maximum of two electrons (with opposite spins), it has a definite energy, and we can visualize its electron-density distribution by using a contour representation, as we did with atomic orbitals. Unlike atomic orbitals, however, MOs are associated with an entire molecule, not with a single atom.

### Molecular Orbitals of the Hydrogen Molecule

We begin our study of MO theory with the hydrogen molecule,  $H_2$ . We will use the two  $1s$  atomic orbitals (one on each H atom) to construct molecular orbitals for  $H_2$ . *Whenever two atomic orbitals overlap, two molecular orbitals form.* Thus, the overlap of the  $1s$  orbitals of two hydrogen atoms to form  $H_2$  produces two MOs. The first MO, which is shown at the bottom right of **Figure 9.31**, is formed by adding the wave functions for the two  $1s$  orbitals. We refer to this as *constructive combination*. The energy of the resulting MO is lower in energy than the two atomic orbitals from which it was made. It is called the **bonding molecular orbital**.

The second MO is formed by what is called *destructive combination*: combining the two atomic orbitals in a way that causes the electron density to be canceled in the central region where the two overlap. The process is discussed more fully in the “Closer Look” box later in the chapter. The energy of the resulting MO, referred to as the **antibonding molecular orbital**, is higher than the energy of the atomic orbitals. The antibonding MO of  $H_2$  is shown at the top right in **Figure 9.31**.

As illustrated in **Figure 9.31**, in the bonding MO electron density is concentrated in the region between the two nuclei. This sausage-shaped MO results from summing

the two atomic orbitals so that the atomic orbital wave functions combine in the region between the two nuclei. Because an electron in this MO is attracted to both nuclei, the electron is more stable (it has lower energy) than it is in the 1s atomic orbital of an isolated hydrogen atom. Further, because this bonding MO concentrates electron density between the nuclei, it holds the atoms together in a covalent bond.

By contrast, the antibonding MO has very little electron density between the nuclei. Instead of combining in the region between the nuclei, the atomic orbital wave functions cancel each other in this region, leaving the greatest electron density on opposite sides of the two nuclei. Thus, an antibonding MO excludes electrons from the very region in which a bond must be formed. Antibonding orbitals invariably have a *plane* in the region between the nuclei where the electron density is zero. This plane is called a **nodal plane** of the MO. (The nodal plane is shown as a dashed line in Figure 9.31 and subsequent figures.) An electron in an antibonding MO is repelled from the bonding region and is therefore less stable (it has higher energy) than it is in the 1s atomic orbital of a hydrogen atom.

Notice from Figure 9.31 that the electron density in both the bonding MO and the antibonding MO of H<sub>2</sub> is centered about the internuclear axis. MOs of this type are called **sigma ( $\sigma$ ) molecular orbitals** (by analogy to  $\sigma$  bonds). The bonding sigma MO of H<sub>2</sub> is labeled  $\sigma_{1s}$ ; the subscript indicates that the MO is formed from two 1s orbitals. The antibonding sigma MO of H<sub>2</sub> is labeled  $\sigma_{1s}^*$  (read “sigma-star-one-s”); the asterisk denotes that the MO is antibonding.

The relative energies of two 1s atomic orbitals and the molecular orbitals formed from them are represented by an **energy-level diagram** (also called a **molecular orbital diagram**). Such diagrams show the interacting atomic orbitals on the left and right and the MOs in the middle, as shown in Figure 9.32. Like atomic orbitals, each MO can accommodate two electrons with their spins paired (Pauli exclusion principle). ∞ (Section 6.7)

As the MO diagram for H<sub>2</sub> in Figure 9.32 shows, each H atom has one electron, so there are two electrons in H<sub>2</sub>. These two electrons occupy the lower-energy bonding ( $\sigma_{1s}$ ) MO, and their spins are paired. Electrons occupying a bonding molecular orbital are called **bonding electrons**. Because the  $\sigma_{1s}$  MO is lower in energy than the H 1s atomic orbitals, the H<sub>2</sub> molecule is more stable than the two separate H atoms.

By analogy with atomic electron configurations, the electron configurations for molecules can be written with superscripts to indicate electron occupancy. The electron configuration for H<sub>2</sub>, then, is  $\sigma_{1s}^2$ .

## Bond Order

In molecular orbital theory, the stability of a covalent bond is related to its **bond order**, defined as half the difference between the number of bonding electrons and the number of antibonding electrons:

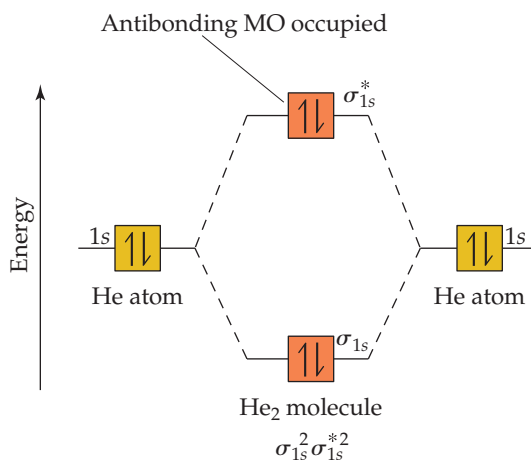

$$\text{Bond order} = \frac{1}{2} (\text{number of bonding electrons} - \text{number of antibonding electrons}) \quad [9.1]$$

We take half the difference because we are used to thinking of bonds as pairs of electrons. A bond order of 1 represents a single bond, a bond order of 2 represents a double bond, and a bond order of 3 represents a triple bond. Because MO theory also treats molecules containing an odd number of electrons, bond orders of  $1/2$ ,  $3/2$ , or  $5/2$  are possible.

Let's now consider the bond order in  $H_2$  and  $He_2$ , referring to Figures 9.32 and 9.33.  $H_2$  has two bonding electrons and zero antibonding electrons, so it has a bond order of 1.

**Figure 9.33** shows the energy-level diagram for the hypothetical  $He_2$  molecule, which requires four electrons to fill its molecular orbitals. Because only two electrons can go in the  $\sigma_{1s}$  MO, the other two electrons must go in the  $\sigma_{1s}^*$  MO. The electron configuration of  $He_2$  is thus  $\sigma_{1s}^2 \sigma_{1s}^{*2}$ . The energy decrease realized in going from He atomic orbitals to the He bonding MO is offset by the energy increase realized in going from the atomic orbitals to the He

► **Figure 9.33** Energy-level diagram and electron configuration for  $He_2$ .

antibonding MO.\* Because  $\text{He}_2$  has two bonding electrons and two antibonding electrons, it has a bond order of 0. A bond order of 0 means that no bond exists. Molecular orbital theory correctly predicts that hydrogen forms diatomic molecules but helium does not.

### Give It Some Thought

Suppose one electron in  $\text{H}_2$  is excited from the  $\sigma_{1s}$  MO to the  $\sigma_{1s}^*$  MO. Would you expect the H atoms to remain bonded to each other, or would the molecule fall apart?

## Sample Exercise 9.8

### Bond Order

What is the bond order of the  $\text{He}_2^+$  ion? Would you expect this ion to be stable relative to the separated He atom and  $\text{He}^+$  ion?

### SOLUTION

**Analyze** We will determine the bond order for the  $\text{He}_2^+$  ion and use it to predict whether the ion is stable.

**Plan** To determine the bond order, we must determine the number of electrons in the molecule and how these electrons populate the available MOs. The valence electrons of He are in the  $1s$  orbital, and the  $1s$  orbitals combine to give an MO diagram like that for  $\text{H}_2$  or  $\text{He}_2$  (Figure 9.33). If the bond order is greater than 0, we expect a bond to exist, and the ion is stable.

**Solve** The energy-level diagram for the  $\text{He}_2^+$  ion is shown in Figure 9.34. This ion has three electrons. Two are placed in the bonding orbital and the third in the antibonding orbital. Thus, the bond order is

$$\text{Bond order} = \frac{1}{2}(2 - 1) = \frac{1}{2}$$

Because the bond order is greater than 0, we predict the  $\text{He}_2^+$  ion to be stable relative to the separated He and  $\text{He}^+$ . Formation of  $\text{He}_2^+$  in the gas phase has been demonstrated in laboratory experiments.

### Practice Exercise 1

How many of the following molecules and ions have a bond order of  $\frac{1}{2}$ :  $\text{H}_2$ ,  $\text{H}_2^+$ ,  $\text{H}_2^-$ , and  $\text{He}_2^{2+}$ ?

(a) 0 (b) 1 (c) 2 (d) 3 (e) 4

### Practice Exercise 2

What are the electron configuration and the bond order of the  $\text{H}_2^-$  ion?

## 9.8 | Bonding in Period 2 Diatomic Molecules

In considering the MO description of diatomic molecules other than  $\text{H}_2$ , we will initially restrict our discussion to *homonuclear* diatomic molecules (those composed of two identical atoms) of period 2 elements.

Period 2 atoms have valence  $2s$  and  $2p$  orbitals, and we need to consider how they interact to form MOs. The following rules summarize some of the guiding principles for the formation of MOs and for how they are populated by electrons:

1. The number of MOs formed equals the number of atomic orbitals combined.
2. Atomic orbitals combine most effectively with other atomic orbitals of similar energy.
3. The effectiveness with which two atomic orbitals combine is proportional to their overlap. That is, as the overlap increases, the energy of the bonding MO is lowered and the energy of the antibonding MO is raised.
4. Each MO can accommodate, at most, two electrons, with their spins paired (Pauli exclusion principle). [∞ \(Section 6.7\)](#)
5. When MOs of the same energy are populated, one electron enters each orbital (with the same spin) before spin pairing occurs (Hund's rule). [∞ \(Section 6.8\)](#)

\*Antibonding MOs are slightly more energetically unfavorable than bonding MOs are energetically favorable. Thus, whenever there is an equal number of electrons in bonding and antibonding orbitals, the energy of the molecule is slightly higher than that for the separated atoms. As a result, no bond is formed.

### Go Figure

What is the electron configuration of the  $\text{He}_2^+$  ion?

▲ **Figure 9.34** Energy-level diagram for the  $\text{He}_2^+$  ion.

## Molecular Orbitals for Li<sub>2</sub> and Be<sub>2</sub>

Lithium has the electron configuration  $1s^2 2s^1$ . When lithium metal is heated above its boiling point (1342 °C), Li<sub>2</sub> molecules are found in the vapor phase. The Lewis structure for Li<sub>2</sub> indicates a Li—Li single bond. We will now use MOs to describe the bonding in Li<sub>2</sub>.

Figure 9.35 shows that the Li 1s and 2s atomic orbitals have substantially different energy levels. From this, we can assume that the 1s orbital on one Li atom interacts only with the 1s orbital on the other atom (rule 2). Likewise, the 2s orbitals interact only with each other. Notice that combining four atomic orbitals produces four MOs (rule 1).

The Li 1s orbitals combine to form  $\sigma_{1s}$  and  $\sigma_{1s}^*$  bonding and antibonding MOs, as they did for H<sub>2</sub>. The 2s orbitals interact with one another in exactly the same way, producing bonding ( $\sigma_{2s}$ ) and antibonding ( $\sigma_{2s}^*$ ) MOs. In general, the separation between bonding and antibonding MOs depends on the extent to which the constituent atomic orbitals overlap. Because the Li 2s orbitals extend farther from the nucleus than the 1s orbitals do, the 2s orbitals overlap more effectively. As a result, the energy difference between the  $\sigma_{2s}$  and  $\sigma_{2s}^*$  orbitals is greater than the energy difference between the  $\sigma_{1s}$  and  $\sigma_{1s}^*$  orbitals. The 1s orbitals of Li are much lower in energy than the 2s orbitals; therefore, the energy of the  $\sigma_{1s}^*$  antibonding MO is much lower than the energy of the  $\sigma_{2s}$  bonding MO.

Each Li atom has three electrons, so six electrons must be placed in Li<sub>2</sub> MOs. As shown in Figure 9.35, these electrons occupy the  $\sigma_{1s}$ ,  $\sigma_{1s}^*$ , and  $\sigma_{2s}$  MOs, each with two electrons. There are four electrons in bonding orbitals and two in antibonding orbitals, so the bond order is  $\frac{1}{2}(4 - 2) = 1$ . The molecule has a single bond, in agreement with its Lewis structure.

Because both the  $\sigma_{1s}$  and  $\sigma_{1s}^*$  MOs of Li<sub>2</sub> are completely filled, the 1s orbitals contribute almost nothing to the bonding. The single bond in Li<sub>2</sub> is due essentially to the interaction of the valence 2s orbitals on the Li atoms. This example illustrates the general rule that *core electrons usually do not contribute significantly to bonding in molecules*. The rule is equivalent to using only the valence electrons when drawing Lewis structures. Thus, we need not consider further the 1s orbitals while discussing the other period 2 diatomic molecules.

The MO description of Be<sub>2</sub> follows readily from the energy-level diagram for Li<sub>2</sub>. Each Be atom has four electrons ( $1s^2 2s^2$ ), so we must place eight electrons in molecular orbitals. Therefore, we completely fill the  $\sigma_{1s}$ ,  $\sigma_{1s}^*$ ,  $\sigma_{2s}$ , and  $\sigma_{2s}^*$  MOs. With equal numbers of bonding and antibonding electrons, the bond order is zero; thus, Be<sub>2</sub> does not exist.

### Give It Some Thought

Would you expect Be<sub>2</sub><sup>+</sup> to be a stable ion?

### Go Figure

Which of the MOs in the diagram will have nodal planes?

## Molecular Orbitals from 2p Atomic Orbitals

Before we can consider the remaining period 2 diatomic molecules, we must look at the MOs that result from combining 2p atomic orbitals. The interactions between p orbitals are shown in **Figure 9.36**, where we have arbitrarily chosen the internuclear axis to be the z-axis. The  $2p_z$  orbitals face each other head to head. Just as with s orbitals, we can combine  $2p_z$  orbitals in two ways. One combination concentrates electron density between the nuclei and is, therefore, a bonding molecular orbital. The other combination excludes electron density from the bonding region and so is an antibonding molecular orbital. In both MOs, the electron density lies along the internuclear axis, so they are  $\sigma$  molecular orbitals:  $\sigma_{2p}$  and  $\sigma_{2p}^*$ .

The other 2p orbitals overlap sideways and thus concentrate electron density above and below the internuclear axis. MOs of this type are called **pi ( $\pi$ ) molecular orbitals** by analogy to  $\pi$  bonds. We get one  $\pi$  bonding MO by combining the  $2p_x$  atomic orbitals and another from the  $2p_y$  atomic orbitals. These two  $\pi_{2p}$  molecular orbitals have the same energy; in other words, they are degenerate. Likewise, we get two degenerate  $\pi_{2p}^*$

▲ **Figure 9.36** Contour representations of the molecular orbitals formed by 2p orbitals.

antibonding MOs that are perpendicular to each other like the  $2p$  orbitals from which they were made. These  $\pi_{2p}^*$  orbitals have four lobes, pointing away from the two nuclei, as shown in Figure 9.36.

The  $2p_z$  orbitals on two atoms point directly at each other. Hence, overlap of two  $2p_z$  orbitals is greater than that of two  $2p_x$  or  $2p_y$  orbitals. We therefore expect the  $\sigma_{2p}$  MO to be lower in energy (more stable) than the  $\pi_{2p}$  MOs. Similarly, the  $\sigma_{2p}^*$  MO should be higher in energy (less stable) than the  $\pi_{2p}^*$  MOs.

## A CLOSER LOOK Phases in Atomic and Molecular Orbitals

Our discussion of atomic orbitals in Chapter 6 and molecular orbitals in this chapter highlights some of the most important applications of quantum mechanics in chemistry. In the quantum-mechanical treatment of electrons in atoms and molecules, we are mainly interested in determining two characteristics of the electrons—their energies and their distribution in space. Recall that solving Schrödinger's wave equation yields the electron's energy,  $E$ , and wave function,  $\psi$ , but that  $\psi$  does not have a direct physical meaning. [∞](#) (Section 6.5) The contour representations of atomic and molecular orbitals we have presented thus far are based on  $\psi^2$  (the *probability density*), which gives the probability of finding the electron at a given point in space.

Because probability densities are squares of functions, their values must be nonnegative (zero or positive) at all points in space. However, the functions themselves can have negative values. The situation is like that of the sine function plotted in Figure 9.37. In the top graph, the sine function is negative for  $x$  between 0 and  $-\pi$  and positive for  $x$  between 0 and  $+\pi$ . We say that the *phase* of the sine function is negative between 0 and  $-\pi$  and positive between 0 and  $+\pi$ . If we square the sine function (bottom graph), we get two peaks that are symmetrical about the origin. Both peaks are positive because squaring a negative number produces a positive number. In other words, we *lose the phase information of the function upon squaring it*.

Like the sine function, the more complicated wave functions for atomic orbitals can also have phases. Consider, for example, the representations of the  $1s$  orbital in Figure 9.38. Note that here we plot this orbital a bit differently from what is shown in Section 6.6. The origin is the point where the nucleus resides, and the wave function for the  $1s$  orbital extends from the origin out into space. The plot shows the value of  $\psi$  for a slice taken along the  $z$ -axis. Below the plot is a contour representation of the  $1s$  orbital. Notice that the value of the  $1s$  wave function is always a positive number (we show positive values in red in Figure 9.38). Thus, it has only one phase. Notice also that the wave function approaches zero only at a long distance from the nucleus. It therefore has no nodes, as we saw in Figure 6.22.

In the graph for the  $2p_z$  orbital in Figure 9.38, the wave function changes sign when it passes through  $z = 0$ . Notice that the two halves of the wave have the same shape except that one has positive (red) values and the other negative (blue) values. Analogously to the sine function, the wave function changes phase when it passes through the origin. Mathematically, the  $2p_z$  wave function is equal to zero whenever  $z = 0$ . This corresponds to any point on the  $xy$  plane, so we say that the  $xy$  plane is a *nodal plane* of the  $2p_z$  orbital. The wave function for a  $p$  orbital is much like a sine function because it has two equal parts that have opposite phases. Figure 9.38 gives a typical representation used by chemists of the wave function for a  $p_z$  orbital.\*

\*The mathematical development of this three-dimensional function (and its square) is beyond the scope of this book, and, as is typically done by chemists, we have used lobes that are the same shape as in Figure 6.23.

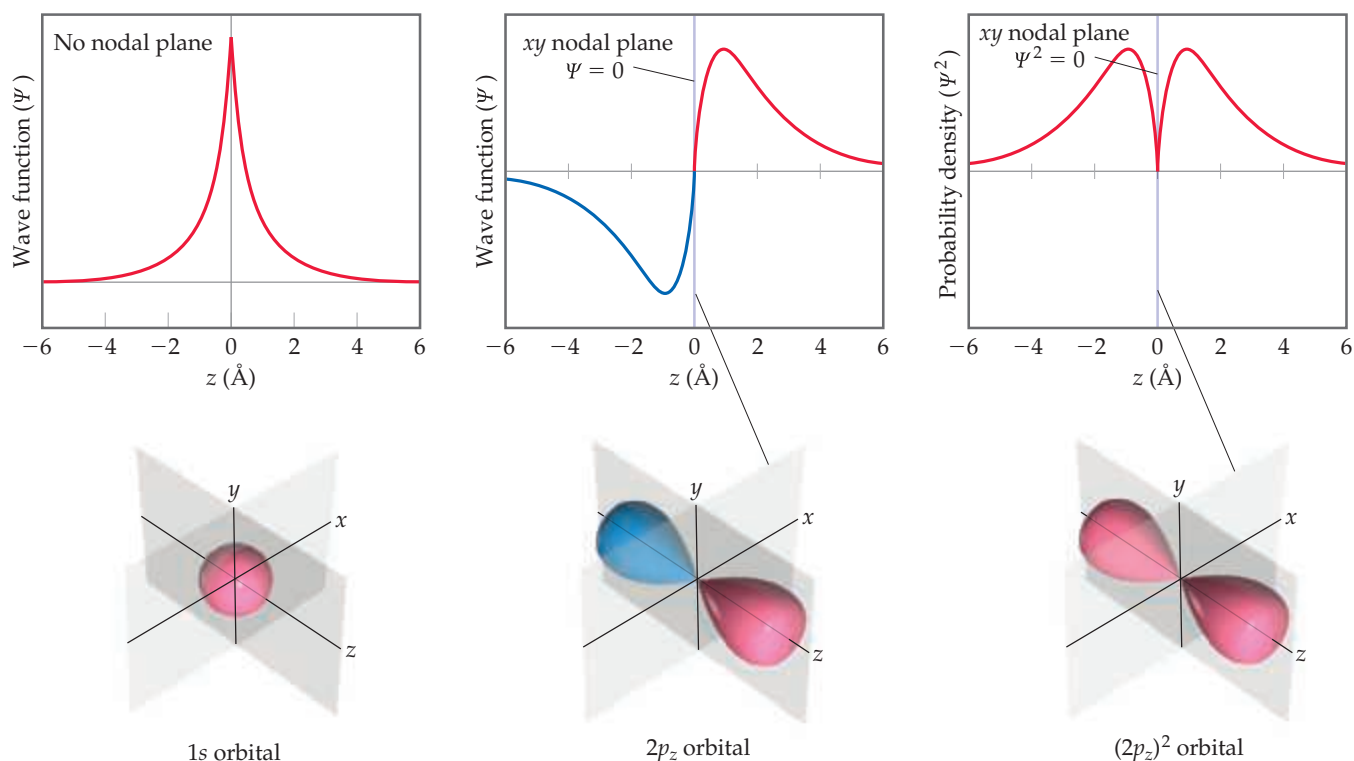

▲ Figure 9.37 Graphs for a sine function and the same function squared.

The red and blue lobes indicate the different phases of the orbital. (Note: The colors do *not* represent charge, as they did in the plots in Figures 9.10 and 9.11.) As with the sine function, the origin is a node.

The third graph in Figure 9.38 shows that when we square the wave function of the  $2p_z$  orbital, we get two peaks that are symmetrical about the origin. Both peaks are positive because squaring a negative number produces a positive number. Thus, we *lose the phase information of the function upon squaring it* just as we did for the sine function. When we square the wave function for the  $p_z$  orbital, we get the probability density for the orbital, which is given as a contour representation in Figure 9.38. This is what we saw in the earlier presentation of  $p$  orbitals. [∞](#) (Section 6.6) For this squared wave function, both lobes have the same phase and therefore the same sign. We use this representation throughout most of this book because it has a simple physical interpretation: The square of the wave function at any point in space represents the electron density at that point.

The lobes of the wave functions for the  $d$  orbitals also have different phases. For example, the wave function for a  $d_{xy}$  orbital has four lobes, with the phase of each lobe opposite the phase of its nearest neighbors (Figure 9.39). The wave functions for the

▲ **Figure 9.38** Phases in wave functions of *s* and *p* atomic orbitals. Red shading means a positive value for the wave function, and blue shading means a negative value.

other *d* orbitals likewise have lobes in which the phase in one lobe is opposite that in an adjacent lobe.

Why do we need to consider the complexity introduced by considering the phase of the wave function? While it is true that the phase is not necessary to visualize the shape of an atomic orbital in an isolated atom, it does become important when we consider overlap of orbitals in molecular orbital theory. Let's use the sine function as an example again. If you add two sine functions having the same phase, they add *constructively*, resulting in increased amplitude:

▲ **Figure 9.39** Phases in *d* orbitals.

but if you add two sine functions having opposite phases, they add *destructively* and cancel each other.

The idea of constructive and destructive interactions of wave functions is key to understanding the origin of bonding and antibonding molecular orbitals. For example, the wave function of the  $\sigma_{1s}$  MO of  $H_2$  is generated by adding the wave function for the  $1s$  orbital on one atom to the wave function for the  $1s$  orbital on the other atom, with both orbitals having the same phase. The atomic wave functions overlap *constructively* in this case to increase the electron density between the two atoms (Figure 9.40). The wave function of the  $\sigma_{1s}^*$  MO of  $H_2$  is generated by subtracting the wave function for a  $1s$  orbital on one atom from the wave function for a  $1s$  orbital on the other atom. The result is that the atomic orbital wave functions overlap *destructively* to create a region of zero electron density between the two atoms—a node. Notice the similarity between this figure and Figure 9.32. In Figure 9.40, we use red and blue shading to denote positive and negative phases in the H atomic orbitals.

▲ **Figure 9.40** Molecular orbitals from atomic orbital wave functions.

However, chemists may alternatively draw contour representations in different colors, or with one phase shaded and one unshaded, to denote the two phases.

When we square the wave function of the  $\sigma_{1s}^*$  MO, we get the electron density representation which we saw earlier, in Figure 9.32. Notice once again that we lose the phase information when we look at the electron density.

The wave functions of atomic and molecular orbitals are used by chemists to understand many aspects of chemical bonding, spectroscopy, and reactivity. If you take a course in organic chemistry, you will probably see orbitals drawn to show the phases as in this box.

## Electron Configurations for $B_2$ through $Ne_2$

We can combine our analyses of MOs formed from  $s$  orbitals (Figure 9.32) and from  $p$  orbitals (Figure 9.36) to construct an energy-level diagram (Figure 9.41) for homonuclear diatomic molecules of the elements boron through neon, all of which have valence  $2s$  and  $2p$  atomic orbitals. The following features of the diagram are notable:

- The  $2s$  atomic orbitals are substantially lower in energy than the  $2p$  atomic orbitals. Consequently, both MOs formed from the  $2s$  orbitals are lower in energy than the lowest-energy MO derived from the  $2p$  atomic orbitals.

▲ **Figure 9.41** Energy-level diagram for MOs of period 2 homonuclear diatomic molecules. The diagram assumes no interaction between the  $2s$  atomic orbital on one atom and the  $2p$  atomic orbitals on the other atom, and experiment shows that it fits only for  $O_2$ ,  $F_2$ , and  $Ne_2$ .

## Go Figure

Which molecular orbitals have switched relative energy in the group on the right as compared with the group on the left?

▲ Figure 9.42 The effect of interactions between  $2s$  and  $2p$  atomic orbitals.

- The overlap of the two  $2p_z$  orbitals is greater than that of the two  $2p_x$  or  $2p_y$  orbitals. As a result, the bonding  $\sigma_{2p}$  MO is lower in energy than the  $\pi_{2p}$  MOs, and the antibonding  $\sigma_{2p}^*$  MO is higher in energy than the  $\pi_{2p}^*$  MOs.
- Both the  $\pi_{2p}$  and  $\pi_{2p}^*$  MOs are *doubly degenerate*; that is, there are two degenerate MOs of each type.

Before we can add electrons to Figure 9.41, we must consider one more effect. We have constructed the diagram assuming no interaction between the  $2s$  orbital on one atom and the  $2p$  orbitals on the other. In fact, such interactions can and do take place. Figure 9.42 shows the overlap of a  $2s$  orbital on one of the atoms with a  $2p$  orbital on the other. These interactions increase the energy difference between the  $\sigma_{2s}$  and  $\sigma_{2p}$  MOs, with the  $\sigma_{2s}$  energy decreasing and the  $\sigma_{2p}$  energy increasing (Figure 9.42). These  $2s-2p$  interactions can be strong enough that the energetic ordering of the MOs can be altered: For  $B_2$ ,  $C_2$ , and  $N_2$ , the  $\sigma_{2p}$  MO is above the  $\pi_{2p}$  MOs in energy. For  $O_2$ ,  $F_2$ , and  $Ne_2$ , the  $\sigma_{2p}$  MO is below the  $\pi_{2p}$  MOs.

Given the energy ordering of the molecular orbitals, it is a simple matter to determine the electron configurations for the diatomic molecules  $B_2$  through  $Ne_2$ . For example, a boron atom has three valence electrons. (Remember that we are ignoring the core  $1s$  electrons.) Thus, for  $B_2$  we must place six electrons in MOs. Four of them fill the  $\sigma_{2s}$  and  $\sigma_{2s}^*$  MOs, leading to no net bonding. The fifth electron goes in one  $\pi_{2p}$  MO, and the sixth goes in the other  $\pi_{2p}$  MO, with the two electrons having the same spin. Therefore,  $B_2$  has a bond order of 1.

Each time we move one element to the right in period 2, two more electrons must be placed in the diagram of Figure 9.41. For example, on moving to  $C_2$ , we have two more electrons than in  $B_2$ , and these electrons are placed in the  $\pi_{2p}$  MOs, completely filling them. The electron configurations and bond orders for  $B_2$  through  $Ne_2$  are given in Figure 9.43.

## Electron Configurations and Molecular Properties

The way a substance behaves in a magnetic field can in some cases provide insight into the arrangements of its electrons. Molecules with one or more unpaired electrons are attracted to a magnetic field. The more unpaired electrons in a species, the stronger the attractive force. This type of magnetic behavior is called **paramagnetism**.

▲ **Figure 9.43** Molecular orbital electron configurations and some experimental data for period 2 diatomic molecules.

Substances with no unpaired electrons are weakly repelled by a magnetic field. This property is called **diamagnetism**. The distinction between paramagnetism and diamagnetism is nicely illustrated in an older method for measuring magnetic properties (**Figure 9.44**). It involves weighing the substance in the presence and absence of a magnetic field. A paramagnetic substance appears to weigh more in the magnetic field; a diamagnetic substance appears to weigh less. The magnetic behaviors observed for the period 2 diatomic molecules agree with the electron configurations shown in Figure 9.43.

Electron configurations in molecules can also be related to bond distances and bond enthalpies. ∞ (Sections 5.8 and 8.8) As bond order increases, bond distances decrease and bond enthalpies increase. N<sub>2</sub>, for example, whose bond order is 3, has a short bond distance and a large bond enthalpy. The N<sub>2</sub> molecule does not react readily with other

## Give It Some Thought

Figure 9.43 indicates that C<sub>2</sub> is diamagnetic. Would that be expected if the  $\sigma_{2p}$  MO were lower in energy than the  $\pi_{2p}$  MOs?

## Go Figure

What would you expect to see if liquid nitrogen were poured between the poles of the magnet?

▲ **Figure 9.45** Paramagnetism of  $\text{O}_2$ . When liquid oxygen is poured through a magnet, it “sticks” to the poles.

substances to form nitrogen compounds. The high bond order of the molecule helps explain its exceptional stability. We should also note, however, that molecules with the same bond orders do *not* have the same bond distances and bond enthalpies. Bond order is only one factor influencing these properties. Other factors include nuclear charge and extent of orbital overlap.

Bonding in  $\text{O}_2$  provides an interesting test case for molecular orbital theory. The Lewis structure for this molecule shows a double bond and complete pairing of electrons:

The short O—O bond distance (1.21 Å) and relatively high bond enthalpy (495 kJ/mol) are in agreement with the presence of a double bond. However, Figure 9.43 tells us that the molecule contains two unpaired electrons and should therefore be paramagnetic, a detail not discernible in the Lewis structure. The paramagnetism of  $\text{O}_2$  is demonstrated in Figure 9.45, which confirms the prediction from MO theory. The MO description also correctly predicts a bond order of 2 as did the Lewis structure.

Going from  $\text{O}_2$  to  $\text{F}_2$ , we add two electrons, completely filling the  $\pi_{2p}^*$  MOs. Thus,  $\text{F}_2$  is expected to be diamagnetic and have an F—F single bond, in accord with its Lewis structure. Finally, the addition of two more electrons to make  $\text{Ne}_2$  fills all the bonding and antibonding MOs. Therefore, the bond order of  $\text{Ne}_2$  is zero, and the molecule is not expected to exist.

## Sample Exercise 9.9

## Molecular Orbitals of a Period 2 Diatomic Ion

For the  $\text{O}_2^+$  ion predict (a) number of unpaired electrons, (b) bond order, (c) bond enthalpy and bond length.

## SOLUTION

**Analyze** Our task is to predict several properties of the cation  $\text{O}_2^+$ .

**Plan** We will use the MO description of  $\text{O}_2^+$  to determine the desired properties. We must first determine the number of electrons in  $\text{O}_2^+$  and then draw its MO energy diagram. The unpaired electrons are those without a partner of opposite spin. The bond order is one-half the difference between the number of bonding and antibonding electrons. After calculating the bond order, we can use Figure 9.43 to estimate the bond enthalpy and bond length.

## Solve

- (a) The  $\text{O}_2^+$  ion has 11 valence electrons, one fewer than  $\text{O}_2$ . The electron removed from  $\text{O}_2$  to form  $\text{O}_2^+$  is one of the two unpaired  $\pi_{2p}^*$  electrons (see Figure 9.43). Therefore,  $\text{O}_2^+$  has one unpaired electron.
- (b) The molecule has eight bonding electrons (the same as  $\text{O}_2$ ) and three antibonding electrons (one fewer than  $\text{O}_2$ ). Thus, its bond order is

$$\frac{1}{2}(8 - 3) = 2\frac{1}{2}$$

Continued

- (c) The bond order of  $\text{O}_2^+$  is between that for  $\text{O}_2$  (bond order 2) and  $\text{N}_2$  (bond order 3). Thus, the bond enthalpy and bond length should be about midway between those for  $\text{O}_2$  and  $\text{N}_2$ , approximately 700 kJ/mol and 1.15 Å. (The experimentally measured values are 625 kJ/mol and 1.123 Å.)

### ► Practice Exercise 1

Place the following molecular ions in order from smallest to largest bond order:  $\text{C}_2^{2+}$ ,  $\text{N}_2^-$ ,  $\text{O}_2^-$ , and  $\text{F}_2^-$ .

- (a)  $\text{C}_2^{2+} < \text{N}_2^- < \text{O}_2^- < \text{F}_2^-$

- (b)  $\text{F}_2^- < \text{O}_2^- < \text{N}_2^- < \text{C}_2^{2+}$

- (c)  $\text{O}_2^- < \text{C}_2^{2+} < \text{F}_2^- < \text{N}_2^-$

- (d)  $\text{C}_2^{2+} < \text{F}_2^- < \text{O}_2^- < \text{N}_2^-$

- (e)  $\text{F}_2^- < \text{C}_2^{2+} < \text{O}_2^- < \text{N}_2^-$

### ► Practice Exercise 2

Predict the magnetic properties and bond orders of (a) the peroxide ion,  $\text{O}_2^{2-}$ ; (b) the acetylide ion,  $\text{C}_2^{2-}$ .

## Heteronuclear Diatomic Molecules

The principles we have used in developing an MO description of homonuclear diatomic molecules can be extended to *heteronuclear* diatomic molecules—those in which the two atoms in the molecule are not the same. We conclude this section with a fascinating heteronuclear diatomic molecule—nitric oxide, NO.

The NO molecule controls several important human physiological functions. Our bodies use it, for example, to relax muscles, kill foreign cells, and reinforce memory. The 1998 Nobel Prize in Physiology or Medicine was awarded to three scientists for their research that uncovered the importance of NO as a “signaling” molecule in the cardiovascular system. NO also functions as a neurotransmitter and is implicated in many other biological pathways. That NO plays such an important role in human metabolism was unsuspected before 1987 because NO has an odd number of electrons and is highly reactive. The molecule has 11 valence electrons, and two possible Lewis structures can be drawn. The Lewis structure with the lower formal charges places the odd electron on the N atom:

Both structures indicate the presence of a double bond, but when compared with the molecules in Figure 9.43, the experimental bond length of NO (1.15 Å) suggests a bond order greater than 2. How do we treat NO using the MO model?

If the atoms in a heteronuclear diatomic molecule do not differ too greatly in electronegativities, their MOs resemble those in homonuclear diatomics, with one important modification: The energy of the atomic orbitals of the more electronegative atom is lower than that of the atomic orbitals of the less electronegative element. In Figure 9.46, you see that the 2s and 2p atomic orbitals of oxygen are slightly lower than those of nitrogen because oxygen is more electronegative than nitrogen. The MO energy-level diagram for NO is much like that of a homonuclear diatomic molecule—because the 2s and 2p orbitals on the two atoms interact, the same types of MOs are produced.

There is one other important difference in the MOs of heteronuclear molecules. The MOs are still a mix of atomic orbitals from both atoms, but in general an MO in a heteronuclear diatomic molecule has a greater contribution from the atomic orbital to which it is closer in energy. In the case of NO, for example, the  $\sigma_{2s}$  bonding MO is closer in energy to the O 2s atomic orbital than to the N 2s atomic orbital. As a result, the  $\sigma_{2s}$  MO has a slightly greater contribution from O than from N—the orbital is no longer an equal mixture of the two atoms, as was the case for the homonuclear diatomic molecules. Similarly, the  $\sigma_{2s}^*$  antibonding MO is weighted more heavily toward the N atom because that MO is closest in energy to the N 2s atomic orbital.

We complete the MO diagram for NO by filling the MOs in Figure 9.46 with the 11 valence electrons. Eight bonding and three antibonding electrons give a bond order of  $\frac{1}{2}(8 - 3) = 2\frac{1}{2}$ , which agrees better with experiment than the Lewis structures do. The unpaired electron resides in one of the  $\pi_{2p}^*$  MOs, which have a greater contribution from the N atom. (We could have placed this electron in either the left or right  $\pi_{2p}^*$  MO.) Thus, the Lewis structure that places the unpaired electron on nitrogen (the one preferred on the basis of formal charge) is the more accurate description of the true electron distribution in the molecule.

## CHEMISTRY PUT TO WORK Orbitals and Energy

Asked to identify the major technological challenge for the twenty-first century, you might say “energy,” reasoning that development of sustainable energy sources is crucial to meet the needs of future generations of people on our planet. One of the most remarkable sources of clean energy is the Sun, which sends enough energy to power the world for millions of years. Our challenge is to capture enough of this energy in a form that allows us to use it as needed. *Photovoltaic solar cells* convert the light from the Sun into usable electricity, and the development of more efficient solar cells is one way to address Earth’s future energy needs.

How does solar energy conversion work? Fundamentally, we need to be able to use photons from the Sun, especially from the visible portion of the spectrum, to excite electrons in molecules and materials to different energy levels. The brilliant colors around you—those of your clothes, the photographs in this book, the foods you eat—are due to the selective absorption of visible light by chemicals. It is helpful to think of this process in the context of molecular orbital theory: Light excites an electron from a filled molecular orbital to an empty one at higher energy. Because MOs have definite energies, only light of the proper wavelengths can excite electrons.

In discussing light absorption by molecules, we can focus on the two MOs shown in **Figure 9.47**. The *highest occupied molecular orbital* (HOMO) is the MO of highest energy that has electrons in it. The *lowest unoccupied molecular orbital* (LUMO) is the MO of lowest energy that does not have electrons in it. In  $N_2$ , for example, the HOMO is the  $\sigma_{2p}$  MO and the LUMO is the  $\pi_{2p}^*$  MO (Figure 9.43).

▲ **Figure 9.47** Definitions of the highest occupied and lowest unoccupied molecular orbitals. The energy difference between these is the HOMO-LUMO gap.

The energy difference between the HOMO and the LUMO—known as the HOMO-LUMO gap—is related to the minimum energy needed to excite an electron in the molecule. Colorless or

*Continued*

white substances usually have such a large HOMO–LUMO gap that visible light is not energetic enough to excite an electron to the higher level. The minimum energy needed to excite an electron from the HOMO to the LUMO in  $N_2$  corresponds to light with a wavelength of less than 200 nm, which is far into the ultraviolet part of the spectrum.  (Figure 6.4) As a result,  $N_2$  cannot absorb visible light and is therefore colorless.

The magnitude of the energy gap between filled and empty electronic states is critical for solar energy conversion. Ideally, we want a substance that absorbs as many solar photons as possible and then converts the energy of those photons into a useful form of energy. Titanium dioxide is a readily available material that can be reasonably efficient at converting light directly into electricity. However,  $TiO_2$  is white and absorbs only a small amount of the Sun's

radiant energy. Scientists are working to make solar cells in which  $TiO_2$  is mixed with highly colored molecules, whose HOMO–LUMO gaps correspond to visible and near-infrared light to absorb more of the solar spectrum. If the HOMO of these molecules is higher in energy than the HOMO of  $TiO_2$ , the excited electrons will flow from the molecules into the  $TiO_2$ , thereby generating electricity when the device is illuminated with light and connected to an external circuit.

Efficient solar energy conversion promises to be one of the most interesting and important areas of both scientific and technological development in our future. Many of you may ultimately end up working in fields that have an impact on the world's energy portfolio.

## Sample Integrative Exercise

### Putting Concepts Together

Elemental sulfur is a yellow solid that consists of  $S_8$  molecules. The structure of the  $S_8$  molecule is a puckered, eight-membered ring (see Figure 7.27). Heating elemental sulfur to high temperatures produces gaseous  $S_2$  molecules:

(a) The electron configuration of which period 2 element is most similar to that of sulfur? (b) Use the VSEPR model to predict the  $S-S-S$  bond angles in  $S_8$  and the hybridization at S in  $S_8$ . (c) Use MO theory to predict the sulfur–sulfur bond order in  $S_2$ . Do you expect this molecule to be diamagnetic or paramagnetic? (d) Use average bond enthalpies (Table 8.3) to estimate the enthalpy change for this reaction. Is the reaction exothermic or endothermic?

### SOLUTION

(a) Sulfur is a group 6A element with an  $[Ne]3s^23p^4$  electron configuration. It is expected to be most similar electronically to oxygen (electron configuration,  $[He]2s^22p^4$ ), which is immediately above it in the periodic table.

(b) The Lewis structure of  $S_8$  is

There is a single bond between each pair of S atoms and two nonbonding electron pairs on each S atom. Thus, we see four electron domains around each S atom and expect a tetrahedral electron-domain geometry corresponding to  $sp^3$  hybridization. Because of the nonbonding pairs, we expect the  $S-S-S$  angles to be somewhat less than  $109.5^\circ$ , the tetrahedral angle. Experimentally, the  $S-S-S$  angle in  $S_8$  is  $108^\circ$ , in good agreement with this prediction. Interestingly, if  $S_8$  were a planar ring, it would have  $S-S-S$  angles of  $135^\circ$ . Instead, the  $S_8$  ring

puckers to accommodate the smaller angles dictated by  $sp^3$  hybridization.

(c) The MOs of  $S_2$  are analogous to those of  $O_2$ , although the MOs for  $S_2$  are constructed from the 3s and 3p atomic orbitals of sulfur. Further,  $S_2$  has the same number of valence electrons as  $O_2$ . Thus, by analogy with  $O_2$ , we expect  $S_2$  to have a bond order of 2 (a double bond) and to be paramagnetic with two unpaired electrons in the  $\pi_{3p}^*$  molecular orbitals of  $S_2$ .

(d) We are considering the reaction in which an  $S_8$  molecule falls apart into four  $S_2$  molecules. From parts (b) and (c), we see that  $S_8$  has  $S-S$  single bonds and  $S_2$  has  $S=S$  double bonds. During the reaction, therefore, we are breaking eight  $S-S$  single bonds and forming four  $S=S$  double bonds. We can estimate the enthalpy of the reaction by using Equation 5.33 and the average bond enthalpies in Table 8.3:

$$\begin{aligned}\Delta H_{\text{rxn}} &= 8 D(S-S) - 4 D(S=S) \\ &= 8(266 \text{ kJ}) - 4(418 \text{ kJ}) = +456 \text{ kJ}\end{aligned}$$

Recall that  $D(X-Y)$  represents the  $X-Y$  bond enthalpy. Because  $\Delta H_{\text{rxn}} > 0$ , the reaction is endothermic (Section 5.3). The very positive value of  $\Delta H_{\text{rxn}}$  suggests that high temperatures are required to cause the reaction to occur.

## Chapter Summary and Key Terms

**MOLECULAR SHAPES (INTRODUCTION AND SECTION 9.1)** The three-dimensional shapes and sizes of molecules are determined by their **bond angles** and bond lengths. Molecules with a central atom A surrounded by  $n$  atoms B, denoted  $AB_n$ , adopt a number of different geometric shapes, depending on the value of  $n$  and on the particular atoms involved. In the overwhelming majority of cases, these geometries are related to five basic shapes (linear, trigonal pyramidal, tetrahedral, trigonal bipyramidal, and octahedral).

**THE VSEPR MODEL (SECTION 9.2)** The **valence-shell electron-pair repulsion (VSEPR) model** rationalizes molecular geometries based on the repulsions between **electron domains**, which are regions about a central atom in which electrons are likely to be found. **Bonding pairs** of electrons, which are those involved in making bonds, and **nonbonding pairs** of electrons, also called **lone pairs**, both create electron domains around an atom. According to the VSEPR model, electron domains orient themselves to

minimize electrostatic repulsions; that is, they remain as far apart as possible.

Electron domains from nonbonding pairs exert slightly greater repulsions than those from bonding pairs, which leads to certain preferred positions for nonbonding pairs and to the departure of bond angles from idealized values. Electron domains from multiple bonds exert slightly greater repulsions than those from single bonds. The arrangement of electron domains around a central atom is called the **electron-domain geometry**; the arrangement of atoms is called the **molecular geometry**.

**MOLECULAR POLARITY (SECTION 9.3)** The dipole moment of a polyatomic molecule depends on the vector sum of the dipole moments associated with the individual bonds, called the **bond dipoles**. Certain molecular shapes, such as linear  $AB_2$  and trigonal planar  $AB_3$ , lead to cancellation of the bond dipoles, producing a nonpolar molecule, which is one whose overall dipole moment is zero. In other shapes, such as bent  $AB_2$  and trigonal pyramidal  $AB_3$ , the bond dipoles do not cancel and the molecule will be polar (that is, it will have a nonzero dipole moment).

**COVALENT BONDING AND VALENCE-BOND THEORY (SECTION 9.4)** Valence-bond theory is an extension of Lewis's notion of electron-pair bonds. In valence-bond theory, covalent bonds are formed when atomic orbitals on neighboring atoms overlap one another. The overlap region is one of greater stability for the two electrons because of their simultaneous attraction to two nuclei. The greater the overlap between two orbitals, the stronger the bond that is formed.

**HYBRID ORBITALS (SECTION 9.5)** To extend the ideas of valence-bond theory to polyatomic molecules, we must envision mixing  $s$  and  $p$  orbitals to form **hybrid orbitals**. The process of **hybridization** leads to hybrid atomic orbitals that have a large lobe directed to overlap with orbitals on another atom to make a bond. Hybrid orbitals can also accommodate nonbonding pairs. A particular mode of hybridization can be associated with each of three common electron-domain geometries (linear =  $sp$ ; trigonal planar =  $sp^2$ ; tetrahedral =  $sp^3$ ). The bonding in **hypervalent** molecules—those with more than an octet of electrons—is not as readily discussed in terms of hybrid orbitals.

**MULTIPLE BONDS (SECTION 9.6)** Covalent bonds in which the electron density lies along the line connecting the atoms (the internuclear axis) are called **sigma ( $\sigma$ ) bonds**. Bonds can also be formed from the sideways overlap of  $p$  orbitals. Such a bond is called a **pi ( $\pi$ ) bond**. A double bond, such as that in  $C_2H_4$ , consists of one  $\sigma$  bond and one  $\pi$  bond; each carbon atom has an unhybridized  $p$  orbital, and these are the orbitals that overlap to form  $\pi$  bonds. A triple bond, such as that in  $C_2H_2$ , consists of one  $\sigma$  and two  $\pi$  bonds. The formation of a  $\pi$  bond requires that molecules adopt a specific orientation; the two  $CH_2$  groups in  $C_2H_4$ , for example, must lie in the same plane. As a result, the presence of  $\pi$  bonds introduces rigidity into molecules. In molecules that have multiple bonds and more than one resonance structure, such as  $C_6H_6$ , the  $\pi$  bonds are **delocalized**; that is, the  $\pi$  bonds are spread among several atoms.

**MOLECULAR ORBITALS (SECTION 9.7)** Molecular orbital theory is another model used to describe the bonding in molecules. In this model, the electrons exist in allowed energy states called **molecular orbitals (MOs)**. An MO can extend over all the atoms of a molecule. Like an atomic orbital, a molecular orbital has a definite energy and can hold two electrons of opposite spin. We can build molecular orbitals by combining atomic orbitals on different atomic centers. In the simplest case, the combination of two atomic orbitals leads to the formation of two MOs, one at lower energy and one at higher energy relative to the energy of the atomic orbitals. The lower-energy MO concentrates charge density in the region between the nuclei and is called a **bonding molecular orbital**. The higher-energy MO excludes electrons from the region between the nuclei and is called an **antibonding molecular orbital**. Antibonding MOs exclude electron density from the region between the nuclei and have a **nodal plane**—a place at which the electron density is zero—between the nuclei. Occupation of bonding MOs favors bond formation, whereas occupation of antibonding MOs is unfavorable. The bonding and antibonding MOs formed by the combination of  $s$  orbitals are **sigma ( $\sigma$ ) molecular orbitals**; they lie on the internuclear axis.

The combination of atomic orbitals and the relative energies of the molecular orbitals are shown by an **energy-level (or molecular orbital) diagram**. When the appropriate number of electrons is put into the MOs, we can calculate the **bond order** of a bond, which is half the difference between the number of electrons in bonding MOs and the number of electrons in antibonding MOs. A bond order of 1 corresponds to a single bond, and so forth. Bond orders can be fractional numbers.

#### BONDING IN PERIOD 2 DIATOMIC MOLECULES (SECTION 9.8)

Electrons in core orbitals do not contribute to the bonding between atoms, so a molecular orbital description usually needs to consider only electrons in the outermost electron subshells. To describe the MOs of period 2 homonuclear diatomic molecules, we need to consider the MOs that can form by the combination of  $p$  orbitals. The  $p$  orbitals that point directly at one another can form  $\sigma$  bonding and  $\sigma^*$  antibonding MOs. The  $p$  orbitals that are oriented perpendicular to the internuclear axis combine to form **pi ( $\pi$ ) molecular orbitals**. In diatomic molecules, the  $\pi$  molecular orbitals occur as a pair of degenerate (same energy) bonding MOs and a pair of degenerate antibonding MOs. The  $\sigma_{2p}$  bonding MO is expected to be lower in energy than the  $\pi_{2p}$  bonding MOs because of larger orbital overlap of the  $p$  orbitals directed along the internuclear axis. However, this ordering is reversed in  $B_2$ ,  $C_2$ , and  $N_2$  because of interaction between the  $2s$  and  $2p$  atomic orbitals of different atoms.

The molecular orbital description of period 2 diatomic molecules leads to bond orders in accord with the Lewis structures of these molecules. Further, the model predicts correctly that  $O_2$  should exhibit **paramagnetism**, which leads to attraction of a molecule into a magnetic field due to the influence of unpaired electrons. Molecules in which all the electrons are paired exhibit **diamagnetism**, which leads to weak repulsion from a magnetic field. The molecular orbitals of heteronuclear diatomic molecules are often closely related to those of homonuclear diatomic molecules.

## Learning Outcomes After studying this chapter, you should be able to:

- Draw and name the predicted three-dimensional shapes of molecules using the VSEPR model. (Section 9.2) *Related Exercises: 9.25, 9.26*
- Determine whether a molecule is polar or nonpolar based on its geometry and the individual bond dipole moments. (Section 9.3) *Related Exercises: 9.41, 9.42*
- Explain the role of orbital overlap in the formation of covalent bonds. (Section 9.4) *Related Exercises: 9.47, 9.48*
- Determine the hybridization of atoms in molecules based on observed molecular structures. (Section 9.5) *Related Exercises: 9.51, 9.52*
- Sketch how orbitals overlap to form sigma ( $\sigma$ ) and pi ( $\pi$ ) bonds. (Section 9.6) *Related Exercises: 9.55, 9.56*
- Explain the existence of delocalized  $\pi$  bonds in molecules such as benzene. (Section 9.6) *Related Exercises: 9.63, 9.64*
- Count the number of electrons in a delocalized  $\pi$  system. (Section 9.6) *Related Exercises: 9.65, 9.66*
- Explain the concept of bonding and antibonding molecular orbitals and draw examples of  $\sigma$  and  $\pi$  MOs. (Section 9.7) *Related Exercises: 9.69, 9.70*

- Draw molecular orbital energy-level diagrams and place electrons into them to obtain the bond orders and electron configurations of diatomic molecules using molecular orbital theory. (Sections 9.7 and 9.8) *Related Exercises:* 9.71, 9.72
- Correlate bond order, bond strength (bond enthalpy), bond length, and magnetic properties with molecular orbital descriptions of molecules. (Section 9.8) *Related Exercises:* 9.79, 9.80

## Key Equations

- Bond order =  $\frac{1}{2}$  (number of bonding electrons – number of antibonding electrons) [9.1]

## Exercises

### Visualizing Concepts

- 9.1** A certain  $AB_4$  molecule has a “seesaw” shape

From which of the fundamental geometries shown in Figure 9.3 could you remove one or more atoms to create a molecule having this seesaw shape? [Section 9.1]

- 9.2** (a) If these three balloons are all the same size, what angle is formed between the red one and the green one? (b) If additional air is added to the blue balloon so that it gets larger, will the angle between the red and green balloons increase, decrease, or stay the same? (c) Which of the following aspects of the VSEPR model is illustrated by part (b): (i) The electron-domain geometry for four electron domains is tetrahedral. (ii) The electron domains for nonbonding pairs are larger than those for bonding pairs. (iii) The hybridization that corresponds to a trigonal planar electron-domain geometry is  $sp^2$ . [Section 9.2]

- 9.3** For each molecule (a)–(f), indicate how many different electron-domain geometries are consistent with the molecular geometry shown. [Section 9.2]

- 9.4** The molecule shown here is *difluoromethane* ( $CH_2F_2$ ), which is used as a refrigerant called R-32. (a) Based on the structure, how many electron domains surround the C atom in this molecule? (b) Would the molecule have a nonzero dipole moment? (c) If the molecule is polar, which of the following describes the direction of the overall dipole moment vector in the molecule: (i) from the carbon atom toward a fluorine atom, (ii) from the carbon atom to a point midway between the fluorine atoms, (iii) from the carbon atom to a point midway between the hydrogen atoms, or (iv) from the carbon atom toward a hydrogen atom? [Sections 9.2 and 9.3]

- 9.5** The following plot shows the potential energy of two Cl atoms as a function of the distance between them. (a) If the two atoms are very far away from each other, what is their potential energy of interaction? (b) We know that the  $Cl_2$  molecule exists. What is the approximate bond length and bond strength for the Cl–Cl bond in  $Cl_2$  from this graph? (c) If the  $Cl_2$  molecule is compressed under higher and higher pressure, does the Cl–Cl bond become stronger or weaker?

- 9.6 The orbital diagram that follows presents the final step in the formation of hybrid orbitals by a silicon atom. (a) Which of the following best describes what took place before the step pictured in the diagram: (i) Two  $3p$  electrons became unpaired, (ii) An electron was promoted from the  $2p$  orbital to the  $3s$  orbital, or (iii) An electron was promoted from the  $3s$  orbital to the  $3p$  orbital? (b) What type of hybrid orbital is produced in this hybridization? [Section 9.5]

- 9.7 In the hydrocarbon

- (a) What is the hybridization at each carbon atom in the molecule? (b) How many  $\sigma$  bonds are there in the molecule? (c) How many  $\pi$  bonds? (d) Identify all the  $120^\circ$  bond angles in the molecule. [Section 9.6]
- 9.8 The drawing below shows the overlap of two hybrid orbitals to form a bond in a hydrocarbon. (a) Which of the following types of bonds is being formed: (i)  $\text{C}-\text{C}$   $\sigma$ , (ii)  $\text{C}-\text{C}$   $\pi$ , or (iii)  $\text{C}-\text{H}$   $\sigma$ ? (b) Which of the following could be the identity of the hydrocarbon: (i)  $\text{CH}_4$ , (ii)  $\text{C}_2\text{H}_6$ , (iii)  $\text{C}_2\text{H}_4$ , or (iv)  $\text{C}_2\text{H}_2$ ? [Section 9.6]

- 9.9 The molecule shown below is called *furan*. It is represented in typical shorthand way for organic molecules, with hydrogen atoms not shown, and each of the 4 vertices representing a carbon atom.

- (a) What is the molecular formula for furan? (b) How many valence electrons are there in the molecule? (c) What is the hybridization at each of the carbon atoms? (d) How many electrons are in the  $\pi$  system of the molecule? (e) The  $\text{C}-\text{C}-\text{C}$  bond angles in furan are much smaller than those in benzene. The likely reason is which of the following: (i) The hybridization of the carbon atoms in furan is different from that in benzene, (ii) Furan does not have another resonance structure equivalent to the one above, or (iii) The atoms in a five-membered ring are forced to adopt smaller angles than in a six-membered ring. [Section 9.5]
- 9.10 The following is part of a molecular orbital energy-level diagram for MOs constructed from  $1s$  atomic orbitals.

- (a) What labels do we use for the two MOs shown? (b) For which of the following molecules or ions could this be the energy-level diagram:

- (c) What is the bond order of the molecule or ion? (d) If an electron is added to the system, into which of the MOs will it be added? [Section 9.7]

- 9.11 For each of these contour representations of molecular orbitals, identify (a) the atomic orbitals ( $s$  or  $p$ ) used to construct the MO (b) the type of MO ( $\sigma$  or  $\pi$ ), (c) whether the MO is bonding or antibonding, and (d) the locations of nodal planes. [Sections 9.7 and 9.8]

- 9.12 The diagram that follows shows the highest-energy occupied MOs of a neutral molecule  $\text{CX}$ , where element  $\text{X}$  is in the same row of the periodic table as  $\text{C}$ . (a) Based on the number of electrons, can you determine the identity of  $\text{X}$ ? (b) Would the molecule be diamagnetic or paramagnetic? (c) Consider the  $\pi_{2p}$  MOs of the molecule. Would you expect them to have a greater atomic orbital contribution from  $\text{C}$ , have a greater atomic orbital contribution from  $\text{X}$ , or be an equal mixture of atomic orbitals from the two atoms? [Section 9.8]

## Molecular Shapes; the VSEPR Model (Sections 9.1 and 9.2)

- 9.13 (a) An  $\text{AB}_2$  molecule is linear. How many nonbonding electron pairs are around the  $\text{A}$  atom from this information? (b) How many nonbonding electrons surround the  $\text{Xe}$  in  $\text{XeF}_2$ ? (c) Is  $\text{XeF}_2$  linear?
- 9.14 (a) Methane ( $\text{CH}_4$ ) and the perchlorate ion ( $\text{ClO}_4^-$ ) are both described as tetrahedral. What does this indicate about their bond angles? (b) The  $\text{NH}_3$  molecule is trigonal pyramidal, while  $\text{BF}_3$  is trigonal planar. Which of these molecules is flat?
- 9.15 How does a trigonal pyramid differ from a tetrahedron so far as molecular geometry is concerned?
- 9.16 Describe the bond angles to be found in each of the following molecular structures: (a) trigonal planar, (b) tetrahedral, (c) octahedral, (d) linear.
- 9.17 (a) An  $\text{AB}_6$  molecule has no lone pairs of electrons on the  $\text{A}$  atom. What is its molecular geometry? (b) An  $\text{AB}_4$  molecule has two lone pairs of electrons on the  $\text{A}$  atom (in addition to the four  $\text{B}$  atoms). What is the electron-domain geometry around the  $\text{A}$  atom? (c) For the  $\text{AB}_4$  molecule in part (b), predict the molecular geometry.

- 9.18** Would you expect the nonbonding electron-pair domain in  $\text{NH}_3$  to be greater or less in size than the corresponding one in  $\text{PH}_3$ ?
- 9.19** In which of these molecules or ions does the presence of nonbonding electron pairs produce an effect on molecular shape? (a)  $\text{SiH}_4$ , (b)  $\text{PF}_3$ , (c)  $\text{HBr}$ , (d)  $\text{HCN}$ , (e)  $\text{SO}_2$ .
- 9.20** In which of the following molecules can you confidently predict the bond angles about the central atom, and for which would you be a bit uncertain? Explain in each case. (a)  $\text{H}_2\text{S}$ , (b)  $\text{BCl}_3$ , (c)  $\text{CH}_3\text{I}$ , (d)  $\text{CBr}_4$ , (e)  $\text{TeBr}_4$ .
- 9.21** How many nonbonding electron pairs are there in each of the following molecules: (a)  $(\text{CH}_3)_2\text{S}$ , (b)  $\text{HCN}$ , (c)  $\text{C}_2\text{H}_2$ , (d)  $\text{CH}_3\text{F}$ ?
- 9.22** Describe the characteristic electron-domain geometry of each of the following numbers of electron domains about a central atom: (a) 3, (b) 4, (c) 5, (d) 6.
- 9.23** Give the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom: (a) four bonding domains and no nonbonding domains, (b) three bonding domains and two nonbonding domains, (c) five bonding domains and one nonbonding domain, (d) four bonding domains and two nonbonding domains.
- 9.24** What are the electron-domain and molecular geometries of a molecule that has the following electron domains on its central atom? (a) Three bonding domains and no nonbonding domains, (b) three bonding domains and one nonbonding domain, (c) two bonding domains and two nonbonding domains.
- 9.25** Give the electron-domain and molecular geometries for the following molecules and ions: (a)  $\text{HCN}$ , (b)  $\text{SO}_3^{2-}$ , (c)  $\text{SF}_4$ , (d)  $\text{PF}_6^-$ , (e)  $\text{NH}_3\text{Cl}^+$ , (f)  $\text{N}_3^-$ .
- 9.26** Draw the Lewis structure for each of the following molecules or ions, and predict their electron-domain and molecular geometries: (a)  $\text{AsF}_3$ , (b)  $\text{CH}_3^+$ , (c)  $\text{BrF}_3$ , (d)  $\text{ClO}_3^-$ , (e)  $\text{XeF}_2$ , (f)  $\text{BrO}_2^-$ .
- 9.27** The figure that follows shows ball-and-stick drawings of three possible shapes of an  $\text{AF}_3$  molecule. (a) For each shape, give the electron-domain geometry on which the molecular geometry is based. (b) For each shape, how many nonbonding electron domains are there on atom A? (c) Which of the following elements will lead to an  $\text{AF}_3$  molecule with the shape in (ii): Li, B, N, Al, P, Cl? (d) Name an element A that is expected to lead to the  $\text{AF}_3$  structure shown in (iii).

- 9.28** The figure that follows contains ball-and-stick drawings of three possible shapes of an  $\text{AF}_4$  molecule. (a) For each shape, give the electron-domain geometry on which the molecular geometry is based. (b) For each shape, how many nonbonding electron domains are there on atom A? (c) Which of the following elements will lead to an  $\text{AF}_4$  molecule with the shape in (iii): Be, C, S, Se, Si, Xe? (d) Name an element A that is expected to lead to the  $\text{AF}_4$  structure shown in (i).

- 9.29** Give the approximate values for the indicated bond angles in the following molecules:

- 9.30** Give approximate values for the indicated bond angles in the following molecules:

- 9.31** Ammonia,  $\text{NH}_3$ , reacts with incredibly strong bases to produce the amide ion,  $\text{NH}_2^-$ . Ammonia can also react with acids to produce the ammonium ion,  $\text{NH}_4^+$ . (a) Which species (amide ion, ammonia, or ammonium ion) has the largest  $\text{H}-\text{N}-\text{H}$  bond angle? (b) Which species has the smallest  $\text{H}-\text{N}-\text{H}$  bond angle?
- 9.32** In which of the following  $\text{AF}_n$  molecules or ions is there more than one  $\text{F}-\text{A}-\text{F}$  bond angle:  $\text{SiF}_4$ ,  $\text{PF}_5$ ,  $\text{SF}_6$ ,  $\text{AsF}_3$ ?
- 9.33** (a) Explain why  $\text{BrF}_4^-$  is square planar, whereas  $\text{BF}_4^-$  is tetrahedral. (b) How would you expect the  $\text{H}-\text{X}-\text{H}$  bond angle to vary in the series  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{Se}$ ? Explain. (Hint: The size of an electron pair domain depends in part on the electronegativity of the central atom.)
- 9.34** Name the proper three-dimensional molecular shapes for each of the following molecules or ions, showing lone pairs as needed: (a)  $\text{ClO}_2^-$  (b)  $\text{SO}_4^{2-}$  (c)  $\text{NF}_3$  (d)  $\text{CCl}_2\text{Br}_2$  (e)  $\text{SF}_4^{2+}$

### Shapes and Polarity of Polyatomic Molecules (Section 9.3)

- 9.35** What is the distinction between a bond dipole and a molecular dipole moment?
- 9.36** Consider a molecule with formula  $\text{AX}_3$ . Supposing the  $\text{A}-\text{X}$  bond is polar, how would you expect the dipole moment of the  $\text{AX}_3$  molecule to change as the  $\text{X}-\text{A}-\text{X}$  bond angle increases from  $100^\circ$  to  $120^\circ$ ?

- 9.37** (a) Does  $\text{SCl}_2$  have a dipole moment? If so, in which direction does the net dipole point? (b) Does  $\text{BeCl}_2$  have a dipole moment? If so, in which direction does the net dipole point?
- 9.38** (a) The  $\text{PH}_3$  molecule is polar. Does this offer experimental proof that the molecule cannot be planar? Explain. (b) It turns out that ozone,  $\text{O}_3$ , has a small dipole moment. How is this possible, given that all the atoms are the same?
- 9.39** (a) Is the molecule  $\text{BF}_3$  polar or nonpolar? (b) If you react  $\text{BF}_3$  to make the ion  $\text{BF}_3^{2-}$ , is this ion planar? (c) Does the molecule  $\text{BF}_2\text{Cl}$  have a dipole moment?
- 9.40** (a) Consider the  $\text{AF}_3$  molecules in Exercise 9.27. Which of these will have a nonzero dipole moment? (b) Which of the  $\text{AF}_4$  molecules in Exercise 9.28 will have a zero dipole moment?
- 9.41** Predict whether each of the following molecules is polar or nonpolar: (a)  $\text{IF}$ , (b)  $\text{CS}_2$ , (c)  $\text{SO}_3$ , (d)  $\text{PCl}_3$ , (e)  $\text{SF}_6$ , (f)  $\text{IF}_5$ .
- 9.42** Predict whether each of the following molecules is polar or nonpolar: (a)  $\text{CCl}_4$ , (b)  $\text{NH}_3$ , (c)  $\text{SF}_4$ , (d)  $\text{XeF}_4$ , (e)  $\text{CH}_3\text{Br}$ , (f)  $\text{GaH}_3$ .
- 9.43** Dichloroethylene ( $\text{C}_2\text{H}_2\text{Cl}_2$ ) has three forms (isomers), each of which is a different substance. (a) Draw Lewis structures of the three isomers, all of which have a carbon-carbon double bond. (b) Which of these isomers has a zero dipole moment? (c) How many isomeric forms can chloroethylene,  $\text{C}_2\text{H}_3\text{Cl}$ , have? Would they be expected to have dipole moments?
- 9.44** Dichlorobenzene,  $\text{C}_6\text{H}_4\text{Cl}_2$ , exists in three forms (isomers) called *ortho*, *meta*, and *para*:

Which of these has a nonzero dipole moment?

### Orbital Overlap; Hybrid Orbitals (Sections 9.4 and 9.5)

- 9.45** For each statement, indicate whether it is true or false. (a) In order to make a covalent bond, the orbitals on each atom in the bond must overlap. (b) A  $p$  orbital on one atom cannot make a bond to an  $s$  orbital on another atom. (c) Lone pairs of electrons on an atom in a molecule influence the shape of a molecule. (d) The  $1s$  orbital has a nodal plane. (e) The  $2p$  orbital has a nodal plane.
- 9.46** Draw sketches illustrating the overlap between the following orbitals on two atoms: (a) the  $2s$  orbital on each atom, (b) the  $2p_z$  orbital on each atom (assume both atoms are on the  $z$ -axis), (c) the  $2s$  orbital on one atom and the  $2p_z$  orbital on the other atom.
- 9.47** For each statement, indicate whether it is true or false. (a) The greater the orbital overlap in a bond, the weaker the bond. (b) The greater the orbital overlap in a bond, the shorter the bond. (c) To create a hybrid orbital, you could use the  $s$  orbital on one atom with a  $p$  orbital on another atom. (d) Nonbonding electron pairs cannot occupy a hybrid orbital.
- 9.48** How would you expect the extent of overlap of the bonding atomic orbitals to vary in the series  $\text{IF}$ ,  $\text{ICl}$ ,  $\text{IBr}$ , and  $\text{I}_2$ ? Explain your answer.

- 9.49** Consider the molecule  $\text{BF}_3$ . (a) What is the electron configuration of an isolated B atom? (b) What is the electron configuration of an isolated F atom? (c) What hybrid orbitals should be constructed on the B atom to make the B-F bonds in  $\text{BF}_3$ ? (d) What valence orbitals, if any, remain unhybridized on the B atom in  $\text{BF}_3$ ?
- 9.50** Consider the  $\text{SCl}_2$  molecule. (a) What is the electron configuration of an isolated S atom? (b) What is the electron configuration of an isolated Cl atom? (c) What hybrid orbitals should be constructed on the S atom to make the S-Cl bonds in  $\text{SCl}_2$ ? (d) What valence orbitals, if any, remain unhybridized on the S atom in  $\text{SCl}_2$ ?
- 9.51** Indicate the hybridization of the central atom in (a)  $\text{BCl}_3$ , (b)  $\text{AlCl}_4^-$ , (c)  $\text{CS}_2$ , (d)  $\text{GeH}_4$ .
- 9.52** What is the hybridization of the central atom in (a)  $\text{SiCl}_4$ , (b)  $\text{HCN}$ , (c)  $\text{SO}_3$ , (d)  $\text{TeCl}_2$ ?
- 9.53** Shown here are three pairs of hybrid orbitals, with each set at a characteristic angle. For each pair, determine the type of hybridization, if any, that could lead to hybrid orbitals at the specified angle.

- 9.54** (a) Which geometry and central atom hybridization would you expect in the series  $\text{BH}_4^-$ ,  $\text{CH}_4$ ,  $\text{NH}_4^+$ ? (b) What would you expect for the magnitude and direction of the bond dipoles in this series? (c) Write the formulas for the analogous species of the elements of period 3; would you expect them to have the same hybridization at the central atom?

### Multiple Bonds (Section 9.6)

- 9.55** (a) Draw a picture showing how two  $p$  orbitals on two different atoms can be combined to make a  $\sigma$  bond. (b) Sketch a  $\pi$  bond that is constructed from  $p$  orbitals. (c) Which is generally stronger, a  $\sigma$  bond or a  $\pi$  bond? Explain. (d) Can two  $s$  orbitals combine to form a  $\pi$  bond? Explain.
- 9.56** (a) If the valence atomic orbitals of an atom are  $sp$  hybridized, how many unhybridized  $p$  orbitals remain in the valence shell? How many  $\pi$  bonds can the atom form? (b) Imagine that you could hold two atoms that are bonded together, twist them, and not change the bond length. Would it be easier to twist (rotate) around a single  $\sigma$  bond or around a double ( $\sigma$  plus  $\pi$ ) bond, or would they be the same?
- 9.57** (a) Draw Lewis structures for ethane ( $\text{C}_2\text{H}_6$ ), ethylene ( $\text{C}_2\text{H}_4$ ), and acetylene ( $\text{C}_2\text{H}_2$ ). (b) What is the hybridization of the carbon atoms in each molecule? (c) Predict which molecules, if any, are planar. (d) How many  $\sigma$  and  $\pi$  bonds are there in each molecule?
- 9.58** The nitrogen atoms in  $\text{N}_2$  participate in multiple bonding, whereas those in hydrazine,  $\text{N}_2\text{H}_4$ , do not. (a) Draw Lewis structures for both molecules. (b) What is the hybridization of the nitrogen atoms in each molecule? (c) Which molecule has the stronger N—N bond?
- 9.59** Propylene,  $\text{C}_3\text{H}_6$ , is a gas that is used to form the important polymer called polypropylene. Its Lewis structure is

(a) What is the total number of valence electrons in the propylene molecule? (b) How many valence electrons are used to make  $\sigma$  bonds in the molecule? (c) How many valence electrons are used to make  $\pi$  bonds in the molecule? (d) How many valence electrons remain in nonbonding pairs in the molecule? (e) What is the hybridization at each carbon atom in the molecule?

**9.60** Ethyl acetate,  $C_4H_8O_2$ , is a fragrant substance used both as a solvent and as an aroma enhancer. Its Lewis structure is

(a) What is the hybridization at each of the carbon atoms of the molecule? (b) What is the total number of valence electrons in ethyl acetate? (c) How many of the valence electrons are used to make  $\sigma$  bonds in the molecule? (d) How many valence electrons are used to make  $\pi$  bonds? (e) How many valence electrons remain in nonbonding pairs in the molecule?

**9.61** Consider the Lewis structure for glycine, the simplest amino acid:

(a) What are the approximate bond angles about each of the two carbon atoms, and what are the hybridizations of the orbitals on each of them? (b) What are the hybridizations of the orbitals on the two oxygens and the nitrogen atom, and what are the approximate bond angles at the nitrogen? (c) What is the total number of  $\sigma$  bonds in the entire molecule, and what is the total number of  $\pi$  bonds?

**9.62** Acetylsalicylic acid, better known as aspirin, has the Lewis structure

(a) What are the approximate values of the bond angles labeled 1, 2, and 3? (b) What hybrid orbitals are used about the central atom of each of these angles? (c) How many  $\sigma$  bonds are in the molecule?

**9.63** (a) What is the difference between a localized  $\pi$  bond and a delocalized one? (b) How can you determine whether a molecule or ion will exhibit delocalized  $\pi$  bonding? (c) Is the  $\pi$  bond in  $NO_2^-$  localized or delocalized?

**9.64** (a) Write a single Lewis structure for  $SO_3$ , and determine the hybridization at the S atom. (b) Are there other equivalent Lewis structures for the molecule? (c) Would you expect  $SO_3$  to exhibit delocalized  $\pi$  bonding?

**9.65** In the formate ion,  $HCO_2^-$ , the carbon atom is the central atom with the other three atoms attached to it. (a) Draw a Lewis structure for the formate ion. (b) What hybridization is exhibited by the C atom? (c) Are there multiple equivalent resonance structures for the ion? (d) How many electrons are in the  $\pi$  system of the ion?

**9.66** Consider the Lewis structure shown below.

(a) Does the Lewis structure depict a neutral molecule or an ion? If it is an ion, what is the charge on the ion? (b) What hybridization is exhibited by each of the carbon atoms? (c) Are there multiple equivalent resonance structures for the species? (d) How many electrons are in the  $\pi$  system of the species?

**9.67** Predict the molecular geometry of each of the following molecules:

**9.68** What hybridization do you expect for the atom indicated in red in each of the following species? (a)  $CH_3CO_2^-$ ; (b)  $PH_4^+$ ; (c)  $AlF_3$ ; (d)  $H_2C=CH-CH_2^+$

## Molecular Orbitals and Period 2 Diatomic Molecules (Sections 9.7 and 9.8)

**9.69** (a) What is the difference between hybrid orbitals and molecular orbitals? (b) How many electrons can be placed into each MO of a molecule? (c) Can antibonding molecular orbitals have electrons in them?

**9.70** (a) If you combine two atomic orbitals on two different atoms to make a new orbital, is this a hybrid orbital or a molecular orbital? (b) If you combine two atomic orbitals on one atom to make a new orbital, is this a hybrid orbital or a molecular orbital? (c) Does the Pauli exclusion principle (Section 6.7) apply to MOs? Explain.

**9.71** Consider the  $H_2^+$  ion. (a) Sketch the molecular orbitals of the ion and draw its energy-level diagram. (b) How many electrons are there in the  $H_2^+$  ion? (c) Write the electron configuration of the ion in terms of its MOs. (d) What is the bond order in  $H_2^+$ ? (e) Suppose that the ion is excited by light so that an electron moves from a lower-energy to a higher-energy MO. Would you expect the excited-state  $H_2^+$  ion to be stable or to fall apart? (f) Which of the following statements about part (e) is correct: (i) The light excites an electron from a bonding orbital to an antibonding orbital, (ii) The light excites an electron from an antibonding orbital to a bonding orbital, or (iii) In the excited state there are more bonding electrons than antibonding electrons?

**9.72** (a) Sketch the molecular orbitals of the  $H_2^-$  ion and draw its energy-level diagram. (b) Write the electron configuration of the ion in terms of its MOs. (c) Calculate the bond order in  $H_2^-$ . (d) Suppose that the ion is excited by light, so that an electron moves from a lower-energy to a higher-energy molecular orbital. Would you expect the excited-state  $H_2^-$  ion to be stable? (e) Which of the following statements about part (d)

is correct: (i) The light excites an electron from a bonding orbital to an antibonding orbital, (ii) The light excites an electron from an antibonding orbital to a bonding orbital, or (iii) In the excited state there are more bonding electrons than antibonding electrons?

- 9.73** Draw a picture that shows all three  $2p$  orbitals on one atom and all three  $2p$  orbitals on another atom. (a) Imagine the atoms coming close together to bond. How many  $\sigma$  bonds can the two sets of  $2p$  orbitals make with each other? (b) How many  $\pi$  bonds can the two sets of  $2p$  orbitals make with each other? (c) How many antibonding orbitals, and of what type, can be made from the two sets of  $2p$  orbitals?
- 9.74** Indicate whether each statement is true or false. (a)  $s$  orbitals can only make  $\sigma$  or  $\sigma^*$  molecular orbitals. (b) The probability is 100% for finding an electron at the nucleus in a  $\pi^*$  orbital. (c) Antibonding orbitals are higher in energy than bonding orbitals (if all orbitals are created from the same atomic orbitals). (d) Electrons cannot occupy an antibonding orbital.
- 9.75** (a) What are the relationships among bond order, bond length, and bond energy? (b) According to molecular orbital theory, would either  $\text{Be}_2$  or  $\text{Be}_2^+$  be expected to exist? Explain.
- 9.76** Explain the following: (a) The peroxide ion,  $\text{O}_2^{2-}$ , has a longer bond length than the superoxide ion,  $\text{O}_2^-$ . (b) The magnetic properties of  $\text{B}_2$  are consistent with the  $\pi_{2p}$  MOs being lower in energy than the  $\sigma_{2p}$  MO. (c) The  $\text{O}_2^{2+}$  ion has a stronger O—O bond than  $\text{O}_2$  itself.
- 9.77** (a) What does the term *diamagnetism* mean? (b) How does a diamagnetic substance respond to a magnetic field? (c) Which of the following ions would you expect to be diamagnetic:  $\text{N}_2^{2-}$ ,  $\text{O}_2^{2-}$ ,  $\text{Be}_2^{2+}$ ,  $\text{C}_2^-$ ?
- 9.78** (a) What does the term *paramagnetism* mean? (b) How can one determine experimentally whether a substance is paramagnetic? (c) Which of the following ions would you expect to be paramagnetic:  $\text{O}_2^+$ ,  $\text{N}_2^{2-}$ ,  $\text{Li}_2^+$ ,  $\text{O}_2^{2-}$ ? For those ions that are paramagnetic, determine the number of unpaired electrons.
- 9.79** Using Figures 9.35 and 9.43 as guides, draw the molecular orbital electron configuration for (a)  $\text{B}_2^+$ , (b)  $\text{Li}_2^+$ , (c)  $\text{N}_2^+$ , (d)  $\text{Ne}_2^{2+}$ . In each case indicate whether the addition of an electron to the ion would increase or decrease the bond order of the species.
- 9.80** If we assume that the energy-level diagrams for homonuclear diatomic molecules shown in Figure 9.43 can be applied to heteronuclear diatomic molecules and ions, predict

the bond order and magnetic behavior of (a)  $\text{CO}^+$ , (b)  $\text{NO}^-$ , (c)  $\text{OF}^+$ , (d)  $\text{NeF}^+$ .

- 9.81** Determine the electron configurations for  $\text{CN}^+$ ,  $\text{CN}$ , and  $\text{CN}^-$ . (a) Which species has the strongest C—N bond? (b) Which species, if any, has unpaired electrons?
- 9.82** (a) The nitric oxide molecule,  $\text{NO}$ , readily loses one electron to form the  $\text{NO}^+$  ion. Which of the following is the best explanation of why this happens: (i) Oxygen is more electronegative than nitrogen, (ii) The highest energy electron in  $\text{NO}$  lies in a  $\pi_{2p}^*$  molecular orbital, or (iii) The  $\pi_{2p}^*$  MO in  $\text{NO}$  is completely filled. (b) Predict the order of the N—O bond strengths in  $\text{NO}$ ,  $\text{NO}^+$ , and  $\text{NO}^-$ , and describe the magnetic properties of each. (c) With what neutral homonuclear diatomic molecules are the  $\text{NO}^+$  and  $\text{NO}^-$  ions isoelectronic (same number of electrons)?
- [9.83]** Consider the molecular orbitals of the  $\text{P}_2$  molecule. Assume that the MOs of diatomics from the third row of the periodic table are analogous to those from the second row. (a) Which valence atomic orbitals of P are used to construct the MOs of  $\text{P}_2$ ? (b) The figure that follows shows a sketch of one of the MOs for  $\text{P}_2$ . What is the label for this MO? (c) For the  $\text{P}_2$  molecule, how many electrons occupy the MO in the figure? (d) Is  $\text{P}_2$  expected to be diamagnetic or paramagnetic?

- [9.84]** The iodine bromide molecule,  $\text{IBr}$ , is an *interhalogen compound*. Assume that the molecular orbitals of  $\text{IBr}$  are analogous to the homonuclear diatomic molecule  $\text{F}_2$ . (a) Which valence atomic orbitals of I and of Br are used to construct the MOs of  $\text{IBr}$ ? (b) What is the bond order of the  $\text{IBr}$  molecule? (c) One of the valence MOs of  $\text{IBr}$  is sketched here. Why are the atomic orbital contributions to this MO different in size? (d) What is the label for the MO sketched below? (e) For the  $\text{IBr}$  molecule, how many electrons occupy the MO sketched below?

## Additional Exercises

- 9.85** (a) What is the physical basis for the VSEPR model? (b) When applying the VSEPR model, we count a double or triple bond as a single electron domain. Why is this justified?
- 9.86** An  $\text{AB}_3$  molecule is described as having a trigonal-bipyramidal electron-domain geometry. (a) How many nonbonding domains are on atom A? (b) Based on the information given, which of the following is the molecular geometry of the molecule: (i) trigonal planar, (ii) trigonal pyramidal, (iii) T-shaped, or (iv) tetrahedral?
- 9.87** Consider the following  $\text{XF}_4$  ions:  $\text{PF}_4^-$ ,  $\text{BrF}_4^-$ ,  $\text{ClF}_4^+$ , and  $\text{AlF}_4^-$ . (a) Which of the ions have more than an octet of electrons around the central atom? (b) For which of the ions will the electron-domain and molecular geometries be the same? (c) Which of the ions will have an octahedral electron-domain geometry? (d) Which of the ions will exhibit a see-saw molecular geometry?
- 9.88** Consider the molecule  $\text{PF}_4\text{Cl}$ . (a) Draw a Lewis structure for the molecule, and predict its electron-domain geometry. (b) Which would you expect to take up more space, a P—F bond or a P—Cl bond? Explain. (c) Predict the molecular geometry of  $\text{PF}_4\text{Cl}$ . How did your answer for part (b) influence your answer here in part (c)? (d) Would you expect the molecule to distort from its ideal electron-domain geometry? If so, how would it distort?
- [9.89]** The vertices of a tetrahedron correspond to four alternating corners of a cube. By using analytical geometry, demonstrate that the angle made by connecting two of the vertices to a point at the center of the cube is  $109.5^\circ$ , the characteristic angle for tetrahedral molecules.
- 9.90** Fill in the blank spaces in the following chart. If the molecule column is blank, find an example that fulfills the conditions of the rest of the row.

| Molecule         | Electron-Domain Geometry | Hybridization of Central Atom | Dipole Moment? Yes or No |
|------------------|--------------------------|-------------------------------|--------------------------|
| CO <sub>2</sub>  |                          | $sp^3$                        | Yes                      |
|                  |                          | $sp^3$                        | No                       |
|                  | Trigonal planar          |                               | No                       |
| SF <sub>4</sub>  |                          |                               | No                       |
|                  | Octahedral               |                               | No                       |
|                  |                          | $sp^2$                        | Yes                      |
|                  | Trigonal bipyramidal     |                               | No                       |
|                  |                          |                               |                          |
| XeF <sub>2</sub> |                          |                               |                          |

**9.91** From their Lewis structures, determine the number of  $\sigma$  and  $\pi$  bonds in each of the following molecules or ions: (a) CO<sub>2</sub>; (b) cyanogen, (CN)<sub>2</sub>; (c) formaldehyde, H<sub>2</sub>CO; (d) formic acid, HCOOH, which has one H and two O atoms attached to C.

**9.92** The lactic acid molecule, CH<sub>3</sub>CH(OH)COOH, gives sour milk its unpleasant, sour taste. (a) Draw the Lewis structure for the molecule, assuming that carbon always forms four bonds in its stable compounds. (b) How many  $\pi$  and how many  $\sigma$  bonds are in the molecule? (c) Which CO bond is shortest in the molecule? (d) What is the hybridization of atomic orbitals around the carbon atom associated with that short bond? (e) What are the approximate bond angles around each carbon atom in the molecule?

**9.93** An AB<sub>5</sub> molecule adopts the geometry shown here. (a) What is the name of this geometry? (b) Do you think there are any nonbonding electron pairs on atom A? (c) Suppose the B atoms are halogen atoms. Of which group in the periodic table is atom A a member: (i) Group 5A, (ii) Group 6A, (iii) Group 7A, (iv) Group 8A, or (v) More information is needed?

**9.94** There are two compounds of the formula Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>:

The compound on the right is called *cisplatin*, and the compound on the left is called *transplatin*. (a) Which compound has a nonzero dipole moment? (b) One of these compounds is an anticancer drug, and one is inactive. The anticancer drug works by its chloride ions undergoing a substitution reaction with nitrogen atoms in DNA that are close together, forming a N—Pt—N angle of about 90°. Which compound would you predict to be the anticancer drug?

**[9.95]** The O—H bond lengths in the water molecule (H<sub>2</sub>O) are 0.96 Å, and the H—O—H angle is 104.5°. The dipole moment of the water molecule is 1.85 D. (a) In what directions do the bond dipoles of the O—H bonds point? In what direction does the dipole moment vector of the water molecule point? (b) Calculate the magnitude of the bond dipole of the O—H bonds. (Note: You will need to use vector

addition to do this.) (c) Compare your answer from part (b) to the dipole moments of the hydrogen halides (Table 8.3). Is your answer in accord with the relative electronegativity of oxygen?

**9.96** (a) Predict the electron-domain geometry around the central Xe atom in XeF<sub>2</sub>, XeF<sub>4</sub>, and XeF<sub>6</sub>. (b) The molecule IF<sub>7</sub> has a pentagonal bipyramid structure: five fluorines are equatorial, forming a flat pentagon around the central iodine atom, and the other two fluorines are axial. Predict the molecular geometry of IF<sub>6</sub><sup>−</sup>.

**9.97** Which of the following statements about hybrid orbitals is or are true? (i) After an atom undergoes  $sp$  hybridization, there is one unhybridized  $p$  orbital on the atom, (ii) Under  $sp^2$  hybridization, the large lobes point to the vertices of an equilateral triangle, and (iii) The angle between the large lobes of  $sp^3$  hybrids is 109.5°.

**[9.98]** The Lewis structure for allene is

Make a sketch of the structure of this molecule that is analogous to Figure 9.25. In addition, answer the following three questions: (a) Is the molecule planar? (b) Does it have a nonzero dipole moment? (c) Would the bonding in allene be described as delocalized? Explain.

**9.99** Consider the molecule C<sub>4</sub>H<sub>5</sub>N, which has the connectivity shown below. (a) After the Lewis structure for the molecule is completed, how many  $\sigma$  and how many  $\pi$  bonds are there in this molecule? (b) How many atoms in the molecule exhibit (i)  $sp$  hybridization, (ii)  $sp^2$  hybridization, and (iii)  $sp^3$  hybridization?

**[9.100]** Sodium azide is a shock-sensitive compound that releases N<sub>2</sub> upon physical impact. The compound is used in automobile airbags. The azide ion is N<sub>3</sub><sup>−</sup>. (a) Draw the Lewis structure of the azide ion that minimizes formal charge (it does not form a triangle). Is it linear or bent? (b) State the hybridization of the central N atom in the azide ion. (c) How many  $\sigma$  bonds and how many  $\pi$  bonds does the central nitrogen atom make in the azide ion?

**[9.101]** In ozone, O<sub>3</sub>, the two oxygen atoms on the ends of the molecule are equivalent to one another. (a) What is the best choice of hybridization scheme for the atoms of ozone? (b) For one of the resonance forms of ozone, which of the orbitals are used to make bonds and which are used to hold nonbonding pairs of electrons? (c) Which of the orbitals can be used to delocalize the  $\pi$  electrons? (d) How many electrons are delocalized in the  $\pi$  system of ozone?

**9.102** Butadiene, C<sub>4</sub>H<sub>6</sub>, is a planar molecule that has the following carbon-carbon bond lengths:

(a) Predict the bond angles around each of the carbon atoms and sketch the molecule. (b) From left to right, what is the hybridization of each carbon atom in butadiene? (c) The middle C—C bond length in butadiene (1.48 Å) is a little shorter than the average C—C single bond length (1.54 Å). Does this imply that the middle C—C bond in butadiene is weaker or stronger than the average C—C single bond? (d) Based on your answer for part (c), discuss what

additional aspects of bonding in butadiene might support the shorter middle C—C bond.

- 9.103** The structure of *borazine*,  $B_3N_3H_6$ , is a six-membered ring of alternating B and N atoms. There is one H atom bonded to each B and to each N atom. The molecule is planar. (a) Write a Lewis structure for borazine in which the formal charge on every atom is zero. (b) Write a Lewis structure for borazine in which the octet rule is satisfied for every atom. (c) What are the formal charges on the atoms in the Lewis structure from part (b)? Given the electronegativities of B and N, do the formal charges seem favorable or unfavorable? (d) Do either of the Lewis structures in parts (a) and (b) have multiple resonance structures? (e) What are the hybridizations at the B and N atoms in the Lewis structures from parts (a) and (b)? Would you expect the molecule to be planar for both Lewis structures? (f) The six B—N bonds in the borazine molecule are all identical in length at 1.44 Å. Typical values for the bond lengths of B—N single and double bonds are 1.51 Å and 1.31 Å, respectively. Does the value of the B—N bond length seem to favor one Lewis structure over the other? (g) How many electrons are in the  $\pi$  system of borazine?

- 9.104** The highest occupied molecular orbital of a molecule is abbreviated as the HOMO. The lowest unoccupied molecular orbital in a molecule is called the LUMO. Experimentally, one can measure the difference in energy between the HOMO and LUMO by taking the electronic absorption (UV-visible) spectrum of the molecule. Peaks in the electronic absorption spectrum can be labeled as  $\pi_{2p}-\pi_{2p}^*$ ,  $\sigma_{2s}-\sigma_{2s}^*$ , and so on, corresponding to electrons being promoted from one orbital to another. The HOMO-LUMO transition corresponds to molecules going from their ground state to their first excited state. (a) Write out the molecular orbital valence electron configurations for the ground state and first excited state for  $N_2$ . (b) Is  $N_2$  paramagnetic or diamagnetic in its first excited state? (c) The electronic absorption spectrum of the  $N_2$  molecule has the lowest energy peak at 170 nm. To what orbital transition does this correspond? (d) Calculate the energy of the HOMO-LUMO transition in part (a) in terms of kJ/mol. (e) Is the N—N bond in the first excited state stronger or weaker compared to that in the ground state?

- 9.105** One of the molecular orbitals of the  $H_2^-$  ion is sketched below:

(a) Is the molecular orbital a  $\sigma$  or  $\pi$  MO? Is it bonding or antibonding? (b) In  $H_2^-$ , how many electrons occupy the MO shown above? (c) What is the bond order in the  $H_2^-$  ion? (d) Compared to the H—H bond in  $H_2$ , the H—H bond in  $H_2^-$  is expected to be which of the following: (i) Shorter and stronger, (ii) longer and stronger, (iii) shorter and weaker, (iv) longer and weaker, or (v) the same length and strength?

- 9.106** Place the following molecules and ions in order from smallest to largest bond order:  $H_2^+$ ,  $B_2$ ,  $N_2^+$ ,  $F_2^+$ , and  $Ne_2$ .

- [9.107]** The following sketches show the atomic orbital wave functions (with phases) used to construct some of the MOs of a homonuclear diatomic molecule. For each sketch, determine the type of MO that will result from mixing the atomic orbital wave functions as drawn. Use the same labels for the MOs as in the “Closer Look” box on phases.

- 9.108** Molecules that are brightly colored have a small energy gap between filled and empty electronic states (the HOMO-LUMO gap; see Exercise 9.104). Sometimes you can visually tell which HOMO-LUMO gap is larger for one molecule than another. Suppose you have samples of two crystalline powders—one is white, and one is green. Which one has the larger HOMO-LUMO gap?

- 9.109** *Azo dyes* are organic dyes that are used for many applications, such as the coloring of fabrics. Many azo dyes are derivatives of the organic substance *azobenzene*,  $C_{12}H_{10}N_2$ . A closely related substance is *hydrazobenzene*,  $C_{12}H_{12}N_2$ . The Lewis structures of these two substances are

(Recall the shorthand notation used for benzene.)

(a) What is the hybridization at the N atom in each of the substances? (b) How many unhybridized atomic orbitals are there on the N and the C atoms in each of the substances? (c) Predict the N—N—C angles in each of the substances. (d) Azobenzene is said to have greater delocalization of its  $\pi$  electrons than hydrazobenzene. Discuss this statement in light of your answers to (a) and (b). (e) All the atoms of azobenzene lie in one plane, whereas those of hydrazobenzene do not. Is this observation consistent with the statement in part (d)? (f) Azobenzene is an intense red-orange color, whereas hydrazobenzene is nearly colorless. Which molecule would be a better one to use in a solar energy conversion device? (See the “Chemistry Put to Work” box for more information about solar cells.)

- [9.110]** (a) Using only the valence atomic orbitals of a hydrogen atom and a fluorine atom, and following the model of Figure 9.46, how many MOs would you expect for the HF molecule? (b) How many of the MOs from part (a) would be occupied by electrons? (c) It turns out that the difference in energies between the valence atomic orbitals of H and F are sufficiently different that we can neglect the interaction of the 1s orbital of hydrogen with the 2s orbital of fluorine. The 1s orbital of hydrogen will mix only with one 2p orbital of fluorine. Draw pictures showing the proper orientation of all three 2p orbitals on F interacting with a 1s orbital on H. Which of the 2p orbitals can actually make a bond with a 1s orbital, assuming that the atoms lie on the z-axis? (d) In the most accepted picture of HF, all the other atomic orbitals on fluorine move over at the same energy into the molecular orbital energy-level diagram for HF. These are called “nonbonding orbitals.” Sketch the energy-level diagram for HF using this information and calculate the bond order. (Nonbonding electrons do not contribute to bond order.) (e) Look at the Lewis structure for HF. Where are the nonbonding electrons?

- [9.111]** Carbon monoxide, CO, is isoelectronic to N<sub>2</sub>. **(a)** Draw a Lewis structure for CO that satisfies the octet rule. **(b)** Assume that the diagram in Figure 9.46 can be used to describe the MOs of CO. What is the predicted bond order for CO? Is this answer in accord with the Lewis structure you drew in part (a)? **(c)** Experimentally, it is found that the highest energy electrons in CO reside in a  $\sigma$ -type MO. Is that observation consistent with Figure 9.46? If not, what modification needs to be made to the diagram? How does this modification relate to Figure 9.43? **(d)** Would you expect the  $\pi_{2p}$  MOs of CO to have equal atomic orbital contributions from the C and O atoms? If not, which atom would have the greater contribution?

- 9.112** The energy-level diagram in Figure 9.36 shows that the sideways overlap of a pair of  $p$  orbitals produces two molecular orbitals, one bonding and one antibonding. In ethylene there is a pair of electrons in the bonding  $\pi$  orbital between the two carbons. Absorption of a photon of the appropriate wavelength can result in promotion of one of the bonding electrons from the  $\pi_{2p}$  to the  $\pi_{2p}^*$  molecular orbital. **(a)** Assuming this electronic transition corresponds to the HOMO-LUMO transition, what is the HOMO in ethylene? **(b)** Assuming this electronic transition corresponds to the HOMO-LUMO transition, what is the LUMO in ethylene? **(c)** Is the C—C bond in ethylene stronger or weaker in the excited state than in the ground state? Why? **(d)** Is the C—C bond in ethylene easier to twist in the ground state or in the excited state?

## Integrative Exercises

- 9.113** A compound composed of 2.1% H, 29.8% N, and 68.1% O has a molar mass of approximately 50 g/mol. **(a)** What is the molecular formula of the compound? **(b)** What is its Lewis structure if H is bonded to O? **(c)** What is the geometry of the molecule? **(d)** What is the hybridization of the orbitals around the N atom? **(e)** How many  $\sigma$  and how many  $\pi$  bonds are there in the molecule?

- 9.114** Sulfur tetrafluoride (SF<sub>4</sub>) reacts slowly with O<sub>2</sub> to form sulfur tetrafluoride monoxide (OSF<sub>4</sub>) according to the following unbalanced reaction:

The O atom and the four F atoms in OSF<sub>4</sub> are bonded to a central S atom. **(a)** Balance the equation. **(b)** Write a Lewis structure of OSF<sub>4</sub> in which the formal charges of all atoms are zero. **(c)** Use average bond enthalpies (Table 8.3) to estimate the enthalpy of the reaction. Is it endothermic or exothermic? **(d)** Determine the electron-domain geometry of OSF<sub>4</sub>, and write two possible molecular geometries for the molecule based on this electron-domain geometry. **(e)** For each of the molecules you drew in part (d), state how many fluorines are equatorial and how many are axial.

- [9.115]** The phosphorus trihalides (PX<sub>3</sub>) show the following variation in the bond angle X—P—X: PF<sub>3</sub>, 96.3°; PCl<sub>3</sub>, 100.3°; PBr<sub>3</sub>, 101.0°; PI<sub>3</sub>, 102.0°. The trend is generally attributed to the change in the electronegativity of the halogen. **(a)** Assuming that all electron domains are the same size, what value of the X—P—X angle is predicted by the VSEPR model? **(b)** What is the general trend in the X—P—X angle as the halide electronegativity increases? **(c)** Using the VSEPR model, explain the observed trend in X—P—X angle as the electronegativity of X changes. **(d)** Based on your answer to part (c), predict the structure of PBrCl<sub>4</sub>.

- [9.116]** The molecule 2-butene, C<sub>4</sub>H<sub>8</sub>, can undergo a geometric change called *cis-trans isomerization*:

As discussed in the “Chemistry and Life” box on the chemistry of vision, such transformations can be induced by light and are the key to human vision. **(a)** What is the hybridization at the two central carbon atoms of 2-butene? **(b)** The isomerization occurs by rotation about the central C—C bond. With reference to Figure 9.29, explain why the  $\pi$  bond between the two central carbon atoms is

destroyed halfway through the rotation from *cis*- to *trans*-2-butene. **(c)** Based on average bond enthalpies (Table 8.3), how much energy per molecule must be supplied to break the C—C  $\pi$  bond? **(d)** What is the longest wavelength of light that will provide photons of sufficient energy to break the C—C  $\pi$  bond and cause the isomerization? **(e)** Is the wavelength in your answer to part (d) in the visible portion of the electromagnetic spectrum? Comment on the importance of this result for human vision.

- 9.117** **(a)** Compare the bond enthalpies (Table 8.3) of the carbon-carbon single, double, and triple bonds to deduce an average  $\pi$ -bond contribution to the enthalpy. What fraction of a single bond does this quantity represent? **(b)** Make a similar comparison of nitrogen-nitrogen bonds. What do you observe? **(c)** Write Lewis structures of N<sub>2</sub>H<sub>4</sub>, N<sub>2</sub>H<sub>2</sub>, and N<sub>2</sub>, and determine the hybridization around nitrogen in each case. **(d)** Propose a reason for the large difference in your observations of parts (a) and (b).

- 9.118** Use average bond enthalpies (Table 8.3) to estimate  $\Delta H$  for the atomization of benzene, C<sub>6</sub>H<sub>6</sub>:

Compare the value to that obtained by using  $\Delta H_f^\circ$  data given in Appendix C and Hess’s law. To what do you attribute the large discrepancy in the two values?

- [9.119]** Many compounds of the transition-metal elements contain direct bonds between metal atoms. We will assume that the  $z$ -axis is defined as the metal-metal bond axis. **(a)** Which of the  $3d$  orbitals (Figure 6.23) is most likely to make a  $\sigma$  bond between metal atoms? **(b)** Sketch the  $\sigma_{3d}$  bonding and  $\sigma_{3d}^*$  antibonding MOs. **(c)** With reference to the “Closer Look” box on the phases of orbitals, explain why a node is generated in the  $\sigma_{3d}^*$  MO. **(d)** Sketch the energy-level diagram for the Sc<sub>2</sub> molecule, assuming that only the  $3d$  orbital from part (a) is important. **(e)** What is the bond order in Sc<sub>2</sub>?

- [9.120]** The organic molecules shown here are derivatives of benzene in which six-membered rings are “fused” at the edges of the hexagons.

Naphthalene

Anthracene

Tetracene

- (a)** Determine the empirical formula of benzene and of these three compounds. **(b)** Suppose you are given a sample of one of the compounds. Could combustion analysis

be used to determine unambiguously which of the three it is? (c) Naphthalene, the active ingredient in mothballs, is a white solid. Write a balanced equation for the combustion of naphthalene to  $\text{CO}_2(g)$  and  $\text{H}_2\text{O}(g)$ . (d) Using the Lewis structure for naphthalene and the average bond enthalpies in Table 8.3, estimate the heat of combustion of naphthalene in kJ/mol. (e) Benzene, naphthalene, and anthracene are colorless, but tetracene is orange. What does this imply about the relative HOMO–LUMO energy gaps in these molecules? See the “Chemistry Put to Work” box on orbitals and energy.

- [9.121] Antibonding molecular orbitals can be used to make bonds to other atoms in a molecule. For example, metal atoms can use appropriate  $d$  orbitals to overlap with the  $\pi_{2p}^*$  orbitals of the carbon monoxide molecule. This is called  $d$ - $\pi$  backbonding. (a) Draw a coordinate axis system in which the  $y$ -axis is vertical in the plane of the paper and the  $x$ -axis horizontal. Write “M” at the origin to denote a metal atom. (b) Now, on the  $x$ -axis to the right of M, draw the Lewis structure of a CO molecule, with the carbon

nearest the M. The CO bond axis should be on the  $x$ -axis. (c) Draw the CO  $\pi_{2p}^*$  orbital, with phases (see the “Closer Look” box on phases) in the plane of the paper. Two lobes should be pointing toward M. (d) Now draw the  $d_{xy}$  orbital of M, with phases. Can you see how they will overlap with the  $\pi_{2p}^*$  orbital of CO? (e) What kind of bond is being made with the orbitals between M and C,  $\sigma$  or  $\pi$ ? (f) Predict what will happen to the strength of the CO bond in a metal–CO complex compared to CO alone.

- 9.122 Methyl isocyanate,  $\text{CH}_3\text{NCO}$ , was made infamous in 1984 when an accidental leakage of this compound from a storage tank in Bhopal, India, resulted in the deaths of about 3800 people and severe and lasting injury to many thousands more. (a) Draw a Lewis structure for methyl isocyanate. (b) Draw a ball-and-stick model of the structure, including estimates of all the bond angles in the compound. (c) Predict all the bond distances in the molecule. (d) Do you predict that the molecule will have a dipole moment? Explain.

## Design an Experiment

In this chapter we have seen a number of new concepts, including the delocalization of  $\pi$  systems of molecules and the molecular orbital description of molecular bonding. A connection between these concepts is provided by the field of *organic dyes*, molecules with delocalized  $\pi$  systems that have color. The color is due to the

excitation of an electron from the *highest occupied molecular orbital* (HOMO) to the *lowest unoccupied molecular orbital* (LUMO). It is hypothesized that the energy gap between the HOMO and the LUMO depends on the length of the  $\pi$  system. Imagine that you are given samples of the following substances to test this hypothesis:

$\beta$ -Carotene is the substance chiefly responsible for the bright orange color of carrots. It is also an important nutrient for the body's production of retinal (see the “Chemistry and Life” box in Section 9.6). (a) What experiments could you design to determine the amount of energy needed to excite an electron from the HOMO to the LUMO in each of these molecules? (b) How might you graph your data to determine whether a relationship exists between the length of the

$\pi$  system and the excitation energy? (c) What additional molecules might you want to procure to further test the ideas developed here? (d) How could you design an experiment to determine whether the delocalized  $\pi$  systems and not some other molecular features, such as molecular length or the presence of  $\pi$  bonds, are important in making the excitations occur in the visible portion of the spectrum? (Hint: You might want to test some additional molecules not shown here.)

10

# GASES

What is the weather going to be like today or this week? Such knowledge not only helps us choose the clothing we wear during the day, but it also assists the farmer in planting and harvesting, and the sailor in charting a course. The gases in our atmosphere, primarily  $\text{N}_2$  and  $\text{O}_2$  molecules, are heated by the Sun and moved here and there by pressure differences that create wind.

It is the behavior of gases that creates our weather—the gentle breezes, the violent storms, the humidity, and the rain. Tornadoes, like the one shown in the chapter-opening photo, form when moist, warm air at lower elevations converges with cooler, dry air above. The resultant air flows produce winds that can approach speeds up to 500 km/hr (300 mph).

In this chapter, we examine the physical properties of gases—what is atmospheric pressure, how do gases respond to changes in pressure and temperature, and what does temperature measure at the molecular level? Because gases are the simplest state of matter, they serve as an excellent starting point for probing the behavior of large collections of atoms or molecules. Indeed, it is fairly straightforward to formulate a simple model for gases that explains their behavior under most common conditions. We gain further insight by then comparing how real gases differ from this ideal model as conditions change. Thus, while we start with a description that treats all gases the same regardless of their chemical identity, we end by gaining an understanding of important aspects of the physical behavior of molecules.

◀ **A TORNADO** is a violent, rotating column of air characterized by a funnel-shaped cloud. A tornado can be more than 3 km (2 mi) in diameter, with wind speeds approaching 500 km/hr.

## WHAT'S AHEAD

- 10.1** ► **Characteristics of Gases** Compare the distinguishing characteristics of gases with those of liquids and solids.
- 10.2** ► **Pressure** Describe gas *pressure*, the units used to express it, and consider Earth's atmosphere and the pressure it exerts.
- 10.3** ► **The Gas Laws** Express the state of a gas in terms of its volume, pressure, temperature, and quantity and examine several *gas laws*, which are empirical relationships among these four variables.
- 10.4** ► **The Ideal-Gas Equation** Examine and use the *ideal-gas equation*,  $PV = nRT$ . Although this equation is not obeyed exactly by any real gas, most gases come very close to obeying it at ordinary temperatures and pressures.
- 10.5** ► **Further Applications of the Ideal-Gas Equation** Use the ideal-gas equation in additional calculations, such as the calculation of the density or molar mass of a gas.
- 10.6** ► **Gas Mixtures and Partial Pressures** Recognize and utilize the fact that in a mixture of gases, each gas exerts a pressure that is part of the total pressure. This *partial pressure* is the pressure the gas would exert if it were by itself.
- 10.7** ► **The Kinetic-Molecular Theory of Gases** Relate the macroscopic properties of gases to their behavior at the molecular level. According to the theory, the atoms or molecules that make up a gas are in constant random motion and move with an average kinetic energy that is proportional to the temperature of the gas.
- 10.8** ► **Molecular Effusion and Diffusion** Use kinetic-molecular theory to predict relative rates of *effusion* and *diffusion*.
- 10.9** ► **Real Gases: Deviations from Ideal Behavior** Consider how real gases deviate from ideal behavior because the gas molecules have finite volume and because attractive forces exist between molecules. The *van der Waals equation* accounts for real gas behavior at high pressures and low temperatures.

## 10.1 | Characteristics of Gases

Of the few elements that exist as gases at ordinary temperatures and pressures, He, Ne, Ar, Kr, and Xe are monatomic and  $\text{H}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ ,  $\text{F}_2$ , and  $\text{Cl}_2$  are diatomic. Many molecular compounds are gases, and Table 10.1 lists a few of them. Notice that all of these gases are composed entirely of nonmetallic elements. Furthermore, all have simple molecular formulas and, therefore, low molar masses.

Substances that are liquids or solids under ordinary conditions can also exist in the gaseous state, where they are often referred to as **vapors**. The substance  $\text{H}_2\text{O}$ , for example, can exist as liquid water, solid ice, or water vapor.

Even though different gaseous substances may have very different *chemical* properties, they behave quite similarly as far as their *physical* properties are concerned. For example, the  $\text{N}_2$  and  $\text{O}_2$  that account for approximately 99% of our atmosphere have very different chemical properties— $\text{O}_2$  supports human life but  $\text{N}_2$  does not, to name just one difference—but these two components of air behave physically as one gaseous material because their physical properties are essentially identical.

The physical properties of gases differ significantly from those of solids and liquids. For example, a gas expands spontaneously to fill its container. Consequently, the volume of a gas equals the volume of its container. Gases also are highly compressible: When pressure is applied to a gas, its volume readily decreases. Solids and liquids, on the other hand, do not expand to fill their containers and are not readily compressible.

Two or more gases form a homogeneous mixture regardless of the identities or relative proportions of the gases; the atmosphere serves as an excellent example. Two or more liquids or two or more solids may or may not form homogeneous mixtures, depending on their chemical nature. For example, when water and gasoline are mixed, the two liquids remain as separate layers. In contrast, the water vapor and gasoline vapors above the liquids form a homogeneous gas mixture.

The characteristic properties of gases—expanding to fill a container, being highly compressible, forming homogeneous mixtures—arise because the molecules are relatively far apart. In any given volume of air, for example, the molecules take up only about 0.1% of the total volume with the rest being empty space. Thus, each molecule behaves largely as though the others were not present. As a result, different gases behave similarly even though they are made up of different molecules.

**TABLE 10.1** Some Common Compounds That Are Gases at Room Temperature

| Formula                | Name              | Characteristics                           |
|------------------------|-------------------|---|
| HCN                    | Hydrogen cyanide  | Very toxic, slight odor of bitter almonds |
| $\text{H}_2\text{S}$   | Hydrogen sulfide  | Very toxic, odor of rotten eggs           |
| CO                     | Carbon monoxide   | Toxic, colorless, odorless                |
| $\text{CO}_2$          | Carbon dioxide    | Colorless, odorless                       |
| $\text{CH}_4$          | Methane           | Colorless, odorless, flammable            |
| $\text{C}_2\text{H}_4$ | Ethene (Ethylene) | Colorless, ripens fruit                   |
| $\text{C}_3\text{H}_8$ | Propane           | Colorless, odorless, bottled gas          |
| $\text{N}_2\text{O}$   | Nitrous oxide     | Colorless, sweet odor, laughing gas       |
| $\text{NO}_2$          | Nitrogen dioxide  | Toxic, red-brown, irritating odor         |
| $\text{NH}_3$          | Ammonia           | Colorless, pungent odor                   |
| $\text{SO}_2$          | Sulfur dioxide    | Colorless, irritating odor                |

### Give It Some Thought

Xenon is the heaviest stable noble gas with a molar mass of 131 g/mol. Do any of the gases listed in Table 10.1 have molar masses larger than Xe?

## 10.2 | Pressure

The molecules of a gas move chaotically, colliding with each other and with the walls of their container. The impacts with the container walls exert a force—an outward push against the walls. The **pressure**,  $P$ , that a gas exerts is defined as the force,  $F$ , divided by the area,  $A$ , of the surface on which the force is acting:

$$P = \frac{F}{A} \quad [10.1]$$

Gases exert a pressure on any surface with which they are in contact. The gas in an inflated balloon, for example, exerts a pressure on the inside surface of the balloon.

### Atmospheric Pressure and the Barometer

People, coconuts, and nitrogen molecules all experience an attractive gravitational force that pulls them toward the center of the Earth. When a coconut comes loose from a tree, for example, this force causes the coconut to be accelerated toward Earth, its speed increasing as its potential energy is converted into kinetic energy. [Section 1.4](#) The gas atoms and molecules of the atmosphere also experience a gravitational acceleration. Because these particles have such tiny masses, however, their thermal energies of motion (their kinetic energies) override the gravitational forces, so the particles that make up the atmosphere don't pile up at the Earth's surface. Nevertheless, the gravitational force does operate, and it causes the atmosphere as a whole to press down on the Earth's surface, creating *atmospheric pressure*, defined as the force exerted by the atmosphere on a given surface area.

You can demonstrate the existence of atmospheric pressure with an empty plastic water bottle. If you suck on the mouth of the empty bottle, chances are you can cause the bottle to partially cave in. When you break the partial vacuum you have created, the bottle pops out to its original shape. The bottle caves in because, once you've sucked out some of the air molecules, the air molecules in the atmosphere exert a force on the outside of the bottle that is greater than the force exerted by the lesser number of air molecules inside the bottle.

We can calculate the magnitude of the atmospheric pressure using Equation 10.1. The force,  $F$ , exerted by any object is the product of its mass,  $m$ , and its acceleration,  $a$ :  $F = ma$ . When applied to our atmosphere, the force is the gravitational force, which is also commonly called weight. The acceleration is that due to gravity,  $g = 9.8 \text{ m/s}^2$ . Thus, the gravitational force of the atmosphere on the Earth's surface (the weight of the atmosphere) is given by  $F = mg$ .

Now imagine a column of air,  $1 \text{ m}^2$  in cross section, extending through the entire atmosphere ([Figure 10.1](#)). That column has a mass of roughly 10,000 kg. The downward gravitational force exerted on this column is

$$F = (10,000 \text{ kg})(9.8 \text{ m/s}^2) = 1 \times 10^5 \text{ kg}\cdot\text{m/s}^2 = 1 \times 10^5 \text{ N}$$

where N is the abbreviation for *newton*, the SI unit for force:  $1 \text{ N} = 1 \text{ kg}\cdot\text{m/s}^2$ .

The pressure exerted by the column is this force divided by the cross-sectional area,  $A$ , over which the force is applied. Because our air column has a cross-sectional area of  $1 \text{ m}^2$ , we have for the magnitude of atmospheric pressure at sea level

$$P = \frac{F}{A} = \frac{1 \times 10^5 \text{ N}}{1 \text{ m}^2} = 1 \times 10^5 \text{ N/m}^2 = 1 \times 10^5 \text{ Pa} = 1 \times 10^2 \text{ kPa}$$

The SI unit of pressure is the **pascal** (Pa), named for Blaise Pascal (1623–1662), a French scientist who studied pressure:  $1 \text{ Pa} = 1 \text{ N/m}^2$ . A related pressure unit is the **bar**:  $1 \text{ bar} = 10^5 \text{ Pa} = 10^5 \text{ N/m}^2$ . Thus, the atmospheric pressure at sea level we just

▲ **Figure 10.1** Calculating atmospheric pressure.

calculated, 100 kPa, can be reported as 1 bar. (The actual atmospheric pressure at any location depends on weather conditions and altitude.) Another pressure unit is pounds per square inch (psi, lbs/in.<sup>2</sup>). At sea level, atmospheric pressure is 14.7 psi.

### Give It Some Thought

(a) Assume that the top of your head has a surface area of 25 cm × 25 cm. How many newtons of force push on your head at sea level? (b) If you estimate this area to be 100 in.<sup>2</sup>, what is the force in pounds?

In the seventeenth century, many scientists and philosophers believed that the atmosphere had no weight. Evangelista Torricelli (1608–1647), a student of Galileo's, proved this untrue. He invented the *barometer* (Figure 10.2), which is made from a glass tube more than 760 mm long that is closed at one end, completely filled with mercury, and inverted into a dish of mercury. (Care must be taken so that no air gets into the tube.) When the tube is inverted into the dish, some of the mercury flows out of the tube, but a column of mercury remains in the tube. Torricelli argued that the mercury surface in the dish experiences the full force of Earth's atmosphere, which pushes the mercury up the tube until the pressure exerted by the mercury column downward, due to gravity, equals the atmospheric pressure at the base of the tube. Therefore *the height,  $h$ , of the mercury column is a measure of atmospheric pressure and changes as atmospheric pressure changes.*

**Standard atmospheric pressure**, which corresponds to the typical pressure at sea level, is the pressure sufficient to support a column of mercury 760 mm high. In SI units, this pressure is  $1.01325 \times 10^5$  Pa. Standard atmospheric pressure defines some common non-SI units used to express gas pressure, such as the **atmosphere** (atm) and the *millimeter of mercury* (mm Hg). The latter unit is also called the **torr**, after Torricelli: 1 torr = 1 mm Hg. Thus, we have

$$1 \text{ atm} = 760. \text{ mm Hg} = 760. \text{ torr} = 1.01325 \times 10^5 \text{ Pa} = 101.325 \text{ kPa} = 1.01325 \text{ bar}$$

We will express gas pressure in a variety of units throughout this chapter, so you should become comfortable converting pressures from one unit to another.

### Go Figure

What happens to  $h$ , the height of the mercury column, if the atmospheric pressure increases?

▲ Figure 10.2 A mercury barometer.

### Give It Some Thought

Convert a pressure of 745 torr to a pressure in (a) mm Hg, (b) atm, (c) kPa, (d) bar.

## Sample Exercise 10.1

### Calculating Pressure

What is the pressure, in kilopascals, on the body of a diver if she is 31.0 m below the surface of the water when the atmospheric pressure on the surface is 98 kPa? Assume that the density of the water is  $1.00 \text{ g/cm}^3 = 1.00 \times 10^3 \text{ kg/m}^3$ . The gravitational constant is  $9.81 \text{ m/s}^2$ , and  $1 \text{ Pa} = 1 \text{ kg/m}\cdot\text{s}^2$ .

### SOLUTION

**Analyze** We are asked to calculate the pressure on the diver given the atmospheric pressure (98 kPa) and the depth of the water (31.0 m).

**Plan** The total pressure on the diver equals that of the atmosphere plus that of the water. The pressure of the water can be calculated starting with Equation 10.1,  $P = F/A$ . The force,  $F$ , due to the water above the diver is given by its mass times the acceleration due to gravity,  $F = mg$ , where  $g = 9.81 \text{ m/s}^2$ .

**Solve** The pressure caused by the water is

$$P = \frac{F}{A} = \frac{mg}{A}$$

The mass of the water is related to its density ( $d = m/V$ , so  $m = d \times V$ ). We can treat the water as a column whose volume equals its cross-sectional area times its height:  $V = A \times h$ . When we make these substitutions for mass ( $m = d \times V$ ) and volume ( $V = A \times h$ ), we have

$$P = \frac{mg}{A} = \frac{dVg}{A} = \frac{d(Ah)g}{A} = dhg$$

Inserting SI quantities, we have

$$\begin{aligned} P &= dhg = (1.00 \times 10^3 \text{ kg/m}^3)(31.0 \text{ m})(9.81 \text{ m/s}^2) \\ &= 3.00 \times 10^5 \frac{\text{kg}}{\text{m}\cdot\text{s}^2} = 3.00 \times 10^5 \text{ Pa} \end{aligned}$$

Thus, the total pressure on the diver is

$$P_{\text{total}} = 98 \text{ kPa} + 300 \text{ kPa} = 398 \text{ kPa}$$

This corresponds to a pressure of 3.94 atm.

### Practice Exercise 1

What would be the height of the column in a barometer if the external pressure was 101 kPa and water ( $d = 1.00 \text{ g/cm}^3$ ) was used in place of mercury?

- (a) 0.0558 m (b) 0.760 m (c)  $1.03 \times 10^4 \text{ m}$   
(d) 10.3 m (e) 0.103 m

### Practice Exercise 2

Gallium melts just above room temperature and is liquid over a very wide temperature range (30–2204 °C), which means it would be a suitable fluid for a high-temperature barometer. Given its density,  $d_{\text{Ga}} = 6.0 \text{ g/cm}^3$ , what would be the height of the column if gallium is used as the barometer fluid and the external pressure is  $9.5 \times 10^4 \text{ Pa}$ ?

We use various devices to measure the pressures of enclosed gases. Tire gauges, for example, measure the pressure of air in automobile and bicycle tires. In laboratories, we sometimes use a *manometer*, which operates on a principle similar to that of a barometer, as shown in Sample Exercise 10.2.

## Sample Exercise 10.2

### Using a Manometer to Measure Gas Pressure

On a certain day, a laboratory barometer indicates that the atmospheric pressure is 764.7 torr. A sample of gas is placed in a flask attached to an open-end mercury manometer (Figure 10.3), and a meter stick is used to measure the height of the mercury in the two arms of the U tube. The height of the mercury in the open-ended arm is 136.4 mm, and the height in the arm in contact with the gas in the flask is 103.8 mm. What is the pressure of the gas in the flask (a) in atmospheres, (b) in kilopascals?

### SOLUTION

**Analyze** We are given the atmospheric pressure (764.7 torr) and the mercury heights in the two arms of the manometer and asked to determine the gas pressure in the flask. Recall that millimeters of mercury is a pressure unit. We know that the gas pressure from the flask must be greater than atmospheric pressure because the mercury level in the arm on the flask side (103.8 mm) is lower than the level in the arm open to the atmosphere (136.4 mm). Therefore, the gas from the flask is pushing mercury from the arm in contact with the flask into the arm open to the atmosphere.

▲ Figure 10.3 A mercury manometer.

**Plan** We will use the difference in height between the two arms ( $h$  in Figure 10.3) to obtain the amount by which the pressure of the gas exceeds atmospheric pressure. Because an open-end

mercury manometer is used, the height difference directly measures the pressure difference in mm Hg or torr between the gas and the atmosphere.

### Solve

(a) The pressure of the gas equals the atmospheric pressure plus  $h$ :

$$\begin{aligned} P_{\text{gas}} &= P_{\text{atm}} + h \\ &= 764.7 \text{ torr} + (136.4 \text{ torr} - 103.8 \text{ torr}) \\ &= 797.3 \text{ torr} \end{aligned}$$

We convert the pressure of the gas to atmospheres:

$$P_{\text{gas}} = (797.3 \text{ torr}) \left( \frac{1 \text{ atm}}{760 \text{ torr}} \right) = 1.049 \text{ atm}$$

(b) To calculate the pressure in kPa, we employ the conversion factor between atmospheres and kPa:

$$1.049 \text{ atm} \left( \frac{101.3 \text{ kPa}}{1 \text{ atm}} \right) = 106.3 \text{ kPa}$$

**Check** The calculated pressure is a bit more than 1 atm, which is about 101 kPa. This makes sense because we anticipated that the pressure in the flask would be greater than the atmospheric pressure ( $764.7 \text{ torr} = 1.01 \text{ atm}$ ) acting on the manometer.

### Practice Exercise 1

If the gas inside the flask in the above exercise is cooled so that its pressure is reduced to a value of 715.7 torr, what will

be the height of the mercury in the open-ended arm?

(Hint: The sum of the heights in both arms must remain constant regardless of the change in pressure.)

(a) 49.0 mm (b) 95.6 mm (c) 144.6 mm (d) 120.1 mm

### Practice Exercise 2

If the pressure of the gas inside the flask were increased and the height of the column in the open-ended arm went up by 5.0 mm, what would be the new pressure of the gas in the flask, in torr?

## 10.3 | The Gas Laws

Four variables are needed to define the physical condition, or *state*, of a gas: temperature, pressure, volume, and amount of gas, usually expressed as number of moles. The equations that express the relationships among these four variables are known as the *gas laws*. Because volume is easily measured, the first gas laws to be studied expressed the effect of one of the variables on volume, with the remaining two variables held constant.

### The Pressure–Volume Relationship: Boyle’s Law

Gas volume increases as the pressure exerted on the gas decreases. Thus, an inflated weather balloon released at the Earth’s surface expands as it rises (Figure 10.4) because the pressure of the atmosphere decreases with increasing elevation.

The British chemist Robert Boyle (1627–1691) was the first person to investigate the quantitative relationship between the pressure of a gas and its volume. He found, for example, that decreasing the pressure of a gas to half its original value causes the volume to double. Conversely, doubling the pressure causes the volume to decrease to half its original value.

**Boyle’s law**, which summarizes these observations, states that:

*The volume of a fixed quantity of gas maintained at constant temperature is inversely proportional to the pressure.*

When two measurements are inversely proportional, one gets smaller as the other gets larger. Boyle’s law can be expressed mathematically as

$$V = \text{constant} \times \frac{1}{P} \quad \text{or} \quad PV = \text{constant} \quad [10.2]$$

The value of the constant depends on temperature and on the amount of gas in the sample.

The graph of  $V$  versus  $P$  in Figure 10.5 shows the curve obtained for a given quantity of gas at a fixed temperature. A linear relationship is obtained when  $V$  is plotted versus  $1/P$  as shown on the right in Figure 10.5.

### Go Figure

Does atmospheric pressure increase or decrease as altitude increases? (Neglect changes in temperature.)

▲ **Figure 10.4** As a balloon rises in the atmosphere, its volume increases.

## Go Figure

What would a plot of  $P$  versus  $1/V$  look like for a fixed quantity of gas at a fixed temperature?

▲ **Figure 10.5 Boyle's Law.** For a fixed quantity of gas at constant temperature, the volume of the gas is inversely proportional to its pressure.

Boyle's law occupies a special place in the history of science because Boyle was the first to carry out experiments in which one variable was systematically changed to determine the effect on another variable. The data from the experiments were then employed to establish an empirical relationship—a “law.”

We apply Boyle's law every time we breathe. The rib cage, which can expand and contract, and the diaphragm, a muscle beneath the lungs, govern the volume of the lungs. Inhalation occurs when the rib cage expands and the diaphragm moves downward. Both actions increase the volume of the lungs, thus decreasing the gas pressure inside the lungs. Atmospheric pressure then forces air into the lungs until the pressure in the lungs equals atmospheric pressure. Exhalation reverses the process—the rib cage contracts and the diaphragm moves up, decreasing the volume of the lungs. Air is forced out of the lungs by the resulting increase in pressure.

## Give It Some Thought

What happens to the pressure of a gas in a closed container if you double its volume while its temperature is held constant?

▲ **Figure 10.6** The effect of temperature on volume.

## The Temperature–Volume Relationship: Charles's Law

As **Figure 10.6** illustrates, the volume of an inflated balloon increases when the temperature of the gas inside the balloon increases and decreases when the temperature of the gas decreases. This relationship between gas volume and temperature was discovered in 1787 by French scientist Jacques Charles (1746–1823). Some typical volume–temperature data are shown in **Figure 10.7**. Notice that the extrapolated (dashed) line passes through  $-273^\circ\text{C}$ . Note also that the gas is predicted to have zero volume at this temperature. This condition is never realized, however, because all gases liquefy or solidify before reaching this temperature.

In 1848, William Thomson (1824–1907), a British physicist whose title was Lord Kelvin, proposed an absolute-temperature scale, now known as the Kelvin scale. On this scale, 0 K, called *absolute zero*, equals  $-273.15^\circ\text{C}$ . ∞ (Section 1.5) In terms of the Kelvin scale, **Charles's law** states:

*The volume of a fixed amount of gas maintained at constant pressure is directly proportional to its absolute temperature.*

Thus, doubling the absolute temperature causes the gas volume to double. Mathematically, Charles's law takes the form

$$V = \text{constant} \times T \quad \text{or} \quad \frac{V}{T} = \text{constant} \quad [10.3]$$

with the value of the constant depending on the pressure and on the amount of gas.

▲ **Figure 10.7 Charles's Law.** For a fixed quantity of gas at constant pressure, the volume of the gas is proportional to its temperature.

**Give It Some Thought**

Does the volume of a fixed quantity of gas decrease to half its original value when the temperature is lowered from 100 °C to 50 °C?

**The Quantity–Volume Relationship: Avogadro’s Law**

The relationship between the quantity of a gas and its volume follows from the work of Joseph Louis Gay-Lussac (1778–1823) and Amedeo Avogadro (1776–1856).

Gay-Lussac was one of those extraordinary figures in the history of science who could truly be called an adventurer. In 1804, he ascended to 23,000 ft in a hot-air balloon—an exploit that held the altitude record for several decades. To better control the balloon, Gay-Lussac studied the properties of gases. In 1808, he observed the *law of combining volumes*: At a given pressure and temperature, the volumes of gases that react with one another are in the ratios of small whole numbers. For example, two volumes of hydrogen gas react with one volume of oxygen gas to form two volumes of water vapor.

⚙ (Section 3.1)

Three years later, Amedeo Avogadro interpreted Gay-Lussac’s observation by proposing what is now known as **Avogadro’s hypothesis**:

*Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules.*

For example, 22.4 L of any gas at 0 °C and 1 atm contain  $6.02 \times 10^{23}$  gas molecules (that is, 1 mol), as depicted in **Figure 10.8**.

**Avogadro’s law** follows from Avogadro’s hypothesis:

*The volume of a gas maintained at constant temperature and pressure is directly proportional to the number of moles of the gas.*

That is,

$$V = \text{constant} \times n \quad \text{or} \quad \frac{V}{n} = \text{constant} \quad [10.4]$$

where  $n$  is number of moles. Thus, for instance, doubling the number of moles of gas causes the volume to double if  $T$  and  $P$  remain constant.

**Go Figure**

How many moles of gas are in each vessel?

|                         | He                    | N <sub>2</sub>        | CH <sub>4</sub>       |
|-------------------------|-----------------------|-----------------------|-----------------------|
| Volume                  | 22.4 L                | 22.4 L                | 22.4 L                |
| Pressure                | 1 atm                 | 1 atm                 | 1 atm                 |
| Temperature             | 0 °C                  | 0 °C                  | 0 °C                  |
| Mass of gas             | 4.00 g                | 28.0 g                | 16.0 g                |
| Number of gas molecules | $6.02 \times 10^{23}$ | $6.02 \times 10^{23}$ | $6.02 \times 10^{23}$ |

▲ **Figure 10.8** Avogadro’s hypothesis. At the same volume, pressure, and temperature, samples of different gases have the same number of molecules but different masses.

## Sample Exercise 10.3

### Evaluating the Effects of Changes in $P$ , $V$ , $n$ , and $T$ on a Gas

Suppose we have a gas confined to a cylinder with a movable piston that is sealed so there are no leaks. (Sections 5.2, 5.3) How will each of the following changes affect (i) the pressure of the gas, (ii) the number of moles of gas in the cylinder, (iii) the average distance between molecules: (a) Heating the gas while maintaining a constant pressure; (b) Reducing the volume while maintaining a constant temperature; (c) Injecting additional gas while keeping the temperature and volume constant.

### SOLUTION

**Analyze** We need to think how each change affects (1) the pressure of the gas, (2) the number of moles of gas in the cylinder, and (3) the average distance between molecules.

**Plan** We can use the gas laws to evaluate the changes in pressure. The number of moles of gas in the cylinder will not change unless gas is either added or removed. Assessing the average distance between molecules is not quite as straightforward. For a given number of gas molecules, the average distance between molecules increases as the volume increases. Conversely, for constant volume, the average distance between molecules decreases as the number of moles increases. Thus, the average distance between molecules will be proportional to  $V/n$ .

### Solve

- (a) Because it is stipulated that the pressure remains constant, pressure is not a variable in this problem, and the total number of moles of gas will also remain constant. We know from Charles's law, however, that heating the gas while maintaining constant pressure will cause the piston to move and the volume to increase. Thus, the distance between molecules will increase.
- (b) The reduction in volume causes the pressure to increase (Boyle's law). Compressing the gas into a smaller volume does not change the total number of gas molecules; thus, the total number of moles remains the same. The average distance between molecules, however, must decrease because of the smaller volume.

- (c) Injecting more gas into the cylinder means that more molecules are present and there will be an increase in the number of moles of gas in the cylinder. Because we have added more molecules while keeping the volume constant, the average distance between molecules must decrease. Avogadro's law tells us that the volume of the cylinder should have increased when we added more gas, provided the pressure and temperature were held constant. Here the volume is held constant, as is the temperature, which means the pressure must change. Knowing from Boyle's law that there is an inverse relationship between volume and pressure ( $PV = \text{constant}$ ), we conclude that if the volume does not increase on injecting more gas the pressure must increase.

### Practice Exercise 1

A helium balloon is filled to a volume of 5.60 L at 25 °C. What will the volume of the balloon become if it is put into liquid nitrogen to lower the temperature of the helium to 77 K?

- (a) 17 L (b) 22 L (c) 1.4 L (d) 0.046 L (e) 3.7 L

### Practice Exercise 2

An oxygen cylinder used in a hospital contains 35.4 L of oxygen gas at a pressure of 149.6 atm. How much volume would the oxygen occupy if it were transferred to a container that maintained a pressure of 1.00 atm if the temperature remains constant?

## 10.4 | The Ideal-Gas Equation

All three laws we just examined were obtained by holding two of the four variables  $P$ ,  $V$ ,  $T$ , and  $n$  constant and seeing how the remaining two variables affect each other. We can express each law as a proportionality relationship. Using the symbol  $\propto$  for "is proportional to," we have

$$\text{Boyle's law: } V \propto \frac{1}{P} \quad (\text{constant } n, T)$$

$$\text{Charles's law: } V \propto T \quad (\text{constant } n, P)$$

$$\text{Avogadro's law: } V \propto n \quad (\text{constant } P, T)$$

We can combine these relationships into a general gas law:

$$V \propto \frac{nT}{P}$$

If we call the proportionality constant  $R$ , we obtain an equality:

$$V = R \left( \frac{nT}{P} \right)$$

which we can rearrange to

$$PV = nRT \quad [10.5]$$

which is the **ideal-gas equation** (also called the **ideal-gas law**). An **ideal gas** is a hypothetical gas whose pressure, volume, and temperature relationships are described completely by the ideal-gas equation.

**TABLE 10.2 Numerical Values of the Gas Constant  $R$  in Various Units**

| Units                     | Numerical Value |
|---------------------------|-----------------|
| L-atm/mol-K               | 0.08206         |
| J/mol-K*                  | 8.314           |
| cal/mol-K                 | 1.987           |
| m <sup>3</sup> -Pa/mol-K* | 8.314           |
| L-torr/mol-K              | 62.36           |

\*SI unit

In deriving the ideal-gas equation, we make two assumptions:

- the molecules of an ideal gas do not interact with one another,
- the combined volume of the molecules is much smaller than the volume the gas occupies.

For these reasons, we consider the molecules as taking up no space in the container. In many cases, the small error introduced by these assumptions is acceptable. If more accurate calculations are needed, we can correct for the assumptions if we know something about the attraction molecules have for one another and the size of the molecules.

The term  $R$  in the ideal-gas equation is the **gas constant**. The value and units of  $R$  depend on the units of  $P$ ,  $V$ ,  $n$ , and  $T$ . The value for  $T$  in the ideal-gas equation must *always* be the absolute temperature (in kelvins instead of degrees Celsius). The quantity of gas,  $n$ , is normally expressed in moles. The units chosen for pressure and volume are most often atmospheres and liters, respectively. However, other units can be used. In countries other than the United States, the pascal is the most commonly used unit for pressure. **Table 10.2** shows the numerical value for  $R$  in various units. In working with the ideal-gas equation, you must choose the form of  $R$  in which the units agree with the units of  $P$ ,  $V$ ,  $n$ , and  $T$  given in the problem. In this chapter, we will most often use  $R = 0.08206$  L-atm/mol-K because pressure is most often given in atmospheres.

Suppose we have 1.000 mol of an ideal gas at 1.000 atm and 0.00 °C (273.15 K). According to the ideal-gas equation, the volume of the gas is

$$V = \frac{nRT}{P} = \frac{(1.000 \text{ mol})(0.08206 \text{ L-atm/mol-K})(273.15 \text{ K})}{1.000 \text{ atm}} = 22.41 \text{ L}$$

The conditions 0 °C and 1 atm are referred to as **standard temperature and pressure (STP)**. The volume occupied by 1 mol of ideal gas at STP, 22.41 L, is known as the *molar volume* of an ideal gas at STP.

### Give It Some Thought

If 1.00 mol of an ideal gas at STP were confined to a cube, what would be the length in cm of an edge of this cube?

The ideal-gas equation accounts adequately for the properties of most gases under a variety of circumstances. The equation is not exactly correct, however, for any real gas. Thus, the measured volume for given values of  $P$ ,  $n$ , and  $T$  might differ from the volume calculated from  $PV = nRT$  (**Figure 10.9**). Although real gases do not always behave ideally, their behavior differs so little from ideal behavior that we can ignore any deviations for all but the most accurate work.

### Go Figure

Which gas deviates most from ideal behavior?

▲ **Figure 10.9** Comparison of molar volumes at STP.

## Sample Exercise 10.4

### Using the Ideal-Gas Equation

Calcium carbonate,  $\text{CaCO}_3(\text{s})$ , the principal compound in limestone, decomposes upon heating to  $\text{CaO}(\text{s})$  and  $\text{CO}_2(\text{g})$ . A sample of  $\text{CaCO}_3$  is decomposed, and the carbon dioxide is collected in a 250-mL flask. After decomposition is complete, the gas has a pressure of 1.3 atm at a temperature of 31 °C. How many moles of  $\text{CO}_2$  gas were generated?

### SOLUTION

**Analyze** We are given the volume (250 mL), pressure (1.3 atm), and temperature (31 °C) of a sample of  $\text{CO}_2$  gas and asked to calculate the number of moles of  $\text{CO}_2$  in the sample.

**Plan** Because we are given  $V$ ,  $P$ , and  $T$ , we can solve the ideal-gas equation for the unknown quantity,  $n$ .

**Solve** In analyzing and solving gas law problems, it is helpful to tabulate the information given in the problems and then to convert the values to units that are consistent with those for  $R$  (0.08206 L-atm/mol-K). In this case, the given values are

$$V = 250 \text{ mL} = 0.250 \text{ L}$$

$$P = 1.3 \text{ atm}$$

$$T = 31^\circ\text{C} = (31 + 273) \text{ K} = 304 \text{ K}$$

Remember: *Absolute temperature must always be used when the ideal-gas equation is solved.*

We now rearrange the ideal-gas equation (Equation 10.5) to solve for  $n$

$$n = \frac{PV}{RT}$$

$$\begin{aligned} n &= \frac{(1.3 \text{ atm})(0.250 \text{ L})}{(0.08206 \text{ L-atm/mol-K})(304 \text{ K})} \\ &= 0.013 \text{ mol CO}_2 \end{aligned}$$

**Check** Appropriate units cancel, thus ensuring that we have properly rearranged the ideal-gas equation and have converted to the correct units.

### Practice Exercise 1

The Goodyear blimp contains  $5.74 \times 10^6 \text{ L}$  of helium at 25 °C and 1.00 atm. What is the mass in grams of the helium inside the blimp?

- (a)  $2.30 \times 10^7 \text{ g}$  (b)  $2.80 \times 10^6 \text{ g}$  (c)  $1.12 \times 10^7 \text{ g}$   
(d)  $2.34 \times 10^5 \text{ g}$  (e)  $9.39 \times 10^5 \text{ g}$

### Practice Exercise 2

Tennis balls are usually filled with either air or  $\text{N}_2$  gas to a pressure above atmospheric pressure to increase their bounce. If a tennis ball has a volume of  $144 \text{ cm}^3$  and contains 0.33 g of  $\text{N}_2$  gas, what is the pressure inside the ball at 24 °C?

## STRATEGIES FOR SUCCESS Calculations Involving Many Variables

In this chapter, we encounter a variety of problems based on the ideal-gas equation, which contains four variables— $P$ ,  $V$ ,  $n$ , and  $T$ —and one constant,  $R$ . Depending on the type of problem, we might need to solve for any of the four variables.

To extract the necessary information from problems involving more than one variable, we suggest the following steps:

- 1. Tabulate information.** Read the problems carefully to determine which variable is the unknown and which variables have numeric values given. Every time you encounter a numerical value, jot it down. In many cases, constructing a table of the given information will be useful.
- 2. Convert to consistent units.** Make certain that quantities are converted to the proper units. In using the ideal-gas equation, for example, we usually use the value of  $R$  that has units of L-atm/mol-K. If you are given a pressure in torr, you will need to convert it to atmospheres before using this value of  $R$  in your calculations.
- 3. If a single equation relates the variables, solve the equation for the unknown.** For the ideal-gas equation, these algebraic rearrangements will all be used at one time or another:

$$P = \frac{nRT}{V}, \quad V = \frac{nRT}{P}, \quad n = \frac{PV}{RT}, \quad T = \frac{PV}{nR}$$

- 4. Use dimensional analysis.** Carry the units through your calculation. Using dimensional analysis enables you to check that you have solved an equation correctly. If the units in the equation cancel to give the units of the desired variable, you have probably used the equation correctly.

Sometimes you will not be given explicit values for several variables, making it look like a problem that cannot be solved. In these cases, however, you should look for information that can be used to determine the needed variables. For example, suppose you are using the ideal-gas equation to calculate a pressure in a problem that gives a value for  $T$  but not for  $n$  or  $V$ . However, the problem states that “the sample contains 0.15 mol of gas per liter.” You can turn this statement into the expression

$$\frac{n}{V} = 0.15 \text{ mol/L}$$

Solving the ideal-gas equation for pressure yields

$$P = \frac{nRT}{V}$$

which we can rewrite as follows:

$$P = \left( \frac{n}{V} \right) RT$$

Thus, we can solve the equation even though we are not given values for  $n$  and  $V$ .

As we have continuously stressed, the most important thing you can do to become proficient at solving chemistry problems is to do the practice exercises and end-of-chapter exercises. By using systematic procedures, such as those described here, you should be able to minimize difficulties in solving problems involving many variables.

## Relating the Ideal-Gas Equation and the Gas Laws

The gas laws we discussed in Section 10.3 are special cases of the ideal-gas equation. For example, when  $n$  and  $T$  are held constant, the product  $nRT$  contains three constants and so must itself be a constant:

$$PV = nRT = \text{constant} \quad \text{or} \quad PV = \text{constant} \quad [10.6]$$

Note that this rearrangement gives Boyle's law. We see that if  $n$  and  $T$  are constant, the values of  $P$  and  $V$  can change, but the product  $PV$  must remain constant.

We can use Boyle's law to determine how the volume of a gas changes when its pressure changes. For example, if a cylinder fitted with a movable piston holds 50.0 L of  $O_2$  gas at 18.5 atm and  $21^\circ\text{C}$ , what volume will the gas occupy if the temperature is maintained at  $21^\circ\text{C}$  while the pressure is reduced to 1.00 atm? Because the product  $PV$  is a constant when a gas is held at constant  $n$  and  $T$ , we know that

$$P_1V_1 = P_2V_2 \quad [10.7]$$

where  $P_1$  and  $V_1$  are initial values and  $P_2$  and  $V_2$  are final values. Dividing both sides of this equation by  $P_2$  gives the final volume,  $V_2$ :

$$V_2 = V_1 \times \frac{P_1}{P_2} = (50.0 \text{ L}) \left( \frac{18.5 \text{ atm}}{1.00 \text{ atm}} \right) = 925 \text{ L}$$

The answer is reasonable because a gas expands as its pressure decreases.

In a similar way, we can start with the ideal-gas equation and derive relationships between any other two variables,  $V$  and  $T$  (Charles's law),  $n$  and  $V$  (Avogadro's law), or  $P$  and  $T$ .

We are often faced with the situation in which  $P$ ,  $V$ , and  $T$  all change for a fixed number of moles of gas. Because  $n$  is constant in this situation, the ideal-gas equation gives

$$\frac{PV}{T} = nR = \text{constant}$$

If we represent the initial and final conditions by subscripts 1 and 2, respectively, we can write an equation that is often called the *combined gas law*:

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \quad [10.8]$$

### Sample Exercise 10.5

#### Calculating the Effect of Temperature Changes on Pressure

The gas pressure in an aerosol can is 1.5 atm at  $25^\circ\text{C}$ . Assuming that the gas obeys the ideal-gas equation, what is the pressure when the can is heated to  $450^\circ\text{C}$ ?

#### SOLUTION

**Analyze** We are given the initial pressure (1.5 atm) and temperature ( $25^\circ\text{C}$ ) of the gas and asked for the pressure at a higher temperature ( $450^\circ\text{C}$ ).

**Plan** The volume and number of moles of gas do not change, so we must use a relationship connecting pressure and temperature. Converting temperature to the Kelvin scale and tabulating the given information, we have

|                | $P$     | $T$   |
|----------------|---------|-------|
| <b>Initial</b> | 1.5 atm | 298 K |
| <b>Final</b>   | $P_2$   | 723 K |

**Solve** To determine how  $P$  and  $T$  are related, we start with the ideal-gas equation and isolate the quantities that do not change ( $n$ ,  $V$ , and  $R$ ) on one side and the variables ( $P$  and  $T$ ) on the other side.

$$\frac{P}{T} = \frac{nR}{V} = \text{constant}$$

Because the quotient  $P/T$  is a constant, we can write

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}$$

(where the subscripts 1 and 2 represent the initial and final states, respectively). Rearranging to solve for  $P_2$  and substituting the

given data give

$$P_2 = (1.5 \text{ atm}) \left( \frac{723 \text{ K}}{298 \text{ K}} \right) = 3.6 \text{ atm}$$

**Check** This answer is intuitively reasonable—increasing the temperature of a gas increases its pressure.

**Comment** It is evident from this example why aerosol cans carry a warning not to incinerate.

#### Practice Exercise 1

If you fill your car tire to a pressure of 32 psi (pounds per square inch) on a hot summer day when the temperature is  $35^\circ\text{C}$  ( $95^\circ\text{F}$ ), what is the pressure (in psi) on a cold winter day when the temperature is  $-15^\circ\text{C}$  ( $5^\circ\text{F}$ )? Assume no gas leaks out between measurements and the volume of the tire does not change.

- (a) 38 psi (b) 27 psi (c)  $-13.7$  psi (d) 1.8 psi  
(e) 13.7 psi

#### Practice Exercise 2

The pressure in a natural-gas tank is maintained at 2.20 atm. On a day when the temperature is  $-15^\circ\text{C}$ , the volume of gas in the tank is  $3.25 \times 10^3 \text{ m}^3$ . What is the volume of the same quantity of gas on a day when the temperature is  $31^\circ\text{C}$ ?

## Sample Exercise 10.6

### Using the Combined Gas Law

An inflated balloon has a volume of 6.0 L at sea level (1.0 atm) and is allowed to ascend until the pressure is 0.45 atm. During ascent, the temperature of the gas falls from 22 °C to −21 °C. Calculate the volume of the balloon at its final altitude.

#### SOLUTION

**Analyze** We need to determine a new volume for a gas sample when both pressure and temperature change.

**Plan** Let's again proceed by converting temperatures to kelvins and tabulating our information.

|                | <i>P</i> | <i>V</i>              | <i>T</i> |
|----------------|----------|-----------------------|----------|
| <b>Initial</b> | 1.0 atm  | 6.0 L                 | 295 K    |
| <b>Final</b>   | 0.45 atm | <i>V</i> <sub>2</sub> | 252 K    |

Because *n* is constant, we can use Equation 10.8.

**Solve** Rearranging Equation 10.8 to solve for *V*<sub>2</sub> gives

$$\begin{aligned}
 V_2 &= V_1 \times \frac{P_1}{P_2} \times \frac{T_2}{T_1} \\
 &= (6.0 \text{ L}) \left( \frac{1.0 \text{ atm}}{0.45 \text{ atm}} \right) \left( \frac{252 \text{ K}}{295 \text{ K}} \right) = 11 \text{ L}
 \end{aligned}$$

**Check** The result appears reasonable. Notice that the calculation involves multiplying the initial volume by a ratio of pressures and a ratio of temperatures. Intuitively, we expect decreasing pressure to cause the volume to increase, while decreasing the temperature should have the opposite effect. Because the change in pressure is more dramatic than the change in temperature, we expect the effect of the pressure change to predominate in determining the final volume, as it does.

#### Practice Exercise 1

A gas occupies a volume of 0.75 L at 20 °C at 720 torr. What volume would the gas occupy at 41 °C and 760 torr?

(a) 1.45 L (b) 0.85 L (c) 0.76 L (d) 0.66 L (e) 0.35 L

#### Practice Exercise 2

A 0.50-mol sample of oxygen gas is confined at 0 °C and 1.0 atm in a cylinder with a movable piston. The piston compresses the gas so that the final volume is half the initial volume and the final pressure is 2.2 atm. What is the final temperature of the gas in degrees Celsius?

## 10.5 | Further Applications of the Ideal-Gas Equation

In this section, we use the ideal-gas equation first to define the relationship between the density of a gas and its molar mass, and then to calculate the volumes of gases formed or consumed in chemical reactions.

### Gas Densities and Molar Mass

Recall that density has units of mass per unit volume ( $d = m/V$ ). (Section 1.5) We can arrange the ideal-gas equation to obtain similar units of moles per unit volume:

$$\frac{n}{V} = \frac{P}{RT}$$

If we multiply both sides of this equation by the molar mass,  $\mathcal{M}$ , which is the number of grams in 1 mol of a substance (Section 3.4), we obtain

$$\frac{n\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT} \quad [10.9]$$

The term on the left equals the density in grams per liter:

$$\frac{\text{moles}}{\text{liter}} \times \frac{\text{grams}}{\text{mole}} = \frac{\text{grams}}{\text{liter}}$$

Thus, the density of the gas is also given by the expression on the right in Equation 10.9:

$$d = \frac{n\mathcal{M}}{V} = \frac{P\mathcal{M}}{RT} \quad [10.10]$$

This equation tells us that the density of a gas depends on its pressure, molar mass, and temperature. The higher the molar mass and pressure, the denser the gas. The higher the temperature, the less dense the gas. Although gases form homogeneous

## Sample Exercise 10.7

## Calculating Gas Density

What is the density of carbon tetrachloride vapor at 714 torr and 125 °C?

## SOLUTION

**Analyze** We are asked to calculate the density of a gas given its name, its pressure, and its temperature. From the name, we can write the chemical formula of the substance and determine its molar mass.

**Plan** We can use Equation 10.10 to calculate the density. Before we can do that, however, we must convert the given quantities to the appropriate units, degrees Celsius to kelvins and pressure to atmospheres. We must also calculate the molar mass of  $\text{CCl}_4$ .

**Solve** The absolute temperature is  $125 + 273 = 398 \text{ K}$ . The pressure is  $(714 \text{ torr}) (1 \text{ atm}/760 \text{ torr}) = 0.939 \text{ atm}$ . The molar mass of  $\text{CCl}_4$  is  $12.01 + (4)(35.45) = 153.8 \text{ g/mol}$ . Therefore,

$$d = \frac{PM}{RT} = \frac{(0.939 \text{ atm})(153.8 \text{ g/mol})}{(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(398 \text{ K})} = 4.42 \text{ g/L}$$

**Check** If we divide molar mass (g/mol) by density (g/L), we end up with L/mol. The numerical value is roughly  $154/4.4 = 35$ , which is in the right ballpark for the molar volume of a gas heated to 125 °C at near atmospheric pressure. We may thus conclude our answer is reasonable.

## Practice Exercise 1

What is the density of methane,  $\text{CH}_4$ , in a vessel where the pressure is 910 torr and the temperature is 255 K?

- (a) 0.92 g/L (b) 697 g/L (c) 0.057 g/L (d) 16 g/L (e) 0.72 g/L

## Practice Exercise 2

The mean molar mass of the atmosphere at the surface of Titan, Saturn's largest moon, is 28.6 g/mol. The surface temperature is 95 K, and the pressure is 1.6 atm. Assuming ideal behavior, calculate the density of Titan's atmosphere.

▲ **Figure 10.10** Carbon dioxide gas flows downward because it is denser than air.

mixtures, a less dense gas will lie above a denser gas in the absence of mixing. For example,  $\text{CO}_2$  has a higher molar mass than  $\text{N}_2$  or  $\text{O}_2$  and is therefore denser than air. For this reason,  $\text{CO}_2$  released from a  $\text{CO}_2$  fire extinguisher blankets a fire, preventing  $\text{O}_2$  from reaching the combustible material. “Dry ice,” which is solid  $\text{CO}_2$ , converts directly to  $\text{CO}_2$  gas at room temperature, and the resulting “fog” (which is actually condensed water droplets cooled by the  $\text{CO}_2$ ) is carried downward by the heavier, but colorless,  $\text{CO}_2$  (Figure 10.10).

When we have equal molar masses of two gases at the same pressure but different temperatures, the hotter gas is less dense than the cooler one, so the hotter gas rises. The difference between the densities of hot and cold air is responsible for the lift of hot-air balloons. It is also responsible for many phenomena in weather, such as the formation of large thunderheads during thunderstorms.

## Give It Some Thought

Is water vapor more or less dense than  $\text{N}_2$  under the same conditions of temperature and pressure?

Equation 10.10 can be rearranged to solve for the molar mass of a gas:

$$M = \frac{dRT}{P} \quad [10.11]$$

Thus, we can use the experimentally measured density of a gas to determine the molar mass of the gas molecules, as shown in Sample Exercise 10.8.

## Sample Exercise 10.8

## Calculating the Molar Mass of a Gas

A large evacuated flask initially has a mass of 134.567 g. When the flask is filled with a gas of unknown molar mass to a pressure of 735 torr at 31 °C, its mass is 137.456 g. When the flask is evacuated again and then filled with water at 31 °C, its mass is 1067.9 g. (The density of water at this temperature is 0.997 g/mL.) Assuming the ideal-gas equation applies, calculate the molar mass of the gas.

**SOLUTION**

**Analyze** We are given the temperature (31 °C) and pressure (735 torr) for a gas, together with information to determine its volume and mass, and we are asked to calculate its molar mass.

**Plan** The data obtained when the flask is filled with water can be used to calculate the volume of the container. The mass of the empty flask and of the flask when filled with gas can be used to calculate the mass of the gas. From these quantities we calculate the gas density and then apply Equation 10.11 to calculate the molar mass of the gas.

**Solve** The gas volume equals the volume of water the flask can hold, calculated from the mass and density of the water. The mass of the water is the difference between the masses of the full and evacuated flask:

$$1067.9 \text{ g} - 134.567 \text{ g} = 933.3 \text{ g}$$

Rearranging the equation for density ( $d = m/V$ ), we have

$$V = \frac{m}{d} = \frac{(933.3 \text{ g})}{(0.997 \text{ g/mL})} = 936 \text{ mL} = 0.936 \text{ L}$$

The gas mass is the difference between the mass of the flask filled with gas and the mass of the evacuated flask:

$$137.456 \text{ g} - 134.567 \text{ g} = 2.889 \text{ g}$$

Knowing the mass of the gas (2.889 g) and its volume (0.936 L), we can calculate the density of the gas:

$$d = 2.889 \text{ g}/0.936 \text{ L} = 3.09 \text{ g/L}$$

After converting pressure to atmospheres and temperature to kelvins, we can use Equation 10.11 to calculate the molar mass:

$$\begin{aligned} \mathcal{M} &= \frac{dRT}{P} \\ &= \frac{(3.09 \text{ g/L})(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(304 \text{ K})}{(0.967 \text{ atm})} \\ &= 79.7 \text{ g/mol} \end{aligned}$$

**Check** The units work out appropriately, and the value of molar mass obtained is reasonable for a substance that is gaseous near room temperature.

**Practice Exercise 1**

What is the molar mass of an unknown hydrocarbon whose density is measured to be 1.97 g/L at STP?

- (a) 4.04 g/mol (b) 30.7 g/mol (c) 44.1 g/mol (d) 48.2 g/mol

**Practice Exercise 2**

Calculate the average molar mass of dry air if it has a density of 1.17 g/L at 21 °C and 740.0 torr.

**Volumes of Gases in Chemical Reactions**

We are often concerned with knowing the identity and/or quantity of a gas involved in a chemical reaction. Thus, it is useful to be able to calculate the volumes of gases consumed or produced in reactions. Such calculations are based on the mole concept and balanced chemical equations.  (Section 3.6) The coefficients in a balanced chemical equation tell us the relative amounts (in moles) of reactants and products in a reaction. The ideal-gas equation relates the number of moles of a gas to  $P$ ,  $V$ , and  $T$ .

**Sample Exercise 10.9****Relating Gas Variables and Reaction Stoichiometry**

Automobile air bags are inflated by nitrogen gas generated by the rapid decomposition of sodium azide,  $\text{NaN}_3$ :

If an air bag has a volume of 36 L and is to be filled with nitrogen gas at 1.15 atm and 26 °C, how many grams of  $\text{NaN}_3$  must be decomposed?

**SOLUTION**

**Analyze** This is a multistep problem. We are given the volume, pressure, and temperature of the  $\text{N}_2$  gas and the chemical equation for the reaction by which the  $\text{N}_2$  is generated. We must use this information to calculate the number of grams of  $\text{NaN}_3$  needed to obtain the necessary  $\text{N}_2$ .

**Plan** We need to use the gas data ( $P$ ,  $V$ , and  $T$ ) and the ideal-gas equation to calculate the number of moles of  $\text{N}_2$  gas that should be formed for the air bag to operate correctly. We can then use the balanced equation to determine the number of moles of  $\text{NaN}_3$  needed. Finally, we can convert moles of  $\text{NaN}_3$  to grams.

**Solve**

The conversion sequence is:

Continued

The number of moles of  $N_2$  is determined using the ideal-gas equation:

$$n = \frac{PV}{RT} = \frac{(1.15 \text{ atm})(36 \text{ L})}{(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(299 \text{ K})} \\ = 1.7 \text{ mol } N_2$$

We use the coefficients in the balanced equation to calculate the number of moles of  $NaN_3$ :

$$(1.7 \text{ mol } N_2) \left( \frac{2 \text{ mol } NaN_3}{3 \text{ mol } N_2} \right) = 1.1 \text{ mol } NaN_3$$

Finally, using the molar mass of  $NaN_3$ , we convert moles of  $NaN_3$  to grams:

$$(1.1 \text{ mol } NaN_3) \left( \frac{65.0 \text{ g } NaN_3}{1 \text{ mol } NaN_3} \right) = 72 \text{ g } NaN_3$$

**Check** The units cancel properly at each step in the calculation, leaving us with the correct units in the answer, g  $NaN_3$ .

### Practice Exercise 1

Silver oxide decomposes when heated:

If 5.76 g of  $\text{Ag}_2\text{O}$  is heated and the  $\text{O}_2$  gas produced by the reaction is collected in an evacuated flask, what is the pressure of the  $\text{O}_2$  gas if the volume of the flask is 0.65 L and the gas temperature is  $25^\circ\text{C}$ ?

- (a) 0.94 atm   (b) 0.039 atm   (c) 0.012 atm  
(d) 0.47 atm   (e) 3.2 atm

### Practice Exercise 2

In the first step of the industrial process for making nitric acid, ammonia reacts with oxygen in the presence of a suitable catalyst to form nitric oxide and water vapor:

How many liters of  $\text{NH}_3(g)$  at  $850^\circ\text{C}$  and 5.00 atm are required to react with 1.00 mol of  $\text{O}_2(g)$  in this reaction?

## 10.6 | Gas Mixtures and Partial Pressures

Thus far we have considered mainly pure gases—those that consist of only one substance in the gaseous state. How do we deal with mixtures of two or more different gases? While studying the properties of air, John Dalton (Section 2.1) made an important observation:

*The total pressure of a mixture of gases equals the sum of the pressures that each would exert if it were present alone.*

The pressure exerted by a particular component of a mixture of gases is called the **partial pressure** of that component. Dalton's observation is known as **Dalton's law of partial pressures**.

If we let  $P_t$  be the total pressure of a mixture of gases and  $P_1, P_2, P_3$ , and so forth be the partial pressures of the individual gases, we can write Dalton's law of partial pressures as

$$P_t = P_1 + P_2 + P_3 + \dots \quad [10.12]$$

This equation implies that each gas behaves independently of the others, as we can see by the following analysis. Let  $n_1, n_2, n_3$ , and so forth be the number of moles of each of the gases in the mixture and  $n_t$  be the total number of moles of gas. If each gas obeys the ideal-gas equation, we can write

$$P_1 = n_1 \left( \frac{RT}{V} \right); \quad P_2 = n_2 \left( \frac{RT}{V} \right); \quad P_3 = n_3 \left( \frac{RT}{V} \right); \quad \text{and so forth}$$

All of the gases in a container must occupy the same volume and will come to the same temperature in a relatively short period of time. Using these facts to simplify Equation 10.12, we obtain

$$P_t = (n_1 + n_2 + n_3 + \dots) \left( \frac{RT}{V} \right) = n_t \left( \frac{RT}{V} \right) \quad [10.13]$$

That is, at constant temperature and constant volume the total pressure of a gas sample is determined by the total number of moles of gas present, whether that total represents just one gas or a mixture of gases.

**Give It Some Thought**

How is the partial pressure exerted by  $\text{N}_2$  gas affected when some  $\text{O}_2$  is introduced into a container if the temperature and volume remain constant? How is the total pressure affected?

**Sample Exercise 10.10****Applying Dalton's Law of Partial Pressures**

A mixture of 6.00 g of  $\text{O}_2(g)$  and 9.00 g of  $\text{CH}_4(g)$  is placed in a 15.0-L vessel at  $0^\circ\text{C}$ . What is the partial pressure of each gas, and what is the total pressure in the vessel?

**SOLUTION**

**Analyze** We need to calculate the pressure for two gases in the same volume and at the same temperature.

**Plan** Because each gas behaves independently, we can use the ideal-gas equation to calculate the pressure each would exert if the other were not present. Per Dalton's law, the total pressure is the sum of these two partial pressures.

**Solve** We first convert the mass of each gas to moles:

$$n_{\text{O}_2} = (6.00 \text{ g O}_2) \left( \frac{1 \text{ mol O}_2}{32.0 \text{ g O}_2} \right) = 0.188 \text{ mol O}_2$$

$$n_{\text{CH}_4} = (9.00 \text{ g CH}_4) \left( \frac{1 \text{ mol CH}_4}{16.0 \text{ g CH}_4} \right) = 0.563 \text{ mol CH}_4$$

We use the ideal-gas equation to calculate the partial pressure of each gas:

$$P_{\text{O}_2} = \frac{n_{\text{O}_2}RT}{V} = \frac{(0.188 \text{ mol})(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(273 \text{ K})}{15.0 \text{ L}} = 0.281 \text{ atm}$$

$$P_{\text{CH}_4} = \frac{n_{\text{CH}_4}RT}{V} = \frac{(0.563 \text{ mol})(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(273 \text{ K})}{15.0 \text{ L}} = 0.841 \text{ atm}$$

According to Dalton's law of partial pressures (Equation 10.12), the total pressure in the vessel is the sum of the partial pressures:

$$\begin{aligned} P_t &= P_{\text{O}_2} + P_{\text{CH}_4} \\ &= 0.281 \text{ atm} + 0.841 \text{ atm} = 1.122 \text{ atm} \end{aligned}$$

**Check** A pressure of roughly 1 atm seems right for a mixture of about 0.2 mol  $\text{O}_2$  and a bit more than 0.5 mol  $\text{CH}_4$ , together in a 15-L volume, because 1 mol of an ideal gas at 1 atm pressure and  $0^\circ\text{C}$  occupies about 22 L.

**Practice Exercise 1**

A 15-L cylinder contains 4.0 g of hydrogen and 28 g of nitrogen. If the temperature is  $27^\circ\text{C}$  what is the total pressure of the mixture?

- (a) 0.44 atm   (b) 1.6 atm   (c) 3.3 atm  
(d) 4.9 atm   (e) 9.8 atm

**Practice Exercise 2**

What is the total pressure exerted by a mixture of 2.00 g of  $\text{H}_2(g)$  and 8.00 g of  $\text{N}_2(g)$  at 273 K in a 10.0-L vessel?

**Partial Pressures and Mole Fractions**

Because each gas in a mixture behaves independently, we can relate the amount of a given gas in a mixture to its partial pressure. For an ideal gas, we can write

$$\frac{P_1}{P_t} = \frac{n_1RT/V}{n_tRT/V} = \frac{n_1}{n_t} \quad [10.14]$$

The ratio  $n_1/n_t$  is called the *mole fraction of gas 1*, which we denote  $X_1$ . The **mole fraction**,  $X$ , is a dimensionless number that expresses the ratio of the number of moles of one component in a mixture to the total number of moles in the mixture. Thus, for gas 1 we have

$$X_1 = \frac{\text{Moles of compound 1}}{\text{Total moles}} = \frac{n_1}{n_t} \quad [10.15]$$

We can combine Equations 10.14 and 10.15 to give

$$P_1 = \left( \frac{n_1}{n_t} \right) P_t = X_1 P_t \quad [10.16]$$

The mole fraction of  $\text{N}_2$  in air is 0.78—that is, 78% of the molecules in air are  $\text{N}_2$ . This means that if the barometric pressure is 760 torr, the partial pressure of  $\text{N}_2$  is

$$P_{\text{N}_2} = (0.78)(760 \text{ torr}) = 590 \text{ torr}$$

This result makes intuitive sense: Because  $\text{N}_2$  makes up 78% of the mixture, it contributes 78% of the total pressure.

**Sample Exercise 10.11****Relating Mole Fractions and Partial Pressures**

A study of the effects of certain gases on plant growth requires a synthetic atmosphere composed of 1.5 mol % CO<sub>2</sub>, 18.0 mol % O<sub>2</sub> and 80.5 mol % Ar. (a) Calculate the partial pressure of O<sub>2</sub> in the mixture if the total pressure of the atmosphere is to be 745 torr. (b) If this atmosphere is to be held in a 121-L space at 295 K, how many moles of O<sub>2</sub> are needed?

**SOLUTION**

**Analyze** For (a) we need to calculate the partial pressure of O<sub>2</sub> given its mole percent and the total pressure of the mixture. For (b) we need to calculate the number of moles of O<sub>2</sub> in the mixture given its volume (121 L), temperature (295 K), and partial pressure from part (a).

**Plan** We calculate the partial pressures using Equation 10.16, and then use  $P_{O_2}$ ,  $V$ , and  $T$  in the ideal-gas equation to calculate the number of moles of O<sub>2</sub>.

**Solve**

(a) The mole percent is the mole fraction times 100. Therefore, the mole fraction of O<sub>2</sub> is 0.180. Equation 10.16 gives:

$$P_{O_2} = (0.180)(745 \text{ torr}) = 134 \text{ torr}$$

(b) Tabulating the given variables and converting to appropriate units, we have:

$$P_{O_2} = (134 \text{ torr}) \left( \frac{1 \text{ atm}}{760 \text{ torr}} \right) = 0.176 \text{ atm}$$

$$V = 121 \text{ L}$$

$$n_{O_2} = ?$$

$$R = 0.08206 \frac{\text{L}\cdot\text{atm}}{\text{mol}\cdot\text{K}}$$

$$T = 295 \text{ K}$$

Solving the ideal-gas equation for  $n_{O_2}$ , we have:

$$\begin{aligned} n_{O_2} &= P_{O_2} \left( \frac{V}{RT} \right) \\ &= (0.176 \text{ atm}) \frac{121 \text{ L}}{(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(295 \text{ K})} = 0.880 \text{ mol} \end{aligned}$$

**Check** The units check out, and the answer seems to be the right order of magnitude.

**Practice Exercise 1**

A 4.0-L vessel containing N<sub>2</sub> at STP and a 2.0-L vessel containing H<sub>2</sub> at STP are connected by a valve. If the valve is opened allowing the two gases to mix, what is the mole fraction of hydrogen in the mixture? (a) 0.034 (b) 0.33 (c) 0.50 (d) 0.67 (e) 0.96

**Practice Exercise 2**

From data gathered by *Voyager 1*, scientists have estimated the composition of the atmosphere of Titan, Saturn's largest moon. The pressure on the surface of Titan is 1220 torr. The atmosphere consists of 82 mol % N<sub>2</sub>, 12 mol % Ar, and 6.0 mol % CH<sub>4</sub>. Calculate the partial pressure of each gas.

## 10.7 | The Kinetic-Molecular Theory of Gases

The ideal-gas equation describes *how* gases behave but not *why* they behave as they do. Why does a gas expand when heated at constant pressure? Or why does its pressure increase when the gas is compressed at constant temperature? To understand the physical properties of gases, we need a model that helps us picture what happens to gas particles when conditions such as pressure or temperature change. Such a model, known as the **kinetic-molecular theory of gases**, was developed over a period of about 100 years, culminating in 1857 when Rudolf Clausius (1822–1888) published a complete and satisfactory form of the theory.

The kinetic-molecular theory (the theory of moving molecules) is summarized by the following statements:

- 1. Random motion** Gases consist of large numbers of molecules that are in continuous, random motion. (The word *molecule* is used here to designate the smallest particle of any gas even though some gases, such as the noble gases, consist of individual atoms. All we learn about gas behavior from the kinetic-molecular theory applies equally to atomic gases.)

- 2. Negligible molecular volume** The combined volume of all the molecules of the gas is negligible relative to the total volume in which the gas is contained.
- 3. Negligible forces** Attractive and repulsive forces between gas molecules are negligible.
- 4. Constant average kinetic energy** Energy can be transferred between molecules during collisions but, as long as temperature remains constant, the *average* kinetic energy of the molecules does not change with time.
- 5. Average kinetic energy proportional to temperature** The average kinetic energy of the molecules is proportional to the absolute temperature. At any given temperature, the molecules of all gases have the same average kinetic energy.

The kinetic-molecular theory explains both pressure and temperature at the molecular level. The pressure of a gas is caused by collisions of the molecules with the walls of the container (**Figure 10.11**). The magnitude of the pressure is determined by how often and how forcefully the molecules strike the walls.

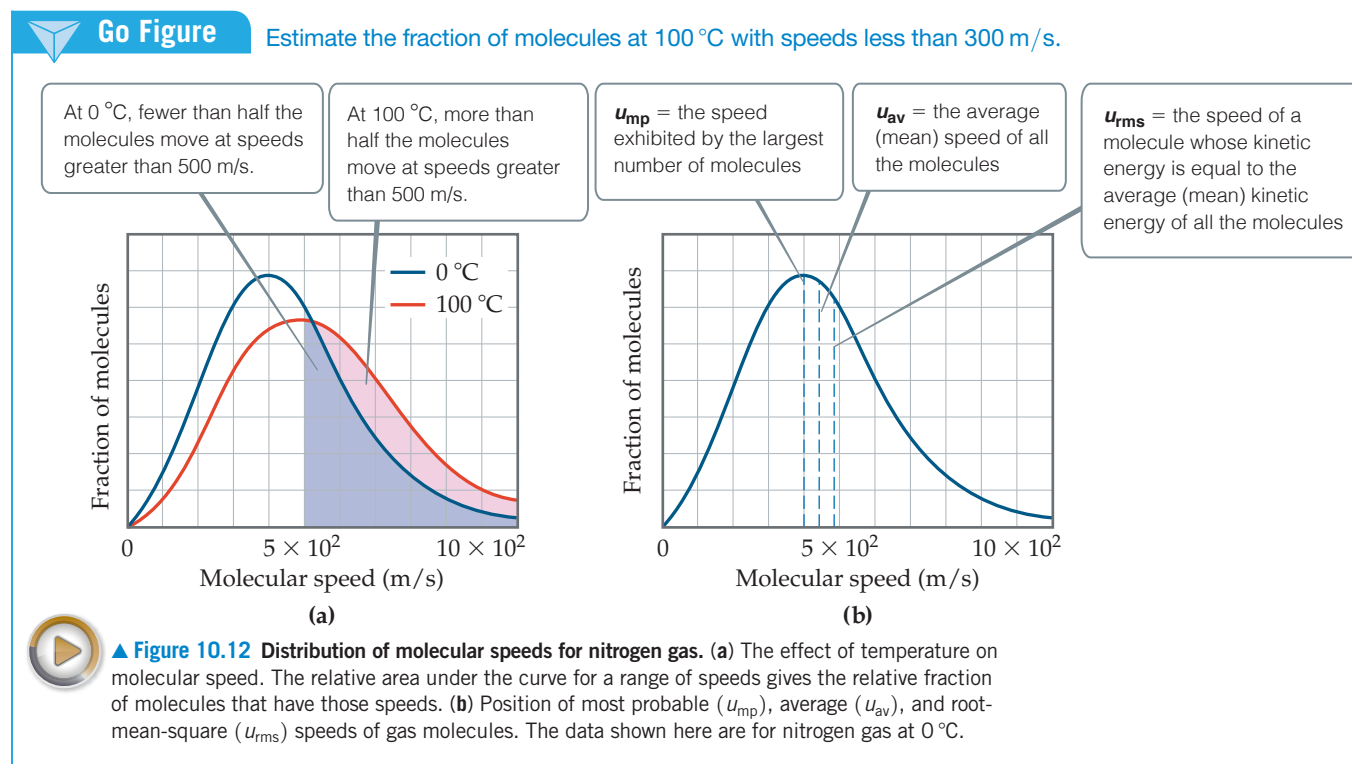

The absolute temperature of a gas is a measure of the *average* kinetic energy of its molecules. If two gases are at the same temperature, their molecules have the same average kinetic energy (statement 5 of the kinetic-molecular theory). If the absolute temperature of a gas is doubled, the average kinetic energy of its molecules doubles. Thus, molecular motion increases with increasing temperature.

▲ **Figure 10.11** The molecular origin of gas pressure.

## Distributions of Molecular Speed

Although collectively the molecules in a sample of gas have an *average* kinetic energy and hence an average speed, the individual molecules are moving at different speeds. Each molecule collides frequently with other molecules. Momentum is conserved in each collision, but one of the colliding molecules might be deflected off at high speed while the other is nearly stopped. The result is that, at any instant, the molecules in the sample have a wide range of speeds. In **Figure 10.12(a)**, which shows the distribution of molecular speeds for nitrogen gas at 0 °C and 100 °C, we see that a larger fraction of the 100 °C molecules moves at the higher speeds. This means that the 100 °C sample has the higher average kinetic energy.

In any graph of the distribution of molecular speeds in a gas sample, the peak of the curve represents the most probable speed,  $u_{\text{mp}}$  [Figure 10.12(b)]. The most probable speeds in Figure 10.12(a), for instance, are  $4 \times 10^2$  m/s for the  $0^\circ\text{C}$  sample and  $5 \times 10^2$  m/s for the  $100^\circ\text{C}$  sample. Figure 10.12(b) also shows the **root-mean-square (rms) speed**,  $u_{\text{rms}}$ , of the molecules. This is the speed of a molecule possessing a kinetic energy identical to the average kinetic energy of the sample. The rms speed is not quite the same as the average (mean) speed,  $u_{\text{av}}$ . The difference between the two is small, however. In Figure 10.12(b), for example, the root-mean-square speed is about  $4.9 \times 10^2$  m/s and the average speed is about  $4.5 \times 10^2$  m/s.

If you calculate the rms speeds (as we will in Section 10.8), you will find that the rms speed is almost  $6 \times 10^2$  m/s for the  $100^\circ\text{C}$  sample but slightly less than  $5 \times 10^2$  m/s for the  $0^\circ\text{C}$  sample. Notice that the distribution curve broadens as we go to a higher temperature, which tells us that the range of molecular speeds increases with temperature.

The rms speed is important because the average kinetic energy of the gas molecules in a sample is equal to  $\frac{1}{2} m(u_{\text{rms}})^2$ .  (Section 1.4) Because mass does not change with temperature, the increase in the average kinetic energy  $\frac{1}{2} m(u_{\text{rms}})^2$  as the temperature increases implies that the rms speed of the molecules (as well as  $u_{\text{av}}$  and  $u_{\text{mp}}$ ) increases as temperature increases.

### Give It Some Thought

Consider three gases all at 298 K: HCl,  $\text{H}_2$ , and  $\text{O}_2$ . List the gases in order of increasing average speed.

## Application of Kinetic-Molecular Theory to the Gas Laws

The empirical observations of gas properties as expressed by the various gas laws are readily understood in terms of the kinetic-molecular theory. The following examples illustrate this point:

- 1. An increase in volume at constant temperature causes pressure to decrease.** A constant temperature means that the average kinetic energy of the gas molecules remains unchanged. This means that the rms speed of the molecules remains unchanged. When the volume is increased, the molecules must move a longer distance between collisions. Consequently, there are fewer collisions per unit time with the container walls, which means the pressure decreases. Thus, kinetic-molecular theory explains Boyle's law.
- 2. A temperature increase at constant volume causes pressure to increase.** An increase in temperature means an increase in the average kinetic

## A CLOSER LOOK The Ideal-Gas Equation

The ideal-gas equation can be derived from the five statements given in the text for the kinetic-molecular theory. Rather than perform the derivation, however, let's consider in qualitative terms how the ideal-gas equation might follow from these statements. The total force of the molecular collisions on the walls and hence the pressure (force per unit area, Section 10.2) produced by these collisions depend both on how strongly the molecules strike the walls (impulse imparted per collision) and on the rate at which the collisions occur:

$$P \propto \text{impulse imparted per collision} \times \text{collision rate}$$

For a molecule traveling at the rms speed, the impulse imparted by a collision with a wall depends on the momentum of the molecule; that is, it depends on the product of the molecule's mass and speed:  $mu_{\text{rms}}$ . The collision rate is proportional to the number of molecules per unit volume,  $n/V$ , and to their speed, which is  $u_{\text{rms}}$

because we are talking about only molecules traveling at this speed. Thus, we have

$$P \propto mu_{\text{rms}} \times \frac{n}{V} \times u_{\text{rms}} \propto \frac{nm(u_{\text{rms}})^2}{V} \quad [10.17]$$

Because the average kinetic energy,  $\frac{1}{2} m(u_{\text{rms}})^2$ , is proportional to temperature, we have  $m(u_{\text{rms}})^2 \propto T$ . Making this substitution in Equation 10.17 gives

$$P \propto \frac{nm(u_{\text{rms}})^2}{V} \propto \frac{nT}{V} \quad [10.18]$$

If we put in a proportionality constant, calling it  $R$ , the gas constant, you can see that we obtain the ideal-gas equation:

$$P = \frac{nRT}{V} \quad [10.19]$$

**Related Exercises: 10.75, 10.76**

energy of the molecules and in  $u_{\text{rms}}$ . Because there is no change in volume, the temperature increase causes more collisions with the walls per unit time because the molecules are all moving faster. Furthermore, the momentum in each collision increases (the molecules strike the walls more forcefully). A greater number of more forceful collisions means the pressure increases, and the theory explains this increase.

### Sample Exercise 10.12

#### Applying the Kinetic-Molecular Theory

A sample of  $\text{O}_2$  gas initially at STP is compressed to a smaller volume at constant temperature. What effect does this change have on (a) the average kinetic energy of the molecules, (b) their average speed, (c) the number of collisions they make with the container walls per unit time, (d) the number of collisions they make with a unit area of container wall per unit time, (e) the pressure?

#### SOLUTION

**Analyze** We need to apply the concepts of the kinetic-molecular theory of gases to a gas compressed at constant temperature.

**Plan** We will determine how each of the quantities in (a)–(e) is affected by the change in volume at constant temperature.

**Solve** (a) Because the average kinetic energy of the  $\text{O}_2$  molecules is determined only by temperature, this energy is unchanged by the compression. (b) Because the average kinetic energy of the molecules does not change, their average speed remains constant. (c) The number of collisions with the walls per unit time increases because the molecules are moving in a smaller volume but with the same average speed as before. Under these conditions they will strike the walls of the container more frequently. (d) The number of collisions with a unit area of wall per unit time increases because the total number of collisions with the walls per unit time increases and the area of the walls decreases. (e) Although the average force with which the molecules collide with the walls remains constant, the pressure increases because there are more collisions per unit area of wall per unit time.

**Check** In a conceptual exercise of this kind, there is no numerical answer to check. All we can check in such cases is our reasoning in the course of solving the problem. The increase in pressure seen in part (e) is consistent with Boyle's law.

#### Practice Exercise 1

Consider two gas cylinders of the same volume and temperature, one containing 1.0 mol of propane,  $\text{C}_3\text{H}_8$ , and the other 2.0 mol of methane,  $\text{CH}_4$ . Which of the following statements is true? (a) The  $\text{C}_3\text{H}_8$  and  $\text{CH}_4$  molecules have the same  $u_{\text{rms}}$  (b) The  $\text{C}_3\text{H}_8$  and  $\text{CH}_4$  molecules have the same average kinetic energy (c) The rate at which the molecules collide with the cylinder walls is the same for both cylinders (d) The gas pressure is the same in both cylinders

#### Practice Exercise 2

How is the rms speed of  $\text{N}_2$  molecules in a gas sample changed by (a) an increase in temperature, (b) an increase in volume, (c) mixing with a sample of Ar at the same temperature?

## 10.8 | Molecular Effusion and Diffusion

According to the kinetic-molecular theory of gases, the average kinetic energy of *any* collection of gas molecules,  $\frac{1}{2}m(u_{\text{rms}})^2$ , has a specific value at a given temperature. Thus, for two gases at the same temperature a gas composed of low-mass particles, such as He, has the same average kinetic energy as one composed of more massive particles, such as Xe. The mass of the particles in the He sample is smaller than that in the Xe sample. Consequently, the He particles must have a higher rms speed than the Xe particles. The equation that expresses this fact quantitatively is

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} \quad [10.20]$$

where  $\mathcal{M}$  is the molar mass of the particles, which can be derived from the kinetic-molecular theory. Because  $\mathcal{M}$  appears in the denominator, the less massive the gas particles, the higher their rms speed.

Figure 10.13 shows the distribution of molecular speeds for several gases at 25 °C. Notice how the distributions are shifted toward higher speeds for gases of lower molar masses.

The most probable speed of a gas molecule can also be derived:

$$u_{\text{mp}} = \sqrt{\frac{2RT}{\mathcal{M}}} \quad [10.21]$$

## Go Figure

Which of these gases has the largest molar mass? Which has the smallest?

▲ Figure 10.13 The effect of molar mass on molecular speed at 25 °C.

## Give It Some Thought

What is the ratio of  $u_{\text{rms}}$  to  $u_{\text{mp}}$  for a sample of  $\text{O}_2(g)$  at 300 K? Will this ratio change as the temperature changes? Will it be different for a different gas?

The dependence of molecular speed on mass has two interesting consequences. The first is **effusion**, which is the escape of gas molecules through a tiny hole (Figure 10.14). The second is **diffusion**, which is the spread of one substance throughout a space or throughout a second substance. For example, the molecules of a perfume diffuse throughout a room.

## Graham's Law of Effusion

In 1846, Thomas Graham (1805–1869) discovered that the effusion rate of a gas is inversely proportional to the square root of its molar mass. Assume we have two gases at

Gas molecules in top half effuse through pinhole only when they happen to hit the pinhole.

▲ Figure 10.14 Effusion.

## Sample Exercise 10.13

## Calculating a Root-Mean-Square Speed

Calculate the rms speed of the molecules in a sample of  $\text{N}_2$  gas at 25 °C.

## SOLUTION

**Analyze** We are given the identity of a gas and the temperature, the two quantities we need to calculate the rms speed.

**Plan** We calculate the rms speed using Equation 10.20.

**Solve** We must convert each quantity in our equation to SI units. We will also use  $R$  in units of J/mol·K (Table 10.2) to make the units cancel correctly.

$$T = 25 + 273 = 298 \text{ K}$$

$$\mathcal{M} = 28.0 \text{ g/mol} = 28.0 \times 10^{-3} \text{ kg/mol}$$

$$R = 8.314 \text{ J/mol}\cdot\text{K} = 8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2\cdot\text{mol}\cdot\text{K} \text{ (Since } 1 \text{ J} = 1 \text{ kg}\cdot\text{m}^2/\text{s}^2\text{)}$$

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} = \sqrt{\frac{3(8.314 \text{ kg}\cdot\text{m}^2/\text{s}^2\cdot\text{mol}\cdot\text{K})(298 \text{ K})}{28.0 \times 10^{-3} \text{ kg/mol}}} = 5.15 \times 10^2 \text{ m/s}$$

**Comment** This corresponds to a speed of 1150 mi/hr. Because the average molecular weight of air molecules is slightly greater than that of  $\text{N}_2$ , the rms speed of air molecules is a little smaller than that for  $\text{N}_2$ .

## Practice Exercise 1

Fill in the blanks for the following statement: The rms speed of the molecules in a sample of  $\text{H}_2$  gas at 300 K will be \_\_\_\_\_ times larger than the rms speed of  $\text{O}_2$  molecules at the same temperature, and the ratio  $u_{\text{rms}}(\text{H}_2)/u_{\text{rms}}(\text{O}_2)$  \_\_\_\_\_ with increasing temperature.

(a) four, will not change (b) four, will increase (c) sixteen, will not change (d) sixteen, will decrease (e) Not enough information is given to answer this question.

## Practice Exercise 2

What is the rms speed of an atom in a sample of He gas at 25 °C?

the same temperature and pressure in two containers with identical pinholes. If the rates of effusion of the two gases are  $r_1$  and  $r_2$  and their molar masses are  $\mathcal{M}_1$  and  $\mathcal{M}_2$ , **Graham's law** states that

$$\frac{r_1}{r_2} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}} \quad [10.22]$$

a relationship that indicates that the lighter gas has the higher effusion rate.

The only way for a molecule to escape from its container is for it to “hit” the hole in the partitioning wall of Figure 10.14. The faster the molecules are moving, the more often they hit the partition wall and the greater the likelihood that a molecule will hit the hole and effuse. This implies that the rate of effusion is directly proportional to the rms speed of the molecules. Because  $R$  and  $T$  are constant, we have, from Equation 10.22

$$\frac{r_1}{r_2} = \frac{u_{\text{rms}1}}{u_{\text{rms}2}} = \sqrt{\frac{3RT/\mathcal{M}_1}{3RT/\mathcal{M}_2}} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}} \quad [10.23]$$

As expected from Graham's law, helium escapes from containers through tiny pinhole leaks more rapidly than other gases of higher molecular weight (Figure 10.15).

### Sample Exercise 10.14

#### Applying Graham's Law

An unknown gas composed of homonuclear diatomic molecules effuses at a rate that is 0.355 times the rate at which  $\text{O}_2$  gas effuses at the same temperature. Calculate the molar mass of the unknown and identify it.

#### SOLUTION

**Analyze** We are given the rate of effusion of an unknown gas relative to that of  $\text{O}_2$  and asked to find the molar mass and identity of the unknown. Thus, we need to connect relative rates of effusion to relative molar masses.

**Plan** We use Equation 10.22 to determine the molar mass of the unknown gas. If we let  $r_x$  and  $\mathcal{M}_x$  represent the rate of effusion and molar mass of the gas, we can write

$$\frac{r_x}{r_{\text{O}_2}} = \sqrt{\frac{\mathcal{M}_{\text{O}_2}}{\mathcal{M}_x}}$$

**Solve** From the information given,

$$r_x = 0.355 \times r_{\text{O}_2}$$

Thus,

$$\begin{aligned} \frac{r_x}{r_{\text{O}_2}} &= 0.355 = \sqrt{\frac{32.0 \text{ g/mol}}{\mathcal{M}_x}} \\ \frac{32.0 \text{ g/mol}}{\mathcal{M}_x} &= (0.355)^2 = 0.126 \\ \mathcal{M}_x &= \frac{32.0 \text{ g/mol}}{0.126} = 254 \text{ g/mol} \end{aligned}$$

Because we are told that the unknown gas is composed of homonuclear diatomic molecules, it must be an element. The molar mass must represent twice the atomic weight of the atoms in the unknown gas. We conclude that the unknown gas must have an atomic weight of 127 g/mol and therefore is  $\text{I}_2$ .

#### Practice Exercise 1

In a system for separating gases, a tank containing a mixture of hydrogen and carbon dioxide is connected to a much larger tank where the pressure is kept very low. The two tanks are separated by a porous membrane through which the molecules must effuse. If the initial partial pressure of each gas is 5.00 atm, what will be the mole fraction of hydrogen in the tank after the partial pressure of carbon dioxide has declined to 4.50 atm?

(a) 52.1% (b) 37.2% (c) 32.1% (d) 4.68% (e) 27.4%

#### Practice Exercise 2

Calculate the ratio of the effusion rates of  $\text{N}_2$  gas and  $\text{O}_2$  gas.

## Diffusion and Mean Free Path

Although diffusion, like effusion, is faster for lower-mass molecules than for higher-mass ones, molecular collisions make diffusion more complicated than effusion.

Graham's law, Equation 10.22, approximates the ratio of the diffusion rates of two gases under identical conditions. We can see from the horizontal axis in Figure 10.13 that the speeds of molecules are quite high. For example, the rms speed of molecules of  $\text{N}_2$  gas at room temperature is 515 m/s. In spite of this high speed, if someone opens a vial of perfume at one end of a room, some time elapses—perhaps a few minutes—before the scent is detected at the other end of the room. This tells us that the diffusion rate of gases

## Go Figure

Because pressure and temperature are constant in this figure but volume changes, which other quantity in the ideal-gas equation must also change?

▲ Figure 10.15 An illustration of Graham's law of effusion.

## CHEMISTRY PUT TO WORK Gas Separations

The fact that lighter molecules move at higher average speeds than more massive ones has many interesting applications. For example, developing the atomic bomb during World War II required scientists to separate the relatively low-abundance uranium isotope  $^{235}\text{U}$  (0.7%) from the much more abundant  $^{238}\text{U}$  (99.3%). This separation was accomplished by converting the uranium into a volatile compound,  $\text{UF}_6$ , that was then allowed to pass through a porous barrier (Figure 10.16). Because of the pore diameters, this process is not simple effusion. Nevertheless, the way in which rate of passing through the pores depends on molar mass is essentially the same as that in effusion. The slight difference in molar mass between  $^{235}\text{UF}_6$  and  $^{238}\text{UF}_6$  caused the molecules to move at slightly different rates:

$$\frac{r_{235}}{r_{238}} = \sqrt{\frac{352.04}{349.03}} = 1.0043$$

Thus, the gas initially appearing on the opposite side of the barrier is very slightly enriched in  $^{235}\text{U}$ . The process is repeated thousands of times, leading to a nearly complete separation of the two

isotopes. Because of the large number of steps needed to adequately separate the isotopes, gaseous diffusion facilities are large-scale structures. The largest diffusion plant in the United States is located outside of Paducah, Kentucky. It contains approximately 400 miles of piping and the buildings where the separation takes place take up over 75 acres.

An increasingly popular method of separating uranium isotopes is by a technique that uses centrifuges. In this procedure, cylindrical rotors containing  $\text{UF}_6$  vapor spin at high speed inside an evacuated casing. Molecules of  $^{238}\text{UF}_6$  move closer to the spinning walls, whereas molecules of  $^{235}\text{UF}_6$  remain in the middle of the cylinders. A stream of gas moves the  $^{235}\text{UF}_6$  from the center of one centrifuge into another. Plants that use centrifuges consume less energy than those that use effusion and can be constructed in a more compact, modular fashion. Such plants are frequently in the news today as countries such as Iran and North Korea enrich uranium in the  $^{235}\text{U}$  isotope for both nuclear power and nuclear weaponry.

**Related Exercises:** 10.85, 10.86

▲ Figure 10.16 Uranium enrichment by gaseous diffusion. The lighter  $^{235}\text{UF}_6$  effuses through a porous barrier at a slightly faster rate than  $^{238}\text{UF}_6$ . The pressure difference across the membrane drives the effusion. The enrichment shown here for a single step is exaggerated for illustrative purposes.

throughout a volume of space is much slower than molecular speeds.\* This difference is due to molecular collisions, which occur frequently for a gas at atmospheric pressure—about  $10^{10}$  times per second for each molecule. Collisions occur because real gas molecules have finite volumes.

Because of molecular collisions, the direction of motion of a gas molecule is constantly changing. Therefore, the diffusion of a molecule from one point to another consists of many short, straight-line segments as collisions buffet it around in random directions (Figure 10.17).

The average distance traveled by a molecule between collisions, called the molecule's **mean free path**, varies with pressure as the following analogy illustrates. Imagine walking through a shopping mall. When the mall is crowded (high pressure), the average distance you can walk before bumping into someone is short (short mean free path). When the mall is empty (low pressure), you can walk a long way (long mean free path) before bumping into someone. The mean free path for air molecules at sea level is about 60 nm. At about 100 km in altitude, where the air pressure is much lower, the mean free path is about 10 cm, over 1 million times longer than at the Earth's surface.

### Give It Some Thought

Will these changes increase, decrease, or have no effect on the mean free path of the molecules in a gas sample?

- (a) increasing pressure.
- (b) increasing temperature.

▲ Figure 10.17 Diffusion of a gas molecule. For clarity, no other gas molecules in the container are shown.

## 10.9 | Real Gases: Deviations from Ideal Behavior

The extent to which a real gas departs from ideal behavior can be seen by rearranging the ideal-gas equation to solve for  $n$ :

$$\frac{PV}{RT} = n \quad [10.24]$$

This form of the equation tells us that for 1 mol of ideal gas, the quantity  $PV/RT$  equals 1 at all pressures. In Figure 10.18,  $PV/RT$  is plotted as a function of  $P$  for 1 mol of several real gases. At high pressures (generally above 10 atm), the deviation from ideal behavior

◀ Figure 10.18 The effect of pressure on the behavior of several real gases. Data for 1 mol of gas in all cases. Data for  $\text{N}_2$ ,  $\text{CH}_4$ , and  $\text{H}_2$  are at 300 K; for  $\text{CO}_2$  data are at 313 K because under high pressure  $\text{CO}_2$  liquefies at 300 K.

\*The rate at which the perfume moves across the room also depends on how well stirred the air is from temperature gradients and the movement of people. Nevertheless, even with the aid of these factors, it still takes much longer for the molecules to traverse the room than one would expect from their rms speed.

## Go Figure

True or false: Nitrogen gas behaves more like an ideal gas as the temperature increases.

▲ Figure 10.19 The effect of temperature and pressure on the behavior of nitrogen gas.

( $PV/RT = 1$ ) is large and different for each gas. *Real gases, in other words, do not behave ideally at high pressure.* At lower pressures (usually below 10 atm), however, the deviation from ideal behavior is small, and we can use the ideal-gas equation without generating serious error.

Deviation from ideal behavior also depends on temperature. As temperature increases, the behavior of a real gas more nearly approaches that of the ideal gas (Figure 10.19). In general, *the deviation from ideal behavior increases as temperature decreases*, becoming significant near the temperature at which the gas liquefies.

## Give It Some Thought

Under which conditions do you expect helium gas to deviate most from ideal behavior? (a) 100 K and 1 atm, (b) 100 K and 5 atm, (c) 300 K and 2 atm.

▲ Figure 10.20 Gases behave more ideally at low pressure than at high pressure.

The basic assumptions of the kinetic-molecular theory of gases give us insight into why real gases deviate from ideal behavior. The molecules of an ideal gas are assumed to occupy no space and have no attraction for one another. *Real molecules, however, do have finite volumes and do attract one another.* As Figure 10.20 shows, the unoccupied space in which real molecules can move is less than the container volume. At low pressures, the combined volume of the gas molecules is negligible relative to the container volume. Thus, the unoccupied volume available to the molecules is essentially the container volume. At high pressures, the combined volume of the gas molecules is *not* negligible relative to the container volume. Now the unoccupied volume available to the molecules is less than the container volume. At high pressures, therefore, gas volumes tend to be slightly greater than those predicted by the ideal-gas equation.

Another reason for nonideal behavior at high pressures is that the attractive forces between molecules come into play at the short intermolecular distances found when molecules are crowded together at high pressures. Because of these attractive forces, the impact of a given molecule with the container wall is lessened. If we could stop the motion in a gas, as illustrated in Figure 10.21, we would see that a molecule about to collide with the wall experiences the attractive forces of nearby molecules. These attractions lessen the force with which the molecule hits the wall. As a result, the gas pressure is less than that of an ideal gas. This effect decreases  $PV/RT$  to below its

## Go Figure

How would you expect the pressure of a gas to change if suddenly the intermolecular forces were repulsive rather than attractive?

▲ **Figure 10.21** In any real gas, attractive intermolecular forces reduce pressure to values lower than in an ideal gas.

ideal value, as seen at the lower pressures in Figures 10.18 and 10.19. When the pressure is sufficiently high, however, the volume effects dominate and  $PV/RT$  increases to above the ideal value.

Temperature determines how effective attractive forces between gas molecules are in causing deviations from ideal behavior at lower pressures. Figure 10.19 shows that, at pressures below about 400 atm, cooling increases the extent to which a gas deviates from ideal behavior. As the gas cools, the average kinetic energy of the molecules decreases. This drop in kinetic energy means the molecules do not have the energy needed to overcome intermolecular attraction, and the molecules will be more likely to stick to each other than bounce off each other.

As the temperature of a gas increases—as, say, from 200 to 1000 K in Figure 10.19—the negative deviation of  $PV/RT$  from the ideal value of 1 disappears. As noted earlier, the deviations seen at high temperatures stem mainly from the effect of the finite volumes of the molecules.

## Give It Some Thought

Explain the negative deviation from ideal gas behavior of  $N_2$  below 300 atm in Figure 10.19.

## The van der Waals Equation

Engineers and scientists who work with gases at high pressures often cannot use the ideal-gas equation because departures from ideal behavior are too large. One useful equation developed to predict the behavior of real gases was proposed by the Dutch scientist Johannes van der Waals (1837–1923).

As we have seen, a real gas has a lower pressure due to intermolecular forces, and a larger volume due to the finite volume of the molecules, relative to an ideal gas. Van der Waals recognized that it would be possible to retain the form of the ideal-gas equation,  $PV = nRT$ , if corrections were made to the pressure and the volume. He introduced two constants for these corrections:  $a$ , a measure of how strongly the gas molecules attract one another, and  $b$ , a measure of the finite volume occupied by the molecules. His description of gas behavior is known as the **van der Waals equation**:

$$\left(P + \frac{n^2a}{V^2}\right)(V - nb) = nRT \quad [10.25]$$

The term  $n^2a/V^2$  accounts for the attractive forces. The equation adjusts the pressure upward by adding  $n^2a/V^2$  because attractive forces between molecules tend to reduce the pressure (Figure 10.21). The added term has the form  $n^2a/V^2$  because the attractive force between pairs of molecules increases as the square of the number of molecules per unit volume,  $(n/V)^2$ .

The term  $nb$  accounts for the small but finite volume occupied by the gas molecules (Figure 10.20). The van der Waals equation subtracts  $nb$  to adjust the volume downward to give the volume that would be available to the molecules in the ideal case. The constants  $a$  and  $b$ , called *van der Waals constants*, are experimentally determined positive quantities that differ from one gas to another. Notice in Table 10.3 that  $a$  and  $b$  generally increase with increasing molecular mass. Larger, more massive molecules have larger volumes and tend to have greater intermolecular attractive forces.

**TABLE 10.3 Van der Waals Constants for Gas Molecules**

| Substance        | $a$ (L <sup>2</sup> ·atm/mol <sup>2</sup> ) | $b$ (L/mol) |
|------------------|---|-------------|
| He               | 0.0341                                      | 0.02370     |
| Ne               | 0.211                                       | 0.0171      |
| Ar               | 1.34  | 0.0322      |
| Kr               | 2.32  | 0.0398      |
| Xe               | 4.19  | 0.0510      |
| H <sub>2</sub>   | 0.244                                       | 0.0266      |
| N <sub>2</sub>   | 1.39  | 0.0391      |
| O <sub>2</sub>   | 1.36  | 0.0318      |
| F <sub>2</sub>   | 1.06  | 0.0290      |
| Cl <sub>2</sub>  | 6.49  | 0.0562      |
| H <sub>2</sub> O | 5.46  | 0.0305      |
| NH <sub>3</sub>  | 4.17  | 0.0371      |
| CH <sub>4</sub>  | 2.25  | 0.0428      |
| CO <sub>2</sub>  | 3.59  | 0.0427      |
| CCl <sub>4</sub> | 20.4  | 0.1383      |

### Sample Exercise 10.15

#### Using the van der Waals Equation

If 10.00 mol of an ideal gas were confined to 22.41 L at 0.0 °C, it would exert a pressure of 10.00 atm. Use the van der Waals equation and Table 10.3 to estimate the pressure exerted by 1.000 mol of Cl<sub>2</sub>(g) in 22.41 L at 0.0 °C.

#### SOLUTION

**Analyze** We need to determine a pressure. Because we will use the van der Waals equation, we must identify the appropriate values for the constants in the equation.

**Plan** Rearrange Equation 10.25 to isolate  $P$ .

**Solve** Substituting  $n = 10.00$  mol,  $R = 0.08206$  L·atm/mol·K,  $T = 273.2$  K,  $V = 22.41$  L,  $a = 6.49$  L<sup>2</sup>·atm/mol<sup>2</sup>, and  $b = 0.0562$  L/mol:

$$\begin{aligned}
 P &= \frac{(10.00 \text{ mol})(0.08206 \text{ L}\cdot\text{atm/mol}\cdot\text{K})(273.2 \text{ K})}{22.41 \text{ L} - (10.00 \text{ mol})(0.0562 \text{ L/mol})} \\
 &\quad - \frac{(10.00 \text{ mol})^2(6.49 \text{ L}^2\cdot\text{atm/mol}^2)}{(22.41 \text{ L})^2} \\
 &= 10.26 \text{ atm} - 1.29 \text{ atm} = 8.97 \text{ atm}
 \end{aligned}$$

**Comment** Notice that the term 10.26 atm is the pressure corrected for molecular volume. This value is higher than the ideal value, 10.00 atm, because the volume in which the molecules are free to move is smaller than the container volume, 22.41 L. Thus, the

molecules collide more frequently with the container walls and the pressure is higher than that of a real gas. The term 1.29 atm makes a correction in the opposite direction for intermolecular forces. The correction for intermolecular forces is the larger of the two, and thus the pressure 8.97 atm is smaller than would be observed for an ideal gas.

#### Practice Exercise 1

Calculate the pressure of a 2.975-mol sample of N<sub>2</sub> in a 0.7500-L flask at 300.0 °C using the van der Waals equation and then repeat the calculation using the ideal-gas equation. Within the limits of the significant figures justified by these parameters, will the ideal-gas equation overestimate or underestimate the pressure, and if so by how much?

- (a) Underestimate by 17.92 atm    (b) Overestimate by 21.87 atm  
(c) Underestimate by 0.06 atm    (d) Overestimate by 0.06 atm

#### Practice Exercise 2

A sample of 1.000 mol of CO<sub>2</sub>(g) is confined to a 3.000-L container at 0.000 °C. Calculate the pressure of the gas using (a) the ideal-gas equation and (b) the van der Waals equation.

## Sample Integrative Exercise

### Putting Concepts Together

Cyanogen, a highly toxic gas, is 46.2% C and 53.8% N by mass. At 25 °C and 751 torr, 1.05 g of cyanogen occupies 0.500 L. (a) What is the molecular formula of cyanogen? Predict (b) its molecular structure and (c) its polarity.

### SOLUTION

**Analyze** We need to determine the molecular formula of a gas from elemental analysis data and data on its properties. Then we need to predict the structure of the molecule and from that, its polarity.

- (a) **Plan** We can use the percentage composition of the compound to calculate its empirical formula. [∞∞ \(Section 3.5\)](#) Then we can determine the molecular formula by comparing the mass of the empirical formula with the molar mass. [∞∞ \(Section 3.5\)](#)

**Solve** To determine the empirical formula, we assume we have a 100-g sample and calculate the number of moles of each element in the sample:

$$\text{Moles C} = (46.2 \text{ g C}) \left( \frac{1 \text{ mol C}}{12.01 \text{ g C}} \right) = 3.85 \text{ mol C}$$

$$\text{Moles N} = (53.8 \text{ g N}) \left( \frac{1 \text{ mol N}}{14.01 \text{ g N}} \right) = 3.84 \text{ mol N}$$

Because the ratio of the moles of the two elements is essentially 1:1, the empirical formula is CN. To determine the molar mass, we use Equation 10.11.

$$\begin{aligned} \mathcal{M} &= \frac{dRT}{P} = \frac{(1.05 \text{ g}/0.500 \text{ L})(0.08206 \text{ L}\cdot\text{atm}/\text{mol}\cdot\text{K})(298 \text{ K})}{(751/760) \text{ atm}} \\ &= 52.0 \text{ g/mol} \end{aligned}$$

The molar mass associated with the empirical formula CN is  $12.0 + 14.0 = 26.0 \text{ g/mol}$ . Dividing the molar mass by that of its

empirical formula gives  $(52.0 \text{ g/mol})/(26.0 \text{ g/mol}) = 2.00$ . Thus, the molecule has twice as many atoms of each element as the empirical formula, giving the molecular formula  $\text{C}_2\text{N}_2$ .

- (b) **Plan** To determine the molecular structure, we must determine the Lewis structure. [∞∞ \(Section 8.5\)](#) We can then use the VSEPR model to predict the structure. [∞∞ \(Section 9.2\)](#)

**Solve** The molecule has  $2(4) + 2(5) = 18$  valence-shell electrons. By trial and error, we seek a Lewis structure with 18 valence electrons in which each atom has an octet and the formal charges are as low as possible. The structure

meets these criteria. (This structure has zero formal charge on each atom.)

The Lewis structure shows that each atom has two electron domains. (Each nitrogen has a nonbonding pair of electrons and a triple bond, whereas each carbon has a triple bond and a single bond.) Thus, the electron-domain geometry around each atom is linear, causing the overall molecule to be linear.

- (c) **Plan** To determine the polarity of the molecule, we must examine the polarity of the individual bonds and the overall geometry of the molecule.

**Solve** Because the molecule is linear, we expect the two dipoles created by the polarity in the carbon–nitrogen bond to cancel each other, leaving the molecule with no dipole moment.

## Chapter Summary and Key Terms

**CHARACTERISTICS OF GASES (SECTION 10.1)** Substances that are gases at room temperature tend to be molecular substances with low molar masses. Air, a mixture composed mainly of  $\text{N}_2$  and  $\text{O}_2$ , is the most common gas we encounter. Some liquids and solids can also exist in the gaseous state, where they are known as **vapors**. Gases are compressible; they mix in all proportions because their component molecules are far apart from each other.

**PRESSURE (SECTION 10.2)** To describe the state or condition of a gas, we must specify four variables: pressure ( $P$ ), volume ( $V$ ), temperature ( $T$ ), and quantity ( $n$ ). Volume is usually measured in liters, temperature in kelvins, and quantity of gas in moles. **Pressure** is the force per unit area and is expressed in SI units as **pascals**, Pa ( $1 \text{ Pa} = 1 \text{ N/m}^2$ ). A related unit, the **bar**, equals  $10^5 \text{ Pa}$ . In chemistry, **standard atmospheric pressure** is used to define the **atmosphere** (atm) and the **torr** (also called the millimeter of mercury). One atmosphere of pressure equals 101.325 kPa, or 760 torr. A barometer is often used to measure the atmospheric pressure. A manometer can be used to measure the pressure of enclosed gases.

**THE GAS LAWS (SECTION 10.3)** Studies have revealed several simple gas laws: For a constant quantity of gas at constant temperature, the volume of the gas is inversely proportional to the pressure (**Boyle's law**). For a fixed quantity of gas at constant pressure, the volume is directly proportional to its absolute temperature (**Charles's law**). Equal volumes of gases at the same temperature and pressure contain equal numbers of molecules (**Avogadro's hypothesis**). For a gas at constant

temperature and pressure, the volume of the gas is directly proportional to the number of moles of gas (**Avogadro's law**). Each of these gas laws is a special case of the ideal-gas equation.

**THE IDEAL-GAS EQUATION (SECTIONS 10.4 AND 10.5)** The **ideal-gas equation**,  $PV = nRT$ , is the equation of state for an **ideal gas**. The term  $R$  in this equation is the **gas constant**. We can use the ideal-gas equation to calculate variations in one variable when one or more of the others are changed. Most gases at pressures less than 10 atm and temperatures near 273 K and above obey the ideal-gas equation reasonably well. The conditions of 273 K ( $0^\circ\text{C}$ ) and 1 atm are known as the **standard temperature and pressure (STP)**. In all applications of the ideal-gas equation, we must remember to convert temperatures to the absolute-temperature scale (the kelvin scale).

Using the ideal-gas equation, we can relate the density of a gas to its molar mass:  $\mathcal{M} = dRT/P$ . We can also use the ideal-gas equation to solve problems involving gases as reactants or products in chemical reactions.

**GAS MIXTURES AND PARTIAL PRESSURES (SECTION 10.6)** In gas mixtures, the total pressure is the sum of the **partial pressures** that each gas would exert if it were present alone under the same conditions (**Dalton's law of partial pressures**). The partial pressure of a component of a mixture is equal to its mole fraction times the total pressure:  $P_1 = X_1P$ . The **mole fraction**  $X$  is the ratio of the moles of one component of a mixture to the total moles of all components.

**THE KINETIC-MOLECULAR THEORY OF GASES (SECTION 10.7)** The kinetic-molecular theory of gases accounts for the properties of an ideal gas in terms of a set of statements about the nature of gases. Briefly, these statements are as follows: Molecules are in continuous chaotic motion. The volume of gas molecules is negligible compared to the volume of their container. The gas molecules neither attract nor repel each other. The average kinetic energy of the gas molecules is proportional to the absolute temperature and does not change if the temperature remains constant.

The individual molecules of a gas do not all have the same kinetic energy at a given instant. Their speeds are distributed over a wide range; the distribution varies with the molar mass of the gas and with temperature. The **root-mean-square (rms) speed**,  $u_{\text{rms}}$ , varies in proportion to the square root of the absolute temperature and inversely with the square root of the molar mass:  $u_{\text{rms}} = \sqrt{3RT/\mathcal{M}}$ . The most probable speed of a gas molecule is given by  $u_{\text{mp}} = \sqrt{2RT/\mathcal{M}}$ .

**MOLECULAR EFFUSION AND DIFFUSION (SECTION 10.8)** It follows from kinetic-molecular theory that the rate at which a gas undergoes

**effusion** (escapes through a tiny hole) is inversely proportional to the square root of its molar mass (**Graham's law**). The **diffusion** of one gas through the space occupied by a second gas is another phenomenon related to the speeds at which molecules move. Because moving molecules undergo frequent collisions with one another, the **mean free path**—the mean distance traveled between collisions—is short. Collisions between molecules limit the rate at which a gas molecule can diffuse.

### REAL GASES: DEVIATIONS FROM IDEAL BEHAVIOR (SECTION 10.9)

Departures from ideal behavior increase in magnitude as pressure increases and as temperature decreases. Real gases depart from ideal behavior because (1) the molecules possess finite volume and (2) the molecules experience attractive forces for one another. These two effects make the volumes of real gases larger and their pressures smaller than those of an ideal gas. The **van der Waals equation** is an equation of state for gases, which modifies the ideal-gas equation to account for intrinsic molecular volume and intermolecular forces.

## Learning Outcomes After studying this chapter, you should be able to:

- Calculate pressure and convert between pressure units with an emphasis on torr and atmospheres. (Section 10.2)  
*Related Exercises: 10.15, 10.17, 10.19, 10.21*
- Calculate  $P$ ,  $V$ ,  $n$ , or  $T$  using the ideal-gas equation. (Section 10.4)  
*Related Exercises: 10.33, 10.39, 10.43*
- Explain how the gas laws relate to the ideal-gas equation and apply the gas laws in calculations. (Sections 10.3 and 10.4)  
*Related Exercises: 10.25, 10.39, 10.41*
- Calculate the density or molecular weight of a gas. (Section 10.5)  
*Related Exercises: 10.47, 10.51, 10.53*
- Calculate the volume of gas consumed or formed in a chemical reaction. (Section 10.5) *Related Exercises: 10.55, 10.57*
- Calculate the total pressure of a gas mixture given its partial pressures or given information for calculating partial pressures. (Section 10.6) *Related Exercises: 10.7, 10.61, 10.63*
- Describe the kinetic-molecular theory of gases and how it explains the pressure and temperature of a gas, the gas laws, and the rates of effusion and diffusion. (Sections 10.7 and 10.8)  
*Related Exercises: 10.9, 10.75, 10.79, 10.85*
- Explain why intermolecular attractions and molecular volumes cause real gases to deviate from ideal behavior at high pressure or low temperature. (Section 10.9)  
*Related Exercises: 10.89, 10.91, 10.114*

## Key Equations

- $PV = nRT$  [10.5] Ideal-gas equation
- $\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2}$  [10.8] The combined gas law, showing how  $P$ ,  $V$ , and  $T$  are related for a constant  $n$
- $d = \frac{P\mathcal{M}}{RT}$  [10.10] Density or molar mass of a gas
- $P_t = P_1 + P_2 + P_3 + \dots$  [10.12] Relating the total pressure of a gas mixture to the partial pressures of its components (Dalton's law of partial pressures)
- $P_1 = \left(\frac{n_1}{n_t}\right) P_t = X_1 P_t$  [10.16] Relating partial pressure to mole fraction
- $u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}}$  [10.20] Definition of the root-mean-square (rms) speed of gas molecules
- $\frac{r_1}{r_2} = \sqrt{\frac{\mathcal{M}_2}{\mathcal{M}_1}}$  [10.22] Relating the relative rates of effusion of two gases to their molar masses
- $\left(P + \frac{n^2 a}{V^2}\right)(V - nb) = nRT$  [10.25] The van der Waals equation

## Exercises

### Visualizing Concepts

- 10.1** Mars has an average atmospheric pressure of 0.007 atm. Would it be easier or harder to drink from a straw on Mars than on Earth? Explain. [Section 10.2]

- 10.2** You have a sample of gas in a container with a movable piston, such as the one in the drawing. (a) Redraw the container to show what it might look like if the temperature of the gas is increased from 300 to 500 K while the pressure is kept constant. (b) Redraw the container to show what it might look

like if the external pressure on the piston is increased from 1.0 atm to 2.0 atm while the temperature is kept constant. (c) Redraw the container to show what it might look like if the temperature of the gas decreases from 300 to 200 K while the pressure is kept constant (assume the gas does not liquefy). [Section 10.3]

- 10.3** Consider the sample of gas depicted here. What would the drawing look like if the volume and temperature remained constant while you removed enough of the gas to decrease the pressure by a factor of 2? [Section 10.3]
- (a) It would contain the same number of molecules.  
 (b) It would contain half as many molecules.  
 (c) It would contain twice as many molecules.  
 (d) There is insufficient data to say.

- 10.4** Imagine that the reaction  $2\text{CO}(g) + \text{O}_2(g) \longrightarrow 2\text{CO}_2(g)$  occurs in a container that has a piston that moves to maintain a constant pressure when the reaction occurs at constant temperature. Which of the following statements describes how the volume of the container changes due to the reaction: (a) the volume increases by 50%, (b) the volume increases by 33%, (c) the volume remains constant, (d) the volume decreases by 33%, (e) the volume decreases by 50%. [Sections 10.3 and 10.4]
- 10.5** Suppose you have a fixed amount of an ideal gas at a constant volume. If the pressure of the gas is doubled while the volume is held constant, what happens to its temperature? [Section 10.4]
- 10.6** The apparatus shown here has two gas-filled containers and one empty container, all attached to a hollow horizontal tube. When the valves are opened and the gases are allowed to mix at constant temperature, what is the distribution of atoms in each container? Assume that the containers are of equal volume and ignore the volume of the connecting tube. Which gas has the greater partial pressure after the valves are opened? [Section 10.6]

- 10.7** The accompanying drawing represents a mixture of three different gases. (a) Rank the three components in order of increasing partial pressure. (b) If the total pressure of the mixture is 1.40 atm, calculate the partial pressure of each gas. [Section 10.6]

- 10.8** On a single plot, qualitatively sketch the distribution of molecular speeds for (a) Kr(g) at  $-50^\circ\text{C}$ , (b) Kr(g) at  $0^\circ\text{C}$ , (c) Ar(g) at  $0^\circ\text{C}$ . [Section 10.7]
- 10.9** Consider the following graph. (a) If curves A and B refer to two different gases, He and  $\text{O}_2$ , at the same temperature, which curve corresponds to He? (b) If A and B refer to the same gas at two different temperatures, which represents the higher temperature? (c) For each curve, which speed is highest: the most probable speed, the root-mean-square speed, or the average speed? [Section 10.7]

- 10.10** Consider the following samples of gases:

If the three samples are all at the same temperature, rank them with respect to (a) total pressure, (b) partial pressure of helium, (c) density, (d) average kinetic energy of particles. [Sections 10.6 and 10.7]

- 10.11** A thin glass tube 1 m long is filled with Ar gas at 1 atm, and the ends are stoppered with cotton plugs as shown below. HCl gas is introduced at one end of the tube, and simultaneously  $\text{NH}_3$  gas is introduced at the other end. When the two gases diffuse through the cotton plugs down the tube and meet, a white ring appears due to the formation of  $\text{NH}_4\text{Cl}(s)$ . At which location—a, b, or c—do you expect the ring to form? [Section 10.8]

- 10.12** The graph below shows the change in pressure as the temperature increases for a 1-mol sample of a gas confined to a 1-L container. The four plots correspond to an ideal gas and three real gases:  $\text{CO}_2$ ,  $\text{N}_2$ , and  $\text{Cl}_2$ . (a) At room temperature, all three real gases have a pressure less than the ideal gas. Which van der Waals constant,  $a$  or  $b$ , accounts for the influence intermolecular forces have in lowering the pressure of a real gas? (b) Use the van der Waals constants in Table 10.3 to match the labels in the plot (A, B, and C) with the respective gases ( $\text{CO}_2$ ,  $\text{N}_2$ , and  $\text{Cl}_2$ ). [Section 10.9]

### Gas Characteristics; Pressure (Sections 10.1 and 10.2)

- 10.13** Which of the following statements is false?
- Gases are far less dense than liquids.
  - Gases are far more compressible than liquids.
  - Because liquid water and liquid carbon tetrachloride do not mix, neither do their vapors.
  - The volume occupied by a gas is determined by the volume of its container.
- 10.14** (a) Are you more likely to see the density of a gas reported in g/mL, g/L, or kg/cm<sup>3</sup>? (b) Which units are appropriate for expressing atmospheric pressures, N, Pa, atm, kg/m<sup>2</sup>? (c) Which is most likely to be a gas at room temperature and ordinary atmospheric pressure,  $\text{F}_2$ ,  $\text{Br}_2$ ,  $\text{K}_2\text{O}$ .
- 10.15** Suppose that a woman weighing 130 lb and wearing high-heeled shoes momentarily places all her weight on the heel of one foot. If the area of the heel is 0.50 in.<sup>2</sup>, calculate the pressure exerted on the underlying surface in (a) pounds per square inch, (b) kilopascals, and (c) atmospheres.
- 10.16** A set of bookshelves rests on a hard floor surface on four legs, each having a cross-sectional dimension of  $3.0 \times 4.1$  cm in contact with the floor. The total mass of the shelves plus the books stacked on them is 262 kg. Calculate the pressure in pascals exerted by the shelf footings on the surface.
- 10.17** (a) How high in meters must a column of glycerol be to exert a pressure equal to that of a 760-mm column of mercury? The density of glycerol is 1.26 g/mL, whereas that of mercury is 13.6 g/mL. (b) What pressure, in atmospheres, is exerted on the body of a diver if she is 15 ft below the surface of the water when the atmospheric pressure is 750 torr? Assume that the density of the water is 1.00 g/cm<sup>3</sup> =  $1.00 \times 10^3$  kg/m<sup>3</sup>. The gravitational constant is 9.81 m/s<sup>2</sup>, and 1 Pa = 1 kg/m·s<sup>2</sup>.
- 10.18** (a) The compound 1-iodododecane is a nonvolatile liquid with a density of 1.20 g/mL. The density of mercury is 13.6 g/mL. What do you predict for the height of a barometer column based on 1-iodododecane, when the atmospheric pressure is 749 torr? (b) What is the pressure, in atmospheres, on the body of a diver if he is 21 ft below the surface of the water when the atmospheric pressure is 742 torr?
- 10.19** The typical atmospheric pressure on top of Mount Everest (29,028 ft) is about 265 torr. Convert this pressure to (a) atm, (b) mm Hg, (c) pascals, (d) bars, (e) psi.
- 10.20** Perform the following conversions: (a) 0.912 atm to torr, (b) 0.685 bar to kilopascals, (c) 655 mm Hg to atmospheres, (d)  $1.323 \times 10^5$  Pa to atmospheres, (e) 2.50 atm to psi.
- 10.21** In the United States, barometric pressures are generally reported in inches of mercury (in. Hg). On a beautiful summer day in Chicago, the barometric pressure is 30.45 in. Hg. (a) Convert this pressure to torr. (b) Convert this pressure to atm.
- 10.22** Hurricane Wilma of 2005 is the most intense hurricane on record in the Atlantic basin, with a low-pressure reading of 882 mbar (millibars). Convert this reading into (a) atmospheres, (b) torr, and (c) inches of Hg.
- 10.23** If the atmospheric pressure is 0.995 atm, what is the pressure of the enclosed gas in each of the three cases depicted in the drawing? Assume that the gray liquid is mercury.

- 10.24** An open-end manometer containing mercury is connected to a container of gas, as depicted in Sample Exercise 10.2. What is the pressure of the enclosed gas in torr in each of the following situations? (a) The mercury in the arm attached to the gas is 15.4 mm higher than in the one open to the atmosphere; atmospheric pressure is 0.985 atm. (b) The mercury in the arm attached to the gas is 12.3 mm lower than in the one open to the atmosphere; atmospheric pressure is 0.99 atm.

### The Gas Laws (Section 10.3)

- 10.25** You have a gas at 25 °C confined to a cylinder with a movable piston. Which of the following actions would double the gas pressure? (a) Lifting up on the piston to double the volume while keeping the temperature constant; (b) Heating the gas so that its temperature rises from 25 °C to 50 °C, while keeping the volume constant; (c) Pushing down on the piston to halve the volume while keeping the temperature constant.
- 10.26** A fixed quantity of gas at 21 °C exhibits a pressure of 752 torr and occupies a volume of 5.12 L. (a) Calculate the volume the gas will occupy if the pressure is increased to 1.88

atm while the temperature is held constant. **(b)** Calculate the volume the gas will occupy if the temperature is increased to 175 °C while the pressure is held constant.

- 10.27** **(a)** Amonton's law expresses the relationship between pressure and temperature. Use Charles's law and Boyle's law to derive the proportionality relationship between  $P$  and  $T$ . **(b)** If a car tire is filled to a pressure of 32.0 lb/in.<sup>2</sup> (psi) measured at 75 °F, what will be the tire pressure if the tires heat up to 120 °F during driving?

- 10.28** Nitrogen and hydrogen gases react to form ammonia gas as follows:

At a certain temperature and pressure, 1.2 L of  $\text{N}_2$  reacts with 3.6 L of  $\text{H}_2$ . If all the  $\text{N}_2$  and  $\text{H}_2$  are consumed, what volume of  $\text{NH}_3$ , at the same temperature and pressure, will be produced?

### The Ideal-Gas Equation (Section 10.4)

- 10.29** **(a)** What conditions are represented by the abbreviation STP? **(b)** What is the molar volume of an ideal gas at STP? **(c)** Room temperature is often assumed to be 25 °C. Calculate the molar volume of an ideal gas at 25 °C and 1 atm pressure. **(d)** If you measure pressure in bars instead of atmospheres, calculate the corresponding value of  $R$  in L-bar/mol-K.

- 10.30** To derive the ideal-gas equation, we assume that the volume of the gas atoms/molecules can be neglected. Given the atomic radius of neon, 0.69 Å, and knowing that a sphere has a volume of  $4\pi r^3/3$ , calculate the fraction of space that Ne atoms occupy in a sample of neon at STP.

- 10.31** Suppose you are given two 1-L flasks and told that one contains a gas of molar mass 30, the other a gas of molar mass 60, both at the same temperature. The pressure in flask A is  $x$  atm, and the mass of gas in the flask is 1.2 g. The pressure in flask B is 0.5 $x$  atm, and the mass of gas in that flask is 1.2 g. Which flask contains the gas of molar mass 30, and which contains the gas of molar mass 60?

- 10.32** Suppose you are given two flasks at the same temperature, one of volume 2 L and the other of volume 3 L. The 2-L flask contains 4.8 g of gas, and the gas pressure is  $x$  atm. The 3-L flask contains 0.36 g of gas, and the gas pressure is 0.1 $x$ . Do the two gases have the same molar mass? If not, which contains the gas of higher molar mass?

- 10.33** Complete the following table for an ideal gas:

| $P$       | $V$     | $n$       | $T$   |
|-----------|---------|-----------|-------|
| 2.00 atm  | 1.00 L  | 0.500 mol | ? K   |
| 0.300 atm | 0.250 L | ? mol     | 27 °C |
| 650 torr  | ? L     | 0.333 mol | 350 K |
| ? atm     | 585 mL  | 0.250 mol | 295 K |

- 10.34** Calculate each of the following quantities for an ideal gas: **(a)** the volume of the gas, in liters, if 1.50 mol has a pressure of 1.25 atm at a temperature of -6 °C; **(b)** the absolute temperature of the gas at which  $3.33 \times 10^{-3}$  mol occupies 478 mL at 750 torr; **(c)** the pressure, in atmospheres, if 0.00245 mol occupies 413 mL at 138 °C; **(d)** the quantity of gas, in moles, if 126.5 L at 54 °C has a pressure of 11.25 kPa.

- 10.35** The Goodyear blimps, which frequently fly over sporting events, hold approximately 175,000 ft<sup>3</sup> of helium. If the gas is at 23 °C and 1.0 atm, what mass of helium is in a blimp?

- 10.36** A neon sign is made of glass tubing whose inside diameter is 2.5 cm and whose length is 5.5 m. If the sign contains neon at a pressure of 1.78 torr at 35 °C, how many grams of neon are in the sign? (The volume of a cylinder is  $\pi r^2 h$ .)

- 10.37** **(a)** Calculate the number of molecules in a deep breath of air whose volume is 2.25 L at body temperature, 37 °C, and a pressure of 735 torr. **(b)** The adult blue whale has a lung capacity of  $5.0 \times 10^3$  L. Calculate the mass of air (assume an average molar mass of 28.98 g/mol) contained in an adult blue whale's lungs at 0.0 °C and 1.00 atm, assuming the air behaves ideally.

- 10.38** **(a)** If the pressure exerted by ozone,  $\text{O}_3$ , in the stratosphere is  $3.0 \times 10^{-3}$  atm and the temperature is 250 K, how many ozone molecules are in a liter? **(b)** Carbon dioxide makes up approximately 0.04% of Earth's atmosphere. If you collect a 2.0-L sample from the atmosphere at sea level (1.00 atm) on a warm day (27 °C), how many  $\text{CO}_2$  molecules are in your sample?

- 10.39** A scuba diver's tank contains 0.29 kg of  $\text{O}_2$  compressed into a volume of 2.3 L. **(a)** Calculate the gas pressure inside the tank at 9 °C. **(b)** What volume would this oxygen occupy at 26 °C and 0.95 atm?

- 10.40** An aerosol spray can with a volume of 250 mL contains 2.30 g of propane gas ( $\text{C}_3\text{H}_8$ ) as a propellant. **(a)** If the can is at 23 °C, what is the pressure in the can? **(b)** What volume would the propane occupy at STP? **(c)** The can's label says that exposure to temperatures above 130 °F may cause the can to burst. What is the pressure in the can at this temperature?

- 10.41** A 35.1 g sample of solid  $\text{CO}_2$  (dry ice) is added to a container at a temperature of 100 K with a volume of 4.0 L. If the container is evacuated (all of the gas removed), sealed and then allowed to warm to room temperature ( $T = 298$  K) so that all of the solid  $\text{CO}_2$  is converted to a gas, what is the pressure inside the container?

- 10.42** A 334-mL cylinder for use in chemistry lectures contains 5.225 g of helium at 23 °C. How many grams of helium must be released to reduce the pressure to 75 atm assuming ideal gas behavior?

- 10.43** Chlorine is widely used to purify municipal water supplies and to treat swimming pool waters. Suppose that the volume of a particular sample of  $\text{Cl}_2$  gas is 8.70 L at 895 torr and 24 °C. **(a)** How many grams of  $\text{Cl}_2$  are in the sample? **(b)** What volume will the  $\text{Cl}_2$  occupy at STP? **(c)** At what temperature will the volume be 15.00 L if the pressure is  $8.76 \times 10^2$  torr? **(d)** At what pressure will the volume equal 5.00 L if the temperature is 58 °C?

- 10.44** Many gases are shipped in high-pressure containers. Consider a steel tank whose volume is 55.0 gallons that contains  $\text{O}_2$  gas at a pressure of 16,500 kPa at 23 °C. **(a)** What mass of  $\text{O}_2$  does the tank contain? **(b)** What volume would the gas occupy at STP? **(c)** At what temperature would the pressure in the tank equal 150.0 atm? **(d)** What would be the pressure of the gas, in kPa, if it were transferred to a container at 24 °C whose volume is 55.0 L?

- 10.45** In an experiment reported in the scientific literature, male cockroaches were made to run at different speeds on a miniature treadmill while their oxygen consumption was measured. In 1 hr the average cockroach running at 0.08 km/hr consumed 0.8 mL of  $\text{O}_2$  at 1 atm pressure and 24 °C per gram of insect mass. **(a)** How many moles of  $\text{O}_2$  would be consumed in 1 hr by a 5.2-g cockroach moving at this speed? **(b)** This same cockroach is caught by a child and placed in a 1-qt fruit jar with a tight lid. Assuming the same level of continuous activity as in the research, will the cockroach consume more than 20% of the available  $\text{O}_2$  in a 48-hr period? (Air is 21 mol%  $\text{O}_2$ .)

- 10.46** The physical fitness of athletes is measured by “ $V_{O_2}$  max,” which is the maximum volume of oxygen consumed by an individual during incremental exercise (for example, on a treadmill). An average male has a  $V_{O_2}$  max of 45 mL  $O_2$ /kg body mass/min, but a world-class male athlete can have a  $V_{O_2}$  max reading of 88.0 mL  $O_2$ /kg body mass/min. (a) Calculate the volume of oxygen, in mL, consumed in 1 hr by an average man who weighs 185 lbs and has a  $V_{O_2}$  max reading of 47.5 mL  $O_2$ /kg body mass/min. (b) If this man lost 20 lb, exercised, and increased his  $V_{O_2}$  max to 65.0 mL  $O_2$ /kg body mass/min, how many mL of oxygen would he consume in 1 hr?

### Further Applications of the Ideal-Gas Equation (Section 10.5)

- 10.47** Rank the following gases from least dense to most dense at 1.00 atm and 298 K:  $CO$ ,  $N_2O$ ,  $Cl_2$ ,  $HF$ .

- 10.48** Rank the following gases from least dense to most dense at 1.00 atm and 298 K:  $SO_2$ ,  $HBr$ ,  $CO_2$ .

- 10.49** Which of the following statements best explains why a closed balloon filled with helium gas rises in air?

- Helium is a monatomic gas, whereas nearly all the molecules that make up air, such as nitrogen and oxygen, are diatomic.
- The average speed of helium atoms is greater than the average speed of air molecules, and the greater speed of collisions with the balloon walls propels the balloon upward.
- Because the helium atoms are of lower mass than the average air molecule, the helium gas is less dense than air. The mass of the balloon is thus less than the mass of the air displaced by its volume.
- Because helium has a lower molar mass than the average air molecule, the helium atoms are in faster motion. This means that the temperature of the helium is greater than the air temperature. Hot gases tend to rise.

- 10.50** Which of the following statements best explains why nitrogen gas at STP is less dense than Xe gas at STP?

- Because Xe is a noble gas, there is less tendency for the Xe atoms to repel one another, so they pack more densely in the gaseous state.
- Xe atoms have a higher mass than  $N_2$  molecules. Because both gases at STP have the same number of molecules per unit volume, the Xe gas must be denser.
- The Xe atoms are larger than  $N_2$  molecules and thus take up a larger fraction of the space occupied by the gas.
- Because the Xe atoms are much more massive than the  $N_2$  molecules, they move more slowly and thus exert less upward force on the gas container and make the gas appear denser.

- 10.51** (a) Calculate the density of  $NO_2$  gas at 0.970 atm and 35 °C. (b) Calculate the molar mass of a gas if 2.50 g occupies 0.875 L at 685 torr and 35 °C.

- 10.52** (a) Calculate the density of sulfur hexafluoride gas at 707 torr and 21 °C. (b) Calculate the molar mass of a vapor that has a density of 7.135 g/L at 12 °C and 743 torr.

- 10.53** In the Dumas-bulb technique for determining the molar mass of an unknown liquid, you vaporize the sample of a liquid that boils below 100 °C in a boiling-water bath and determine the mass of vapor required to fill the bulb. From the following data, calculate the molar mass of the unknown liquid: mass of unknown vapor, 1.012 g; volume of bulb, 354 cm<sup>3</sup>; pressure, 742 torr; temperature, 99 °C.

- 10.54** The molar mass of a volatile substance was determined by the Dumas-bulb method described in Exercise 10.53. The unknown vapor had a mass of 0.846 g; the volume of the bulb was 354 cm<sup>3</sup>, pressure 752 torr, and temperature 100 °C. Calculate the molar mass of the unknown vapor.

- 10.55** Magnesium can be used as a “getter” in evacuated enclosures to react with the last traces of oxygen. (The magnesium is usually heated by passing an electric current through a wire or ribbon of the metal.) If an enclosure of 0.452 L has a partial pressure of  $O_2$  of  $3.5 \times 10^{-6}$  torr at 27 °C, what mass of magnesium will react according to the following equation?

- 10.56** Calcium hydride,  $CaH_2$ , reacts with water to form hydrogen gas:

This reaction is sometimes used to inflate life rafts, weather balloons, and the like, when a simple, compact means of generating  $H_2$  is desired. How many grams of  $CaH_2$  are needed to generate 145 L of  $H_2$  gas if the pressure of  $H_2$  is 825 torr at 21 °C?

- 10.57** The metabolic oxidation of glucose,  $C_6H_{12}O_6$ , in our bodies produces  $CO_2$ , which is expelled from our lungs as a gas:

(a) Calculate the volume of dry  $CO_2$  produced at body temperature (37 °C) and 0.970 atm when 24.5 g of glucose is consumed in this reaction. (b) Calculate the volume of oxygen you would need, at 1.00 atm and 298 K, to completely oxidize 50.0 g of glucose.

- 10.58** Both Jacques Charles and Joseph Louis Guy-Lussac were avid balloonists. In his original flight in 1783, Jacques Charles used a balloon that contained approximately 31,150 L of  $H_2$ . He generated the  $H_2$  using the reaction between iron and hydrochloric acid:

How many kilograms of iron were needed to produce this volume of  $H_2$  if the temperature was 22 °C?

- 10.59** Hydrogen gas is produced when zinc reacts with sulfuric acid:

If 159 mL of wet  $H_2$  is collected over water at 24 °C and a barometric pressure of 738 torr, how many grams of Zn have been consumed? (The vapor pressure of water is tabulated in Appendix B.)

- 10.60** Acetylene gas,  $C_2H_2(g)$ , can be prepared by the reaction of calcium carbide with water:

Calculate the volume of  $\text{C}_2\text{H}_2$  that is collected over water at  $23^\circ\text{C}$  by reaction of 1.524 g of  $\text{CaC}_2$  if the total pressure of the gas is 753 torr. (The vapor pressure of water is tabulated in Appendix B.)

### Partial Pressures (Section 10.6)

- 10.61** Consider the apparatus shown in the following drawing. (a) When the valve between the two containers is opened and the gases are allowed to mix, how does the volume occupied by the  $\text{N}_2$  gas change? What is the partial pressure of  $\text{N}_2$  after mixing? (b) How does the volume of the  $\text{O}_2$  gas change when the gases mix? What is the partial pressure of  $\text{O}_2$  in the mixture? (c) What is the total pressure in the container after the gases mix?

- 10.62** Consider a mixture of two gases, A and B, confined in a closed vessel. A quantity of a third gas, C, is added to the same vessel at the same temperature. How does the addition of gas C affect the following: (a) the partial pressure of gas A, (b) the total pressure in the vessel, (c) the mole fraction of gas B?
- 10.63** A mixture containing 0.765 mol  $\text{He(g)}$ , 0.330 mol  $\text{Ne(g)}$ , and 0.110 mol  $\text{Ar(g)}$  is confined in a 10.00-L vessel at  $25^\circ\text{C}$ . (a) Calculate the partial pressure of each of the gases in the mixture. (b) Calculate the total pressure of the mixture.
- 10.64** A deep-sea diver uses a gas cylinder with a volume of 10.0 L and a content of 51.2 g of  $\text{O}_2$  and 32.6 g of  $\text{He}$ . Calculate the partial pressure of each gas and the total pressure if the temperature of the gas is  $19^\circ\text{C}$ .
- 10.65** The atmospheric concentration of  $\text{CO}_2$  gas is presently 407 ppm (parts per million, by volume; that is, 407 L of every  $10^6$  L of the atmosphere are  $\text{CO}_2$ ). What is the mole fraction of  $\text{CO}_2$  in the atmosphere?
- 10.66** A plasma-screen TV contains thousands of tiny cells filled with a mixture of  $\text{Xe}$ ,  $\text{Ne}$ , and  $\text{He}$  gases that emits light of specific wavelengths when a voltage is applied. A particular plasma cell,  $0.900\text{ mm} \times 0.300\text{ mm} \times 10.0\text{ mm}$ , contains 4%  $\text{Xe}$  in a 1:1  $\text{Ne}:\text{He}$  mixture at a total pressure of 500 torr. Calculate the number of  $\text{Xe}$ ,  $\text{Ne}$ , and  $\text{He}$  atoms in the cell and state the assumptions you need to make in your calculation.
- 10.67** A piece of dry ice (solid carbon dioxide) with a mass of 5.50 g is placed in a 10.0-L vessel that already contains air at 705 torr and  $24^\circ\text{C}$ . After the carbon dioxide has totally sublimed, what is the partial pressure of the resultant  $\text{CO}_2$  gas, and the total pressure in the container at  $24^\circ\text{C}$ ?
- 10.68** A sample of 5.00 mL of diethylether ( $\text{C}_2\text{H}_5\text{OC}_2\text{H}_5$ , density =  $0.7134\text{ g/mL}$ ) is introduced into a 6.00-L vessel that already contains a mixture of  $\text{N}_2$  and  $\text{O}_2$ , whose partial pressures are  $P_{\text{N}_2} = 0.751\text{ atm}$  and  $P_{\text{O}_2} = 0.208\text{ atm}$ . The temperature is held at  $35.0^\circ\text{C}$ , and the diethylether totally evaporates. (a) Calculate the partial pressure of the diethylether. (b) Calculate the total pressure in the container.
- 10.69** A rigid vessel containing a 3:1 mol ratio of carbon dioxide and water vapor is held at  $200^\circ\text{C}$  where it has a total pressure of 2.00 atm. If the vessel is cooled to  $10^\circ\text{C}$  so that all of the water vapor condenses, what is the pressure of carbon dioxide? Neglect the volume of the liquid water that forms on cooling.
- 10.70** If 5.15 g of  $\text{Ag}_2\text{O}$  is sealed in a 75.0-mL tube filled with 760 torr of  $\text{N}_2$  gas at  $32^\circ\text{C}$ , and the tube is heated to  $320^\circ\text{C}$ , the  $\text{Ag}_2\text{O}$  decomposes to form oxygen and silver. What is the total pressure inside the tube assuming the volume of the tube remains constant?
- 10.71** At an underwater depth of 250 ft, the pressure is 8.38 atm. What should the mole percent of oxygen be in the diving gas for the partial pressure of oxygen in the mixture to be 0.21 atm, the same as in air at 1 atm?
- 10.72** (a) What are the mole fractions of each component in a mixture of 15.08 g of  $\text{O}_2$ , 8.17 g of  $\text{N}_2$ , and 2.64 g of  $\text{H}_2$ ? (b) What is the partial pressure in atm of each component of this mixture if it is held in a 15.50-L vessel at  $15^\circ\text{C}$ ?
- 10.73** A quantity of  $\text{N}_2$  gas originally held at 5.25 atm pressure in a 1.00-L container at  $26^\circ\text{C}$  is transferred to a 12.5-L container at  $20^\circ\text{C}$ . A quantity of  $\text{O}_2$  gas originally at 5.25 atm and  $26^\circ\text{C}$  in a 5.00-L container is transferred to this same container. What is the total pressure in the new container?
- 10.74** A sample of 3.00 g of  $\text{SO}_2(\text{g})$  originally in a 5.00-L vessel at  $21^\circ\text{C}$  is transferred to a 10.0-L vessel at  $26^\circ\text{C}$ . A sample of 2.35 g of  $\text{N}_2(\text{g})$  originally in a 2.50-L vessel at  $20^\circ\text{C}$  is transferred to this same 10.0-L vessel. (a) What is the partial pressure of  $\text{SO}_2(\text{g})$  in the larger container? (b) What is the partial pressure of  $\text{N}_2(\text{g})$  in this vessel? (c) What is the total pressure in the vessel?

### Kinetic-Molecular Theory of Gases; Effusion and Diffusion (Sections 10.7 and 10.8)

- 10.75** Determine whether each of the following changes will increase, decrease, or not affect the rate with which gas molecules collide with the walls of their container: (a) increasing the volume of the container, (b) increasing the temperature, (c) increasing the molar mass of the gas.
- 10.76** Indicate which of the following statements regarding the kinetic-molecular theory of gases are correct. (a) The average kinetic energy of a collection of gas molecules at a given temperature is proportional to  $m^{1/2}$ . (b) The gas molecules are assumed to exert no forces on each other. (c) All the molecules of a gas at a given temperature have the same kinetic energy. (d) The volume of the gas molecules is negligible in comparison to the total volume in which the gas is contained. (e) All gas molecules move with the same speed if they are at the same temperature.
- 10.77**  $\text{WF}_6$  is one of the heaviest known gases. How much slower is the root-mean-square speed of  $\text{WF}_6$  than  $\text{He}$  at 300 K?
- [10.78]** You have an evacuated container of fixed volume and known mass and introduce a known mass of a gas sample. Measuring the pressure at constant temperature over time, you are surprised to see it slowly dropping. You measure the mass of the gas-filled container and find that the mass is what it should be—gas plus container—and the mass does not change over time, so you do not have a leak. Suggest an explanation for your observations.
- 10.79** The temperature of a 5.00-L container of  $\text{N}_2$  gas is increased from  $20^\circ\text{C}$  to  $250^\circ\text{C}$ . If the volume is held constant, predict qualitatively how this change affects the following: (a) the average kinetic energy of the molecules; (b) the root-mean-square speed of the molecules; (c) the strength of the impact of an average molecule with the container walls; (d) the total number of collisions of molecules with walls per second.

- 10.80** Suppose you have two 1-L flasks, one containing  $\text{N}_2$  at STP, the other containing  $\text{CH}_4$  at STP. How do these systems compare with respect to (a) number of molecules, (b) density, (c) average kinetic energy of the molecules, (d) rate of effusion through a pinhole leak?
- 10.81** (a) Place the following gases in order of increasing average molecular speed at 25 °C: Ne, HBr,  $\text{SO}_2$ ,  $\text{NF}_3$ , CO. (b) Calculate the rms speed of  $\text{NF}_3$  molecules at 25 °C. (c) Calculate the most probable speed of an ozone molecule in the stratosphere, where the temperature is 270 K.
- 10.82** (a) Place the following gases in order of increasing average molecular speed at 300 K: CO,  $\text{SF}_6$ ,  $\text{H}_2\text{S}$ ,  $\text{Cl}_2$ , HBr. (b) Calculate the rms speeds of CO and  $\text{Cl}_2$  molecules at 300 K. (c) Calculate the most probable speeds of CO and  $\text{Cl}_2$  molecules at 300 K.
- 10.83** Which one or more of the following statements are true?
- (a)  $\text{O}_2$  will effuse faster than  $\text{Cl}_2$ .
  - (b) Effusion and diffusion are different names for the same process.
  - (c) Perfume molecules travel to your nose by the process of effusion.
  - (d) The higher the density of a gas, the shorter the mean free path.
- [10.84]** At constant pressure, the mean free path ( $\lambda$ ) of a gas molecule is directly proportional to temperature. At constant temperature,  $\lambda$  is inversely proportional to pressure. If you compare two different gas molecules at the same temperature and pressure,  $\lambda$  is inversely proportional to the square of the diameter of the gas molecules. Put these facts together to create a formula for the mean free path of a gas molecule with a proportionality constant (call it  $R_{\text{mfp}}$ , like the ideal-gas constant) and define units for  $R_{\text{mfp}}$ .
- 10.85** Hydrogen has two naturally occurring isotopes,  $^1\text{H}$  and  $^2\text{H}$ . Chlorine also has two naturally occurring isotopes,  $^{35}\text{Cl}$  and  $^{37}\text{Cl}$ . Thus, hydrogen chloride gas consists of four distinct types of molecules:  $^1\text{H}^{35}\text{Cl}$ ,  $^1\text{H}^{37}\text{Cl}$ ,  $^2\text{H}^{35}\text{Cl}$ , and  $^2\text{H}^{37}\text{Cl}$ . Place these four molecules in order of increasing rate of effusion.
- 10.86** As discussed in the “Chemistry Put to Work” box in Section 10.8, enriched uranium can be produced by effusion of gaseous  $\text{UF}_6$  across a porous membrane. Suppose a process were developed to allow effusion of gaseous uranium atoms,  $\text{U(g)}$ . Calculate the ratio of effusion rates for  $^{235}\text{U}$  and  $^{238}\text{U}$ , and compare it to the ratio for  $\text{UF}_6$  given in the essay.
- 10.87** Arsenic(III) sulfide sublimes readily, even below its melting point of 320 °C. The molecules of the vapor phase are found to effuse through a tiny hole at 0.28 times the rate of effusion of Ar atoms under the same conditions of temperature and pressure. What is the molecular formula of arsenic(III) sulfide in the gas phase?
- 10.88** A gas of unknown molecular mass was allowed to effuse through a small opening under constant-pressure conditions. It required 105 s for 1.0 L of the gas to effuse. Under identical experimental conditions it required 31 s for 1.0 L of  $\text{O}_2$  gas to effuse. Calculate the molar mass of the

unknown gas. (Remember that the faster the rate of effusion, the shorter the time required for effusion of 1.0 L; in other words, rate is the amount that diffuses over the time it takes to diffuse.)

## Nonideal-Gas Behavior (Section 10.9)

- 10.89** (a) List two experimental conditions under which gases deviate from ideal behavior. (b) List two reasons why the gases deviate from ideal behavior.
- 10.90** The planet Jupiter has a surface temperature of 140 K and a mass 318 times that of Earth. Mercury (the planet) has a surface temperature between 600 K and 700 K and a mass 0.05 times that of Earth. On which planet is the atmosphere more likely to obey the ideal-gas law? Explain.
- 10.91** Which statement concerning the van der Waals constants  $a$  and  $b$  is true?
- (a) The magnitude of  $a$  relates to molecular volume, whereas  $b$  relates to attractions between molecules.
  - (b) The magnitude of  $a$  relates to attractions between molecules, whereas  $b$  relates to molecular volume.
  - (c) The magnitudes of  $a$  and  $b$  depend on pressure.
  - (d) The magnitudes of  $a$  and  $b$  depend on temperature.
- 10.92** Based on their respective van der Waals constants (Table 10.3), is Ar or  $\text{CO}_2$  expected to behave more nearly like an ideal gas at high pressures?
- 10.93** In Sample Exercise 10.16, we found that one mole of  $\text{Cl}_2$  confined to 22.41 L at 0 °C deviated slightly from ideal behavior. Calculate the pressure exerted by 1.00 mol  $\text{Cl}_2$  confined to a smaller volume, 5.00 L, at 25 °C. (a) First use the ideal-gas equation and (b) then use the van der Waals equation for your calculation. (Values for the van der Waals constants are given in Table 10.3.) (c) Why is the difference between the result for an ideal gas and that calculated using the van der Waals equation greater when the gas is confined to 5.00 L compared to 22.4 L?
- 10.94** Calculate the pressure that  $\text{CCl}_4$  will exert at 80 °C if 1.00 mol occupies 33.3 L, assuming that (a)  $\text{CCl}_4$  obeys the ideal-gas equation; (b)  $\text{CCl}_4$  obeys the van der Waals equation. (Values for the van der Waals constants are given in Table 10.3.) (c) Which would you expect to deviate more from ideal behavior under these conditions,  $\text{Cl}_2$  or  $\text{CCl}_4$ ? Explain.
- [10.95]** Table 10.3 shows that the van der Waals  $b$  parameter has units of L/mol. This implies that we can calculate the size of atoms or molecules from  $b$ . Using the value of  $b$  for Xe, calculate the radius of a Xe atom and compare it to the value found in Figure 7.7, that is, 1.40 Å. Recall that the volume of a sphere is  $(4/3)\pi r^3$ .
- [10.96]** Table 10.3 shows that the van der Waals  $b$  parameter has units of L/mol. This means that we can calculate the sizes of atoms or molecules from the  $b$  parameter. Refer back to the discussion in Section 7.3. Is the van der Waals radius we calculate from the  $b$  parameter of Table 10.3 more closely associated with the bonding or nonbonding atomic radius discussed there? Explain.

## Additional Exercises

- 10.97** Torricelli, who invented the barometer, used mercury in its construction because mercury has a very high density, which makes it possible to make a more compact barometer than one based on a less dense fluid. Calculate the density of mercury using the observation that the column of

mercury is 760 mm high when the atmospheric pressure is  $1.01 \times 10^5$  Pa. Assume the tube containing the mercury is a cylinder with a constant cross-sectional area.

- 10.98** A gas bubble with a volume of  $1.0 \text{ mm}^3$  originates at the bottom of a lake where the pressure is 3.0 atm. Calculate

its volume when the bubble reaches the surface of the lake where the pressure is 730 torr, assuming that the temperature doesn't change.

- 10.99** A 15.0-L tank is filled with helium gas at a pressure of  $1.00 \times 10^2$  atm. How many balloons (each 2.00 L) can be inflated to a pressure of 1.00 atm, assuming that the temperature remains constant and that the tank cannot be emptied below 1.00 atm?
- 10.100** To minimize the rate of evaporation of the tungsten filament,  $1.4 \times 10^{-5}$  mol of argon is placed in a 600-cm<sup>3</sup> lightbulb. What is the pressure of argon in the lightbulb at 23 °C?
- 10.101** Carbon dioxide, which is recognized as the major contributor to global warming as a "greenhouse gas," is formed when fossil fuels are combusted, as in electrical power plants fueled by coal, oil, or natural gas. One potential way to reduce the amount of CO<sub>2</sub> added to the atmosphere is to store it as a compressed gas in underground formations. Consider a 1000-megawatt coal-fired power plant that produces about  $6 \times 10^6$  tons of CO<sub>2</sub> per year. (a) Assuming ideal-gas behavior, 1.00 atm, and 27 °C, calculate the volume of CO<sub>2</sub> produced by this power plant. (b) If the CO<sub>2</sub> is stored underground as a liquid at 10 °C and 120 atm and a density of 1.2 g/cm<sup>3</sup>, what volume does it possess? (c) If it is stored underground as a gas at 30 °C and 70 atm, what volume does it occupy?
- 10.102** Propane, C<sub>3</sub>H<sub>8</sub>, liquefies under modest pressure, allowing a large amount to be stored in a container. (a) Calculate the number of moles of propane gas in a 110-L container at 3.00 atm and 27 °C. (b) Calculate the number of moles of liquid propane that can be stored in the same volume if the density of the liquid is 0.590 g/mL. (c) Calculate the ratio of the number of moles of liquid to moles of gas. Discuss this ratio in light of the kinetic-molecular theory of gases.
- [10.103]** Nickel carbonyl, Ni(CO)<sub>4</sub>, is one of the most toxic substances known. The present maximum allowable concentration in laboratory air during an 8-hr workday is 1 ppb (parts per billion) by volume, which means that there is one mole of Ni(CO)<sub>4</sub> for every 10<sup>9</sup> moles of gas. Assume 24 °C and 1.00 atm pressure. What mass of Ni(CO)<sub>4</sub> is allowable in a laboratory room that is 12 ft × 20 ft × 9 ft?
- 10.104** When a large evacuated flask is filled with argon gas, its mass increases by 3.224 g. When the same flask is again evacuated and then filled with a gas of unknown molar mass, the mass increase is 8.102 g. (a) Based on the molar mass of argon, estimate the molar mass of the unknown gas. (b) What assumptions did you make in arriving at your answer?
- 10.105** Consider the arrangement of bulbs shown in the drawing. Each of the bulbs contains a gas at the pressure shown. What is the pressure of the system when all the stopcocks are opened, assuming that the temperature remains constant? (We can neglect the volume of the capillary tubing connecting the bulbs.)

- 10.106** Assume that a single cylinder of an automobile engine has a volume of 524 cm<sup>3</sup>. (a) If the cylinder is full of air at 74 °C

and 0.980 atm, how many moles of O<sub>2</sub> are present? (The mole fraction of O<sub>2</sub> in dry air is 0.2095.) (b) How many grams of C<sub>8</sub>H<sub>18</sub> could be combusted by this quantity of O<sub>2</sub>, assuming complete combustion with formation of CO<sub>2</sub> and H<sub>2</sub>O?

- 10.107** Assume that an exhaled breath of air consists of 74.8% N<sub>2</sub>, 15.3% O<sub>2</sub>, 3.7% CO<sub>2</sub>, and 6.2% water vapor. (a) If the total pressure of the gases is 0.985 atm, calculate the partial pressure of each component of the mixture. (b) If the volume of the exhaled gas is 455 mL and its temperature is 37 °C, calculate the number of moles of CO<sub>2</sub> exhaled. (c) How many grams of glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) would need to be metabolized to produce this quantity of CO<sub>2</sub>? (The chemical reaction is the same as that for combustion of C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>. See Section 3.2 and Problem 10.57.)
- 10.108** A 1.42-g sample of helium and an unknown mass of O<sub>2</sub> are mixed in a flask at room temperature. The partial pressure of the helium is 42.5 torr, and that of the oxygen is 158 torr. What is the mass of the oxygen?
- [10.109]** An ideal gas at a pressure of 1.50 atm is contained in a bulb of unknown volume. A stopcock is used to connect this bulb with a previously evacuated bulb that has a volume of 0.800 L as shown here. When the stopcock is opened, the gas expands into the empty bulb. If the temperature is held constant during this process and the final pressure is 695 torr, what is the volume of the bulb that was originally filled with gas?

- 10.110** The density of a gas of unknown molar mass was measured as a function of pressure at 0 °C, as in the table that follows. (a) Determine a precise molar mass for the gas. [Hint: Graph  $d/P$  versus  $P$ .] (b) Why is  $d/P$  not a constant as a function of pressure?

| Pressure (atm) | 1.00   | 0.666  | 0.500  | 0.333  | 0.250  |
|----------------|--------|--------|--------|--------|--------|
| Density (g/L)  | 2.3074 | 1.5263 | 1.1401 | 0.7571 | 0.5660 |

- [10.111]** A glass vessel fitted with a stopcock valve has a mass of 337.428 g when evacuated. When filled with Ar, it has a mass of 339.854 g. When evacuated and refilled with a mixture of Ne and Ar, under the same conditions of temperature and pressure, it has a mass of 339.076 g. What is the mole percent of Ne in the gas mixture?
- 10.112** You have a sample of gas at -33 °C. You wish to increase the rms speed by a factor of 2. To what temperature should the gas be heated?
- 10.113** Consider the following gases, all at STP: Ne, SF<sub>6</sub>, N<sub>2</sub>, CH<sub>4</sub>. (a) Which gas is most likely to depart from the assumption of the kinetic-molecular theory that says there are no attractive or repulsive forces between molecules? (b) Which one is closest to an ideal gas in its behavior? (c) Which one has the highest root-mean-square molecular speed at a given temperature? (d) Which one has the highest total molecular volume relative to the space occupied by the gas? (e) Which has the highest average kinetic-molecular energy? (f) Which one would effuse more rapidly than N<sub>2</sub>? (g) Which one would have the largest van der Waals  $b$  parameter?

- 10.114** Does the effect of intermolecular attraction on the properties of a gas become more significant or less significant if (a) the gas is compressed to a smaller volume at constant temperature; (b) the temperature of the gas is increased at constant volume?
- 10.115** Which of the noble gases other than radon would you expect to depart most readily from ideal behavior? Use the density data in Table 7.8 to show evidence in support of your answer.
- 10.116** It turns out that the van der Waals constant  $b$  equals four times the total volume actually occupied by the molecules of a mole of gas. Using this figure, calculate the fraction of

the volume in a container actually occupied by Ar atoms (a) at STP, (b) at 200 atm pressure and 0 °C. (Assume for simplicity that the ideal-gas equation still holds.)

- [10.117]** Large amounts of nitrogen gas are used in the manufacture of ammonia, principally for use in fertilizers. Suppose 120.00 kg of  $\text{N}_2(\text{g})$  is stored in a 1100.0-L metal cylinder at 280 °C. (a) Calculate the pressure of the gas, assuming ideal-gas behavior. (b) By using the data in Table 10.3, calculate the pressure of the gas according to the van der Waals equation. (c) Under the conditions of this problem, which correction dominates, the one for finite volume of gas molecules or the one for attractive interactions?

## Integrative Exercises

- 10.118** Cyclopropane, a gas used with oxygen as a general anesthetic, is composed of 85.7% C and 14.3% H by mass. (a) If 1.56 g of cyclopropane has a volume of 1.00 L at 0.984 atm and 50.0 °C, what is the molecular formula of cyclopropane? (b) Judging from its molecular formula, would you expect cyclopropane to deviate more or less than Ar from ideal-gas behavior at moderately high pressures and room temperature? Explain. (c) Would cyclopropane effuse through a pinhole faster or more slowly than methane,  $\text{CH}_4$ ?
- [10.119]** Consider the combustion reaction between 25.0 mL of liquid methanol (density = 0.850 g/mL) and 12.5 L of oxygen gas measured at STP. The products of the reaction are  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{g})$ . Calculate the volume of liquid  $\text{H}_2\text{O}$  formed if the reaction goes to completion and you condense the water vapor.
- 10.120** An herbicide is found to contain only C, H, N, and Cl. The complete combustion of a 100.0-mg sample of the herbicide in excess oxygen produces 83.16 mL of  $\text{CO}_2$  and 73.30 mL of  $\text{H}_2\text{O}$  vapor expressed at STP. A separate analysis shows that the sample also contains 16.44 mg of Cl. (a) Determine the percentage of the composition of the substance. (b) Calculate its empirical formula. (c) What other information would you need to know about this compound to calculate its true molecular formula?
- 10.121** A 4.00-g sample of a mixture of CaO and BaO is placed in a 1.00-L vessel containing  $\text{CO}_2$  gas at a pressure of 730 torr and a temperature of 25 °C. The  $\text{CO}_2$  reacts with the CaO and BaO, forming  $\text{CaCO}_3$  and  $\text{BaCO}_3$ . When the reaction is complete, the pressure of the remaining  $\text{CO}_2$  is 150 torr. (a) Calculate the number of moles of  $\text{CO}_2$  that have reacted. (b) Calculate the mass percentage of CaO in the mixture.
- [10.122]** Ammonia and hydrogen chloride react to form solid ammonium chloride:

Two 2.00-L flasks at 25 °C are connected by a valve, as shown in the drawing. One flask contains 5.00 g of  $\text{NH}_3(\text{g})$ , and the other contains 5.00 g of  $\text{HCl}(\text{g})$ . When the valve is opened, the gases react until one is completely consumed. (a) Which gas will remain in the system after the reaction is complete? (b) What will be the final pressure of the system after the reaction is complete? (Neglect the volume of the ammonium chloride formed.) (c) What mass of ammonium chloride will be formed?

- 10.123** Gas pipelines are used to deliver natural gas (methane,  $\text{CH}_4$ ) to the various regions of the United States. The total volume of natural gas that is delivered is on the order of  $2.7 \times 10^{12}$  L per day, measured at STP. Calculate the total enthalpy change for combustion of this quantity of methane. (Note: Less than this amount of methane is actually combusted daily. Some of the delivered gas is passed through to other regions.)
- 10.124** Chlorine dioxide gas ( $\text{ClO}_2$ ) is used as a commercial bleaching agent. It bleaches materials by oxidizing them. In the course of these reactions, the  $\text{ClO}_2$  is itself reduced. (a) What is the Lewis structure for  $\text{ClO}_2$ ? (b) Why do you think that  $\text{ClO}_2$  is reduced so readily? (c) When a  $\text{ClO}_2$  molecule gains an electron, the chlorite ion,  $\text{ClO}_2^-$ , forms. Draw the Lewis structure for  $\text{ClO}_2^-$ . (d) Predict the O—Cl—O bond angle in the  $\text{ClO}_2^-$  ion. (e) One method of preparing  $\text{ClO}_2$  is by the reaction of chlorine and sodium chlorite:

If you allow 15.0 g of  $\text{NaClO}_2$  to react with 2.00 L of chlorine gas at a pressure of 1.50 atm at 21 °C, how many grams of  $\text{ClO}_2$  can be prepared?

- 10.125** Natural gas is very abundant in many Middle Eastern oil fields. However, the costs of shipping the gas to markets in other parts of the world are high because it is necessary to liquefy the gas, which is mainly methane and has a boiling point at atmospheric pressure of  $-164$  °C. One possible strategy is to oxidize the methane to methanol,  $\text{CH}_3\text{OH}$ , which has a boiling point of 65 °C and can therefore be shipped more readily. Suppose that  $10.7 \times 10^9$  ft<sup>3</sup> of methane at atmospheric pressure and 25 °C is oxidized to methanol. (a) What volume of methanol is formed if the density of  $\text{CH}_3\text{OH}$  is 0.791 g/mL? (b) Write balanced chemical equations for the oxidations of methane and methanol to  $\text{CO}_2(\text{g})$  and  $\text{H}_2\text{O}(\text{l})$ . Calculate the total enthalpy change for complete combustion of the  $10.7 \times 10^9$  ft<sup>3</sup> of methane

just described and for complete combustion of the equivalent amount of methanol, as calculated in part (a). (c) Methane, when liquefied, has a density of 0.466 g/mL; the density of methanol at 25 °C is 0.791 g/mL. Compare the enthalpy change upon combustion of a unit volume of liquid methane and liquid methanol. From the standpoint of energy production, which substance has the higher enthalpy of combustion per unit volume?

- [10.126]** Gaseous iodine pentafluoride,  $\text{IF}_5$ , can be prepared by the reaction of solid iodine and gaseous fluorine:

A 5.00-L flask containing 10.0 g of  $\text{I}_2$  is charged with 10.0 g of  $\text{F}_2$ , and the reaction proceeds until one of the reagents is completely consumed. After the reaction is complete, the temperature in the flask is 125 °C.

(a) What is the partial pressure of  $\text{IF}_5$  in the flask? (b) What is the mole fraction of  $\text{IF}_5$  in the flask? (c) Draw the Lewis structure of  $\text{IF}_5$ . (d) What is the total mass of reactants and products in the flask?

- [10.127]** A 6.53-g sample of a mixture of magnesium carbonate and calcium carbonate is treated with excess hydrochloric acid. The resulting reaction produces 1.72 L of carbon dioxide gas at 28 °C and 743 torr pressure. (a) Write balanced chemical equations for the reactions that occur between hydrochloric acid and each component of the mixture. (b) Calculate the total number of moles of carbon dioxide that forms from these reactions. (c) Assuming that the reactions are complete, calculate the percentage by mass of magnesium carbonate in the mixture.

## Design an Experiment

You are given a cylinder of an unknown, nonradioactive, noble gas and tasked to determine its molar mass and use that value to identify the gas. The tools available to you are several empty mylar balloons that are about the size of a grapefruit when inflated (gases diffuse through mylar much more slowly than conventional latex balloons), an analytical balance, and three graduated glass beakers of different sizes (100 mL, 500 mL, and 2 L). (a) To how many significant figures would you need to determine the molar mass

to identify the gas? (b) Propose an experiment or series of experiments that would allow you to determine the molar mass of the unknown gas. Describe the tools, calculations, and assumptions you would need to use. (c) If you had access to a broader range of analytical instruments, describe an alternative way you could identify the gas using any experimental methods that you have learned about in the earlier chapters.

11

# LIQUIDS AND INTERMOLECULAR FORCES

The lotus plant grows in aquatic environments. To thrive in such an environment the surface of a lotus leaf is highly water repellent. Scientists call surfaces with this property “superhydrophobic.” The superhydrophobic character of the lotus leaf not only allows it to float on water but also causes any water that falls on the leaf to bead up and roll off. The water drops collect dirt as they roll off, keeping the leaf clean, even in the muddy ponds and lakes where lotus plants tend to grow. Because of its self-cleaning properties, the lotus plant is considered a symbol of purity in many Eastern cultures.

What forces cause the lotus leaf to repel water so efficiently? Although this plant’s self-cleaning nature has been known for millennia, the effect was not fully understood until the 1970s when scanning electron microscopy images revealed a rough leaf surface (Figure 11.1). The rough surface helps minimize contact between water and leaf, and also minimizes contact between dirt and leaf so that dirt does not stick.

◀ **BECAUSE THE LEAVES OF THE LOTUS PLANT** are highly water repellent, any water on a leaf beads up to minimize contact with the leaf surface.

## WHAT’S AHEAD

- 11.1 ▶ A Molecular Comparison of Gases, Liquids, and Solids** Compare solids, liquids, and gases from a molecular perspective. Temperature and *intermolecular forces* play critical roles in determining the physical state of a substance.
- 11.2 ▶ Intermolecular Forces** Examine the four intermolecular forces: *dispersion forces*, *dipole–dipole interactions*, *hydrogen bonds*, and *ion–dipole forces*.
- 11.3 ▶ Select Properties of Liquids** Learn how the *viscosity* and *surface tension* of liquids is governed by intermolecular forces.
- 11.4 ▶ Phase Changes** Explore *phase changes*—the transitions of matter between the gaseous, liquid, and solid states—and their associated energies.
- 11.5 ▶ Vapor Pressure** Realize that a dynamic equilibrium exists between the liquid state of a substance and its gaseous state, giving rise to *vapor pressure* that can be measured.
- 11.6 ▶ Phase Diagrams** Learn how to read *phase diagrams*, which are graphic representations of the equilibria among the gas, liquid, and solid phases.
- 11.7 ▶ Liquid Crystals** Marvel at a phase intermediate between liquid and solid: the liquid crystalline phase. A substance in the liquid crystalline phase has some of the structural order of a solid and some of the freedom of motion of a liquid.

▲ **Figure 11.1** A microscopic view of a water droplets on the surface of a lotus leaf.

Another important factor contributing to the plant's self-cleaning nature is the contrast between the molecular composition of the leaf and that of the water. The leaf is coated by hydrocarbon molecules, which are not attracted to water molecules. As a result the water molecules preferentially surround themselves with other water molecules, thereby minimizing contact with the leaf.

The lotus effect has inspired scientists to design superhydrophobic surfaces for applications such as self-cleaning windows and water-repellent clothing. To understand the lotus effect and other phenomena involving liquids and solids, we must understand **intermolecular forces**, the forces that exist *between* molecules. Only by understanding the nature and strength of these forces can we understand how the composition and structure of a substance are related to its physical properties in the liquid or solid state.

## 11.1 | A Molecular Comparison of Gases, Liquids, and Solids

As we learned in Chapter 10, the molecules in a gas are widely separated and in a state of constant, chaotic motion. One of the key tenets of kinetic-molecular theory of gases is the assumption that we can neglect the interactions between molecules. [\(Section 10.7\)](#) The properties of liquids and solids are quite different from those of gases largely because the intermolecular forces in liquids and solids are much stronger. A comparison of the properties of gases, liquids, and solids is given in **Table 11.1**.

In liquids the intermolecular attractive forces are strong enough to hold particles close together. Thus, liquids are much denser and far less compressible than gases. Unlike gases, liquids have a definite volume, independent of the size and shape of their container. The attractive forces in liquids are not strong enough, however, to keep the particles from moving past one another. Thus, any liquid can be poured and assumes the shape of the container it occupies.

In solids the intermolecular attractive forces are strong enough to hold particles close together and to lock them virtually in place. Solids, like liquids, are not very compressible because the particles have little free space between them. Because the particles in a solid or liquid are fairly close together compared with those of a gas, we often refer to solids and liquids as *condensed phases*. We will study solids in Chapter 12. For now it is sufficient to know that the particles of a solid are not free to undergo long-range movement, which makes solids rigid.\*

**TABLE 11.1** Characteristic Properties of the States of Matter

| Gas  | Liquid  | Solid  |
|--|---|--|
| Assumes both volume and shape of its container | Assumes shape of portion of container it occupies | Retains own shape and volume                     |
| Expands to fill its container                  | Does not expand to fill its container             | Does not expand to fill its container            |
| Is compressible                                | Is virtually incompressible                       | Is virtually incompressible                      |
| Flows readily                                  | Flows readily                                     | Does not flow                                    |
| Diffusion within a gas occurs rapidly          | Diffusion within a liquid occurs slowly           | Diffusion within a solid occurs extremely slowly |

\*The atoms in a solid are able to vibrate in place. As the temperature of the solid increases, the vibrational motion increases.

## Go Figure

For a given substance, do you expect the density of the substance in its liquid state to be closer to the density in the gaseous state or in the solid state?

▲ **Figure 11.2** Gases, liquids, and solids. Chlorine, bromine, and iodine are all diatomic molecules as a result of covalent bonding. However, due to differences in the strength of the intermolecular forces, they exist in three different states at room temperature and standard pressure:  $\text{Cl}_2$  is a gas,  $\text{Br}_2$  is a liquid, and  $\text{I}_2$  is a solid.

**Figure 11.2** compares the three states of matter. *The state of a substance depends largely on the balance between the kinetic energies of the particles (atoms, molecules, or ions) and the interparticle energies of attraction.* The kinetic energies, which depend on temperature, tend to keep the particles apart and moving. The interparticle attractions tend to draw the particles together. Substances that are gases at room temperature have much weaker interparticle attractions than those that are liquids; substances that are liquids have weaker interparticle attractions than those that are solids. The different states of matter adopted by the halogens at room temperature—iodine is a solid, bromine is a liquid, and chlorine is a gas—are a direct consequence of a decrease in the strength of the intermolecular forces as we move from  $\text{I}_2$  to  $\text{Br}_2$  to  $\text{Cl}_2$ .

We can change a substance from one state to another by heating or cooling, which changes the average kinetic energy of the particles.  $\text{NaCl}$ , for example, a solid at room temperature, melts at 1074 K and boils at 1686 K under 1 atm pressure, and  $\text{Cl}_2$ , a gas at room temperature, liquefies at 239 K and solidifies at 172 K under 1 atm pressure. As the temperature of a gas decreases, the average kinetic energy of its particles decreases, allowing the attractions between the particles to draw the particles close together, forming a liquid, and

### Go Figure

How would you expect the H—Cl distance represented by the blue line to compare with the H—Cl distance within the HCl molecule?

▲ **Figure 11.3** Intermolecular and intramolecular interactions.

then to virtually lock them in place, forming a solid. Increasing the pressure on a gas can also drive transformations from gas to liquid to solid because the increased pressure brings the molecules closer together, thus making intermolecular forces more effective. For example, propane ( $\text{C}_3\text{H}_8$ ) is a gas at room temperature and 1 atm pressure, whereas liquefied propane (LP) is a liquid at room temperature because it is stored under much higher pressure.

## 11.2 | Intermolecular Forces

The strengths of *intermolecular* forces vary over a wide range but are generally much weaker than *intramolecular* forces—ionic, metallic, or covalent bonds (**Figure 11.3**). Less energy, therefore, is required to vaporize a liquid or melt a solid than to break covalent bonds. For example, only 16 kJ/mol is required to overcome the intermolecular attractions in liquid HCl to vaporize it. In contrast, the energy required to break the covalent bond in HCl is 431 kJ/mol. Thus, when a molecular substance such as HCl changes from solid to liquid to gas, the molecules remain intact.

Many properties of liquids, including boiling points, reflect the strength of the intermolecular forces. A liquid boils when bubbles of its vapor form within the liquid. The molecules of the liquid must overcome their attractive forces to separate and form a vapor. The stronger the attractive forces, the higher the temperature at which the liquid boils. Similarly, the melting points of solids increase as the strengths of the intermolecular forces increase. As shown in **Table 11.2**, the melting and boiling points of substances in which the particles are held together by chemical bonds tend to be much higher than those of substances in which the particles are held together by intermolecular forces.

### Give It Some Thought

When water boils, what are the bubbles composed of?

There are three types of intermolecular attractions that exist between electrically neutral molecules:

- dispersion forces
- dipole–dipole attractions
- hydrogen bonding.

The first two are collectively called *van der Waals forces* after Johannes van der Waals (1837–1923), who developed the equation for predicting the deviation of gases from ideal behavior. ∞ (Section 10.9) Another kind of attractive force, the ion–dipole force, is important in solutions.

All intermolecular interactions are electrostatic, involving attractions between positive and negative species, much like ionic bonds. ∞ (Section 8.2) Why then are intermolecular forces so much weaker than ionic bonds? Recall from Equation 8.4 that electrostatic interactions get stronger as the magnitude of the charges increases and

**TABLE 11.2** Melting and Boiling Points of Representative Substances

| Force Holding Particles Together | Substance                 | Melting Point (K) | Boiling Point (K) |
|----------------------------------|---------------------------|-------------------|-------------------|
| <i>Chemical bonds</i>            |                           |                   |                   |

weaker as the distance between charges increases. The charges responsible for intermolecular forces are generally much smaller than the charges in ionic compounds. For example, from its dipole moment it is possible to estimate charges of  $+0.178$  and  $-0.178$  for the hydrogen and chlorine ends of the HCl molecule, respectively (see Sample Exercise 8.5). Furthermore, the distances between molecules are often larger than the distances between atoms held together by chemical bonds.

## Dispersion Forces

You might think there would be no electrostatic interactions between electrically neutral, nonpolar atoms and/or molecules. Yet some kind of attractive interactions must exist because nonpolar gases like helium, argon, and nitrogen can be liquefied. Fritz London, a German-American physicist, first proposed the origin of this attraction in 1930. London recognized that the motion of electrons in an atom or molecule can create an *instantaneous*, or momentary, dipole moment.

In a collection of helium atoms, for example, the *average* distribution of the electrons about each nucleus is spherically symmetrical, as shown in **Figure 11.4(a)**. The atoms are nonpolar and so possess no permanent dipole moment. The *instantaneous* distribution of the electrons, however, can be different from the average distribution. If we could freeze the motion of the electrons at any given instant, both electrons could be on one side of the nucleus. At just that instant, the atom has an instantaneous dipole moment as shown in **Figure 11.4(b)**. The motions of electrons in one atom influence the motions of electrons in its neighbors. The instantaneous dipole on one atom can induce an instantaneous dipole on an adjacent atom, causing the atoms to be attracted to each other as shown in **Figure 11.4(c)**. This attractive interaction is called the **dispersion force** (also called *London dispersion forces* or *induced dipole–induced dipole interactions*). It is significant only when molecules are very close together.

The strength of the dispersion force depends on the ease with which the charge distribution in a molecule can be distorted to induce an instantaneous dipole. The ease with which the charge distribution is distorted is called the molecule's **polarizability**. We can think of the polarizability of a molecule as a measure of the “squashiness” of its electron cloud: The greater the polarizability, the more easily the electron cloud can be distorted to give an instantaneous dipole. Therefore, more polarizable molecules have larger dispersion forces.

In general, polarizability increases as the number of electrons in an atom or molecule increases. The strength of dispersion forces therefore tends to increase with increasing atomic or molecular size. Because molecular size and mass generally parallel each other, *dispersion forces tend to increase in strength with increasing molecular weight*. We can see this

▲ **Figure 11.4 Dispersion forces.** “Snapshots” of the charge distribution for a pair of helium atoms at three instants.

## Go Figure

Why is the boiling point of the halogen in each period greater than the noble gas?

▲ **Figure 11.5** Boiling points of the halogens and noble gases. This plot shows how the boiling points increase due to stronger dispersion forces as the atomic/molecular weight increases.

**Linear molecule**—larger surface area enhances intermolecular contact and increases dispersion force.

*n*-Pentane (C<sub>5</sub>H<sub>12</sub>)  
bp = 309.4 K

**Spherical molecule**—smaller surface area diminishes intermolecular contact and decreases dispersion force.

Neopentane (C<sub>5</sub>H<sub>12</sub>)  
bp = 282.7 K

▲ **Figure 11.6** Molecular shape affects intermolecular attraction. Molecules of *n*-pentane make more contact with each other than do neopentane molecules. Thus, *n*-pentane has stronger intermolecular attractive forces and therefore a higher boiling point.

## Give It Some Thought

List the substances CCl<sub>4</sub>, CBr<sub>4</sub>, and CH<sub>4</sub> in order of increasing boiling point.

Molecular shape also influences the magnitude of dispersion forces. For example, *n*-pentane\* and neopentane (Figure 11.6) have the same molecular formula (C<sub>5</sub>H<sub>12</sub>), yet the boiling point of *n*-pentane is about 27 K higher than that of neopentane. The difference can be traced to the different shapes of the two molecules. Intermolecular attraction is greater for *n*-pentane because the molecules can come in contact over the entire length of the long, somewhat cylindrical molecules. Less contact is possible between the more compact and nearly spherical neopentane molecules.

## Dipole–Dipole Interactions

The presence of a permanent dipole moment in polar molecules gives rise to **dipole–dipole interactions**. These interactions originate from electrostatic attractions between the partially positive end of one molecule and the partially negative end of a neighboring molecule. Repulsions can also occur when the positive (or negative) ends of two molecules are in close proximity. Dipole–dipole interactions are effective only when molecules are very close together.

To see the effect of dipole–dipole interactions, we compare the boiling points of two compounds of similar molecular weight: acetonitrile (CH<sub>3</sub>CN, MW 41 amu, bp 355 K) and propane (CH<sub>3</sub>CH<sub>2</sub>CH<sub>3</sub>, MW 44 amu, bp 231 K). Acetonitrile is a polar molecule, with a dipole moment of 3.9 D, so dipole–dipole interactions are present. However, propane is essentially nonpolar, which means that dipole–dipole interactions are absent. Because acetonitrile and propane have similar molecular weights, dispersion forces are similar for these two molecules. Therefore, the higher boiling point of acetonitrile can be attributed to dipole–dipole interactions.

\*The *n* in *n*-pentane is an abbreviation for the word *normal*. A normal hydrocarbon is one in which the carbon atoms are arranged in a straight chain. ∞ (Section 2.9)

▲ **Figure 11.7** Dipole–dipole interactions. The dipole–dipole interactions in (a) crystalline  $\text{CH}_3\text{CN}$  and (b) liquid  $\text{CH}_3\text{CN}$ .

To better understand these forces, consider how  $\text{CH}_3\text{CN}$  molecules pack together in the solid and liquid states. In the solid [Figure 11.7(a)], the molecules are arranged with the negatively charged nitrogen end of each molecule close to the positively charged  $-\text{CH}_3$  ends of its neighbors. In the liquid [Figure 11.7(b)], the molecules are free to move with respect to one another, and their arrangement becomes more disordered. This means that, at any given instant, both attractive and repulsive dipole–dipole interactions are present. However, not only are there more attractive interactions than repulsive ones, but also molecules that are attracting each other spend more time near each other than do molecules that are repelling each other. The overall effect is a net attraction strong enough to keep the molecules in liquid  $\text{CH}_3\text{CN}$  from moving apart to form a gas.

For molecules of approximately equal mass and size, the strength of intermolecular attractions increases with increasing polarity, a trend we see in Figure 11.8. Notice how the boiling point increases as the dipole moment increases.

## Hydrogen Bonding

Figure 11.9 shows the boiling points of the binary compounds that form between hydrogen and the elements in groups 4A through 7A. The boiling points of the compounds containing

## Go Figure

To form a hydrogen bond, what must the nonhydrogen atom (N, O, or F) involved in the bond possess?

▲ **Figure 11.10** Hydrogen bonding. Hydrogen bonding occurs between an H atom that is bonded to N, O, or F in one molecule and an N, O, or F atom in another molecule.

group 4A elements ( $\text{CH}_4$  through  $\text{SnH}_4$ , all nonpolar) increase systematically moving down the group. This is the expected trend because polarizability and, hence, dispersion forces generally increase as molecular weight increases. The heavier members of groups 5A, 6A, and 7A follow the same trend, but  $\text{NH}_3$ ,  $\text{H}_2\text{O}$ , and  $\text{HF}$  have boiling points that are much higher than expected. In fact, these three compounds also have many other characteristics that distinguish them from other substances of similar molecular weight and polarity. For example, water has a high melting point, a high specific heat, and a high heat of vaporization. Each of these properties indicates that the intermolecular forces are abnormally strong.

The strong intermolecular attractions in  $\text{HF}$ ,  $\text{H}_2\text{O}$ , and  $\text{NH}_3$  result from *hydrogen bonding*. A **hydrogen bond** is an attraction between a hydrogen atom attached to a highly electronegative atom (usually F, O, or N) and a nearby small electronegative atom in another molecule or chemical group. Thus,  $\text{H}-\text{F}$ ,  $\text{H}-\text{O}$ , or  $\text{H}-\text{N}$  bonds in one molecule can form hydrogen bonds with an F, O, or N atom in another molecule. Several examples of hydrogen bonds are shown in **Figure 11.10**, including the hydrogen bond that exists between the H atom in an  $\text{H}_2\text{O}$  molecule and the O atom of an adjacent  $\text{H}_2\text{O}$  molecule. Notice in each case that the H atom in the hydrogen bond interacts with a nonbonding electron pair.

Hydrogen bonds can be considered a special type of dipole–dipole attraction. Because N, O, and F are so electronegative, a bond between hydrogen and any of these elements is quite polar, with hydrogen at the positive end (remember the + on the right-hand side of the dipole symbol represents the positive end of the dipole):

The hydrogen atom has no inner electrons. Thus, the positive side of the dipole has the concentrated charge of the nearly bare hydrogen nucleus. This positive charge is attracted to the negative charge of an electronegative atom in a nearby molecule. Because the electron-poor hydrogen is so small, it can approach an electronegative atom very closely and, thus, interact strongly with it.

Hydrogen bonding plays important roles in many chemical systems, especially those of biological significance. For example, hydrogen bonding helps stabilize the three-dimensional structure of proteins, which is critical to their function. Hydrogen bonding is also responsible for the double-helical structure of DNA, which is key to its genetic function.

## Sample Exercise 11.1

### Identifying Substances That Can Form Hydrogen Bonds

In which of these substances is hydrogen bonding likely to play an important role in determining physical properties: methane ( $\text{CH}_4$ ), hydrazine ( $\text{H}_2\text{NNH}_2$ ), methyl fluoride ( $\text{CH}_3\text{F}$ ), hydrogen sulfide ( $\text{H}_2\text{S}$ )?

#### SOLUTION

**Analyze** We are given the chemical formulas of four compounds and asked to predict whether they can participate in hydrogen bonding. All the compounds contain H, but hydrogen bonding usually occurs only when the hydrogen is covalently bonded to N, O, or F.

**Plan** We analyze each formula to see if it contains N, O, or F directly bonded to H. There also needs to be a nonbonding pair of electrons on an electronegative atom (usually N, O, or F) in a nearby molecule, which can be revealed by drawing the Lewis structure for the molecule.

**Solve** The foregoing criteria eliminate  $\text{CH}_4$  and  $\text{H}_2\text{S}$ , which do not contain H bonded to N, O, or F. They also eliminate  $\text{CH}_3\text{F}$ , whose Lewis structure shows a central C atom surrounded by three H atoms and an F atom. (Carbon always forms four bonds, whereas hydrogen and fluorine form one each.) Because the molecule contains a C—F bond and not an H—F bond, it does not form hydrogen bonds. In  $\text{H}_2\text{NNH}_2$ , however, we find N—H bonds, and the Lewis structure shows a nonbonding pair of electrons on each N atom, telling us hydrogen bonds can exist between the molecules:

**Check** Although we can generally identify substances that participate in hydrogen bonding based on their containing N, O, or F covalently bonded to H, drawing the Lewis structure for the interaction provides a way to check the prediction.

#### Practice Exercise 1

Which of the following substances is most likely to be a liquid at room temperature?

- (a) formaldehyde,  $\text{H}_2\text{CO}$       (b) fluoromethane,  $\text{CH}_3\text{F}$   
 (c) hydrogen cyanide,  $\text{HCN}$     (d) hydrogen peroxide,  $\text{H}_2\text{O}_2$   
 (e) hydrogen sulfide,  $\text{H}_2\text{S}$

#### Practice Exercise 2

In which of these substances is significant hydrogen bonding possible: methylene chloride ( $\text{CH}_2\text{Cl}_2$ ), phosphine ( $\text{PH}_3$ ), chloramine ( $\text{NH}_2\text{Cl}$ ), acetone ( $\text{CH}_3\text{COCH}_3$ )?

One remarkable consequence of hydrogen bonding is seen in the densities of ice and liquid water. In most substances the molecules in the solid are more densely packed than those in the liquid, making the solid phase denser than the liquid phase. By contrast, the density of ice at  $0^\circ\text{C}$  ( $0.917\text{ g/mL}$ ) is less than that of liquid water at  $0^\circ\text{C}$  ( $1.00\text{ g/mL}$ ), so ice floats on liquid water.

The lower density of ice can be understood in terms of hydrogen bonding. In ice, the  $\text{H}_2\text{O}$  molecules assume the ordered, open arrangement shown in Figure 11.11. This

#### Go Figure

What is the approximate  $\text{H—O} \cdots \text{H}$  bond angle in ice, where  $\text{H—O}$  is the covalent bond and  $\text{O} \cdots \text{H}$  is the hydrogen bond?

▲ **Figure 11.11** Hydrogen bonding in ice. The empty channels in the structure of ice make water less dense as a solid than as a liquid.

▲ **Figure 11.12** Expansion of water upon freezing.

arrangement optimizes hydrogen bonding between molecules, with each  $\text{H}_2\text{O}$  molecule forming hydrogen bonds to four neighboring  $\text{H}_2\text{O}$  molecules. These hydrogen bonds, however, create the cavities seen in the middle image of Figure 11.11. When ice melts, the motions of the molecules cause the structure to collapse. The hydrogen bonding in the liquid is more random than that in the solid but is strong enough to hold the molecules close together. Consequently, liquid water has a denser structure than ice, meaning that a given mass of water occupies a smaller volume than the same mass of ice.

The expansion of water upon freezing (Figure 11.12) is responsible for many phenomena we take for granted. It causes icebergs to float and water pipes to burst in cold weather. The lower density of ice compared to liquid water also profoundly affects life on Earth. Because ice floats, it covers the top of the water when a lake freezes, thereby insulating the water. If ice were denser than water, ice forming at the top of a lake would sink to the bottom, and the lake could freeze solid. Most aquatic life could not survive under these conditions.

### Give It Some Thought

What major type of attractive interaction must be overcome for water to evaporate?

### Go Figure

Why does the O side of  $\text{H}_2\text{O}$  point toward the  $\text{Na}^+$  ion?

Positive ends of polar molecules are oriented toward negatively charged anion.

Negative ends of polar molecules are oriented toward positively charged cation.

▲ **Figure 11.13** Ion–dipole forces.

## Ion–Dipole Forces

An **ion–dipole force** exists between an ion and a polar molecule (Figure 11.13). Cations are attracted to the negative end of a dipole, and anions are attracted to the positive end. The magnitude of the attraction increases as either the ionic charge or the magnitude of the dipole moment increases. Ion–dipole forces are especially important for solutions of ionic substances in polar liquids, such as a solution of  $\text{NaCl}$  in water. (Section 4.1)

### Give It Some Thought

In which mixture do you expect to find ion–dipole forces between solute and solvent to exist:  $\text{CH}_3\text{OH}$  in water or  $\text{Ca}(\text{NO}_3)_2$  in water?

## Comparing Intermolecular Forces

We can identify the intermolecular forces operative in a substance by considering its composition and structure. *Dispersion forces are found in all substances.* The strength of these attractive forces increases with increasing molecular weight and depends on molecular shapes. With polar molecules dipole–dipole interactions are also operative, but these interactions often make a smaller contribution to the total intermolecular attraction than do dispersion forces. For example, in liquid  $\text{HCl}$ , dispersion forces are estimated to account for more than 80% of the total attraction between molecules, while dipole–dipole attractions account for the rest. Hydrogen bonds, when present, make an important contribution to the total intermolecular interaction.

In general, the energies associated with dispersion forces are 0.1–30 kJ/mol. The wide range reflects the wide range in polarizabilities of molecules. By comparison, the energies associated with dipole–dipole interactions and hydrogen bonds are approximately 2–15 kJ/mol and 10–40 kJ/mol, respectively. Ion–dipole forces tend to be stronger than the aforementioned intermolecular forces, with energies typically exceeding 50 kJ/mol. All these interactions are considerably weaker than covalent and ionic bonds, which have energies that are hundreds of kilojoules per mole.

## Go Figure

Can the energies of multiple dispersion forces between two molecules be larger than the energy of hydrogen bonding between the two molecules?

▲ **Figure 11.14** Checklist for determining intermolecular forces. Multiple types of intermolecular forces can be operating in a given substance or mixture. Note that dispersion forces occur in all substances.

**Figure 11.14** presents a systematic way of identifying the intermolecular forces in a particular system.

It is important to realize that the effects of all these attractions are additive. For example, acetic acid, CH<sub>3</sub>COOH, and 1-propanol, CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>OH, have the same molecular weight, 60 amu, and both are capable of forming hydrogen bonds. However, a pair of acetic acid molecules can form two hydrogen bonds, whereas a pair of 1-propanol molecules can form only one (**Figure 11.15**). Hence, the boiling point of acetic acid is higher. These effects can be important, especially for very large polar molecules such as proteins, which have multiple dipoles and hydrogen-bonding groups over their surfaces. These molecules can be held together in solution to a surprisingly high degree due to the presence of multiple attractive interactions.

When comparing the relative strengths of intermolecular attractions, consider these generalizations:

- 1. When the molecules of two substances have comparable molecular weights and shapes, dispersion forces are approximately equal in the two substances.** Differences in the magnitudes of the intermolecular forces are due to differences in the strengths of dipole–dipole attractions. The intermolecular forces get stronger as molecule polarity increases, with those molecules capable of hydrogen bonding having the strongest interactions.
- 2. When the molecules of two substances differ widely in molecular weights, and there is no hydrogen bonding, dispersion forces tend to determine which substance has the stronger intermolecular attractions.** Intermolecular attractive forces are generally higher in the substance with higher molecular weight.

## 11.3 | Select Properties of Liquids

The intermolecular attractions we have just discussed can help us understand many familiar properties of liquids. In this section, we examine three: viscosity, surface tension, and capillary action.

▲ **Figure 11.15** Hydrogen bonding in acetic acid and 1-propanol. The greater the number of hydrogen bonds possible, the more tightly the molecules are held together and, therefore, the higher the boiling point.

## Sample Exercise 11.2

## Predicting Types and Relative Strengths of Intermolecular Attractions

List the substances  $\text{BaCl}_2$ ,  $\text{H}_2$ ,  $\text{CO}$ ,  $\text{HF}$ , and  $\text{Ne}$  in order of increasing boiling point.

## SOLUTION

**Analyze** We need to assess the intermolecular forces in these substances and use that information to determine the relative boiling points.
